PREFACE TO VERSION 2

Version 2 was started in spring of 2010 in response to industrial feedback regarding version 1. Version 2 is an important step forward containing the following major new features:

- Shell structure support
- Global constraints
- Multiple parts
- Symmetry definitions
- Casting direction definitions

Some minor features are:

- Tetrahedral solid element and triangular shell element support
- The speed of some algorithms was improved
- Improved integration with LS-DYNA

Many thanks are due to David Björkevik for the GUI design and implementation, Tushar Goel for the initial global constraints implementation, and Trent Eggleston for assistance with distributed computing. Valuable feedback from customers and co-workers is also acknowledged.

Willem Roux
Livermore CA,
January 2011
The development of the topology code started in the fall of 2007 in response to a request from a vehicle company research group. The alpha version was released in the spring of 2009 to allow the vehicle company research groups to give feedback from an industrial perspective, while the beta version was released in November 2009.

Most of the methodology developments in version 1.0 are due to Tushar Goel who worked on the engine implementation and algorithm design. Additionally, he also wrote the manual together with Willem Roux.

The project architecture was the responsibilities of Willem Roux and David Björkevik. David had the lead role with regard to the graphical user interface aspects, while Willem had the senior role looking after the overall project and the project management.

Thanks are also due to Nielen Stander from LSTC who helped to coordinate the efforts in the LS-OPT group and sourced the initial version of the technology, John Renaud and Neal Patel for discussion regarding topology optimization, Kishore Pydimarry and Ofir Shor for evaluating the alpha version, and Fabio Mantovani and Stefano Mazzalai for their help with LS-DYNA simulations.

Willem Roux

1. INTRODUCTION

1.1. Classification of Structural Optimization Techniques

Engineering optimization finds new designs that satisfy the system specifications at a minimal cost. Different types of structural optimization are:

1.1.1. Topology Optimization
This is a first-principle based approach to develop optimal designs. In this method, the user needs to provide the design domain, load and boundary conditions only. The optimal shape including the shape, size, and location of gaps in the domain is derived by the optimizer. While the most flexible method, topology optimization is indeed the most complex optimization method due to a multitude of reasons, like, large number of design variables, ill-posed nature of the problem, etc. Nevertheless, the benefits of using topology optimization include the possibility of finding new concept designs that have become feasible due to recent advances in technology, e.g., new materials. The LS-aSC program can be used to this design work.

1.1.2. Topometry Optimization
Topometry optimization, a methodology closely related to topology optimization, changes the element properties on an element by element basis. With the LS-TaSC program, the shell thicknesses can be designed.

1.1.3. Size Optimization
In this mode, the designer has already finalized the configuration of the system but improvements are sought by changing the thickness of members of the structure on a part basis instead of an element by element basis as done for topometry optimization. There is usually no need to re-mesh the geometry. This class of optimization problems is the most amenable to meta-model based optimization. The LS-OPT® program should be used for this instead of this program.

1.1.4. Shape Optimization
Shape optimization further expands the scope of design domain by allowing changes in the geometry of the structure, for example the radius of a hole. While there is more freedom to explore the design space, the cost of optimization increases due to the possible need to mesh different candidate optimum designs. Use the LS-OPT® program together with a preprocessor such as LS-PREPOST® instead of this program.

1.2. Brief Overview

Topology optimization in structures has been studied since the 1970s resulting in many books and numerous papers. The books by Rozvany [1] and Bendsøe and Sigmund [2] provide a very comprehensive and contemporary survey of optimization techniques used
in topology optimization. Most previous studies [3, 4] in topology optimization have focused on designing structures with static loading conditions but there is relatively little work on handling problems involving dynamic loads, like those observed in crashworthiness optimization [5]. The topology optimization in the context of crashworthiness is a very complex problem due to non-linear interactions among material non-linearities, geometry, and transient nature of boundary conditions.

The most efficient topology optimization methods use sensitivity information (optimality criterion based methods, Rozvany [1], Bendsoe and Kikuchi [6]) to drive the search for an optimum. Sensitivity calculations are computationally inexpensive for linear-static problems but not for the problems that involve non-linearities. To use the same set of topology optimization methods, one needs to explicitly calculate sensitivities which is practically infeasible due to very high computational cost involved with simulations. Thus the theory used to solve the linear-static load cases, though quite mature, is not practical for the crashworthiness problems and alternate methods need to be explored. Previously different approaches have been adopted by authors to solve topology optimization with nonlinearities. Pedersen used the Method of Moving Asymptotes for crashworthiness optimization of two-dimension structures [7]. They used a quasi-static nonlinear FEA to account for geometric nonlinearities to handle large deformation and rotation of plastic beam elements. However, the method ignored the contact between elements arising due to nonlinear behavior of the structures. Soto [8, 9] presented a heuristics based method using a prescribed plastic strain or stress criterion to vary the density to achieve the desired stress or strains with a constraint on mass. However, this method could not be generalized to solid structures. Pedersen [10] used beam elements to handle topology in crashworthiness optimization. Forsberg and Nilsson [11] proposed two algorithms to get a uniform distribution of the internal energy density in the structure. In the first method, they deleted inefficient elements and in the second method they updated the thickness of the shell elements. This method also was limited to a small set of optimization problems. Shin et al. [12] proposed an equivalent static load method where they calculated an equivalent static load for the dynamic problem and then used the linear-static topology optimization techniques to find the optimal topology. The main difficulty in this method is the requirement to accurately compute the equivalent loads.

1.3. Topology Optimization Method in LS-TaSC

A heuristic topology optimization method developed at the University of Notre Dame, known as hybrid cellular automata [13], showed potential in handling topology optimization problem for crashworthiness problems. This method updates the density of elements based on the information from its neighbors. No gradient information was required. The simplicity and effectiveness of this method for both two- and three-dimensional problems made it an attractive choice for our initial implementation. The methodology has however been enhanced using more established approaches as well; currently, amongst others, it gives mesh independent results.
This manual is divided into parts. The user’s manual describes how to do topology optimization using LS-TaSC. A few examples are provided to cover different options in the topology optimization program. The scripting section lists the command language used to interact with the topology optimization code together with some examples. Some common errors and tips on troubleshooting are provided in a separate chapter. In the theory section, the method for topology optimization is described. Setting up queuing systems is described in an appendix.

1.4. References

2. USER’S MANUAL

Topology optimization consists of describing the topology design problem together with the solution methodology, the scheduling the automated design, and the evaluation of the results.

2.1. Running the Program

The LS-TaSC GUI is launched from the command prompt by running the executable (*lstasc). If a project already exists, then the project database name (*.lstasc) can be supplied in two ways:

1. With the execution command
   
   $ lstasc myProject.lstasc

2. The file open dialogue, available from the File pulldown menu

2.2. Design Goal

The goal of topology optimization is to find the shape of a structure with the maximum utility of the material. For dynamic problems like crashworthiness simulations, this is achieved by designing for a uniform internal energy density in the structure while keeping the mass constrained.

2.3. Problem Definition

The topology design problem is defined by (i) the allowable geometric domain, (ii) how the part will be used, and (iii) properties of the part such as manufacturing constraints. Additionally, you have to specify methodology requirements such as termination criteria and management of the LS-DYNA® evaluations. In the GUI, provide this information using the following headings:

- **Cases** These store the load case data such as, the LS-DYNA® input deck and executable to use. The Cases data therefore contain the information on how to simulate the use of part.
- **Parts** The properties of the parts such as the part ID, mass reduction, and geometric definitions are given here.
- **Constraints** This optional information prescribes the stiffness or compliance of the whole structure.
- **Completion** These are methodology data such as the convergence criterions.

2.4. The Design Parts

The design domain is specified by selecting parts – the optimum parts computed will be inside the boundaries delimited by these parts. The part must be defined using *PART, not *PART_OPTION. The parts may contain holes: a structured mesh is accordingly not required.
2.4.1. Elementwise Material Density and Element Deletion for Solids

The shape of a solid part is described by the subset of the initial elements used. The shape of a solid element is controlled by changing the amount of material in the element. This is achieved by assigning a design variable to the density of each element. The material is parameterized using a so-called density approach. In this approach, a design variable is directly linked to the individual material element such that each cell has its own material model. The design variable $x$, also known as relative density, varies from 0 to 1 where 0 indicates void and 1 represents the full material. The material properties corresponding to the values of design variables are obtained using an appropriate interpolation model as described in the theoretical manual. The upper bound on the design variable is 1, while elements with design variable value less than a user-defined minimum value (0.05 for dynamic problems, and 0.001 for linear) are deleted to improve numerical stability.

2.4.2. Design of Shells

For shells the thickness are changed to achieve a uniform internal energy density in the part. The upper bound on the design variable is the original shell thickness, while elements with design thickness values less than a user-defined minimum value (0.05 for dynamic problems, and 0.001 for linear) are deleted to improve numerical stability.

2.4.3. Element types

Solid elements must be eight-noded solid elements or four-noded tetrahedral elements. Elements shapes close to perfectly cubic are the best for the current neighbor selection algorithm.

Shell elements may be four-noded shell elements or three-noded shell elements. The triangular elements must be specified as four-noded shell elements by specifying the last node twice. Elements shapes close to perfectly square or an equilateral triangle are the best for the current neighbor selection algorithm.

Tetrahedral and triangular elements cannot be extruded.

2.4.4. Material data

The part must be modeled using *MAT_PIECEWISE_LINEAR_PLASTICITY.

The load curve option (LCSS) is not supported; use the EPSi/ESi variables. Test the material using LS-DYNA before using it in LS-TaSC. For some material data the topology algorithm (SIMP algorithm) can only create materials for which the slope of the stress-strain curve is higher in plastic regime than in the elastic one; in this case the errors and warnings should be consulted for feedback on how to modify the material stress-strain curve in the input deck.
2.5. **Geometry and manufacturing definitions**

For each part geometry and manufacturing constraints such as being an extrusion may be specified.

The geometry definitions, as shown in Figure 2-1, are:

- **Symmetry** For these the geometry is duplicated across a symmetry plane. The part as supplied by the user must be symmetric: an element must have a matching element on the other side of the symmetry plane.

- **Extrusion** An element set is extruded in a certain direction. Allowable set definitions are *SET_SOLID, *SET_SOLID_LIST, *SET_SHELL, and *SET_SHELL_LIST. The part as supplied by the user must be an extrusion with every element in the elements set must have the same number of extruded elements. Only hexahedrons and quadrilateral elements can be extruded.

- **Casting** Material is removed only from a given side of the structure. The structure therefore will have no internal holes. The casting constraints can be one sided or two-sided. This capability is available only for solids.

![Figure 2-1: Geometry definitions](image)

Multiple geometry constraints can be specified for each part. Some combinations of geometry constraints may however not be possible. A maximum of three geometry definitions per part is possible. The symmetry planes must be orthogonal to each other, the extrusion direction must be on the symmetry planes, the casting direction must be on the symmetry planes, and the extrusion directions must be orthogonal to casting directions. Only one casting definition may be defined per part.

The symmetry and extrusion definitions are implemented by assigning multiple elements to a variable, while the casting definitions are implemented as inequality constraints requiring certain variables to be larger than others according to the cast direction.
For a casting definition, the free faces are selected as shown in Figure 2-2. It can be seen that the algorithm will select faces inside a hole. All of the material shown can be considered to be defined using a single *PART definition, from which it can be noted that the object to the right is considered for design even though it is in the ‘shadow’ of the object to the left. These extra faces will cause the algorithm to fail. An analyst can enforce a desired behavior by breaking the part up in smaller parts and applying the casting definition only where desired.

![Material removal direction](image)

**Figure 2-2: The faces selected for design in a casting definition are all the faces facing the material removal direction. The extra faces will cause the algorithm to fail.**

### 2.6. Design Variables

#### 2.6.1. Mapping Elements to the Design Variables

A design variable is assigned to every finite element in the design parts. For geometry constraints, the variables are defined only on a subset of elements.

#### 2.6.2. Filtering of Results

Structured grids are not always possible for industrial applications, and the results should be mesh independent. A radius based strategy is therefore used to identify neighbors. In this strategy, a virtual sphere (of default or user-defined radius) is placed at the center of an element. All elements that are within this sphere are considered the neighbors of the corresponding element. The result at an element is computed scaled from its own value and of its neighbors.

For dynamic problems, it was observed that accounting for the history of evolution induces stability by reducing the element deletion rate. Hence, the field variable (internal
energy density) of \(i^{th}\) cell at iteration \(t\) is updated by defining a weighted sum on the field variable of three previous iterations.

2.6.3. **Initialization of the Design Variables**

The design variables are initialized to satisfy the mass fraction. All variables in a part are assigned the same initial value. All associated field variables are also initialized to zero.

2.7. **LS-DYNA\textsuperscript{®} Specifics**

2.7.1. **The Contact Definition**

The contacts involving the design parts should be modeled using either *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE\_ID* or *CONTACT_AUTOMATIC_SINGLE_SURFACE\_ID* options. These contact options are general enough to accommodate the changes in the geometry of the design parts during the optimization to maintain valid contacts. It is also recommended to specify the contact options (e.g., friction coefficients) appropriately accounting for the changes in the geometry may result in significantly different material properties for some elements near the contacts. Too restrictive values may cause instabilities in the LS-DYNA\textsuperscript{®} simulations for intermediate geometries.

2.7.2. **Disallowed keywords**

The *INCLUDE keyword is not supported in the current version.

The portions of the FE model related to the design part are extensively edited by the optimization algorithm. In these segments of the FE model only specific versions of *PART, *SET, and *CONTACT keywords may be used as described in the relevant sections. Portions of the model not edited by the optimization algorithm are not subjected to this rule.

2.7.3. **LS-DYNA\textsuperscript{®} Simulation**

The elements in the finite element model are modified by changing the material models, adding or deleting elements, at each iteration. The input deck is accordingly re-written for every iteration. The relevant field variables for all elements are obtained from the output to completely define the state of each cell. For multiple load case conditions, the state variable is based on the output from simulations of different load cases.

This modified input deck is analyzed using LS-DYNA\textsuperscript{®}. One can take advantage of multiple processors using the MPP version of LS-DYNA\textsuperscript{®}. Queuing system can also be used as described in Section 2.9.2.

The internal densities of the cells are extracted at the end of the analysis for use in the design procedure.
2.8. **Global constraints**

Global responses depend on the design of the whole structure. Two types of global responses are:
- Stiffness. This is specified as displacement constraint.
- Compliance. This is specified as a reaction force constraint.

Local effects such as stress concentrations are not handled by this algorithm.

The algorithm is actually a search for the mass of the structure. If the displacements are too large, then mass are added to the structure to increase the stiffness. If the reaction forces are too large, then mass is removed from the structure to reduce the force.

Multiple global constraints may be specified. If the constraints are in conflict, then a trade-off is done, and a design is selected resulting in the minimum violation of any given constraint.

2.9. **Setting up the Problem**

The GUI consists of a number of panels. Complete the panels from left to right as described in the following subsections.

2.9.1. **The Information Panel**

The information contains only information such as the software version, the name of the current database file, and a description of the problem.
2.9.2. The Cases Panel

The cases panel contains all of the load cases to be analyzed using LS-DYNA®. See the following table and Figure 2-4 for more details.

<table>
<thead>
<tr>
<th>Cases data</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Each case is identified with a unique name e.g., TRUCK. The same name would be used to create a directory to store all simulation data.</td>
</tr>
<tr>
<td>Execution Command</td>
<td>The complete solver command or script (e.g., complete path of LS-DYNA executable) is specified.</td>
</tr>
<tr>
<td>Input File</td>
<td>The LS-DYNA input deck path is provided.</td>
</tr>
<tr>
<td>Weight</td>
<td>The weight associated with a case is defined here. This enables the user to specify non-uniform importance while running multiple cases.</td>
</tr>
<tr>
<td>Number of jobs</td>
<td>This parameter indicates the number of processes to be run simultaneously. A value of zero indicates all processes would be run simultaneously. This parameter only makes sense if multiple cases must be evaluated. The program will allow as many processes as defined for the current case being evaluated.</td>
</tr>
<tr>
<td>Queue system</td>
<td>This parameter is used to indicate the queuing system. The options are: lsf, loadleveler, pbs, nqs, user, aqs, slurm, blackbox, mssql,</td>
</tr>
</tbody>
</table>
pbspro, Honda. By default, no queuing system would be used. See the appendix for a description of setting up the queuing systems. The system is the same as used in LS-OPT®, so a queuing system definition is the same.

Figure 2-4: The cases panel.

2.9.3. The Constraints Panel
The constraint panel contains the global constraints on the structure. See the following table and Figure 2-4 for more details.

<table>
<thead>
<tr>
<th>Cases data</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Each constraint is identified with a unique name e.g., MAX_DISP. Each constraint is associated with a load case.</td>
</tr>
<tr>
<td>Case</td>
<td>One of NODOUT or RCFORC</td>
</tr>
<tr>
<td>Constraint</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>The weight associated with a case is defined here. This enables the user to specify non-uniform importance while running multiple cases.</td>
</tr>
<tr>
<td>Lower and upper bound</td>
<td></td>
</tr>
<tr>
<td>ID</td>
<td>This is the ID of the node in the FE model at which the results must be collected.</td>
</tr>
<tr>
<td>Select</td>
<td>This parameter indicates which value over time must be selected. It can be the last value, the maximum value, the minimum value, or at a specific time. A time, or a time interval can also be specified.</td>
</tr>
<tr>
<td>Filtering</td>
<td>If filtering is desired, select the type of filter, frequency, and time units. LS-PREPOST can be used to investigate the effects of filtering.</td>
</tr>
</tbody>
</table>
Figure 2-5: The constraints overview panel.

Figure 2-6: The constraints creation panel.
2.9.4. The Parts Panel

The part definition panel contains information about the parts to be designed, such as the geometry and mass fraction. See the following table, Figure 2-7 and Figure 2-8 for more details.

<table>
<thead>
<tr>
<th>Part data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design Part ID</td>
</tr>
</tbody>
</table>
| The user needs to specify the design domain for topology optimization. To facilitate the identification of design domain, all elements in the design domain are put in a single part in the LS-DYNA input deck. The information about the design domain is then communicated through the corresponding part-id.  
Note: For multiple load cases, the user must ensure that the design domain mesh and the part-id remain the same in all input decks. |
| Mass Fraction                  |
| This parameter describes the fraction of the mass of the part to be retained. The rest will be removed. A part with an initial weight of 5, designed using a Mass Fraction of 0.3 will have a final weight of 1.5. |
| Neighbor Radius                |
| All elements within a sphere of radius of this value are considered the neighbors of an element. The design variable at an element is updated using the result at the element averaged together with that of its neighbors. Smaller values of this parameter yield finer-grained structures. The default value depends on the average element size. |
| Minimum variable fraction      |
| If the design variable value associated with and elements is too small then that element is deleted to preserve the stability of the model. An appropriate value (0.05 \( < x < 0.95 \)) is supplied here. The default is 0.05 for non-linear problems and 0.001 for linear problems. |
Figure 2-7: The parts panel.

Figure 2-8: The panel to create part and geometry.
2.9.5. *Part Geometry*

The geometric properties can be defined for every part. See the following table and Figure 2-9 for more details.

<table>
<thead>
<tr>
<th>Geometry data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>The geometric property can assigned a name or a default name can be used.</td>
</tr>
<tr>
<td>Extrusion Set ID</td>
</tr>
<tr>
<td>To define an extruded part, the user firstly creates a set of all solid elements that would be extruded (SET_SOLID). The id of this set is specified in the input deck to identify the extrusion set.</td>
</tr>
<tr>
<td>Symmetry Plane</td>
</tr>
<tr>
<td>Specify a symmetry plane to define symmetry.</td>
</tr>
<tr>
<td>Cast direction</td>
</tr>
<tr>
<td>A cast direction is required for a casting constraint. The direction can be negative. This is the direction in which the material will be removed. It is the opposite of the direction in which a casting die will be removed.</td>
</tr>
<tr>
<td>Coordinate System ID</td>
</tr>
<tr>
<td>The geometric property can be defined in a specific coordinate system or the default Cartesian system can be used.</td>
</tr>
</tbody>
</table>

![Figure 2-9: Creating a geometry constraint.](image)

2.9.6. *The Completion Panel*

The completion panel specifies how the optimization problem will be solved. See the following table and Figure 2-10 for more details.

<table>
<thead>
<tr>
<th>Completion data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of design iterations</td>
</tr>
<tr>
<td>This is the maximum number of iterations allowed. The default value is 30.</td>
</tr>
<tr>
<td>Minimum mass redistribution</td>
</tr>
<tr>
<td>The minimum mass redistribution is the termination criterion used to stop the search when the topology has evolved sufficiently. This value is compared with the Mass Redistribution history variable displayed in the view panel. The default value is 0.002.</td>
</tr>
</tbody>
</table>
2.9.7. **The Run Panel**

The control panel is used to submit the design problem. In addition, the LS-DYNA® jobs can also be stopped, and old results deleted. Use this panel and the Viewer panel to monitor job execution. See Figure 2-11 for more details.
2.9.8. The View Panel

The view can be used to monitor both optimization progress and optimization results. Both histories and plots in LS-PREPOST are possible. See Figure 2-12 and Figure 2-13 for more details.

For the histories note that:

- Multiple histories can be plotted simultaneously by holding down the Control key.
- The plot ranges can be set under the View pulldown menu.
- The histories can be printed or saved to file using the Plot pulldown menu.
- The history data can be exported and postprocessed using the scripting interface.
Figure 2-12: The view panel with histories.

Figure 2-13: Viewing the model evolution in LS-PREPOST.
2.10. Databases and Files

The important files and directories are shown in the figure below. Four files are important to know about:

- The project database
- The project results in the lst.binout binary file
- The optimal design in the case directory
- The d3plot files in the run directory inside the case directory

![Diagram of Work Directory]

2.11. Opening and Saving Projects

The standard File pulldown is provides the ability to open and save projects. The name of the database can also be specified on the command line when staring the GUI as lstasc lst_project.lstasc.

2.12. Script Commands

The script commands issued to create the database can be viewed from the View pulldown menu. Use these commands as a template for scripts.
3. EXAMPLE PROBLEMS

The application of the topology code is demonstrated with the help of a few test examples below. The examples are supplied together with the software executables.

3.1. Fixed Beam with Central Load

This example is used as a template to demonstrate
1. how to define a problem,
2. how to add a case,
3. how to optimize the topology for a non-extrusion example,
4. analysis of output.

3.1.1. Problem Description

This example simulates a beam that is fixed on both ends. A pole with assigned initial velocity of 10m/s hits the beam in the center. The design part is meshed using 5mm³ brick elements. The symmetry of the problem is used to design only half-section of the beam. The geometry and loading conditions of the beam are shown in Figure 3-1. The material model used in this example is defined previously.

![Figure 3-1: Geometry and loading condition of a single-load case example.](image)

3.1.2. Input

The problem has a case named BEAM. The name of the DYNA input deck file is “Beam.dyn”. Part 101 is the design part. A maximum of 100 iterations are used to find the optimal topology. The desired mass fraction is 0.25.

The project input data is saved to the file lst_project.lstasc as provided in the examples distribution. Additionally, scripts to recreate the database are also provided. The project database can be investigated using the scripts; use the script in example 5.6.4 to print the project data. The advanced user can conduct the simulations using the LS-DYNA MPP version and hence using a script named “submit_pbs” for the PBS queuing system.
3.1.3. Output

The output of the code is written in the file named lst_output.txt. The error and warning messages are echoed in lst_error and lst_Warning files respectively. The typical output in the lst_output.txt is:

```
ls-dyna analysis time: 161s
it  1:  total IED: 9.933e+03   Mf: 0.250
ls-dyna analysis time: 177s
it  2:  total IED: 9.495e+03   Mf: 0.250  dX: 0.074627 (target: 0.001)
ls-dyna analysis time: 183s
it  3:  total IED: 8.983e+03   Mf: 0.250  dX: 0.077542 (target: 0.001)
ls-dyna analysis time: 187s
it  4:  total IED: 9.252e+03   Mf: 0.250  dX: 0.072176 (target: 0.001)
ls-dyna analysis time: 193s
it  5:  total IED: 9.156e+03   Mf: 0.250  dX: 0.063345 (target: 0.001)
```

a) Convergence History

The convergence is quantified using the change in topology, characterized by the normalized density redistribution, and the total internal energy density as shown in Figure 3-2.

![Figure 3-2: Convergence history of the mass redistribution.](image)

The simulation converged after 57 iterations. It was observed that initially there were significant changes in the topology (upto 30 iterations). Afterwards, small changes were made in the topology. There was a drop in the total internal energy density during the early phase of the optimization but it increased during the later iterations. The final topology is visualized in LS-PREPOST.

b) Density Contours

The initial and final topologies are shown in Figure 3-3, and the topologies at different iterations during the evolution process are shown in Figure 3-4.
The final topology evolved in a truss-like structure. Many holes were carved to satisfy the mass constraint while reducing the non-uniformity in the distribution of the internal energy density. The final structure was also found to have a reasonably homogenous distribution of the material as was desired.

Topologies at different stages of the evolution process show that the main features of the structure were evolved by iteration 20 (row 2, column 1). Further iterations were necessary to bolster the structure by removing the material from relatively non-contributing zones and redistributing it to the desirable sections such as a 0-1 type topology was evolved.

### 3.2. Beam using geometry definitions

This example demonstrates how to setup a problem with geometry definitions.

The same fixed-beam with a central load example is analyzed with an extrusion and two casting definitions. The symmetry face is also defined as the extruded face. In the input deck file, the elements on the extrusion face were grouped in a solid set (*SET_SOLID). Two different casting conditions were applied in two separate design runs: (i) in the first run casting definition was applied in the Z direction, and (ii) in the second run a two-sided casting definition was applied in the Z direction. All other parameters were kept the same.
3.2.1. Input
The main differences in this example compared to the non-extrusion example are:

- An extrusion definition is provided.
- A casting definition in Z direction is provided.

The project input data is saved to the file *Extr_Cast.lstasc* and *Extr_Cast2.lstasc* as provided in the examples distribution in the directory *Beam_extr_cast*. Additionally, scripts to recreate the database are also provided. The project database can be investigated using the GUI or a script; use the script in example 5.6.4 to print the project data.

3.2.2. Output

a) Extrusion and Casting

![Image of beam evolution](image)

*Figure 3-5: Evolution of the beam using extrusion and single-sided casting constraints*

Different phases in the evolution are depicted in Figure 3-5. One can see that a lot of material was removed as early. The final geometry evolved by considering the geometry definitions was significantly different than the case when no manufacturing constraints were considered. The C-section evolved makes intuitively sense.

b) Extrusion and two-sided casting

Different phases in the evolution are depicted in Figure 3-5. One can see that a lot of material was removed as early. The final geometry evolved by considering the geometry...
definitions was significantly different than the case when no manufacturing constraints were considered. The I-section evolved makes intuitively sense.

![Figure 3-6](image)

**Figure 3-6: Evolution of the beam using extrusion and two-sided casting constraints.**

### 3.3. Multiple Load Cases

This example demonstrates a simulation with multiple load cases.

#### 3.3.1. Problem Definition

![Figure 3-7](image)

**Figure 3-7: The geometry and loading conditions of the multiple load case example.**

The geometry and loading conditions for the example are shown in Figure 3-7. This is a fixed-fixed beam with three loads. The design part was meshed with 10mm\(^3\) elements.

#### 3.3.2. Input

The three load cases were identified according to the location of the pole hitting the beam. Side load cases were assigned a unit weight and the center load was assigned a weight of three units. The desired mass fraction for this example was 0.3. A maximum of 100 iterations were allowed. All simulations were run simultaneously.
The project input data is saved to the file `lst_project.lstasc` as provided in the examples distribution. Additionally, scripts to recreate the database are also provided. The project database can be investigated using the scripts; use the script in example 5.6.4 to print the project data. The advanced user can conduct the simulations using the LS-DYNA MPP version and hence using a script named “submit_pbs” for the PBS queuing system.

3.3.3. Output

a) Convergence History

![Convergence History](image)

*Figure 3-8: Convergence history for multiple-load case example.*

The convergence history for the multiple-load example is shown in Figure 3-8. The simulation converged after 67 iterations, though miniscule changes were noted after 40 iterations. As observed before, monotonic reduction in the change in topology was observed. The final structure absorbed approximately 8% less total internal energy.

b) Density Contours

The initial and final structures are shown in Figure 3-9. The final structure evolved in a tabular structure with the two cross-members as legs. The structure had more material in the center section due to the high importance assigned to the center weight. There were many cavities in the structure such that the final structure could be considered equivalent to a truss-like structure as one would expect.

![Density Contours](image)

*Figure 3-9: Initial and final density contours.*
The evolution of the topology under multiple loading conditions is shown in Figure 3-10. While the final form of the structure was largely evolved by 28th iteration (row 2, column 1), the material was re-distributed to remove the low density material and evolve a largely 0-1 (no material or full density material) structure.

![Figure 3-10: Evolution of the geometry for multiple-load case structure.](image)

### 3.4. Force-Displacement Constraints

The next example demonstrates a simulation with multiple constraints.

#### 3.4.1. Problem Definition

![Figure 3-11: The geometry and loading conditions of the multiple constraints example.](image)

The geometry and loading conditions for the example are shown in Figure 3-11. This is a fixed-fixed beam with a central load. The design part was meshed with 10mm³ elements.

#### 3.4.2. Input

The center load was assigned at the location of the pole hitting the beam. The desired mass fraction for this example was 0.25. A maximum of 100 iterations were allowed. The maximum displacement of the indenter was constrained at 34 units and the maximum y-component of the interface force was limited at 1.45e6 units.

The project input data is saved to the file `lst_project.lstasc` as provided in the examples distribution. Additionally, scripts to recreate the database are also provided. The project database can be investigated using the scripts; use the script in example 5.6.4 to print the
3.4.3. Output

a) Convergence History

![Convergence History Graphs](image)

**Figure 3-12: Convergence history for the example with multiple constraints.**

The convergence history for the multiple-constraints example is shown in Figure 3-12. There were minimal changes in the geometry after 25 iterations and the simulation converged after 40 iterations. While there was largely monotonic reduction in the density redistribution, the constraints and IED were oscillatory in the behavior. The oscillatory behavior of the constraints was due to their conflicting nature where an increase in displacement required an increase in the mass fraction which resulted in higher forces. At optimum, a balance between the two quantities was obtained. It is important to note that the mass fraction for this example was not held constant. Instead, it was automatically adjusted to satisfy the force and displacement constraints though the final mass fraction was fairly close to the desired value.
b) **Density Contours**

The evolution of the topology of the clamped beam with multiple constraints is shown in Figure 3-13. The final structure had many cavities and resembled an optimized truss-like structure. The main cavities in the structure were formulated by the 15th iteration and the structure was fully developed in a largely 0-1 type structure by the 30th iteration. Further redistribution of the material refined this structure between the 30th and the 40th iteration.

![Figure 3-13: Evolution of the geometry for multiple-constrained clamped beam.](image)

### 3.5. Linear Static Loading

The next example demonstrates the topology optimization of a statically loaded structure.

#### 3.5.1. Problem Definition

![Figure 3-14: The geometry and loading conditions of a statically loaded structure.](image)

The geometry and loading conditions for the example are shown in Figure 3-10. The design part was meshed with 1.05mm³ elements such that there were approximately 125,000 elements.
3.5.2. **Input**

In this example, a unit load is applied in the center of the structure. The structure was fixed on the bottom. The problem has a case named *TopLoad*. The simulations are carried out using the double precision SMP version of LS-DYNA (*ls971_double*). The name of the DYNA input deck file is “*LinearStructure.dyn*”. Part 102 is the design part. A maximum of 100 iterations are used to find the optimal topology and the desired mass fraction is 0.30.

The project input data is saved to the file *lst_project.lstasc* as provided in the examples distribution. Additionally, scripts to recreate the database are also provided. The project database can be investigated using the scripts; use the script in example 5.6.4 to print the project data.

3.5.3. **Output**

**a) Convergence History**

The convergence history for the statically loaded structure topology optimization example is shown in Figure 3-15. The simulation converged after 28 iterations, though only minor changes were noted after 20 iterations. As observed before, monotonic reduction in the change in topology was observed. The total internal energy of the structure also decreased with topology evolution.

![Convergence history for linear-static example.](image)

**b) Density Contours**

The initial and final structures are shown in Figure 3-16. The final structure evolved in a column-like structure with wider supports on the faces. The shape of the structure also resembled the best-stress design.
Figure 3-16: Initial and final density contours.

Figure 3-17: Evolution of the geometry for statically loaded structure.

The evolution of the topology under the static loading conditions is shown in Figure 3-17. While the final form of the structure was largely evolved by 17th iteration (first structure in the second row), the material was re-distributed to remove the low-density elements that were not contributing sufficiently to support the load and obtain a homogenous material distribution such that the simulation converged after 28 iterations.

3.6. Shell Example

This example shows how to work with shell structures.
3.6.1. Problem Definition

![Diagram of shell example](image)

*Figure 3-18: The geometry and loading conditions of the shell example. The left side is built-in, while a downward load is applied to the right, back corner.*

The geometry and loading conditions for the example are shown in Figure 3-18.

3.6.2. Input

The project input data is saved to the file `Shell.Istasc` as provided in the examples distribution. Additionally, scripts to recreate the database are also provided. The project database can be investigated using the scripts; use the script in example 5.6.4 to print the project data.

3.6.3. Output

a) *Convergence History*

![Convergence history graph](image)

*Figure 3-19: Convergence history for the shell example.*
The convergence history for the shell example is shown in Figure 3-19. The simulation converged after 14 iterations. There was largely monotonic reduction in the density redistribution.

b) **Final Shell Thicknesses**

The final design is shown in Figure 3-20. The final structure had many cavities and resembled an optimized truss-like structure.

*Figure 3-20: Final geometry and thicknesses for the shell problem.*
4. TROUBLESHOOTING

This chapter lists some of the most common errors and suggested remedies.

4.1. Executable failing or no output

For the example problems: check that you changed the name of the LS-DYNA executable in the example problem to what is used on your computer.

Provide the complete path for the solver command instead of using alias. You may also specify necessary DYNA options in the command, e.g.,

/home/Tushar/bin/ls971_single memory=100m

4.2. Design Part

The design part is not found: check that the DYNA input deck has the same part id for the design part as specified in the input file. In the case of the multiple load cases, the design domain must remain the same.

4.3. Extrusion Set

The extrusion set is not found: check that the set of elements on the extruded face are grouped under the *SET_SOLID option in the DYNA input deck. The ID of the set is same for all load cases as specified in the input file.

Unable to find all the slaved elements: if the node numbering order is different for some elements are not the same, then the algorithm may fail. Using a different node number will, for example, cause face 1 to be the top face on one element and to be the left face on another element; the algorithm depends on this not happening.

4.4. Negative Volumes

While care has been taken to avoid running into negative volume errors, sometimes the simulation terminates due to negative volume errors.

A user can take several actions to correct this error.
1. Check the CONTACT cards. Note that the failed run probably has elements with soft material interface with elements with harder material; hence care must be exercised in defining master and slave penalty stiffness factors.
2. Specify SOFT=2 option on the control card
3. Increase minimum density fraction (default 0.05 for dynamic problems).

4.5. The LS-DYNA analysis fails if a smaller mass fraction is requested

Possibly the structure is not strong enough to support the load.
Inspect the d3plot results in the failed iteration to understand what happens in the LS-DYNA analysis.

Fixes are to reduce the load, increasing the mass fraction, changing the FE model to be more robust, using a finer mesh, modify your approach keeping in mind that you cannot get a solution from that starting mass fraction, or accepting that a design does not exist at that mass fraction.

4.6. **Convergence**

For some problems, the code does not converge; instead, oscillations set in. The user must look at the geometry to understand why oscillations are observed. Mostly, oscillations indicate that there is more than one possible optimal solution.

4.7. **LS-PREPOST**

You may need to install another version of LS-PREPOST into the LS-TaSC installation directory. Please follow the instructions on the LS-PREPOST web site. The name of the executable must be `lsprepost`. Do not use a symbolic link. You may need to investigate the latest version of LS-Prepost 2.4 and 3.1.

4.8. **Casting definitions**

Using the scripting interface, you can set a debug flag on the `lst_Method` structure, which will dump a definition of the faces to a file for display in LS-PREPOST.

4.9. **Mysterious Error when/after calling LS-DYNA and/or Errors involving the LSOPT Environment Variable**

Make sure the queuing is set correctly. Specifying the use of a queuing system when none is available may cause (i) mysterious errors or (ii) the LS-DYNA execution not to return after finishing.

Make sure the LSOPT environment variable is not set.
5. APPENDIX A: SCRIPTING

The scripting capability is provided to allow advanced users to customize the application. Normal interaction with the topology optimization code is with the graphical user interface, which issues the scripting commands driving the optimization process.

A script is provided to the program in a file. The commands in a script can perform one of two functions:
- Define the problem and methodology data
- Call the topology design functions

5.1. The scripting language

The script commands use the C programming language syntax to manipulate data. Detailed knowledge of the language is not required to use this manual; the example scripts in this manual give enough information. A complete syntax reference is given in the LS-PREPOST customization manual titled “SCRIPTO A new tool to talk with LS-PREPOST” available at http://www2.lstc.com/lspp/index.shtml.

5.2. Code Execution

The LS-TaSC code is executed from the command prompt by running the executable (lstasc_script). The input command file (script) can be supplied in two manners:
1. With the execution command and a script file name
   $ lstasc_script lst_script.lss
2. The code prompts for the input file, if no input was specified with the execution command
   $ lstasc_script
   Please input command file name:
   lst_inp

Additionally, you can use the execution command and a database file name
   $ lstasc_script lst_project.lstasc

5.3. Data-structures

5.3.1. lst_Root

All input data is encapsulated in a top-level data structure lst_Root. The input data is classified in two sub-categories: the problem definition that does not depend on the optimization method, and the optimization method parameters.

```c
struct lst_Root {
    struct lst_Problem *Problem;
    struct lst_Method *Method;
};
```

5.3.2. lst_Method

The parameters used for optimization method are specified in this data-structure.
struct lst_Method {
    Int   NumIter;
    Float ConvTol;
    Int   NumDiscreteLevels;
    Int   DumpGeomDef;
    Int   StoreFieldHist;
}

NumIter: The maximum number of iterations allowed is specified.

ConvTol: The convergence tolerance is the termination criterion used to stop the search when the topology has evolved sufficiently. If ConvTol ≤ 0.0, then this input would be ignored, and the default will be used.

NumDiscreteLevels: Resolution or the number of steps in the gradation of the material of the part being design. The default value should suffice for almost all problems.

DumpGeomDef: Set this to a non-zero value to obtain debugging information for casting constraints. Files will be created which can be viewed in LS-PREPOST showing the master face (free) elements, and the elements chained to the master elements.

StoreFieldHist: Set this to a non-zero value to obtain the IED histories in the View panel.

5.3.3. lst_Problem
The details of the problem is given in this data structure. The definition is as follows:

struct lst_Problem {
    struct lst_Case *CaseList;
    struct lst_Part *PartList;
    Char * Description;
}

CaseList: The user provides the details of the simulation in this data structure. As the name suggests, the CaseList is the list of all load cases. For multiple load cases, the user would specify one case per load case. A complete description is given in a following section.

PartList: The user provides the details of the parts in this data structure. As the name suggests, the PartList is the list of all parts. A complete description is given in the next section.

Description: This optional string is used to describe the problem.

5.3.4. lst_Part
The details of a part are:
ID: Each part is identified with a unique id as in the LS-DYNA input deck. The design domain for topology optimization is identified as all of the parts given.

ProxTol: All elements within a radius of proximity tolerance would be considered as the neighbors of an element.

MinVarValue: Elements with a density of less than this will be deleted.

MassFractionBound: The material constraint for the topology optimization is necessary for the optimization. An appropriate value (0.05 < x < 0.95) is supplied here.

Continuum: Whether the part is a solid or a shell. Solids have a value of 1, while shells have a value of 2.

GeometryList: These are the geometry and manufacturing constraint on a part. A complete description is given in the next section.

Next: The next part in this linked list. A value of NULL indicates that this is the final part.

5.3.5. lst_Geometry
The details of a geometry definition are:

```c
struct lst_Geometry { Char *Name;
   Int Type;
   Int CID;
   Int Set;
   Int ExtructionDir;
   Int MirrorPlane;
   struct lst_Geometry * Next; }
```

Name: Each geometry definition is identified with a unique name. The name is used to identify the geometry constraint in the output.

Type: The type of extrusion. 2 is an extrusion, 3 is a symmetry constraint, 4 is a single sided casting constraint, and 5 is a double sided casting constraint.

Set: To design an extruded part, the user firstly creates a set of all solid elements that would be extruded (SET_SOLID). The id of this set is specified in the input deck to identify the extrusion set.
ExtrusionDir: X=1 Y=2 Z=3

MirrorPlane: The mirror plane for a symmetry constraint XY=1 YZ =2 ZX = 3.

Next: The next geometry definition in this linked list. A value of NULL indicates that this is the final geometry definition.

5.3.6. lst_Case
The details of the simulation setup are given in this data structure.

    struct lst_Case {
        Char *Name;
        Char *SolverCommand;
        Char *InputFile;
        Int AnalysisType;
        Float Weight;
        struct lst_Constraints *ConstraintList;
        struct lst_JobInfo *JobInfo;
        struct lst_Case *Next;
    }

Name: Each case is identified with a unique name e.g., TRUCK. The same name would be used to create a directory to store all simulation data.

SolverCommand: The complete solver command or script (e.g., complete path of LS-DYNA executable) is specified.

InputFile: The LS-DYNA input deck path is provided.

AnalysisType: The topology optimization code can be used to solve both static and dynamic problems. The user identifies the correct problem type by specifying the correct option:

<table>
<thead>
<tr>
<th>Type</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATIC</td>
<td>1</td>
</tr>
<tr>
<td>DYNAMIC</td>
<td>2</td>
</tr>
</tbody>
</table>

Weight: The weight associated with a case is defined here. This enables the user to specify non-uniform importance while running multiple cases.

ConstraintList: This data structure holds the information about different constraints associated with this case. See the following section for more details.

JobInfo: The user specifies details of the queuing system and number of simultaneous processes in this data structure.

Next: The next case in this linked list. A value of NULL indicates that this is the final geometry case.
Note that the word case is a reserved word in the C programming language.

5.3.7. lst_Constraint
The structural constraints for a discipline are specified in the following data structure:

```c
struct lst_Constraint {
    char * Name;
    Float UpperBound;
    Float LowerBound;
    Char * Command;
    struct lst_Constraint *Next;
}
```

Name: The name of each constraint is a unique character identifier.

UpperBound/LowerBound: The upper and lower bounds on a constraint are specified using these variables. If there is no upper bound, a value of 1.0e+30 must be specified for UpperBound. Similarly, a value of -1.0e+30 should be used for LowerBound when there is no lower bound.

Command: The definition of each constraint provides interface to LS-DYNA® databases. The data extraction from both binout and d3plot databases are supported.

5.3.8. lst_JobInfo
This data structure contains the LS-DYNA® job distribution information. Create and set this data structure to change the default of running LS-DYNA® locally as a single process.

```c
struct lst_JobInfo {
    Int NumProc;
    Int Queuer;
    Char ** EnvVarList;
}
```

NumProc: This parameter indicates the number of processes to be run simultaneously. A value of zero indicates all processes would be run simultaneously.

Queuer: This parameter is used to indicate the queuing system. Different options are tabulated below.

<table>
<thead>
<tr>
<th>Q-system</th>
<th>Option</th>
<th>Q-system</th>
<th>Option</th>
<th>Q-system</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUEUE_NIL</td>
<td>0</td>
<td>NQS</td>
<td>4</td>
<td>BLACKBOX</td>
<td>8</td>
</tr>
<tr>
<td>LSF</td>
<td>1</td>
<td>USER</td>
<td>5</td>
<td>MCCCP</td>
<td>9</td>
</tr>
<tr>
<td>LOADLEVELER</td>
<td>2</td>
<td>AQS</td>
<td>6</td>
<td>PBS PRO</td>
<td>10</td>
</tr>
<tr>
<td>PBS</td>
<td>3</td>
<td>SLURM</td>
<td>7</td>
<td>HONDA</td>
<td>11</td>
</tr>
</tbody>
</table>

By default, no queuing system would be used.
EnvVarList: These parameters are passed to the remote machine by the queuing system. The lst_JobInfoAddEnvVar command is used to set the values.

5.4.  Interactions with the Data Structures

To specify the input data, the user needs to communicate with the program data structures. These data structures are accessed by the user via a script that follows the syntax of C programming language. So the user needs to first define the data structure and then populate the input data.

5.4.1. Definition

Each script must include the following command to access necessary data-structures.

```c
lst_Root *root = lst_RootGet();
```

The root data structure encapsulates both problem and method data and therefore always needs to be accessed.

5.4.2. Initialization

During initialization, the user provides the necessary input data.

a)  Adding Case Data

The solver information is added to the problem data using the lst_ProblemAddCase function, defined as follows:

```c
lst_ProblemAddCase( lst_Problem, Char *CaseName, Char *SolverCmd, Char *InputFileName", Int analysisType, Float Weight );
```

The last two arguments `analysisType`, and `weight` are optional. If not specified then the program will determine whether it is a non-linear analysis and set the weight to 1.0.

<table>
<thead>
<tr>
<th>Example: Add two load cases</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. This load case uses a queuing system for a nonlinear structural problem</td>
</tr>
<tr>
<td>lst_ProblemAddCase( root-&gt;Problem, &quot;LEFT_LOAD&quot;, &quot;submit_pbs&quot;, &quot;MyInputL.k&quot;, 2, 0.5);</td>
</tr>
<tr>
<td>2. Second load case uses a standalone DYNA program for a linear structural problem</td>
</tr>
<tr>
<td>lst_ProblemAddCase( root-&gt;Problem, &quot;RIGHT_LOAD&quot;, &quot;ls971_single&quot;, &quot;MyInputR.k&quot;, 1, 0.9);</td>
</tr>
</tbody>
</table>

b)  Accessing a Specific Case Structure

The cases are stored in a linked list in the lst_Problem structure. Also a pointer to the lst_Case structure is returned when it is created. Note that the word `case` is a reserved word in the C programming language.

```c
lst_Case * cse1 = root->Problem->CaseList;
lst_Case * cse2 = root->Problem->CaseList->Next;
```
c) **Adding Constraints**

A user can add constraints to each case using the following command:

```c
lst_CaseAddConstraint ( struct lst_Case* cse, Char *constraintName, Float UpperBound, Float LowerBound, Char *constraintCommand );
```

Example: Adding two constraints to a case

1. Adding a displacement constraint:
   Maximum resultant displacement of part defined by id=101 should be less than 7.25 units.
   ```c
   lst_CaseAddConstraint (root->Problem->CaseList, "gDisp", 7.25, -1.0e+30, "D3PlotResponse -pids 101 -res_type ndv -cmp result_displacement -select MAX -start_time 0.00");
   ```

2. Adding a force constraint:
   Maximum y-force on the master side of the interface defined by id=9 should be smaller than 2.0e5 units.
   ```c
   lst_CaseAddConstraint (root->Problem->CaseList, "rForce", 2.0e5, -1.0e+30, "BinoutResponse -res_type RCForc -cmp y_force -id 9 -side MASTER -select MAX -start_time 0.00");
   ```

It is recommended to obtain the command definition using the GUI. The LS-OPT manual can also be consulted on how to create the string.

d) **Adding Part Data**

A user can add parts to the problem using the following command:

```c
struct lst_Part * lst_ProblemAddPart( struct lst_Problem *prob, Int partId, Float massFracB, Double minX, Double proxTol );
```

with the items in the command as explained for the part structure. The last two arguments (the minimum variable value and the neighbor radius) are optional.

Example: Adding a part

```c
struct lst_Part * prt = lst_ProblemAddPart( root->Problem, 102, 0.3 );
```
e) **Accessing a Part**

The parts are stored in a linked list in the `lst_Problem` structure. In addition, a pointer to the `lst_Part` structure is returned when it is created.

```c
lst_Part * part1 = root->Problem->PartList;
lst_Part * part2 = root->Problem->PartList->Next;
lst_Part * part4 = part1->Next->Next->Next;
lst_Part * prt = lst_ProblemAddPart( root->Problem, 101, 0.3 );
```

f) **Adding Geometry Data**

A user can add geometry constraints to the problem using the following commands:

```c
struct lst_Geometry * lst_PartAddGeometryExtrusion( struct lst_Part *, const char * name, long set, long CID, long dir );
struct lst_Geometry * lst_PartAddGeometryExtrusionConn( struct lst_Part *, const char * name, long set );
struct lst_Geometry * lst_PartAddGeometrySymmetryXY( struct lst_Part *, const char * name, long CID );
struct lst_Geometry * lst_PartAddGeometrySymmetryYZ( struct lst_Part *, const char * name, long CID );
struct lst_Geometry * lst_PartAddGeometrySymmetryZX( struct lst_Part *, const char * name, long CID );
struct lst_Geometry * lst_PartAddGeometry1SideCasting( struct lst_Part *, const char * name, long dir, long CID );
struct lst_Geometry * lst_PartAddGeometry2SideCasting( struct lst_Part *, const char * name, long dir, long CID );
```

g) **Adding Job Distribution Data**

Details about running the simulation job for each case can be added by creating a `JobInfo` structure and using `lst_CaseSetJobInfo` function. The syntax is as follows.

```c
lst_JobInfo * ji = lst_JobInfoNew();
ji->NumProc = 1;
ji->Queuer = 3;
lst_CaseSetJobInfo( aCase, ji );
```

For jobs submitted using a queuing system, the values of the environment variables can be set on the remote system, if required, using the `lst_JobInfoAddEnvVar` command. The command has the following syntax:

```c
lst_JobInfoAddEnvVar( struct JobInfo* ji, char * variableName, char * value );
lst_JobInfoDeleteEnvVar( struct JobInfo* ji, char * variableName );
```
Example: Adding simulation information to the two cases

1. Adding JobInfo to the case LEFT_LOAD that uses PBS queuing system,

   ```c
   lst_JobInfo * ji = lst_JobInfoNew();
   ji->NumProc = 0;
   ji->Queuer = 3;
   lst_JobInfoAddEnvVar( ji, "LS_NUM_ABC", "5" );
   lst_CaseSetJobInfo( left_load_case, ji );
   ```

2. Adding JobInfo to the case RIGHT_LOAD that does not use any queuing system,

   ```c
   lst_JobInfo * ji = lst_JobInfoNew();
   ji->NumProc = 1;
   ji->Queuer = 0;
   lst_CaseSetJobInfo( right_load_case, ji );
   ```

h) **Specifying Optimization Method Parameters**

   Once the root data structure is obtained, the data in Method data structure can be directly manipulated.

1. Specify the maximum number of iterations

   ```c
   root->Method->NumIter  = Int;
   ```

2. Provide convergence tolerance

   ```c
   root->Method->ConvTol  = Float;
   ```

3. To specify proximity tolerance use

   ```c
   root->Method->ProxTol  = Float;
   ```

5.4.3. **Execution Functions**

a) **Saving the Project Data**

   The program save the project input data in form of a XML database.

   ```c
   lst_RootWriteDb( root );
   ```

   A default filename of “lst_project.lstasc” is used, but you may specify the filename.

   ```c
   lst_RootWriteDb(root, "filename.xml" );
   ```

b) **Reading the Project Data**

   The project input data can be read from disk as:

   ```c
   lst_Root *root = lst_RootReadDb();
   ```

   A default filename of “lst_project.lstasc” is used, but you may also specify the filename.

   ```c
   lst_Root *root = lst_RootReadDb( "filename.xml" );
   ```
c) **Create Topology**

Following command computes the topology:

```
lst_CreateTopology(root);
```

The status of each simulation can optionally be reported every “Interval” seconds as shown in the following command:

```
lst_CreateTopology(root, Interval);
```

d) **Cleaning the directory**

The files created in the directory can be removed:

```
lst_CleanDir("databaseFileName.lstasc");
```

The filename was specified in this case; if omitted, the default of “lst_project.lstasc” will be used. All of the files created for the analysis, except the database, will be removed.

### 5.5. Accessing Results

These commands access the LS-TaSC database and the LS-DYNA® binout database using the LSDA (LSTC Data Archival) interface. Read this section together with the LSDA documentation available from the LSTC ftp site.

#### Open a database

<table>
<thead>
<tr>
<th>Command</th>
<th>Int handle lsda_open(Char *filename)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>Int fout = lsda_open(&quot;lstasc.lsd&quot;)</td>
</tr>
</tbody>
</table>

**handle**

An Int used to indentify this file in further actions.

**filename**

A string giving the filename or path to the database.

#### Close a database

<table>
<thead>
<tr>
<th>Command</th>
<th>Int success lsda_close(Int handle)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>Int flag = lsda_close(fout)</td>
</tr>
</tbody>
</table>

**Success**

An Int specify whether the command succeeded (>0).

**handle**

An Int identifying the lsda database.

#### Change to a database directory

<table>
<thead>
<tr>
<th>Command</th>
<th>Int success lsda_cd(Int handle, Char * dirName)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>Int flag = lsda_cd(fout, &quot;Design#4&quot;)</td>
</tr>
</tbody>
</table>

**Success**

An Int specify whether the command succeeded (>0).

**handle**

An Int identifying the lsda database.

**dirName**

A String specifying the database directory.

#### Get the current directory in a database

<table>
<thead>
<tr>
<th>Command</th>
<th>Char *dirName lsda_getpwd(Int handle)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>Char *currDir = lsda_getpwd(fout)</td>
</tr>
</tbody>
</table>

**dirName**

A String with the name of the current directory in the database. Do not free this
**Print the content of the current directory**

<table>
<thead>
<tr>
<th>Command</th>
<th>Int numItems lsda_ls(Int handle)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>Int n = lsda_ls( fout );</td>
</tr>
<tr>
<td>numItems</td>
<td>An Int specifying the number of items (directories and data vectors) in this directory.</td>
</tr>
<tr>
<td>handle</td>
<td>An Int identifying the lsda database.</td>
</tr>
</tbody>
</table>

**Get Integer data**

<table>
<thead>
<tr>
<th>Command</th>
<th>Int * data lsda_getI4data(Int handle, Char * variableName, Int * numValues )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>Int * results = lsda_getI4data( fout, &quot;elementLabels&quot;, &amp;numV );</td>
</tr>
<tr>
<td>data</td>
<td>A pointer to Int containing the data. You must free this pointer after using.</td>
</tr>
<tr>
<td>handle</td>
<td>An Int identifying the lsda database.</td>
</tr>
<tr>
<td>variableName</td>
<td>The name of the results.</td>
</tr>
<tr>
<td>numValues</td>
<td>The length of the data vector (the number of items).</td>
</tr>
</tbody>
</table>

**Get Float data**

<table>
<thead>
<tr>
<th>Command</th>
<th>Float * data lsda_getR4data(Int handle, Char * variableName, Int * numValues )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>Float * results = lsda_getR4data( fout, &quot;xx-stress&quot;, &amp;numV );</td>
</tr>
<tr>
<td>data</td>
<td>A pointer to Float containing the data. You must free this pointer after using.</td>
</tr>
<tr>
<td>handle</td>
<td>An Int identifying the lsda database.</td>
</tr>
<tr>
<td>variableName</td>
<td>The name of the results.</td>
</tr>
<tr>
<td>numValues</td>
<td>The length of the data vector (the number of items).</td>
</tr>
</tbody>
</table>

### 5.6. Example Script

#### 5.6.1. Retrieving a value from the project database

Retrieving a value from the database is simple: opened the project database and the value is available.

```c
lst_Root *root = lst_RootReadDb();
print( "Existing number of iterations: ", root->Method->NumIter );
```

#### 5.6.2. Restart for an additional iteration

Requiring four lines of code, this is slightly more complex than the previous example.

```c
lst_Root *root = lst_RootReadDb();
root->Method->NumIter = root->Method->NumIter + 1;
lst_RootWriteDb( root );
lst_CreateTopology(root);
```
5.6.3. Creating a topology database

An example script is shown here. The example performs topology optimization of a single load case problem using extrusion mode.

```c
lst_Root *root = lst_RootGet();

lst_Case *cse = lst_ProblemAddCase( root->Problem, "TOPLOAD", "/data1/tushar/submit_pbs", "small_example.k", 2, 1 );

lst_JobInfo *ji = lst_JobInfoNew();
ji->NumProc = 0;
ji->Queuer = 3;
lst_CaseSetJobInfo( cse, ji );

lst_Part *prt = lst_ProblemAddPart( root->Problem, 103, 0.3 );
lst_PartAddGeometryExtrusionConn( prt, "Extr", 1 );
lst_RootWriteDb( root );
```

5.6.4. Printing the content of the project database

The following script prints the content of a project XML database.

```c
#define:
int Print_JobInfo( lst_JobInfo *jInfo, char * whitespace )
{
    int i;

    print( whitespace, "*** JobInfo ***\n" );
    print( whitespace, "\tNumProc\t\t", jInfo->NumProc, "\n" );
    print( whitespace, "\tQueuer\t\t", jInfo->Queuer, "\n" );
    if( jInfo->EnvVarList ) {
        i = 0;
        while( jInfo->EnvVarList[i] ) {
            print( whitespace, "\tEnvVar\t\t", jInfo->EnvVarList[i], "\n" );
        }
        i = i+1;
    }
}
#define:
int Print_Case( lst_Case *cse, char * whitespace )
{
    struct lst_JobInfo *jInf;

    print( whitespace, "*** Case ***\n" );
    print( whitespace, "\tName\t\t", cse->Name, "\n" );
    print( whitespace, "\tSolverCommand\t", cse->SolverCommand, "\n" );
    print( whitespace, "\tInputFile\t", cse->InputFile, "\n" );
    print( whitespace, "\tWeight\t\t", cse->Weight, "\n" );
    print( whitespace, "\tAnalysisType\t", cse->AnalysisType, "\n" );

    jInf = cse->JobInfo;
    Print_JobInfo( jInf, "\t" );
}
#define:
int Print_Geom( lst_Geometry *geom, char * whitespace )
{
define:
int Print_Part( lst_Part *prt, char * whitespace )
{
struct lst_Geometry *geom;

print( whitespace, "*** Part ***\n" );
print( whitespace, "\tID \t\t", prt->ID, "\n" );
print( whitespace, "\tMassFraction\t", prt->MassFraction, "\n" );
print( whitespace, "\tMinVarValue\t", prt->MinVarValue, "\n" );
print( whitespace, "\tProxTol\t\t", prt->ProxTol, "\n" );

geom = prt->GeometryList;
while( geom ){
    Print_Geom( geom, "\t\t" );
    geom = geom->Next;
}
}

define:
int Print_Problem( lst_Problem *prob, char * whitespace )
{
struct lst_Case *cse;
struct lst_Part *prt;

print( whitespace, "*** Problem ***\n" );
print( whitespace, "\tDescription\t\t", prob->Description, "\n" );
print( whitespace, "\tNumCase\t\t\t", prob->NumCase, "\n" );
print( whitespace, "\tNumPart\t\t\t", prob->NumPart, "\n" );

cse = prob->CaseList;
while( cse ){
    Print_Case( cse, "\t" );
    cse = cse->Next;
}

prt = prob->PartList;
while( prt ){
    Print_Part( prt, "\t" );
    prt = prt->Next;
}
}

define:
int Print_Method( lst_Method *meth, char * whitespace )
{
print( whitespace, "*** Method ***\n" );
print( whitespace, "\tNumIter\t\t\t", meth->NumIter, "\n" );
print( whitespace, "\tConvTol\t\t\t", meth->ConvTol, "\n" );
print( whitespace, "\tNumDiscreteLevels\t\t", meth->NumDiscreteLevels, "\n" );
print( whitespace, "\tDebugGeomDef\t\t", meth->DebugGeomDef, "\n" );
}

/*****************************/ PROGRAM TO PRINT LST DATABASE
5.6.5. Printing the content of the results database

Int flag, numV, iter = 1;
Char dirName[1024];
Float *data, *wmEID, *aveChng;

print( "\"ItNum\", \"Total_IED\", \"Density_Redistribution\"\"n" );
Int handle = lsda_open( "lst.binout" );
lsda_cd( handle, "/" );
sprintf( dirName, "/design#%d", iter );
while ( lsda_cd( handle, dirName ) == 1 ) {
    wmEID = lsda_getR8data( handle, "Total_IED", &numV );
    aveChng = lsda_getR8data( handle, "Density_Redistribution", &numV );
    print( iter, ", ", wmEID[0], ", ", aveChng[0], ",\n" );
    iter = iter+1;
    sprintf( dirName, "/design#%d", iter );
    free( wmEID ); free( aveChng );
}
lsda_close( handle );
6. **APPENDIX B: THEORY**

I must say it looks a bit like science fiction to many people. – Ofir Shor, June 2009, while evaluating the alpha version.

### 6.1. Background

The traditional approach for solving topology optimization problems is based on sensitivity analysis that is inexpensive to obtain for linear-static problems. However, deriving analytical sensitivities for dynamic analysis is very difficult due to the complex interactions among material nonlinearities, geometry and mesh, and transient nature of load and boundary conditions. Numerical computation of sensitivities is also not practical due to the high computational expense. Hence the conventional sensitivity based approach of topology optimization is not practical for crashworthiness problems. To overcome the aforementioned difficulties in topology optimization, an optimality criteria approach was proposed. This approach does not require gradients and hence there is no need to compute the sensitivities. In previous versions, the approach was refer to as Hybrid Cellular Algorithm [1,2], but we found older views of the technology to be more representative of what is currently actually implemented.

### 6.2. Implementation

The algorithm for structural optimization is shown pictorially in Figure 6-1. After defining the problem, the topology is evolved using the simple rules defined on the variables. The constraints are accommodated during the state update procedure.

![Figure 6-1: The topology optimization algorithm](image)

#### 6.2.1. Definition

The input data is used to identify the design domain and design material model. The input data comprises of method data e.g., number of iterations, convergence tolerance, and the problem data, e.g. load cases, design part, etc.
6.2.2. Creating the variables

The finite element model is mapped to design variables. Each design variable is assigned to a solid element in the design domain. For extrusion and symmetry constraints, the equality constraints are defined between the variables. For casting constraints, inequality constraints are established.

6.2.3. Filtering of results

Past work were based on the structured grid arrangement of cells. This assumption would breakdown for industrial applications where structured grids are not always possible. Hence, a radius based strategy is used to identify neighbors. In this strategy, a virtual sphere of user-defined radius is placed at the centroids of an element. All elements that are within this sphere are considered the neighbors of the corresponding element, and the results are averaged over the elements in the neighborhood

\[ U_i = \frac{\sum_{j=1}^{n} U_j}{\sum_{j=1}^{n} 1}. \]

6.2.4. Material Parameterization

The material model is parameterized using a so-called density approach. In this approach, a design variable is directly linked to the individual material element such that each variable has its own material model. The material properties corresponding to the values of design variables are obtained using an appropriate interpolation model. The solid isotropic material with penalization (SIMP) model [6] is the most popular interpolation method. This model is power law approach that drives the intermediate material properties towards the boundaries to obtain a 0-1 topology. According to SIMP model, the material properties are defined as,

\[ \rho(x) = x\rho_0, \]

\[ E(x) = x^2E_0, \]

\[ \sigma(x) = x^3\sigma_0, \]

\[ E_h(x) = x^4E_{h0}, \]

where \( \rho \) denotes the density of the material, \( E \) represents the Young’s modulus, \( \sigma \) is the yield stress, and \( E_h \) is the strain hardening modulus. The last two material properties represent material non-linearities and are required for dynamic problems like crash that involve material yielding. The subscript ‘0’ refers to the base material properties. The design variable \( x \), also known as relative density, varies from 0 to 1 where ‘0’ indicates void and ‘1’ represents full material. A more detailed description of the material model parameterization, one should refer to Bendsoe and Sigmund [7], and Patel [8]. The elements with design variable value less than a user-defined minimum value are deleted to improve numerical stability.
6.2.5. Design Objectives and Constraints

The typical goal of topology optimization is to obtain maximum utility of the material. Compliance and the strain energy density are the most commonly used objectives for linear-static problems. For dynamic problems like crashworthiness simulations, the structure needs to absorb maximum energy while maintaining the structural integrity and keeping the peak loads transmitted to the occupants low. Following the formulation proposed by Patel [8], the goal of obtaining uniform internal energy density in the structure is defined as the objective for optimization. This concept is similar to the fully-stressed design and uniform strain energy density approaches (Haftka and Gurdal [9], Patnaik and Hopkins [10]) that are well established in literature for linear-static problems.

The optimization problem is formulated as,

$$\min \sum_{i} \sum_{j=1}^{N} (w_j U_j(x_i) - U^*)$$

subject to:

$$\sum_{i=1}^{N} \rho(x_i) V_i \leq M^*$$

$$C^l_j \leq C_j \leq C^u_j, \ j = 1, 2, \ldots, J$$

$$x_{\min} \leq x_i \leq 1.0.$$  \hspace{1cm} (7)

where $U$ represents the internal energy density of the $i^{th}$ element, $V_i$ is the volume of $i^{th}$ element, $U^*$ represents internal energy density set point, and $C_j$ is the $j^{th}$ constraint. There are $L$ load cases with a total of $J$ constraints. The superscripts ‘l’ and ‘u’ represent lower and upper bounds on the constraints, respectively.

6.2.6. Design Variable Initialization

The design variables are initialized to satisfy the material constraint. All elements are assigned the same design variable values. All associated field variables are also initialized to zero.

6.2.7. Simulation to Obtain Field Variables

The elements in the finite element model are modified by changing the material models, adding or deleting elements, at each iteration. So the input deck is re-written at each iteration. This modified input deck is analyzed using LS-DYNA® [11]. One can take advantage of multiple processors using the MPP version of LS-DYNA. The relevant field variables for all elements are obtained from the output to completely define the state of each variable. For multiple load case conditions, the state variable is based on the output from simulations of different load cases.

For dynamic problems, it was observed that accounting for the history of evolution induces stability by reducing the element deletion rate. Hence, the field variable (internal energy density) of $i^{th}$ variable at iteration $t$ is updated by defining a weighted sum on the field variable of three previous iterations as follows,
\[ U'_i = \frac{\sum_{j=0}^{n} (x_j)^{i+1} U'_j}{\sum_{j=0}^{n} (x_j)^{i+1}}. \]  \hfill (9)

where \( x_i \) is the design variable associated with the \( i^{th} \) variable at iteration \( t \).

### 6.2.8. Constraint Handling

In presence of constraints other than the mass constraints, the target mass constraint is adjusted to satisfy the structural constraints. The mass target \( (M^*) \) is increased in proportion to the constraint violation for all constraints except force constraints for which the mass target is reduced.

\[ M^* = M^* + \Delta M, \]
\[ \Delta M = \left[ \sum_j K^c_j e_j \right] / J, \]  \hfill (10)

where \( J \) is the total number of constraints, \( K^c_j \) is the coefficient used to scale the constraint violation of the \( j^{th} \) constraint, and \( e_j \) is the violation of the \( j^{th} \) constraint. The total change in mass target (\( \Delta M \)) is bounded to allow gradual changes in the structure.

### 6.2.9. State Update Rules

This is the heart of topology optimization method. In this step, the state of a variable is updated based on the state of its neighbors. The state update is carried out in two steps:

1. Field variable update: The field variable (internal energy density) of a variable is updated as accounting for the field variable values of its \( n \) neighbors as,

\[ U_i = \frac{\sum_{j=0}^{n} U_j}{\sum_{j=0}^{n} 1}. \]  \hfill (10)

2. Variable/Material Update: Once the field-variable state of each variable is defined, the design variable is updated to reflect the changes. While numerous rules are proposed in literature [6] to update design variables, a control based rule used by Patel [8] is implemented here (Figure 6-2).

The change in the design variable of \( i^{th} \) variable \( (\Delta x_i) \) is computed as,

\[ \Delta x_i = K \left( U'_i - U^* \right) / U^*. \]  \hfill (11)

where \( K \) is a scaling factor and \( U^* \) denotes the internal energy density set point. The design variable is updated as,

\[ x_i^{(t+1)} = x_i^{(t)} + \Delta x_i^{(t)}. \]  \hfill (12)

The change in the variable is constrained by the bounds on the value of the design variable i.e.,

I. if \( x_i^{(t+1)} < LB \), then \( x_i^{(t+1)} = LB \),

II. if \( x_i^{(t+1)} > UB \), then \( x_i^{(t+1)} = UB \),

and only certain discrete values are allowed.
The mass of each element is then calculated by using the appropriate material model associated with the design variables. If the total mass of the structure meets the constraint, the total change in design variables in this iteration is calculated, and the design variable update is considered completed. If the mass constraint is not satisfied, the IED set point is updated iteratively to accommodate the material constraint as,

$$U^* = U^* M / M^*.$$  \hspace{1cm} (13)

where $M$ is the mass of the structure.

6.2.10. Stopping Criteria

Two termination conditions are used to stop the optimization process.

1. The number of iterations has exceeded the maximum number of iterations, or
2. The change in the topology is smaller than the tolerance, i.e.,

$$dX^i = \sum_{i=1}^N \Delta x^i \leq \varepsilon.$$  \hspace{1cm} (14)

The numerical oscillations in convergence are limited by averaging the total change in topology over two iterations.

6.3. References

7. APPENDIX C: USING A QUEUING SYSTEM

7.1. Relationship with the LS-OPT queuing system

This queuing system is the same as used in LS-OPT. If your queue setup works for LS-OPT then it should work for LS-TaSC as well. This appendix mostly repeats the information for people not using LS-OPT.

In the LS-TaSC GUI the queuing is defined in the Scheduling tab of the Case definition. LS-OPT, on the other hand, define the queuing system in the run panel.

Also, you do not need to reinstall the wrapper program if it is already installed for LS-OPT.

7.2. Experience may be required

Experience with the queuing system and help from the system administer may be required. The queuing systems are not provided by LSTC. Getting the queue system to work may therefore require work and insight from the customer.

7.3. Introduction

The LS-TaSC Queuing Interface interfaces with load sharing facilities (e.g. LSF\textsuperscript{1} or LoadLeveler\textsuperscript{2}) to enable running simulation jobs across a network. LS-TaSC will automatically copy the simulation input files to each remote node, extract the results on the remote directory and transfer the extracted results to the local directory. The interface allows the progress of each simulation run to be monitored via the GUI. The README.queue file should be consulted for the most up to date information about the queuing interface.

7.4. Installation

To run LS-TaSC with a queuing (load-sharing) facility the following binary files are provided in the LSOPT_EXE directory which un-tars (or unzips) from the distribution during installation of LS-TaSC:

\begin{verbatim}
LSOPTOPO_EXE/wrapper
LSOPTOPO_EXE/runqueuer
\end{verbatim}

The runqueuer executes the command line for the purpose of queuing and must remain in the LS-TaSC environment (the same directory as the lsopt executable).

The following instructions should then be followed:

\footnotesize{\textsuperscript{1} Registered Trademark of Platform Computing Inc.}\
\footnotesize{\textsuperscript{2} Registered Trademark of International Business Machines Corporation}
a) **Installation for all remote machines running LS-DYNA**

1. Create a directory on the remote machine for keeping all the executables including lsdyna. Copy the appropriate executable wrapper program to the new directory. e.g. if you are running lsdyna on a Linux machine, place the wrapper appropriate for the architecture and operating system on this machine. You do not need to reinstall the wrapper program if it is already installed for LS-OPT.

b) **Installation on the local machine**

2. Select the queuer option in the GUI for the Case definition.

To pass all the jobs to the queuing system at once, select zero concurrent jobs in the GUI or command file.

In this example, the arguments to the rundyna.hp script are optional and can be hardcoded in the script.

3. Change the script you use to run the solver via the queuing facility by prepending "wrapper" to the solver execution command. Use full path names for both the wrapper and executable or make sure the path on the remote machine includes the directory where the executables are kept.

The argument for the input deck specified in the script must always be the LS-TaSC reserved name for the chosen solver, e.g. for LS-DYNA use `DynaOpt.inp`.

### 7.5. **Example**

*Example:* The LS-TaSC command relating to the queue is "/nec00a/mike/project/submit_pbs". The "submit_pbs" file is:

```csh
#!/bin/csh -f
#
# Run jobs on a remote processor, remote disk
set newdir=`pwd | sed -n '/\(.*\)/\(.*\)/\(.*\)/\1/\2/p'`
# Run jobs on a remote processor, local disk (no transmission)
# set newdir=`pwd`
echo $newdir
cat > dynscr << EOF
#!/bin/csh -f
#
#PBS -l nodes=1:ncpus=1
#
setenv LSOPT /nec00a/mike/codes/LSOPT_EXE
setenv LSOPT_HOST $LSOPT_HOST
setenv LSOPT_PORT $LSOPT_PORT
# Run jobs on a remote processor, remote disk
mkdir -p lsopt/$newdir
cd lsopt/$newdir
# The input file name is required for LS-OPT
```

65
It is also possible to specify the queue command directly on the command line. Environment variables can be specified on the solver command line (e.g. for the PBS queueing system) as well as LS-TaSC input data.

Example:
This example shows how the required environment variables LSOPT_PORT and LSOPT_HOST set by the runqueue program are specified on the solver command line whereas the two user variables LSDYNA971_MPP and LSOPT_WRAPPER are defined and stored as special input entities (see Section 7.13). These can also be set on the command line using the Linux "setenv" command. qsub is a PBS queue submit command and the –v directive defined the names of environment variables to be exported to the job. The qsub manual pages should also be consulted for more details. Say we submit to qsub using the command "qsub -v LSOPT_PORT,LSOPT_HOST ../../dynscr2". The dynscr2 file in this case is:

```bash
#!/bin/csh -f
#$ -cwd -pe mpi 2
setenv NP 2
setenv ROUNDROBIN 0
setenv EXE "$LSDYNA971_MPP $1"
rm -f mpp.hostfile mpp.appfile
filter_hostfile < $PE_HOSTFILE > mpp.hostfile
gen_appfile.hpmpi mpp.hostfile $SGE_O_WORKDIR $NP $ROUNDROBIN $EXE > mpp.appfile
$LSOPT_WRAPPER /opt/hpmpi/bin/mpirun -f mpp.appfile
```

The solver command data and environment variable input are displayed below:
7.6. **Mechanics of the queuing process**

Understanding the mechanics of the queuing process should help to debug the installation:

1. LS-TaSC automatically prepends `runqueuer` to the solver command and executes `runqueuer` which runs the `submit_pbs` script.
   - The `runqueuer` sets the variables `LSOPT_HOST` and `LSOPT_PORT` locally.
   - In the first example, the `submit_pbs` script spawns the `dynscr` script.

2. In Example 1 the queuing system then submits `dynscr` (see `qsub` command at the end of the `submit_pbs` script above) on the remote node which now has fixed values substituted for `LSOPT_HOST` and `LSOPT_PORT`.

3. In Example 2 the LS-TaSC schedules the `qsub` command directly with `LSOPT_HOST` and `LSOPT_PORT` as arguments and `i=DynaOpt.inp` appended at the end of the command. It therefore serves as an argument to `dynscr2`.

4. The wrapper executes on the same machine as LS-DYNA, opens a socket and connects back to the local host using the host/port information. The standard output is then relayed to the local machine. This output is also written to the `logxxxx` file (where `xxxx` is the process number) on the local host. To look at the log of any particular run, the user can select a button on the Run page under the View Log heading. The progress dialog is shown below, followed by the popup log.
An example of an error message resulting from a mistype of “wrapper” in the submit script is given in another example log file as follows:

```
STARTING command /home/jim/bin/runqueuer
PORT=56984
JOB=LoadLeveler
llsubmit: The job "1/1.1" has been submitted.
/home/jim/LSOPT_EXE/Xrapper: Command not found.
Finished with directory
/home/jim/LSOPT/4.1/optQA/QUEUE/EX4a_remote/remote/1/1.1
```

5. The wrapper will also extract the data immediately upon completion on the remote node. A log of the database extraction is provided in the logxxxx file.

### 7.7. Environment variables

These variables are set on the local side by the runqueuer program and their values must be carried to the remote side by the queuing software. The examples above illustrate two methods by which this can be accomplished.

- **LSOPT_HOST**: the machine where LS-TaSC (and therefore the runqueuer) is running.
- **LSOPT_PORT**: TCP/IP port runqueuer listens on for remote connections.

### 7.8. Troubleshooting

1. Diagnostics for a failed run usually appear in the logxxxx file in the run directory. If there is almost no information in this file, the wrapper path may be wrong or the submission script may have the wrong path or permission. For any job, this file can be viewed from the progress dialog on the Run page.

   Please attach the log file (lsopt_output) when emailing support@lstc.com.

2. Make sure that the permissions are set for the executables and submission script.

3. Check all paths to executables e.g. "wrapper", etc. No diagnostic can detect this problem.

4. Make sure that the result database is produced in the same directory as where the wrapper is started, otherwise the data cannot be extracted. (E.g. the front end program such as mpirun may have a specification to change the working directory (-wd dir)).

5. **Running on a remote disk.** Make sure that the file "HostDirectory" is not copied by a user script to the remote disk if the simulation run is done on a remote disk. The "HostDirectory" file is a marker file which is present only on the local disk. Its purpose is to inform the wrapper that it is running on the local disk and, if found on a remote disk, will prevent the wrapper from automatically transferring extracted results back to the local disk. In general the user is not required to do any file copying since input files (including LS-DYNA include files) are copied to the remote disk automatically. The response.* and history.* files are recovered from the remote disk automatically.
6. **Termination of user-defined programs**: LS-DYNA always displays a 'Normal' at the end of its output. When running a user-defined program which does not have this command displayed for a normal termination, the program has to be executed from a script followed by a command to write 'Normal' to standard output. The example file `runscript` shown below first runs the user-defined solver and then signals a normal termination.

```bash
mpiexec -n 2 /home/john/bin/myprogram -i UserOpt.inp
# print normal termination signal to screen
echo 'Normal'
```

which is submitted by the wrapper command in submit_pbs as:

```bash
/home/john/bin/wrapper /home/john/bin/runscript
```

*Note*: Adding "echo Normal" at the end of the wrapper command (after a semicolon) does not work which is why it should be part of the script run by the wrapper.

7.9. **User-defined queuing systems**

To ensure that the LS-TaSC job scheduler can terminate queued jobs, two requirements must be satisfied:

1. The queuer must echo a string

   Job "Stringa Stringb Stringc ..." has been submitted
   or
   Job Stringa has been submitted
   e.g.
   Job "Opteron Aqs4832" has been submitted
   Job aqs4832 has been submitted

   The string will be parsed as separate arguments in the former example or as a single argument in the latter example. The string length is limited to 1024 characters. The syntax of the phrases “Job ” and “ has been submitted” must be exactly as specified. If more than one argument is specified without the double quotes, the string will not be recognized and the termination feature will fail.

2. A termination script (or program) `LsoptJobDel` must be placed either in the main working directory (first default location) or in the directory containing the LS-TaSC binaries (second default). This script will be run with the arguments `stringA, stringB, etc.` and must contain the command for terminating the queue.

   An example of a Unix C shell termination script that uses two arguments is:

   ```bash
   #!/bin/csh -f
   aadmin -c $1 -j $2 stop
   ```

7.10. **Blackbox queueing system**

The Blackbox queueing system is another flavor of the User-defined queueing system. It can be used when the computers running the jobs are separated from the computer
running LS-TaSC by means of a firewall. The key differences between User-defined and Blackbox are:

1. It is the responsibility of the queueing system or the user provided scripts to transfer input and output files for the solver between the queueing system and the workstation running LS-TaSC. LS-TaSC will not attempt to open any communications channel between the compute node and the LS-TaSC workstation.

2. Extraction of responses and histories takes place on the local workstation instead of on the computer running the job.

3. LS-TaSC will not run local placeholder processes (i.e. extractor/runqueueuer) for every submitted job. This makes Blackbox use less system resources, especially when many jobs are run in each iteration.

When using the Blackbox queueing system, a LsoptJobDel script is required, just as in the User-defined case. Furthermore, another script named LsoptJobCheck must also be provided. This script takes one parameter, the job ID, as returned by the submission script. The script should return the status of the given job as a string to standard output.

The Blackbox queuer option requires the user to specify a command that will queue the job. The Blackbox option can also be specified in the Scheduling panel when defining a Case. The command to queue the job must return a job identifier that has one of the following two forms:

```
Job "Any Quoted String" has been submitted
Job AnyUnquotedStringWithoutSpaces has been submitted
```

The Word "Job" must be the first non-white space on the line, and must appear exactly as shown. Any amount of white space may appear between "Job" and the job identifier, as well as after the job identifier and before "has been submitted".

The Blackbox queuer requires the presence of two executable scripts LsoptJobCheck and LsoptJobDel. These scripts must be located in either in the current LS-TaSC project directory or in the directory where the running LS-TaSC program is located. (For Windows, the scripts must have an added extension .exe, .vbs, .cmd or .bat). If the Blackbox queuer option is invoked for some solver, then LS-TaSC checks for the existence of executable scripts in one of these locations, and refuses to run if the LsoptJobCheck and/or LsoptJobDel scripts cannot be found or are not executable. The project directory is searched first.

**LsoptJobCheck script**

The user-supplied LsoptJobCheck script is run each time LS-TaSC tries to update the current status of a job. The LsoptJobCheck script is run with a single commandline argument:
**LsoptJobCheck job_identifier**

The working directory of the LsoptJobCheck script is set to the job directory associated with job_identifier.

The script is expected to print a status statement that LS-TaSC can use to update its status information. The only valid status statements are:

<table>
<thead>
<tr>
<th>String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WAITING</td>
<td>The job has been submitted and is waiting to start</td>
</tr>
<tr>
<td>RUNNING</td>
<td>The job is running.</td>
</tr>
<tr>
<td>RUNNING N/M</td>
<td>After RUNNING, the script may also report the progress as a fraction. RUNNING 75/100 means that the job has ¾ to go. The progress information will be relayed to the user, but not used in any other way by LS-TaSC.</td>
</tr>
<tr>
<td>FAILED</td>
<td>The job failed. This is only to be used when the underlying queueing system reports some kind of problem. Hence, a solver that has terminated in error does not have to be detected by the LsoptJobCheck script.</td>
</tr>
<tr>
<td>FINISHED</td>
<td>The job has completed and any output files needed for extraction has been copied back to the run directory.</td>
</tr>
</tbody>
</table>

Any amount of white space may appear at the beginning of a status statement, and anything may appear after these statements. The optional \(\frac{N}{M}\) argument for RUNNING is interpreted as an estimate of the progress; in this case \(N\) and \(M\) are integers and \(\frac{N}{M}\) is the fractional progress. \(N\) must be not be larger than \(M\).

If LsoptJobCheck terminates without printing a valid status statement, then it is assumed that LsoptJobCheck does not function properly, and LS-TaSC terminates the job using the LsoptJobDel script. All output from the LsoptJobCheck script is logged to the job log file (logxxxx) in the run directory for debugging purposes.

*Note:* The LsoptJobCheck script may print more than one status statement, but only the first one will be used to update the status.

**LsoptJobDel script**

The user-supplied LsoptJobDel script is run whenever the user chooses to terminate a job, or whenever LS-TaSC determines that a job should be killed (for example, if LsoptJobCheck fails). The LsoptJobDel script is run with a single commandline argument:

LsoptJobDel job_identifier.
The working directory of the LsoptJobDel script is set to the job directory associated with job_identifier.

### 7.11. Honda queuing system

The Honda queuing system interface is based on the Blackbox queuing system, but is dedicated to the particular needs of this system.

#### Mechanics of the Honda queuing process

The queuing system generates a status file for which an environment variable has been defined in LS-TASC as:

```
$HONDA_STATUSFILE
```

The status file is the output of the PBS queue check command. During the initialization phase, LS-TASC checks whether this variable setting points to a valid file. If it does not, LS-TASC terminates before starting the scheduler, and prints a standard LSOPT-style error message.

The line which marks the fields in the status file is used to determine how to parse the file; this line has the form "----- ----------- - ----- ---- ....". Fields are extracted based on this line which consists solely of space and dash characters. The following fields are used:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>name</td>
</tr>
<tr>
<td>6</td>
<td>status: 'R' for running or 'Q' for queued</td>
</tr>
<tr>
<td>10</td>
<td>total wall clock time allowed</td>
</tr>
<tr>
<td>11</td>
<td>total wall clock time consumed.</td>
</tr>
</tbody>
</table>

Fields 10 and 11 are used to set the progress indicator. If the indicator ever reaches 100%, then it will terminate due to total wall clock time restrictions.

If a job cannot be found in the status file, then it is assumed to be dead. The job status entry is not looked for until a minimum of 3 seconds after the job has been started. A status file is searched for a particular job status entry only if the status file has a modification time that is later than the start time of the job.

Since there is no way to determine the exit status of a job by looking only at this status file, the determination of the final exit status depends on whether or not the job is an LS-DYNA job. If the job is an LS-DYNA job, then the messag file is parsed for the status statements "Normal" and "Error" termination. If no messag file is found 10 seconds after the job is no longer listed in the status file, then we assume an error termination.

If the job is a non-LS-DYNA job, then LsoptJobCheck (see Section 7.10) is executed just once after the job no longer appears in the status file. LsoptJobCheck should print either (a) FINISHED or (b) ERROR in order to communicate the final exit status. If
LsoptJobCheck cannot be found or cannot be executed, then ERROR is assumed. The job log file will contain a message indicating any problem that may exist which prevents LsoptJobCheck from being run.

The HONDA queued jobs do not use LsoptJobDel as defined in the Blackbox queuing selection. Jobs are deleted using the standard PBSPro qdel command.

Various statements concerning how status information is gathered are logged to the job log files. These are:

1. Job status for LSDYNA jobs found in 'messag' file:
   
   [HONDA] Termination status found in 'messag' file
   [HONDA] exact termination statement

2. The job status line for the current job found in $HONDA_STATUSFILE is saved:
   
   [HONDA] status line

3. The job is assumed finished if there is no status line found:
   
   [HONDA] Job 23551 not found in STATUS file - assuming job is finished.

4. Indication that LsoptJobCheck is run at the end of a non-LS-DYNA job:
   

5. Status returned from LsoptJobCheck.
   
   [HONDA] Job finished - LsoptJobCheck reports normal termination
   [HONDA] Job finished - LsoptJobCheck reports error termination

   Any errors while gathering status information are logged to the job log files such as log12345.

6. Missing messag file after LSDYNA terminates:
   
   [HONDA] Failed to find 'messag' file while FINISHING.
   [HONDA] Assuming ERROR termination for LSDYNA job.

7. Found no termination status statement in messag file
   
   [HONDA] Found no termination status in 'messag' file
   [HONDA] Assuming ERROR termination for LSDYNA job.

8. $HONDA_STATUSFILE variable not set
   
   [HONDA] *** Error $HONDA_STATUSFILE not set.

9. Could not open $HONDA_STATUSFILE
   
   [HONDA] *** Error Failed to open $HONDA_STATUSFILE=pbsq_status

10. LsoptJobCheck script not found for non-LSDYNA job
    
    [HONDA] *** Error LsoptJobCheck cannot be found.
    [HONDA] Assuming error termination for non-LSDYNA job.

11. LsoptJobCheck script did not print either (a) FINISHED or (b) FAILED.
**[HONDA]** *** Error LsoptJobCheck did not return a valid status. Assuming error termination for non-LSDYNA job.***

If `HONDA_STATUSFILE` is not updated in a timely fashion, then the scheduler can hang forever, never moving forward. A message is passed to lsopt through the communication socket if this happens:

*** Warning `HONDA_STATUSFILE` out of date by more than 5 minutes ***
*** Job progress monitoring suspended until next update ***

Even though the status file is checked before starting the scheduler, it is still possible for file errors to occur. These are also sent directly to LS-TASC.

*** Error `$HONDA_STATUSFILE` not set ***
*** Error Failed to open `$HONDA_STATUSFILE=pbsq_status` ***

### 7.12. Microsoft Windows Compute Cluster server

LS-TASC supports submission of jobs to the Microsoft Compute Cluster Pack Scheduler. Two scripts called `submit.cmd` and `submit.vbs`, that work together, are available to interface LS-TASC with CCP. The script can be downloaded from `ftp://ftp.lstc.com/ls-opt/QUEUING/MSCCS`. Before using the scripts the variables in the beginning of the file `submit.cmd` needs to be changed to fit your local environment. Most users do not need to change the `submit.vbs` file.

The example shows how the queue-related parts of an LS-TASC command file look when using the CCP scripts, when they are placed in the same directory as the command file:

### 7.13. Passing environment variables

LSOPT provides a way to define environment variables that will be set before executing a solver command. The desired environment variable settings can be specified directly in the com file with solver commands:

They can be specified within the Scheduling tab when defining a Case.

#### 7.13.1. Adding a new environment variable definition

Select the New button. After selecting this option, an empty, editable environment variable definition will appear.

We do not allow the names of variables to contain anything other than upper- or lower-case letters, numbers, and underscore ( _ ) characters. Variable values are not so limited.
7.13.2. Editing an existing environment variable definition
To edit an environment variable, double-click on the environment variable in the Environment variables list. The display mode of the variables will change to make it editable.

7.13.3. Set by browsing
Select the Select by Browsing button. In order for this option to work, user-supplied executables must be present in the directory $HOME/LSOPT_SCRIPTS
The directory LSOPT_SCRIPTS must exist as a subdirectory of the user's home directory, and it must contain executables. If the directory LSOPT_SCRIPTS does not exist, or if there are no executables in this directory, an error box will appear. Setting the LSOPT_SCRIPT Unix/Linux/Windows system environment variable may specify an alternative script directory.
After selecting the Set by browsing option, a dialog of buttons will appear, one for each executable in this directory. For example, suppose this is the directory listing for $HOME/LSOPT_SCRIPTS:

```
-rwxr-xr-x 1 joe staff 13597 2009-12-01 18:09 lsdyna_submit.autounion*
-rw-r--r-- 1 joe staff 13597 2009-12-01 17:46 stdin.save
-rwxr-xr-x 1 nielen staff 9 2009-08-10 14:23 test*
-rwxr-xr-x 1 nielen staff 9 2009-08-10 14:26 testb*
```

Then, when you select the Set by browsing option, the following dialog appears:
A valid browse command must print environment variable definitions to standard output in the form name='value'; the single quotes are optional if value does not contain spaces. A valid sample output is shown below (the line is wrapped because of its length).

```bash
exe=/home/trent/LSTC/PERL/lsdyna-caec01_pbs_sub.pl menu=batch
time=1:00 host=abcdefgh07 procs=1 jobname='My Job' project=isd
e-mail=No delay=No preemptable=No version='LS-DYNA 970 MPP SP 6763'
ioloc=/home/trent inpfile=DynaOpt.inp mem1=auto mem2=auto
pfile=Generic dumpbdb=No dynamore=No clean=No tail=No copycont=No
optimization=LsOpt
```

All of the name='value' strings are directly imported into the Env Vars tab in bulk. In addition to these Browse List variables, a special browse variable is created that should not be edited. This variable records the program name used to create the Browse List.

NOTE: All variables must be printed on one line, which must be the last line of output from the program. Lines before the last line are ignored.

WARNING: The user-supplied browse program should never define the browse variable in its output. The name browse should be treated as a reserved name.

A simple Linux browse command could be a shell script:

```bash
#!/bin/bash
echo This line is ignored. Only the last line survives
echo A=B C=D
```

Running the browse command shown above will import two variables, A and C, into the browse list.
NOTE: Strings in the Env Vars List appearing above the browse= line are all part of the Browse List. Strings in the Env Vars tab that appear below browse= are never part of the Browse List. User-defined environment variables will always follow after the browse variable definition (e.g., last=first in the figure above was not defined by the browse command.)

7.13.4. Edit browse list

Select the Edit Browse list button. Choosing this option does nothing unless a Browse List has been previously created. If a valid Browse List is present in the Env Vars tab, then selecting this option will run the original program that created the Browse List, together with all of the current Browse List options passed as command line arguments, one per existing environment variable. Each command-line argument has the form name=value. However ‘value’ is not single-quoted because each name=value argument is a separate command-line argument. The customer-supplied browse command should offer the user an opportunity to edit the existing variables, and the browse command should return the newly edited list on one line, in the same format as described above. This would normally be done through some sort of graphical user interface. The returned list will be used to replace all of the previous Browse List.

The next example script returns an initial Browse List consisting of two variables, A and C. Invoking the editing feature appends a new variable (tN=N) to the list.

```
#!/bin/bash
echo This line will be ignored. Only the last line survives.
if [ "$1" == "" ]; then
    echo A=B C=D;
else
    echo $* "t"$$"="$$;
fi
```

When this script is invoked using the “Create by Browse” feature, there are no command-line arguments, and the script prints “A=B C=D” to standard output. However, when the script is invoked using the edit feature for the first time, two command-line arguments “A=B” and “C=D” are passed to the script. This time the return line consists of the original command-line arguments (printed using $*) and tN=N, where N is the PID of the shell process. If the editing feature is invoked a second time, then three command-line arguments are passed to the script (“A=B”, “C=D”, and “tN=N”). Another new variable tN is appended, where N is the newest PID of the script process. This sample script has little practical value, except to illustrate how existing variable settings are passed by command-line to the previous browse command, and to illustrate how one can use the editing feature to modify or add new variables.

Note: The browse command can ABORT the replacement operation by printing a blank line to the standard output and immediately terminating. Otherwise the current Browse List may be deleted. If the browse command abnormally terminates, then an error box will appear with a title bar indicating that the command failed.

7.13.5. How the browse list is used by LS-TaSC

The Browse List (indeed, the complete Env Vars List) is used to set environment variables before running the solver command specified by LS-TaSC. However, if the first variable returned by the browse command is exe, then a pre-processing command is run
before running the actual solver command. The pre-processing command is the value of the \texttt{exe} variable. The pre-processing command has a command line
\begin{verbatim}
$exe \texttt{var1}=$\texttt{var1}, \texttt{var2}=$\texttt{var2}, ... \texttt{varN}=$\texttt{varN}
\end{verbatim}
That is, the command executed is the value of the \texttt{exe} variable; additional command line arguments consist of all \textbf{Browse List} strings with a comma delimiter appended to each intermediate one. (The final argument is not followed by a comma.)

\textit{Note:} Such a pre-processing command is always run from within the current \texttt{LS-TaSC Job Directory}. Therefore, any file that the pre-processing command references must be specified by a fully-qualified path or must be interpreted relative to the current \texttt{LS-TaSC Job Directory}. So, the \texttt{LS-TaSC Case Directory} will be ".." and the \texttt{LS-TaSC Project Directory} will be "./..".
7.14. **Enabling LSTCVM job proxy support**

7.14.1. **LSTCVM options**

There are two ways that LS-TaSC can work with the LSTCVM job proxy.

1. **LSTCVM and LS-TaSC share a common file system.** If LSTCVM and LS-TASC share a common file system, then you may run LS-TASC jobs from within the shared file system by using the solver command:

   ```
   lstcvm_run remote_solver_command
   ```

   For example, solver command "lstcvm_run ls971_single"

   would be the appropriate solver command in LS-TASC if you want to run the "ls971_single" command on the remote LSTCVM server.

2. **LSTCVM and LS-TaSC do not share a common file system.** In this case, you may still execute remote commands on the LSTCVM server, but you must select the following option in the Advanced GUI tab for the Solver: **Use LSTCVM proxy.**

   LS-TASC will take care of prepending the `lstdcm_run` command. So, in this case, if you want to execute "ls971_single" on the remote LSTCVM server, then your solver command should simply be:

   ```
   solver command "ls971_single"
   ```

   All necessary input files will be transferred to the remote LSTCVM server using LS-TASC runqueue/wrapper commands. Extraction results are automatically brought back to the local side once the job has finished.

   **Note:** In order for this option to work, you must install the LS-TaSC "wrapper" executable map file "lstdcm.exemap"

   ```
   wrapper -> full_path_to_wrapper
   ```

   The "wrapper" command is architecture specific. So be sure to obtain the correct program for the LSTCVM architecture.

   **REMOTE FILES:** We do not currently delete files on the LSTCVM server after the job has completed. This must be done by the LSTCVM proxy server administrator.

7.14.2. **LSTCVM server installation**

The LSTCVM server is distributed separately from LS-TASC and, in addition to the executables, contains detailed information and installation instructions. This server installation is usually handled by a systems administrator.

7.14.3. **Environment Variables**

All solver environment variables defined in the LS-TASC EnvVar tab of the Solver are automatically passed to the remote job on the LSTCVM server. (PATH is not passed for security reasons). This provides a convenient way to define licensing variables for LS-DYNA. For example, you can pass the following variables to the remote proxy server job:
7.14.4 Configuring the lstcvm_run client

The lstcvm_run client should be supplied with the LS-TaSC distribution. If you do not have such a command in the LS-TaSC installation directory, then your version of LS-TaSC is probably not LSTCVM ready. We suggest obtaining a later version of LS-TaSC in that case.

In order to configure the "lstcvm_run" client, you should execute

```
lstcvm_run -s lstcvm_server_name
```

The information will be saved so that this step never needs to be repeated. If you are running on a Microsoft Windows platform, then you should execute this command from within a command prompt; the server information will be saved in the Windows registry.

If you are running on a Linux/UNIX platform, then the server information is stored in $HOME/.lstcvm. If, for some reason, a port other than the default is used, then you must specify the port number N with the command

```
lstcvm_run -s N@lstcvm_server_name
```

After setting the server name, then you can test for connectivity using

```
lstcvm_run -info
```

You should see information about the current configuration of the LSTCVM server.

To test the installation, 'cd' to a directory where you are allowed to run the lstcvm_run client, and issue the command

```
lstcvm_run ls -al
```

It is possible that this command will fail if the LSTCVM administrator does not allow the "ls" command to be run. If that is the case, then check with the administrator about which commands are available.

Once you know that the lstcvm_run command is properly configured and able to execute commands remotely, then you are ready to use lstcvm_run with LS-TaSC. Only commands which are allowed and enabled by the LSTCVM administrator will function properly. For example, ls971_single is not available unless the remote administrator has enabled this command.
