	EQ.2: the bulk viscosity is turned on for beam type 1 and 11. The energy contribution is included in the overall energy balance.
TSTYPE	Bulk viscosity for thick shells (default = 0):
	EQ.0: the bulk viscosity is turned off for thick shells.
	EQ.1: the bulk viscosity is turned on for thick shells forms 5, 6, and 7.

Remarks:

The bulk viscosity creates an additional additive pressure term given by:

$$q = \begin{cases} \rho l\left(Q_1 l\dot{\varepsilon}_{kk}^2 - Q_2 a\dot{\varepsilon}_{kk}\right) & \dot{\varepsilon}_{kk} < 0 \\ 0 & \dot{\varepsilon}_{kk} \geq 0 \end{cases}$$

where Q_1 and Q_2 are dimensionless input constants which default to 1.5 and 0.06, respectively, l is a characteristic length given as the square root of the area in two dimensions and as the cube root of the volume in three, and a is the local sound speed. See Chapter 21 in the LS-DYNA Theory Manual for more details.

The Richards-Wilkins, see [Richards 1965, Wilkins 1976], bulk viscosity considers the directional properties of the shock wave which has the effect of turning off the bulk viscosity in converging geometries minimizing the effects of "q-heating." The standard bulk viscosity is active whenever the volumetric strain rate is undergoing compression even though no shock waves are present.

*CONTROL_CHECK_SHELL

Purpose: Check for various problems in the mesh after trimming for metal forming simulations. It only fixes boundary elements. This keyword should be included in a trimming input deck.

Part cards. Include one card for each part or part set to be checked. The next keyword ("*") card terminates this input.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID	IFAUTO	CONVEX	ADPT	ARATIO	ANGLE	SMIN	
Type	I	I	I	I	F	F	F	
Default	0	0	1	1	0.25	150.0	0.0	

VARIABLE	DESCRIPTION
PSID	Part or part set ID to be checked: EQ.0: Do not check GT.0: Part ID LT.0: Part set ID
IFAUTO	Flag to automatically correct bad elements: EQ.0: Write warning message only EQ.1: Fix bad element, write message
CONVEX	Check element convexity (internal angles less than 180 degrees). See Remark 2. EQ.0: Do not check EQ.1: Check
ADPT	Check adaptive constraints: EQ.0: Do not check EQ.1: Check
ARATIO	Minimum allowable aspect ratio. Elements which do not meet minimum aspect ratio test will be treated according to IFAUTO above.

VARIABLE	DESCRIPTION
ANGLE	Maximum allowable internal angle. Elements which fail this test will be treated according to IFAUTO above.
SMIN	Minimum element size. Elements which fail this test will be treated according to IFAUTO above. See Remark 4.

Remarks:

1. **Metal Forming Applications.** Shell element integrity checks which have been identified as important in metal forming applications are performed. These checks can improve springback convergence and accuracy. This keyword will repair bad elements created, for example, during trimming operations.

2. **Convexity.** If the convexity test is activated, all failed elements will be fixed regardless of IFAUTO.

3. **Mesh Connectivities.** In addition to illegal constraint definitions, checks are performed for mesh connectivities which have been found to cause convergence trouble in implicit springback applications.

4. **SMIN.** Variable SMIN should be set between 1/4 and 1/3 of the smallest pre-trim element length.

*CONTROL_COARSEN

Purpose: Adaptively de-refine (coarsen) a shell mesh by selectively merging four adjacent elements into one. Adaptive constraints are added and removed as necessary.

Card 1	1	2	3	4	5	6	7	8
Variable	ICOARSE	ANGLE	NSEED	PSID	SMAX			
Type	I	F	I	I	F			
Default	0	none	0	0	0			

Card 2	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	N5	N6	N7	N8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
ICOARSE	Coarsening flag: EQ.0: do not coarsen (default) EQ.1: coarsen mesh at beginning of simulation for forming model EQ.2: coarsen mesh at beginning of simulation for crash model
ANGLE	Allowable angle change between neighboring elements. Adjacent elements which are flat to within ANGLE degrees are merged. Suggested starting value is 8.0 degrees.
NSEED	Number of seed nodes (optional). EQ.0: use only automatic searching. GT.0: the number of seed nodes with which to supplement the search algorithm. See Remark 2. NSEED must be an integer less than or equal to 8.

VARIABLE	DESCRIPTION
PSID	Part set ID. All the parts defined in this set will be prevented from been coarsened.
SMAX	Maximum element size. For ICOARSE = 2, no elements larger than this size will be created.
N1, …, N8	Optional list of seed node IDs for extra searching. If no seed nodes are specified, leave Card 2 blank.

Remarks:

1. **Coarsened Mesh Input Deck.** Coarsening is performed at the start of a simulation. The first plot state represents the coarsened mesh. By setting the termination time to zero and including the keyword *INTERFACE_SPRINGBACK_-LSDYNA, a keyword input deck can be generated containing the coarsened mesh.

2. **Seed Nodes.** By default, an automatic search is performed to identify elements for coarsening. In some meshes, isolated regions of refinement may be overlooked. Seed nodes can be identified in these regions to assist the automatic search. Seed nodes identify the central node of a four-element group which is coarsened into a single element if the angle criterion is satisfied.

3. **Non-Coarsened Regions.** The keyword *DEFINE_BOX_COARSEN can be used to indicate regions of the mesh which are protected from coarsening.

*CONTROL_CONSTRAINED

Purpose: Define global control parameters for constraint related properties.

Card 1	1	2	3	4	5	6	7	8
Variable	SPRCHK							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
SPRCHK	SPR2/SPR3 initialization check: EQ.0: Automatically increase search radius to find enough nodes (default) EQ.1: Same as 0 but also write a warning EQ.2: Error termination if not enough nodes found immediately

*CONTROL_CONTACT

Purpose: Change defaults for computation with contact surfaces.

Card Summary:

The optional cards (Cards 3 through 7) apply only to the following contact types:

SINGLE_SURFACE

AUTOMATIC_GENERAL

AUTOMATIC_SINGLE_SURFACE

AUTOMATIC_NODES_TO_…

AUTOMATIC_SURFACE_…

AUTOMATIC_ONE_WAY_…

ERODING_SINGLE_SURFACE

The friction coefficients SFRIC, DFRIC, EDC, and VFC are active only when *PART_CONTACT is invoked with FS = -1 in *CONTACT, and the corresponding frictional coefficients in *PART_CONTACT are set to zero. This keyword's TH, TH_SF, and PEN_SF override the corresponding parameters in *CONTACT but will not override corresponding nonzero parameters in *PART_CONTACT.

Card 1. This card is required.

SLSFAC	RWPNAL	ISLCHK	SHLTHK	PENOPT	THKCHG	ORIEN	ENMASS

Card 2. This card is required.

Card 6. This card is optional.

SHLEDG	PSTIFF	ITHCNT	TDCNOF	FTALL		SHLTRW	IGACTC

Card 7. This card is optional.

IREVSPT							

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SLSFAC	RWPNAL	ISLCHK	SHLTHK	PENOPT	THKCHG	ORIEN	ENMASS
Type	F	F	I	I	I	I	I	I
Default	.1	none	1	0	1	0	1	0

VARIABLE	DESCRIPTION
SLSFAC	Scale factor for sliding interface penalties, SLSFAC: EQ.0.0: Default = 0.1.
RWPNAL	Scale factor for rigid wall penalties (see *RIGIDWALL) that treats nodal points interacting with rigid walls. The penalties are set so that an absolute value of unity should be optimal; however, this penalty value may be very problem dependent. If rigid/deformable materials switching is used, this option should be used if the switched materials are interacting with rigid walls. If you have IGA parts in your model, see Remark 10. LT.0.0: All nodes are treated by the penalty method. This is set to -1.0 for implicit calculations. Since seven (7) variables are stored for each possible tracked node (see NSID on *RIGIDWALL_PLANAR/GEOMETRIC), only the nodes that may interact with the wall should be included in the node list. EQ.0.0: The constraint method is used and nodal points which belong to rigid bodies are not considered. GT.0.0: Rigid body nodes are treated by the penalty method, and all other nodes are treated by the constraint method.

VARIABLE	DESCRIPTION
ISLCHK	Initial penetration check in contact surfaces with indication of initial penetration in output files (see Remark 3): EQ.1: No checking (default) EQ.2: Full check of initial penetration is performed.
SHLTHK	Flag for consideration of shell thickness offsets in non-automatic surface-to-surface and non-automatic nodes-to-surface type contacts. Shell thickness offsets are always included in single surface, constraint-based, automatic surface-to-surface, and automatic nodes-to-surface contact types (see Remarks 1 and 2): EQ.0: Thickness is not considered. EQ.1: Thickness is considered, but rigid bodies are excluded. EQ.2: Thickness is considered, including rigid bodies.
PENOPT	Penalty stiffness value option (applies to the Standard Penalty Formulation and the Soft Constraint Penalty Formulation, that is, SOFT = 0 and 1 on *CONTACT_*OPTION*). For default calculation of the penalty value, please refer to the LS-DYNA Theory Manual. EQ.1: Minimum of reference segment and tracked node (default for most contact types) EQ.2: Use reference segment stiffness (old way). EQ.3: Use tracked node value. EQ.4: Use tracked node value, area or mass weighted. EQ.5: Same as 4 but inversely proportional to the shell thickness. This may require special scaling and is not generally recommended. PENOPT = 4 and 5 can be used for metal forming calculations. In general, PENOPT = 2 - 5 should be avoided if both the tracked nodes and the reference segments belong to deformable parts.
THKCHG	Shell thickness changes considered in single surface contact (see Remark 1): EQ.0: No consideration (default) EQ.1: Shell thickness changes are included. EQ.2: Applies to MPP only. Shell thickness changes are included, but a different algorithm is used than for

VARIABLE	DESCRIPTION
	THKCHG = 1. This method is more consistent with the way the initial contact thickness is computed.
ORIEN	Optional automatic reorientation of contact interface segments during initialization. See Remark 4. EQ.1: Active for automated (part) input only (default). Contact surfaces are given by *PART definitions. EQ.2: Active for manual (segment) and automated (part) input EQ.3: Inactive for non-forming contact EQ.4: Inactive for *CONTACT_FORMING types and *CONTACT_DRAWBEAD
ENMASS	Flag for treatment of eroded nodes in contact. An eroded node is defined as a node that is no longer attached to any element owing to element deletion. ENMASS is not supported by all contact types; it is suggested that the user toggle on "Show Deleted Nodes" in LS-PrePost when postprocessing to display eroded nodes as particles, and in so doing, determine if ENMASS affects the contact behavior. ENMASS is not supported when SOFT = 2 on Optional Card A of *CONTACT. EQ.0: Eroded nodes are not considered in the contact algorithm. EQ.1: Eroded nodes of solid elements remain active in the contact algorithm. EQ.2: Eroded nodes of solid and shell elements remain active in the contact algorithm.

Card 2	1	2	3	4	5	6	7	8
Variable	USRSTR	USRFRC	NSBCS	INTERM	XPENE	SSTHK	ECDT	TIEDPRJ
Type	I	I	I	I	F	I	I	I
Default	0	0	10-100	0	4.0	0	0	0

VARIABLE	DESCRIPTION
USRSTR	Storage per contact interface for user supplied interface control subroutine; see Appendix F. If zero, no input data is read, and no

VARIABLE	DESCRIPTION
	interface storage is permitted in the user subroutine. This storage should be large enough to accommodate input parameters and any history data. This input data is available in the user supplied subroutine.
USRFRC	Storage per contact interface for user supplied interface friction subroutine; see Appendix G. If zero, no input data is read, and no interface storage is permitted in the user subroutine. This storage should be large enough to accommodate input parameters and any history data. This input data is available in the user supplied subroutine.
NSBCS	Number of cycles between contact searching using three-dimensional bucket searches. Using the default value for this field is strongly recommended. For mortar contact (option MORTAR on the CONTACT card), the default is 100.
INTERM	Flag for intermittent searching in old surface-to-surface contact using the interval specified as NSBCS above: EQ.0: Off EQ.1: On
XPENE	Contact surface maximum penetration check multiplier. If the small penetration checking option, PENCHK, on the contact surface control card is active, then nodes whose penetration then exceeds the product of XPENE and the element thickness are set free, see *CONTACT_*OPTION*_… EQ.0.0: Set to default which is 4.0.
SSTHK	Flag for determining default contact thickness for shells in single surface contact types. This variable does not apply when SOFT = 2. See Remark 2. EQ.0: Default contact thickness may be controlled by shell thickness or by shell edge length (default). EQ.1: Default contact thickness is equal to the shell thickness.
ECDT	Time step size override for eroding contact: EQ.0: Contact time size may control DT. EQ.1: Contact is not considered in DT determination.

VARIABLE	DESCRIPTION
TIEDPRJ	Bypass projection of SURFA nodes to SURFB surface in types: *CONTACT_TIED_NODES_TO_SURFACE *CONTACT_TIED_SHELL_EDGE_TO_SURFACE *CONTACT_TIED_SURFACE_TO_SURFACE Tied interface options: EQ.0: Eliminate gaps by projection nodes EQ.1: Bypass projection. Gaps create rotational constraints which can substantially affect results.

This card is optional.

Card 3	1	2	3	4	5	6	7	8
Variable	SFRIC	DFRIC	EDC	VFC	TH	TH_SF	PEN_SF	PTSCL
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	1.0

VARIABLE	DESCRIPTION
SFRIC	Default static coefficient of friction (see *PART_CONTACT)
DFRIC	Default dynamic coefficient of friction (see *PART_CONTACT)
EDC	Default exponential decay coefficient (see *PART_CONTACT)
VFC	Default viscous friction coefficient (see *PART_CONTACT)
TH	Default contact thickness (see *PART_CONTACT)
TH_SF	Default thickness scale factor (see *PART_CONTACT)
PEN_SF	Default local penalty scale factor (see *PART_CONTACT)
PTSCL	Scale factor on the contact stress exerted onto shells formulations 25, 26, and 27. When DOF = 3 the scale factor also applies to shell formulations 2, 4, and 16.

This card is optional.

Card 4	1	2	3	4	5	6	7	8
Variable	IGNORE	FRCENG	SKIPRWG	OUTSEG	SPOTSTP	SPOTDEL	SPOTHIN	
Type	I	I	I	I	I	I	F	
Default	0	0	0	0	0	0	inactive	

VARIABLE	DESCRIPTION
IGNORE	Ignore initial penetrations for the *CONTACT_AUTOMATIC options. In the SMP contact this flag is not implemented for the AUTOMATIC_GENERAL option. "Initial" in this context refers to the first time step that a penetration is encountered. This option can also be specified for each interface on the third optional card under the keyword, *CONTACT. The value defined here will be the default. EQ.0: Move nodes to eliminate initial penetrations in the model definition. EQ.1: Allow initial penetrations to exist by tracking the initial penetrations. EQ.2: Allow initial penetrations to exist by tracking the initial penetrations. However, penetration warning messages are printed with the original coordinates and the recommended coordinates of each penetrating node given.
FRCENG	Flag to activate the calculation of frictional sliding energy: EQ.0: Do not calculate. EQ.1: Calculate frictional energy in contact and store as "Surface Energy Density" in the binary INTFOR file. Convert mechanical frictional energy to heat when doing a coupled thermal-mechanical problem. When PKP_SEN = 1 on the keyword card *DATABASE_EXTENT_BINARY, it is possible to identify the energies generated on the upper and lower shell surfaces, which is important in metal forming applications. This data is mapped after each *h*-adaptive remeshing.

VARIABLE	DESCRIPTION
	EQ.2: Same as behavior as above (set to 1) except that frictional energy is not converted to heat.
SKIPRWG	Flag not to display stationary rigid wall by default: EQ.0: Generate 4 extra nodes and 1 shell element to visualize stationary planar rigid wall. EQ.1: Do not generate stationary rigid wall.
OUTSEG	Flag to determine whether to output for contact type *CONTACT_-SPOTWELD each beam spot weld SURFA node and its SURFB segment into the d3hsp file: EQ.0: No, do not write out this information. EQ.1: Yes, write out this information.
SPOTSTP	Flag to determine whether an error termination should occur if a spot weld node or face, which is related to a *MAT_SPOTWELD beam or solid element, respectively, cannot be found on the SURFB surface: EQ.0: No error termination. Silently delete the weld and continue. EQ.1: Print error message and terminate. EQ.2: No error termination. Delete the weld, print a message, and continue. EQ.3: No error termination; keep the weld. This is not recommended as it can lead to instabilities.
SPOTDEL	This option controls the behavior of spot welds when the parent element erodes. When SPOTDEL is set to 1, the beam or solid spot weld is deleted, and the tied constraint is removed when the parent element erodes. The parent element is the element to which the SURFA node is attached using the TIED interface. This option also works for SPRs, namely, they automatically fail if at least one of the parent elements fails. To avoid instabilities this option is recommended to be set to 1 for any situation in which the parent element is expected to erode. EQ.0: Do not delete the spot weld beam or solid element or SPR. EQ.1: Delete the spot weld elements or SPRs when the attached shells on one side of the element fail.

VARIABLE	DESCRIPTION
	GT.1: Delete the SPR when SPOTDEL nodes are attached to failed elements in the search radius. On vector processors this option can significantly slow down the calculation if many weld elements fail since the vector lengths are reduced. On non-vector processors the cost-penalty is minimal.
SPOTHIN	Optional thickness scale factor. If active, define a factor greater than zero, but less than one. Premature failure of spot welds can occur due to contact of the spot welded parts in the vicinity of the spot weld. This contact creates tensile forces in the spot weld. Although this may seem physical, the compressive forces generated in the contact are large enough to fail the weld in tension before failure is observed in an experimental test. With this option, the thickness of the parts in the vicinity of the weld are automatically scaled, the contact forces do not develop, and the problem is avoided. We recommend setting the IGNORE option to 1 or 2 if SPOTHIN is active. This option applies only to the AUTOMATIC_SINGLE_SURFACE option. See Remark 5.

This card is optional.

Card 5	1	2	3	4	5	6	7	8
Variable	ISYM	NSEROD	RWGAPS	RWGDTH	RWKSF	ICOV	SWRADF	ITHOFF
Type	I	I	I	F	F	I	F	I
Default	0	0	0	0.	1.0	0	0.	0

VARIABLE	DESCRIPTION
ISYM	Symmetry plane option default for automatic segment generation when contact is defined by part IDs: LT.0: |ISYM| is a node set on the symmetry boundary, supported and recommended for Mortar contact. This will allow for a correct treatment of segments close to the symmetry face/edge. See Remark 8. EQ.0: Off

VARIABLE	DESCRIPTION
	EQ.1: Do not include faces with normal boundary constraints (for example, segments of brick elements on a symmetry plane).
	This option is important to retain the correct boundary conditions in the model with symmetry.
NSEROD	Flag to invoke old method for ERODING_NODES_TO_SURFACE (SMP only):
	EQ.0: Use two-way algorithm (default)
	EQ.1: Use one-way algorithm (old method)
RWGAPS	Flag to add rigid wall gap stiffness (see parameter RWGDTH below):
	EQ.1: Add gap stiffness.
	EQ.2: Do not add gap stiffness.
RWGDTH	Death time for gap stiffness. After this time the gap stiffness is no longer added.
RWKSF	Rigid wall penalty scale factor for contact with deformable parts during implicit calculations. This value is independent of SLSFAC and RWPNAL. If RWKSF is also specified in *RIGIDWALL_PLANAR, the stiffness is scaled by the product of the two values.
ICOV	Invokes the covariant formulation of Konyukhov and Schweizerhof in the FORMING contact option.
	EQ.0: Standard formulation (default)
	EQ.1: Covariant contact formulation
SWRADF	Spot weld radius scale factor for neighbor segment thinning:
	EQ.0: Neighbor segments are not thinned (default).
	GT.0: The radius of a beam spot weld is scaled by SWRADF when searching for close neighbor segments to thin.
ITHOFF	Flag for offsetting thermal contact surfaces for thick thermal shells:
	EQ.0: No offset. If thickness is not included in the contact, the heat will be transferred between the mid-surfaces of the corresponding contact segments (shells).

VARIABLE	DESCRIPTION
	EQ.1: Offsets are applied so that contact heat transfer is always between the outer surfaces of the contact segments (shells).

This card is optional.

Card 6	1	2	3	4	5	6	7	8
Variable	SHLEDG	PSTIFF	ITHCNT	TDCNOF	FTALL		SHLTRW	IGACTC
Type	I	I	I	I	I		F	I
Default	0	0	0	0	0		0.	0

VARIABLE	DESCRIPTION
SHLEDG	Flag for assuming edge shape for shells when measuring penetration. This field is available for segment-based contact (see SOFT = 2 on *CONTACT) EQ.0: Shell edges are assumed round (default). EQ.1: Shell edges are assumed square and are flush with the nodes.
PSTIFF	Flag to choose the method for calculating the penalty stiffness. This field is available for segment-based contact (see SOFT = 2 on *CONTACT). See Remark 6. EQ.0: Based on material density and segment dimensions (default). EQ.1: Based on nodal masses.
ITHCNT	Thermal contact heat transfer methodology: LT.0: Conduction evenly distributed (pre R4) EQ.0: Set to default which is 1 EQ.1: Conduction weighted by shape functions, reduced integration EQ.2: Conduction weighted by shape functions, full integration

VARIABLE	DESCRIPTION
TDCNOF	Tied constraint offset contact update option: EQ.0: Update velocities and displacements from accelerations. EQ.1: Update velocities and accelerations from displacements. This option is recommended only when there are large angle changes where the default does not maintain a constant offset to a small tolerance. This latter option is not as stable as the default and may require additional damping for stability. See *CONTROL_BULK_VISCOSITY and *DAMPING_PART_STIFFNESS.
FTALL	Option to output contact forces to RCFORC for all two surface force transducers when the force transducer surfaces overlap. See Remark 7. EQ.0: Output to the first force transducer that matches (default). EQ.1: Output to all force transducers that match.
SHLTRW	Optional shell thickness scale factor for contact with rigid walls. Shell thickness is not considered when SHLTRW = 0.0 (default). SHLTRW = 0.5 will result in an offset of half a shell thickness in contact with rigid walls.
IGACTC	Options to use isogeometric shells for contact detection for contact involving isogeometric shells: EQ.0: Contact between interpolated nodes and interpolated shells EQ.1: Contact between interpolated nodes and isogeometric shells

This card is optional.

Card 7	1	2	3	4	5	6	7	8
Variable	IREVSPT							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
IREVSPT	Flag to revert the spot weld thinning behavior where beam and brick spot welds share nodes with shell parts instead of being tied to the shells: EQ.0: Thinning at shared nodes will be done as it has been in all versions after R9.3.1. EQ.1: Behavior reverts to that of R9.3.1. In this version and previous versions, spot weld thinning was not done.

Remarks:

1. **Shell Thickness Change.** The shell thickness change option (ISTUPD) must first be activated in *CONTROL_SHELL in order for shell thickness to change. Secondly, for a single surface contact to recognize the change in shell thickness, THKCHG must be set to 1. For surface-to-surface contacts with shell thickness offsets, that is, *CONTACT_SURFACE_TO_SURFACE with SHLTHK set to 1 or 2, or *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE, the shell thickness change is recognized by default and THKCHG is not used.

2. **Default Contact Thickness for Single Surface Contacts.** For single surface contact types,

   SINGLE_SURFACE

   AUTOMATIC_SINGLE_SURFACE

   AUTOMATIC_GENERAL

   AUTOMATIC_GENERAL_INTERIOR

   ERODING_SINGLE_SURFACE,

   the default contact thickness is taken as the smaller of two values, namely:

   - shell thickness, and
   - 40% of the minimum edge length.

   The minimum edge length is calculated as the minimum of the distances from N4 to N1, N1 to N2, and N2 to N3. N3 to N4 is neglected owing to the possibility of the shell being triangular. For shells that have a large thickness, the "40% of the minimum edge length" criterion may control the contact thickness. This edge length criterion is an ad hoc criterion included to help prevent solution instability or add a slow down in the contact searching in the case where the shell thickness-to-edge-length ratio is large.

If SSTHK = 1 or if SOFT = 2 (Optional Card A in *CONTACT), the edge length criterion is not considered, that is, the default contact thickness is simply the shell thickness.

3. **Initial Penetration Check.** As of version 950 the initial penetration check option is always performed regardless of the value of ISLCHK. If you do not want to remove initial penetrations, then set the contact birth time (see *CONTACT_…) so that the contact is not active at time 0.0.

4. **Automatic Reorientation.** Automatic reorientation requires offsets between the segments on each side of the contact interface. The reorientation is based on segment connectivity and, once all segments are oriented consistently based on connectivity, a check is made to see if the surfaces on each side of the contact interface face each other based on the right-hand rule. If not, all segments in a given surface are reoriented. This procedure works well for non-disjoint surfaces. If the surfaces are disjoint, the AUTOMATIC contact options, which do not require orientation, are recommended. For the FORMING contact types automatic reorientation works for disjoint surfaces.

5. **Neighbor Segment Thinning Option.** If SPOTHIN is greater than zero and SWRADF is greater than zero, a neighbor segment thinning option is active. The radius of a spot weld is scaled by SWRADF, and then a search is made for shell segments that are neighbors of the tied shell segments that are touched by the weld but not tied by it. The SWRADF option is available for beam element welds, solid element welds, and solid weld assemblies. For solids and solid assemblies, the weld radius is calculated assuming a circular shape with equivalent area.

6. **Segment Masses for Penalty Stiffness.** Segment based contact (see SOFT = 2 on *CONTACT) calculates a penalty stiffness based on the solution time step and the masses of the segments in contact. By default, segment masses are calculated using the material density of the element associated with the segment and the volume of the segment. This method does not take into account added mass introduced by lumped masses or mass scaling and can lead to stiffness that is too low. Therefore, a second method (PSTIFF = 1) was added which estimates the segment mass using the nodal masses. Setting a PSTIFF values here will set the default values for all interfaces. The PSTIFF option can also be specified for individual contact interfaces by defining PSTIFF on Optional Card F of *CONTACT.

7. **Force Transducer Search Option.** Force transducers between two surfaces measure the contact force from any contact interfaces that generate force between the SURFA and SURFB surfaces of the force transducer. When contact is detected, a search is made to see if the contact force should be added to any two surface force transducers. By default, when a force transducer match is found,

the force is added, and the search terminates. When FTALL = 1, the search continues to check for other two surface force transducer matches. This option is useful when the SURFA and SURFB force transducer surfaces overlap. If there is no overlap, the default is recommended.

8. **Symmetry Option for Mortar Contact.** By specifying a node set through ISYM < 0, a segment will be ignored in the Mortar contact if *all* nodes in the segment are contained in the specified node set. Edge treatment will also be avoided on the interface between the symmetry plane and the true contact surface. *Important note:* When using this option, it is important that segments *close* to the symmetry plane but *not in it* have at least one node on the true contact surface. For instance, if a quarter symmetry model is used, avoid using a wedge element at the center as this is likely to render a triangular contact segment with all of its nodes in the symmetry node set.

9. **MORTAR Contact Fields.** The following table lists parameters that in some sense are related to MORTAR contact. Any parameter that is not mentioned in this list is ignored. See also a similar table on *CONTACT.

Data Card	Comment
Card 1	Only SLSFAC applies, and it applies as for any other contact. Other parameters are ignored. Shell thickness offsets are always included, except for SURFB surface thickness with the FORMING option. For the FORMING option the normal of the SURFB surface must point towards the SURFA side of the contact. For any contact, shell thickness changes are considered if ISTUPD on *CONTROL_SHELL is used. Offset of the shell reference surface is considered if NLOC on *SECTION_SHELL is used, regardless of the value of CNTCO on *CONTROL_SHELL.
Card 2	USRFRC and NSBCS apply as for any other contact; all other parameters are ignored.
Card 3	All parameters apply as for any other contact.
Card 4	IGNORE = 0/1/2 applies as described on *CONTACT, as does FRCENG. Other parameters are ignored.
Card 5	ISYM < 0 applies, which indicates a node set on symmetry planes. Other parameters are ignored.
Card 6	No parameters apply. Edges in automatic contact are always flat.

10. **RWPNAL and IGA.** If you have IGA parts in your model specified with either *IGA_SHELL or *IGA_SOLID, then the rigid wall will be enforced through the

interpolation nodes generated for the IGA parts. The interpolation nodes will be treated like nodal points that belong to rigid bodies and will be treated with the penalty method. The actual control points for the IGA parts will be removed from the list of possible tracked nodes.

If RWPNAL = 0.0, rigid nodes are not included in the contact, but the interpolation nodes are still enforced by the penalty method using a rigid wall penalty scale factor.

*CONTROL_COUPLING

Purpose: Change defaults for MADYMO3D/CAL3D coupling; see Appendix I.

Default	1.	1.	1.	0.	0	0	0	1

VARIABLE	DESCRIPTION
UNLENG	Unit conversion factor for length. MADYMO3D/GM-CAL3D lengths are multiplied by UNLENG to obtain LS-DYNA lengths.
UNTIME	Unit conversion factor for time, UNTIME. MADYMO3D/GM-CAL3D time is multiplied by UTIME to obtain LS-DYNA time.
UNFORC	Unit conversion factor for force, UNFORC. MADYMO3D/GM-CAL3D force is multiplied by UNFORC to obtain LS-DYNA force.
TIMIDL	Idle time during which CAL3D or MADYMO is computing and LS-DYNA remains inactive. Important for saving computer time.
FLIPX	Flag for flipping *X*-coordinate of CAL3D/MADYMO3D relative to the LS-DYNA model: EQ.0: off, EQ.1: on.
FLIPY	Flag for flipping *Y*-coordinate of CAL3D/MADYMO3D relative to the LS-DYNA model: EQ.0: off, EQ.1: on.
FLIPZ	Flag for flipping *Z*-coordinate of CAL3D/MADYMO3D relative to the LS-DYNA model: EQ.0: off, EQ.1: on.

VARIABLE	DESCRIPTION
SUBCYL	CAL3D/MADYMO3D subcycling interval (# of cycles): EQ.0: Set to 1, GT.0: SUBCYL must be an integer equal to the number of LS-DYNA time steps between each CAL3D/MADYMO3D step. Then the position of the contacting rigid bodies is assumed to be constant for n LS-DYNA time steps. This may result in some increase in the spikes in contact, thus this option should be used carefully. As the CAL3D/MADYMO3D programs usually work with a very small number of degrees of freedom, not much gain in efficiency can be achieved.

*CONTROL_CPM

Purpose: Global control parameters for CPM (Corpuscular Particle Method).

Card 1	1	2	3	4	5	6	7	8
Variable	CPMOUT	NP2P	NCPMTS	CPMERR	SFFDC	BLKV	CPMMF	P2PMIX
Type	I	I	I	I	F	I	I	I
Default	11	5	0	0	1.0	0	0	0

This card is optional.

Card 2	1	2	3	4	5	6	7	8
Variable	PMIS							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
CPMOUT	Control CPM output database to the d3plot files (see Remark 1): EQ.11: Full CPM database in version 3 format (default) EQ.21: Full CPM database in version 4 format EQ.22: CPM coordinates only in version 4 format EQ.23: CPM summary only in version 4 format
NP2P	Number of cycles for repartition particle among processors. This option is only used in LS-DYNA/MPP. (Default = 5)
NCPMTS	Time step size estimation: EQ.0: Do not consider CPM (default) EQ.1: Use 1 microsecond as CPM time step size. This provides a better time step size if the model is made up of rigid bodies.

VARIABLE	DESCRIPTION
CPMERR	EQ.0: Disable checking and only output warning messages (Default) EQ.1: Enable error checking. If LS-DYNA detects any problem, it will either error terminate the job or try to fix the problem. Activated checks include: 1. *Airbag* integrity (see Remark 2) 2. *Chamber* integrity: this step applies the airbag integrity check to the chamber. 3. Inconsistent orientation between the shell reference geometry and FEM shell connectivity.
SFFDC	Scale factor for the force decay constant. The default value is 1.0 and allowable arrange is [0.01,100.0]. See Remark 3.
BLKV	Allocate additional memory for contact nodal forces, excluding force transducers and airbag single surface contacts using SOFT = 2. These nodal forces will be used to estimate blockage of external vents. BLKV does not affect the porosity and blockage of internal vents.
CPMMF	Flag to consider airbag system velocity based on the coordinates system defined by fields NID1, NID2, and NID3 on *AIRBAG_PARTICLE: EQ.0: No (default) EQ.1: Yes. The flow energy from the rigid body motion is fed back to the CPM particles.
P2PMIX	Control the energy transfer during particle-to-particle collision and change the thermalization of the particles (see Remark 4): EQ.0: Thermalization considered in all particle-to-particle collisions (default). EQ.1: Thermalization only considered within same gas species EQ.2: Same as 0 but treat temperature dependent $\xi(T)$ EQ.3: Same as 1 but treat temperature dependent $\xi(T)$
PMIS	Flag for choosing logic to use when a particle leaks out due to undetected contact (see Remark 5):

VARIABLE	DESCRIPTION
	EQ.0: Return particle to around inflator orifice node (default)
	EQ.1: Return particle to the nearest airbag fabric

Remarks:

1. **D3PLOT Version.** "Version 3" is an older format than "Version 4". Version 4 stores data more efficiently than version 3 and has options for what data is stored but may not be readable by old LS-PrePost executables.

2. **Airbag Integrity Checking.** The bag's volume is used to evaluate all bag state variables. If the volume is ill-defined or inaccurate, then the calculation will fail. Therefore, it is vital that that the volume be closed, and that all shell normal vectors point in the same direction.

   When CPMERR = 1, the calculation will error terminate if either the bag's volume is not closed or if one of its parts is not internally oriented (meaning that it contains elements that are not consistently oriented). Once it is verified that each part has a well-defined orientation, an additional check is performed to verify that all of bag's constituent parts are consistently oriented with respect to each other. If they are not, then the part orientations are flipped until the bag is consistently oriented with an *inward* pointing normal vector.

3. **Force Decay Constant.** Particle impact force is gradually applied to airbag segment by a special smoothing function with the following form.

$$F_{\text{apply}} = \left[1 - \exp\left(\frac{-dt}{\text{SFFDC} \times \tau}\right)\right](F_{\text{current}} + F_{\text{stored}}) \ ,$$

   where τ is the force decay constant stored in LS-DYNA.

4. **P2PMIX.** P2PMIX sets the energy transfer scheme during particle-to-particle collision**.**

   Based on the molecular kinetic theory, a fraction, ξ, of the total internal energy, e, is translational kinetic energy, w_k, for the CPM particle performing PV work:

$$p = \frac{2}{3} w_k = \frac{2}{3} \xi(T) e$$

   This pressure should be the same as the pressure given by the Ideal Gas Law:

$$p = (\gamma - 1) e$$

   In the above, ξ is a weak function of temperature like γ.

Each CPM particle represents a cloud of molecules, and CPM assumes those molecules are under thermal equilibrium with a proper Maxwell-Boltzmann distribution. When two particles collide, they will follow a perfectly elastic collision and the amount of energy transferred between them will keep both particles under the new Maxwell-Boltzmann distribution. By default, CPM assumes constant ζ during the process for better speed.

Since each gas species has its own Maxwell-Boltzmann distribution, the above calculation should only be applied to the same gas species. However, by default (P2PMIX = 0), thermalization is considered for all interactions. When P2PMIX equals 1, CPM particles collide perfectly elastically, and simple energy conservation is enforced when particles of different species interact. In this case the above calculation is only applied to particles of the same gas species.

5. **PMIS.** A particle may leak from a particle-to-surface contact due to numerical error. Once this particle is detected, it will be relocated to the gas inflator orifice node by default. If the bag is modeled with a multiple chamber definition, the default scheme may put the particle into a different chamber and, thus, unintentionally change the chamber pressure. If PMIS equals 1, this particle will be returned to the closest fabric segment.

*CONTROL_CPU

Purpose: Control CPU time.

Card 1	1	2	3	4	5	6	7	8
Variable	CPUTIM	IGLST						
Type	F	I						

VARIABLE	DESCRIPTION
CPUTIM	Seconds of CPU time: EQ.0.0: No CPU time limit set GT.0.0: Time limit for cumulative CPU of the entire simulation, including all restarts. LT.0.0: Absolute value is the CPU time limit in seconds for the first run and for each subsequent restart.
IGLST	Flag for outputting CPU and elapsed times in the glstat file: EQ.0: No EQ.1: Yes

Remarks:

The CPU limit is not checked until after the initialization stage of the calculation. Upon reaching the CPU limit, the code will output a restart dump file and terminate. The CPU limit can also be specified on the LS-DYNA execution line via "c=". The value specified on the execution line will override CPUTIM specified in this keyword.

*CONTROL_DEBUG

Purpose: Write supplemental information to the messag file(s). One effect of this command is that the sequence of subroutines called during initialization and memory allocation is printed. Aside from that, the extra information printed pertains only to a select few features, including:

1. Spot weld connections which use *MAT_100_DA and *DEFINE_CONNECTION_PROPERTIES.

2. The GISSMO damage model invoked using *MAT_ADD_EROSION. (Supplemental information about failed elements is written.)

*CONTROL_DISCRETE_ELEMENT

Purpose: Define global control parameters for discrete element spheres.

Card Summary:

Card 1. This card is required.

NDAMP	TDAMP	FRICS	FRICR	NORMK	SHEARK	CAP	VTK

Card 2. Additional card for CAP ≠ 0. If CAP = 0, include this card as a blank line if optional Card 3 is included.

GAMMA	VOL	ANG	GAP		IGNORE	NBUF	PARALLEL

Card 3. Card 3 and beyond are optional. If any of the following cards are included, then the preceding optional cards must be included, but they can be blank lines.

LNORM	LSHEAR		FRICD	DC	NCRB	BT	DT

Card 4. This card is optional.

CP	TC	TFAC					

Card 5. This card is optional.

IDESOFT	SOFSCL		ISKIP	MAXNEI			

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	NDAMP	TDAMP	FRICS	FRICR	NORMK	SHEARK	CAP	VTK
Type	F	F	F	F	F	F	I	I
Default	0.	0.	0.	0.	0.01	2/7	0	0

VARIABLE	DESCRIPTION
NDAMP	Normal damping coefficient
TDAMP	Tangential damping coefficient

VARIABLE	DESCRIPTION
FRICS	Static coefficient of friction (see Remark 4): EQ.0: 3 DOF NE.0: 6 DOF (consider rotational DOF)
FRICR	Rolling friction coefficient
NORMK	Optional: scale factor of normal spring constant. Norm contact stiffness is calculated as $K_n = \begin{cases} \frac{k_1 r_1 k_2 r_2}{k_1 r_1 + k_2 r_2}\text{NORMK} & \text{if NORMK} > 0 \\ \lvert\text{NORMK}\rvert & \text{if NORMK} < 0 \end{cases}$. NORMK is ignored if LNORM ≠ 0 or IDESOFT = 1.
SHEARK	Optional: ratio between SHEARK/NORMK. Tangential stiffness is calculated as $K_t = \text{SHEARK} \times K_n$. SHEARK is ignored if LSHEAR ≠ 0.
CAP	Capillary force flag: EQ.0: Dry particles NE.0: Wet particles. Capillary force is considered, and an additional input card is needed. See Remark 1.
VTK	Output DES in VTK format for ParaView: EQ.0: No EQ.1: Yes

Capillary Card. Additional card for CAP ≠ 0. If CAP = 0, include as a blank line if optional Card 3 is included.

Card 2	1	2	3	4	5	6	7	8
Variable	GAMMA	VOL	ANG	GAP		IGNORE	NBUF	PARALLEL
Type	F	F	F	F		I	I	I
Default	0.	0.	0.	0.		0	6	0

VARIABLE	DESCRIPTION
GAMMA	Liquid surface tension, γ
VOL	Volume fraction
ANG	Contact angle, θ
GAP	Optional parameter affecting the spatial limit of the liquid bridge. A liquid bridge exists when δ, as illustrated in Figure 12-15, is less than or equal to $\min(\text{GAP}, d_{\text{rup}})$ where d_{rup} is the rupture distance of the bridge automatically calculated by LS-DYNA.
IGNORE	Ignore initial penetration option: EQ.0: Calculate the contact force for DES with initial penetration. GT.0: Ignore the contact force calculation for DES with initial penetration.
NBUF	GE.0: Factor of memory use for asynchronous message buffer (Default = 6). LT.0: Disable asynchronous scheme and use minimum memory for data transfer.
PARALLEL	Flag for calculating contact force between bonded DES: EQ.0: Skip contact force calculation for bonded DES (Default) EQ.1: Consider contact force calculation for bonded DES

Card 3 is optional. If included, then Card 2 must be defined, even as a blank card.

Card 3	1	2	3	4	5	6	7	8
Variable	LNORM	LSHEAR		FRICD	DC	NCRB	BT	DT
Type	I	I		F	F	I	F	F
Default	0	0		FRICS	0	0	0.	10^{20}

VARIABLE	DESCRIPTION
LNORM	Load curve ID of a curve that defines a function for normal stiffness with respect to norm penetration ratio. See Remark 2.
LSHEAR	Load curve ID of a curve that defines a function for shear stiffness with respect to norm penetration ratio. See Remark 3.
FRICD	Dynamic coefficient of friction. See Remark 4.
DC	Exponential decay coefficient. See Remark 4.
NCRB	Rebalancing frequency, that is, the number of cycles between each rebalancing. This parameter only applies to MPP. EQ.0: No rebalancing is performed (default).
BT	Birth time
DT	Death time

Thermal Properties Card. Card 4 is optional.

Card 4	1	2	3	4	5	6	7	8
Variable	CP	TC	TFAC					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
CP, TC, TFAC	DES thermal properties *(Under development)*

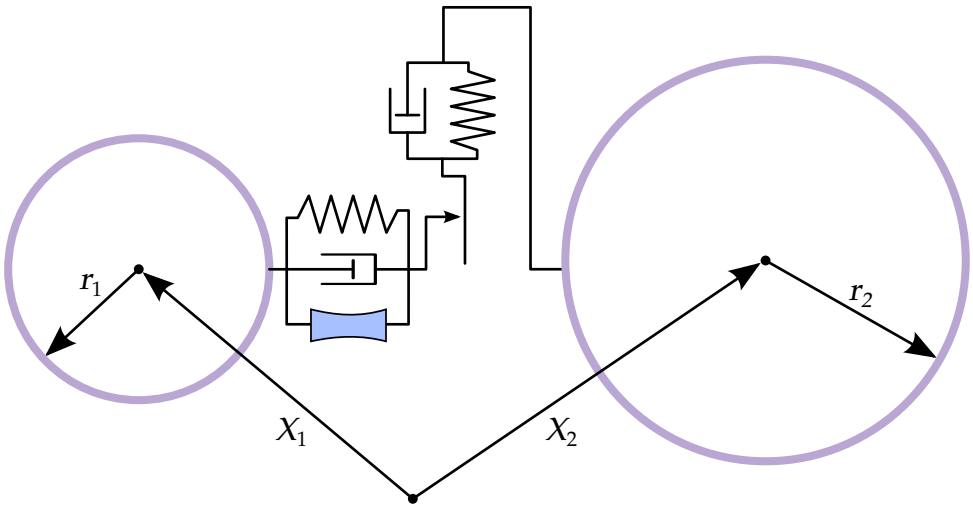

Figure 12-14. Schematic representation of sphere-sphere interaction

Card 5 is optional.

Card 5	1	2	3	4	5	6	7	8
Variable	IDESOFT	SOFSCL		ISKIP	MAXNEI			
Type	I	F		I	I			
Default	0	0.1		0	20			

VARIABLE	DESCRIPTION
IDESOFT	Flag for soft constraint formulation: EQ.1: Soft constraint formulation. The contact stiffness is based on the nodal mass and the global time step size. This input provides a different way for calculating NORMK. NORMK is ignored if IDESOFT = 1. IDESOFT is ignored if LNORM ≠ 0.
SOFSCL	Scale factor applied to the contact stiffness in the soft constrain formulation
ISKIP	Flag for skipping the calculation of contact force between DES: EQ.0: Consider the particle-particle contact calculation (default). EQ.1: Skip the particle-particle contact calculation.

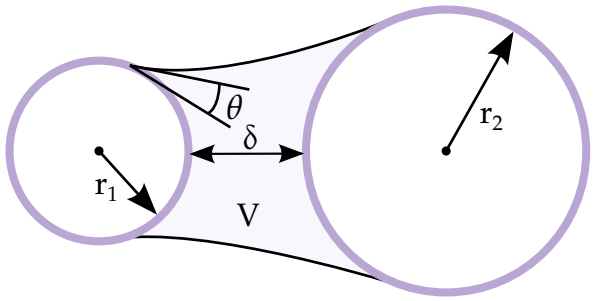

Figure 12-15. Schematic representation of capillary force model.

VARIABLE	DESCRIPTION
MAXNEI	Number of neighbors to be tracked for DES contact and capillary force calculation (default = 20). If particle sizes are very different, MAXNEI needs to be increased to capture more neighbors.

Background:

This method models all parts as being comprised of rigid spheres. These spheres interact with both conventional solids and other spheres. Sphere-sphere interactions are modeled in contact points using springs and dampers as illustrated in Figure 12-14. [Cundall & Strack 1979]

Remarks:

1. **Capillary Forces to Model Cohesion.** This extension is enabled using the CAP field. Capillary force between wet particles is based on the following reference: "Capillary Forces between Two Spheres with a Fixed Volume Liquid Bridges: Theory and Experiment", Yakov I. Rabinovich et al. Langmuir 2005, 21, 10992-10997. See Figure 12-15.

   The capillary force is given by

$$F = -\frac{2\pi R\gamma\cos\theta}{1+\frac{\delta}{2d}},$$

   where

$$d = \frac{\delta}{2}\left(-1+\sqrt{1+\frac{2V}{\pi R\delta^2}}\right),$$

   and

$$R = \frac{2r_1r_2}{r_1+r_2}.$$

2. **User Defined Norm Stiffness.** Let $y = f(x)$ be a load curve specified with LNORM for the norm stiffness between two interacting discrete element spheres. x is the relative penetration, meaning $x = \delta/\min(r_1, r_2)$. δ is penetration. The normal spring force is calculated as

$$F_n = k_{\text{eff}} \times y \times \left(\min(r_1, r_2)\right)^2,$$

where k_{eff} is the effective bulk modulus of the two interacting DEM particles, that is, $k_{\text{eff}} = k_1 k_2/(k_1 + k_2)$. If the curve is defined as $y = cx$, the behavior is the same as NORMK = c.

3. **User Defined Shear Stiffness.** Let $y = f(x)$ be a load curve specified with LSHEAR for the shear stiffness between two interacting discrete element spheres. x is the relative penetration, meaning $x = \delta/\min(r_1, r_2)$. δ is penetration. The tangential stiffness is calculated as $K_t = y \times K_n$, where K_n is the norm stiffness defined by NORMK or a user defined curve. If a curve is defined as $y = c$, the behavior is the same as SHEARK = c.

4. **Coefficient of Friction.** The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the two DEM in contact, that is,

$$\mu_c = \text{FRICD} + (\text{FRICS} - \text{FRICD})e^{-\text{DC} \times |v_{\text{rel}}|}.$$

*CONTROL_DYNAMIC_RELAXATION

Purpose: Initialize stresses and deformation in a model to simulate a preload. Examples of preload include load due to gravity, load due to a constant angular velocity, and load due to torquing of a bolt. After the preloaded state is achieved by one of the methods described below (see field IDRFLG), the time resets to zero and the normal phase of the solution automatically begins from the preloaded state.

Card Summary:

Card 1. This card is required.

NRCYCK	DRTOL	DRFCTR	DRTERM	TSSFDR	IRELAL	EDTTL	IDRFLG

Card 2a. This card is included if IDRFLG = 3 or 6.

DRPSET							

Card 2b. This card is included if IDRFLG = 2.

NC	NP						

Card 2b.1. Include NP of this card.

PSID	VECID						

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	NRCYCK	DRTOL	DRFCTR	DRTERM	TSSFDR	IRELAL	EDTTL	IDRFLG
Type	I	F	F	F	F	I	F	I
Default	250	0.001	0.995	infinity	TSSFAC	0	0.04	0

VARIABLE	DESCRIPTION
NRCYCK	Number of time steps between convergence checks for explicit dynamic relaxation.
DRTOL	Convergence tolerance for explicit dynamic relaxation (default = 0.001). See Remark 1.

VARIABLE	DESCRIPTION
DRFCTR	Dynamic relaxation factor for transient dynamic relaxation (default = .995). See Remark 1.
DRTERM	Optional termination time for dynamic relaxation. Termination occurs at this time or when convergence is attained (default = infinity). See Remarks 1 and 6.
TSSFDR	Scale factor for computed time step during explicit dynamic relaxation. If zero, the value is set to TSSFAC defined on *CONTROL_TIMESTEP. After converging, the scale factor is reset to TSSFAC.
IRELAL	Automatic control for dynamic relaxation option based on algorithm of Papadrakakis [1981]: EQ.0: Not active EQ.1: Active
EDTTL	Convergence tolerance on automatic control of dynamic relaxation.
IDRFLG	Dynamic relaxation flag which controls how the preloaded state is computed: EQ.-999: Dynamic relaxation not activated even if specified on a load curve, see *DEFINE_CURVE. See Remark 3. 2. EQ.-3: Dynamic relaxation is activated as with IDRFLG = 1, but the convergence check is made based only on the part set specified by DRPSET. All parts are active during the dynamic relaxation phase. EQ.-1: Dynamic relaxation is activated, and time history output is produced during dynamic relaxation; see Remarks 1 and 2. EQ.0: Not active. See Remark 3. EQ.1: Dynamic relaxation is activated. See Remark 1. EQ.2: Initialization to a prescribed geometry, see Remark 4, EQ.3: Dynamic relaxation is activated as with IDRFLG = 1, but only for the part set specified by DRPSET; see Remark 5. EQ.5: Initialize implicitly; see Remark 6. EQ.6: Initialize implicitly but only for the part set specified by DRPSET; see Remark 6.

Part Set Card. Additional card for IDRFLG = -3, 3 or 6.

Card 2a	1	2	3	4	5	6	7	8
Variable	DRPSET							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
DRPSET	Part set ID for IDRFLG = -3, 3 or 6.

Optional Card for IDRFLG = 2. This card is included if and only if IDRFLG = 2.

Card 2b	1	2	3	4	5	6	7	8
Variable	NC	NP						
Type	I	I						
Default	100	0						

VARIABLE	DESCRIPTION
NC	Number of time steps for initializing geometry when IDRFLG = 2. This variable applies to IDRFLG = 2 whether polar initialization is invoked or not.
NP	Number of cards defining parts to be initialized using the polar initialization approach and the associated polar coordinate system(s).

Optional Polar Initialization Cards. When IDRFLG = 2 and NP > 0, include NP additional cards which define the parts and polar coordinate systems used in polar initialization. This polar initialization interpolates from the initial to final state using a polar coordinate system. The objective is to avoid creating spurious stresses in parts subjected to large rigid body rotations and this option should not be used if that is not the case.

Card 2b.1	1	2	3	4	5	6	7	8
Variable	PSID	VECID						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
PSID	Part set ID
VECID	Vector ID which defines the origin and axis of rotation of the polar coordinate system used in initializing parts of part set PSID. See Remark 7.

Remarks:

1. **Transient Dynamic Relaxation.** If IDRFLG is 1 or -1, a transient "dynamic relaxation" analysis is invoked in which an explicit analysis, damped by means of scaling nodal velocities by the factor DRFCTR each time step, is performed. When the ratio of current distortional kinetic energy to peak distortional kinetic energy (the convergence factor) falls below the convergence tolerance (DRTOL) or when the time reaches DRTERM, the dynamic relaxation analysis stops, and the current state becomes the initial state of the subsequent normal analysis.

   Distortional kinetic energy is defined as total kinetic energy less the kinetic energy due to rigid body motion. A history of the distortional kinetic energy computed during the dynamic relaxation phase is automatically written to a file called relax. This file can be read as an ASCII file by LS-PrePost and its data plotted. The relax file also includes a history of the convergence factor.

2. **Dynamic Relaxation with Time History Data.** If IDRFLG is set to -1, the dynamic relaxation proceeds as normal, but time history data is written to the d3thdt file in addition to the normal data being written to the d3drlf file. At the end of dynamic relaxation, the problem time is reset to zero. However,

information is written to the d3thdt file with an increment to the time value. The time increment used is reported at the end of dynamic relaxation.

3. **Dynamic Relaxation from Load Curves.** Dynamic relaxation will be invoked if SIDR is set to 1 or 2 in any of the *DEFINE_CURVE commands, even if IDRFLG = 0 in *CONTROL_DYNAMIC_RELAXATION. Curves so tagged are applicable to the dynamic relaxation analysis phase. Curves with SIDR set to 0 or 2 are applicable to the normal phase of the solution. Dynamic relaxation will always be skipped if IDRFLAG is set to -999.

4. **Restarts and Prescribed Geometry File.** Following the dynamic relaxation phase and before the start of the normal solution phase, a binary dump file (d3dump01) and a "prescribed geometry" file (drdisp.sif) are written by LS-DYNA. Either of these files can be used in a subsequent analysis to quickly initialize to the preloaded state without having to repeat the dynamic relaxation run. The binary dump file is used with a restart analysis (see RESTART_INPUT_DATA). The drdisp.sif file is used by setting IDRFLG = 2. The IDRFLG = 2 approach does not initialize the location of rigid bodies in the model.

   When IDRFLG = 2, an ASCII file specified by "m=" on the LS-DYNA execution line is read which describes the initialized state of deformable bodies. The ASCII file contains each node ID with prescribed values of nodal displacement (x, y, z), nodal rotation (x, y, z), and nodal temperature in $(\mathrm{I8}, \mathrm{7E15.0})$ format. The preloaded state is quickly reached by linearly ramping nodal displacements, rotations, and temperatures of deformable bodies to prescribed values over a number of time steps as indicated by the variable NC.

5. **Part Set for Convergence Checking.** When IDRFLG = 3, a dynamic relaxation is performed only for the part set specified by DRPSET. For example, if only the tires are being inflated on a vehicle, it may be sufficient in some cases to apply the dynamic relaxation on the part IDs in the tire and possibly the suspension system.

6. **Implicit Preload.** If IDRFLG is set to 5 or 6, LS-DYNA performs an implicit analysis to obtain the preloaded state. Parameters for controlling the implicit preload solution are defined using appropriate *CONTROL_IMPLICIT keywords to specify solver type, implicit time step, etc. For example, *CONTROL_IMPLICIT_GENERAL specifies the implicit step size. The implicit analysis is, by default, static but can be made transient via the *CONTROL_IMPLICIT_DYNAMICS command.

   DRTERM indicates the termination "time" of the implicit preload analysis. When DRTERM is reached, the implicit preload phase terminates, and LS-DYNA begins the next phase of the analysis according to IMFLAG in *CONTROL_IMPLICIT_GENERAL. For example, if it is desired to run an implicit preload

phase and switch to the explicit solver for the subsequent transient phase, IDRFLG should be set to 5 and IMFLAG should be set to 0.

In contrast to IDRFLG = 5, IDRFLG = 6 performs an implicit analysis only for the part subset specified with DRPSET.

7. **Vector for Prescribed Geometry.** When the displacements for IDRFLG = 2 are associated with large rotations, the linear interpolation of the displacement field introduces spurious compression and tension into the part. If a part set is specified with a vector, the displacement is interpolated by using polar coordinates with the tail of the vector specifying the origin of the coordinate system and the direction specifying the normal to the polar coordinate plane. The run terminates with an error if VECID is not specified. If no large rotations are present, the optional cards may be omitted.

8. **Output Database.** To create a binary output database having the same format as a d3plot database that pertains to the dynamic relaxation analysis, use *DATABASE_BINARY_D3DRLF. The output interval is given by this command as an integer representing the number of convergence checks between output states. The frequency of the convergence checks is controlled by the parameter NRCYCK.

*CONTROL_EFG

Purpose: Define controls for the mesh-free computation.

Card 1	1	2	3	4	5	6	7	8
Variable	ISPLINE	IDILA	ININT					
Type	I	I	I					
Default	0	0	12					
Remarks			1					

Card 2	1	2	3	4	5	6	7	8
Variable	IMLM	ETOL	IDEB	HSORT	SSORT			
Type	I	F	I	I	I			
Default	0	10^{-4}	0	not used	0			

VARIABLE	DESCRIPTION
ISPLINE	Optional choice for the mesh-free kernel functions: EQ.0: Cubic spline function (default) EQ.1: Quadratic spline function EQ.2: Cubic spline function with circular disk (see Remark 2)
IDILA	Optional choice for the normalized dilation parameter: EQ.0: Maximum distance based on the background element EQ.1: Maximum distance based on surrounding nodes
ININT	Factor needed for the estimation of maximum workspace (MWSPAC) that can be used during the initialization phase.

VARIABLE	DESCRIPTION
IMLM	Optional choice for the matrix operation, linear solving and memory usage (see Remark 3): EQ.1: Original BCSLIB-EXT solvers EQ.2: EFGPACK (recommended). When this option is used, ININT in Card 1 becomes redundant.
ETOL	Error tolerance for the IMLM option.
IDEB	Output internal debug message
HSORT	Not used
SSORT	Automatic sorting of background triangular shell elements to FEM #2 when EFG shell type 41 is used: EQ.0: no sorting EQ.1: full sorting

Remarks:

1. **Maximum Workspace.** The mesh-free computation requires calls to use BCSLIB-EXT solvers during the initialization phase. The maximum workspace (MWSPAC) that can be used during the call is calculated as

$$\text{MWSPAC} = \text{ININT}^3 \times \text{NUMNEFG},$$

where NUMNEFG is the total number of mesh-free nodes. ININT, which is the number of nodes that a node influences along each cardinal direction, defaults to 12. When the normalized dilation parameters (DX,DY,DZ) in *SECTION_SOLID_EFG are increased, ININT must likewise increase.

2. **Cubic Spline Function with Circular Disk.** When ISPLINE = 2 is used, the input of the normalized dilation parameters (DX,DY,DZ) for the kernel function in *SECTION_SOILD_EFG and SECTION_SHELL_EFG only requires the DX value.

3. **Solvers.** EFGPACK was added to automatically compute the required maximum workspace in the initialization phase and to improve efficiency in the matrix operations, linear solving, and memory usage. The original BCSLIB-EXT solver requires an explicit workspace (ININT) for the initialization.

*CONTROL_ENERGY

Purpose: Provide controls for energy dissipation options.

Card 1	1	2	3	4	5	6	7	8
Variable	HGEN	RWEN	SLNTEN	RYLEN	IRGEN	MATEN	DRLEN	DISEN
Type	I	I	I	I	I	I	I	I
Default	1	2	1	1	2	1	1	1

VARIABLE	DESCRIPTION
HGEN	Hourglass energy calculation option. This option requires significant additional storage and increases cost by ten percent: EQ.1: Hourglass energy is not computed (default). EQ.2: Hourglass energy is computed and included in the energy balance. The hourglass energies are reported in the ASCII files glstat and matsum, see *DATABASE_*OPTION*. For implicit, or if the DRCPSID is active on *CONTROL_SHELL, the drilling energy is included here.
RWEN	Rigidwall energy (a.k.a. stonewall energy) dissipation option: EQ.1: Energy dissipation is not computed. EQ.2: Energy dissipation is computed and included in the energy balance (default). The rigidwall energy dissipation is reported in the ASCII file glstat; see *DATABASE_*OPTION*.
SLNTEN	Sliding interface energy dissipation option (This parameter is always set to 2 if contact is active. The option SLNTEN = 1 is not available.): EQ.1: Energy dissipation is not computed. EQ.2: Energy dissipation is computed and included in the energy balance. The sliding interface energy is reported in ASCII files glstat and sleout; see *DATABASE_*OPTION*.
RYLEN	Rayleigh energy dissipation option (damping energy dissipation):

VARIABLE	DESCRIPTION
	EQ.1: Energy dissipation is not computed (default).
	EQ.2: Energy dissipation is computed and included in the energy balance. The damping energy is reported in ASCII file glstat and matsum; see *DATABASE_*OPTION*.
IRGEN	Initial reference geometry energy option (included in internal energy, resulting from *INITIAL_FOAM_REFERENCE_GEOMETRY):
	EQ.1: Initial reference geometry energy is not computed.
	EQ.2: Initial reference geometry energy is computed and included in the energy balance as part of the internal energy (default).
MATEN	Detailed material energies option. For a choice of material models (currently supported are 3, 4, 15, 19, 24, 63, 81, 82, 98, 104, 105, 106, 107, 123, 124, 188, 224, 225, 240, and 251 for shell and solid elements), internal energy is additionally split into elastic, plastic, and damage portions:
	EQ.1: Detailed material energies are not computed (default).
	EQ.2: Detailed material energies are computed and reported as *mat_energy_elastic*, *mat_energy_plastic*, and *mat_energy_damage* in the ASCII files glstat and matsum.
DRLEN	Drilling energy calculation option, for implicit and with use of DRCPSID/DRCPRM on *CONTROL_SHELL:
	EQ.1: Drilling energy is not computed (default).
	EQ.2: Drilling energy is computed and included in the energy balance. The drilling energies are reported in the ASCII file glstat, see *DATABASE_*OPTION*.
DISEN	Dissipation energy calculation option, for implicit:
	EQ.1: Dissipated energy is not computed (default).
	EQ.2: Dissipated kinetic and internal energy is computed and included in the energy balance. The dissipation energies are reported in the ASCII file glstat, see *DATABASE_*OPTION*.

*CONTROL_EXPLICIT_THERMAL

The *CONTROL_EXPLICIT_THERMAL_SOLVER keyword activates an explicit finite volume code to solve heat transfer by conduction. Enthalpies and temperatures are element centered. The elements supported by the thermal solver are beams, shells, solids, and multi-material 3D ALE elements. The *CONTROL_EXPLICIT_THERMAL_PROPERTIES keyword defines the heat capacities and conductivities by parts. These 2 keywords are mandatory to properly run the solver. Other keywords can be used to set the initial and boundary conditions and control the outputs. They are all listed below in alphabetical order:

*CONTROL_EXPLICIT_THERMAL_ALE_COUPLING

*CONTROL_EXPLICIT_THERMAL_BOUNDARY

*CONTROL_EXPLICIT_THERMAL_CONTACT

*CONTROL_EXPLICIT_THERMAL_INITIAL

*CONTROL_EXPLICIT_THERMAL_OUTPUT

*CONTROL_EXPLICIT_THERMAL_PROPERTIES

*CONTROL_EXPLICIT_THERMAL_SOLVER

*CONTROL_EXPLICIT_THERMAL_ALE_COUPLING

Purpose: Define the shell and solid parts involved in an explicit finite volume thermal coupling with multi-material ALE groups. This keyword requires *CONSTRAINED_-LAGRANGE_IN_SOLID with CTYPE = 4.

Card 1	1	2	3	4	5	6	7	8
Variable	PARTSET	MMGSET						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
PARTSET	Part set ID (See *SET_PART)
MMGSET	Multi-material set ID (see *SET_MULTI-MATERIAL_GROUP_-LIST)

*CONTROL_EXPLICIT_THERMAL_BOUNDARY

Purpose: Set temperature boundaries with segment sets for an explicit finite volume thermal analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	SEGSET	LCID						
Type	I	F						
Default	none	none						

VARIABLE	DESCRIPTION
SEGSET	Segment set ID (See *SET_SEGMENT)
LCID	*DEFINE_CURVE ID defining the temperature as a function of time

Remarks:

1. **Boundary Elements.** The boundary temperatures are set at segment centers. If shells or beams have all their nodes in the segment set, these elements will be considered boundary elements; the temperatures at their centers will be controlled by the curve LCID.

*CONTROL_EXPLICIT_THERMAL_CONTACT

Purpose: Define the beam, shell and solid parts involved in an explicit finite volume thermal contact.

Card 1	1	2	3	4	5	6	7	8
Variable	PARTSET	NCYCLE						
Type	I	F						
Default	none	1						

VARIABLE	DESCRIPTION
PARTSET	Part set ID (See *SET_PART)
NCYCLE	Number of cycle between checks of new contact

*CONTROL_EXPLICIT_THERMAL_INITIAL

Purpose: Initialize the temperature centered in beams, shells or solids involved in an explicit finite volume thermal analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	IDTYP	TEMPINI					
Type	I	F	F					
Default	none	none	0.0					

VARIABLE	DESCRIPTION
ID	Flag to determine if ID is an element or set ID: GT.0: ID is a set LT.0: |ID| is an element
IDTYP	Type of ID: EQ.1: solid EQ.2: shell EQ.3: beam EQ.4: thick shell
TEMPINI	Initial temperature (see Remark 1)

Remarks:

1. **Material with *EOS.** The volumetric enthalpy is the sum of the pressure and volumetric internal energy (as defined in *EOS). If the material has an equation of state, the enthalpy should not be initialized by the temperature but by the initial volumetric internal energy and pressure set in *EOS.

*CONTROL_EXPLICIT_THERMAL_OUTPUT

Purpose: Output temperatures and enthalpies for an explicit finite volume thermal analysis. See Remark 1.

Card 1	1	2	3	4	5	6	7	8
Variable	DTOUT	DTOUTYP	SETID	SETYP				
Type	F	I	I	I				
Default	none	0	0	0				

VARIABLE	DESCRIPTION
DTOUT	Time interval between outputs
DTOUTYP	Type of DTOUT: EQ.0: DTOUT is a constant EQ.1: DTOUT is the ID of *DEFINE_CURVE defining a table of time as function of DTOUT
SETID	Set ID. If SETID = 0, then temperatures and enthalpies are output for the whole model. See Remark 1.
SETYP	Type of set: EQ.1: solid set (see *SET_SOLID) EQ.2: shell set (see *SET_SHELL) EQ.3: beam set (see *SET_BEAM) EQ.4: thick shell set (see *SET_TSHELL)

Remarks:

1. **Output Files.** The temperatures and enthalpies are calculated at the element center. If SETID is the default 0, then the temperature and enthalpy data is output in d3plot format files with the following basename: xplcth_output. If SETID is not 0, then the temperatures and enthalpies are calculated for a subset of elements defined as specified in the SETYP field. For this case the temperature and enthalpy histories are output by element in a .xy format. The file names are temperature_{beam,shell,solid}ID.xy and enthalpy_{beam,shell,solid}ID.xy.

2. **Viewing Results with LS-Prepost.** When SETID = 0, the output can be viewed with LS-Prepost using a fringe plot. To view the output for solid and shell elements select *FriComp* → *X-stress and Y-stress* (select Mid for the integration points in shells); for beams select *FriComp* → *beam* → *axial force resultant* and *s-force resultant*.

*CONTROL_EXPLICIT_THERMAL_PROPERTIES

Purpose: Define the thermal properties of beam, shell and solid parts involved in an explicit finite volume thermal analysis.

Card 1	1	2	3	4	5	6	7	8

Card 4	1	2	3	4	5	6	7	8
Variable	Kzx	Kzy	Kzz	KzxTYP	KzyTYP	KzzTYP		
Type	F	F	F	I	I	I		
Default	0.0	0.0	0.0	0	0	0		

VARIABLE	DESCRIPTION
PARTSET	Part set ID (See *SET_PART)
CP	Heat capacity
CPTYP	Type of CP: EQ.0: CP is a constant EQ.1: CP is the ID of a *DEFINE_CURVE defining a table of temperature as a function of heat capacity
VECID1, VECID2	*DEFINE_VECTOR IDs to define a specific coordinate system. VECID1 and VECID2 give the x- and y-direction, respectively. The z-vector is a cross product of VECID1 and VECID2. If VECID2 is not orthogonal to VECID1, its direction will be corrected with a cross-product of the z- and x-vectors. The conductivity matrix Kij is applied in this coordinate system.
LOCAL	Flag to activate an element coordinate system: EQ.0: The vectors VECIDj are considered in a global coordinate system. EQ.1: The vectors VECIDj are considered in a local system attached to the element. For shells and solids, the system is the same as DIREC = 1 and CTYPE = 12 in *CONSTRAINED_LAGRANGE_IN_SOLID. For shells, the edge centers replace the face centers. For beams, the x-direction is aligned with the first 2 nodes in *ELEMENT_BEAM and there should be a 3rd node for the y-direction.
Kij	Heat conductivity matrix

VARIABLE	DESCRIPTION
KijTYP	Type of Kij: EQ.0: Kij is a constant EQ.1: Kij is the ID of a *DEFINE_CURVE defining a table of temperature as a function of heat conductivity

*CONTROL_EXPLICIT_THERMAL_SOLVER

Purpose: Define the beam, shell, and solid parts involved in a finite volume thermal analysis. The enthalpies and temperatures are explicitly updated in time.

Card 1	1	2	3	4	5	6	7	8
Variable	PARTSET	DTFAC						
Type	I	F						
Default	none	1.0						

VARIABLE	DESCRIPTION
PARTSET	Part set ID (See *SET_PART)
DTFAC	Time step factor (see Remark 1)

Remarks:

1. **Time Step.** The time step is the minimum of the mechanical and thermal time steps. The thermal time step is the minimum of the element thermal time steps, which are half the enthalpies divided by the right hand side of the heat equation (conductivity × temperature Laplacian). The thermal time step is scaled by DTFAC.

*CONTROL_EXPLOSIVE_SHADOW_{OPTION}

Available option includes:

<BLANK>

SET

Purpose: Compute detonation times for explosive elements for which there is no direct line of sight. If this command is not included in the input, the lighting time for an explosive element is computed using the distance from the center of the element to the nearest detonation point, L_d; the detonation velocity, D; and the lighting time for the detonator, t_d:

$$t_L = t_d + \frac{L_d}{D}$$

The detonation velocity for this option is taken from the element whose lighting time is computed and does not account for the possibilities that the detonation wave may travel through other explosives with different detonation velocities or that the line of sight may pass outside of the explosive material.

If this command is present, the lighting time of each explosive element is based on the shortest path through the explosive material from the associated detonation point(s) to the explosive element. If inert obstacles exist within the explosive material, the lighting time will account for the extra time required for the detonation wave to travel around the obstacles. The lighting times also automatically accounts for variations in the detonation velocity if different explosives are used.

The SET option requires input of a set ID of two-dimensional shell elements or three-dimensional solid elements for which explosive shadowing is active. If the SET option is not used, Card 1 should be omitted and shadowing is active for all explosive elements.

See also *INITIAL_DETONATION and *MAT_HIGH_EXPLOSIVE.

Card 1. Card for SET keyword option.

Card 1	1	2	3	4	5	6	7	8
Variable	SETID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
SETID	Set ID of a *SET_SHELL or *SET_SOLID. If the SET option is active, the lighting times are computed for a set of shells (*SET_SHELL in two dimensions) or solids (*SET_SOLID in three dimensions).

*CONTROL_FORMING

Purpose: Set parameters for metal forming related features.

*CONTROL_FORMING_AUTO_NET

*CONTROL_FORMING_AUTOCHECK

*CONTROL_FORMING_AUTOPOSITION_PARAMETER

*CONTROL_FORMING_BESTFIT

*CONTROL_FORMING_HOME_GAP

*CONTROL_FORMING_INITIAL_THICKNESS

*CONTROL_FORMING_MAXID

*CONTROL_FORMING_ONESTEP

*CONTROL_FORMING_OUTPUT

*CONTROL_FORMING_PARAMETER_READ

*CONTROL_FORMING_POSITION

*CONTROL_FORMING_PRE_BENDING

*CONTROL_FORMING_PROJECTION

*CONTROL_FORMING_REMOVE_ADAPTIVE_CONSTRAINTS

*CONTROL_FORMING_SCRAP_FALL

*CONTROL_FORMING_SHELL_TO_TSHELL

*CONTROL_FORMING_STONING

*CONTROL_FORMING_STRAIN_RATIO_SMOOTH

*CONTROL_FORMING_TEMPLATE

*CONTROL_FORMING_TIPPING

*CONTROL_FORMING_TRAVEL

*CONTROL_FORMING_TRIM_MERGE

*CONTROL_FORMING_TRIM_SOLID_REFINEMENT

*CONTROL_FORMING_TRIMMING

*CONTROL_FORMING_UNFLANGING

*CONTROL_FORMING_USER

*CONTROL_FORMING_AUTO_NET

Purpose: Automatically generate rectangular nets with specified dimensions and positions for use with springback. This keyword is used for simulating springback when the stamping panel is resting on the nets of a checking fixture.

Card Sets. Add to the deck as many pairs of Cards 1 and 2 as needed. This section is terminated by the next keyword ("*") card. In general, for N nets add 2N cards.

Card 1	1	2	3	4	5	6	7	8
Variable	IDNET	ITYPE	IDV	IDP	X	Y	Z	
Type	I		I	I	F	F	F	
Default	none		0	0	0.0	0.0	0.0	

Card 2	1	2	3	4	5	6	7	8
Variable	SX	SY	OFFSET					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
IDNET	ID of the net; must be unique. See Remark 1.
ITYPE	Not used at this time.
IDV	Vector ID for surface normal of the net. See *DEFINE_VECTOR. If not defined, the normal vector will default to the global z-axis.
IDP	Part ID of the panel undergoing springback simulation
X	The x-coordinate of a reference point for the net to be generated
Y	The y-coordinate of a reference point for the net to be generated
Z	The z-coordinate of a reference point for the net to be generated

VARIABLE	DESCRIPTION
SX	Length of the net along the first tangential direction. (The *x*-axis when the normal is aligned along the global *z*-axis).
SY	Length of the net along the second tangential direction. (The *y*-axis when the normal is aligned along the global *z*-axis).
OFFSET	The net center will be offset a distance of OFFSET in the direction of its surface normal. For positive values, the offset is parallel to the normal; for negative values, antiparallel.

Remarks:

1. **Net ID.** The IDNET field of card 1 sets the "net ID," which is distinct from the part ID of the net; the net ID serves distinguishes *this* net from *other* nets.

2. **Properties of the Net.** The part ID assigned to the net is generated by incrementing the largest part ID value in the model. Other properties such as section, material, and contact interfaces between the panel and nets are likewise automatically generated.

3. **Contact Type.** The auto nets use contact type *CONTACT_FORMING_ONE_-WAY_SURFACE_TO_SURFACE.

Examples:

The partial input file (see below) specifies four auto nets having IDs 1 through 4. The vector with ID = 89 is normal to the net. The nets are offset 4 mm *below* their reference points; the direction is *below* because the normal vector (ID = 89) is parallel to the *z*-axis and the offset is negative. This example input can be readily adapted to a typical gravity-loaded springback simulation obviating the need for SPC constraints (see *CON-STRAINED_COORDINATE).

```

Discussion of Figures:

Figure 12-16 shows a formed and trimmed panel of a hat-shaped channel with an auto net at two corners. The nets are offset 4 mm away from the panel. When gravity loading is downward the nets must be below the panel (Figure 12-17 left) so that the panel comes into contact with the nets after springback as expected (Figure 12-17 right). As shown in Figure 12-18 the situation must be reversed when gravity loading points upward.

Revision Information:

This feature is now available starting in implicit static in double precision LS-DYNA Revision 62781.

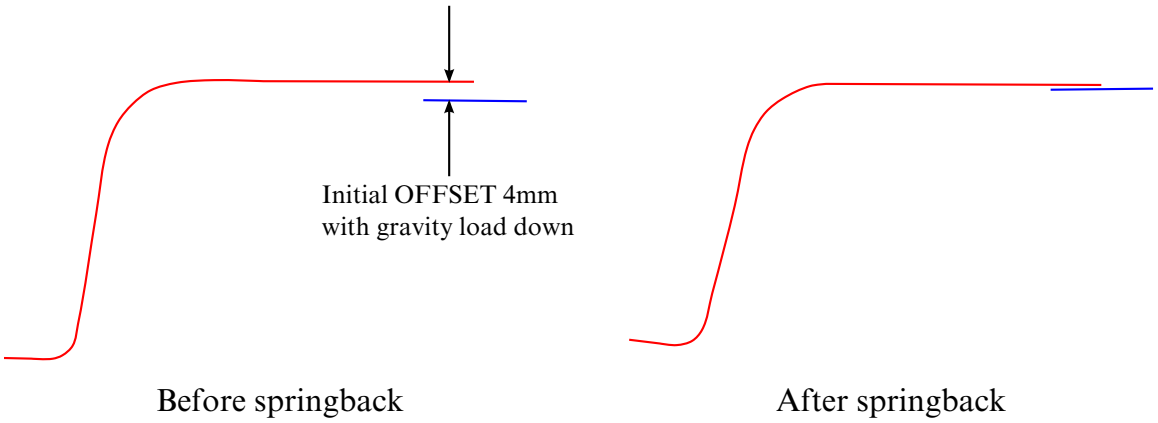

Figure 12-17. Springback and contact with nets - gravity down.

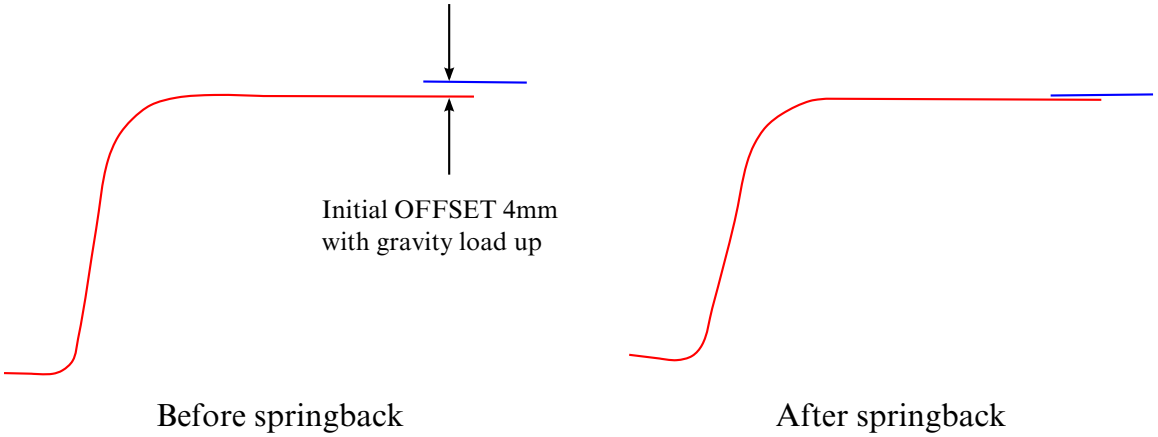

Figure 12-18. Springback and contact with nets – gravity up.

*CONTROL_FORMING_AUTOCHECK

Purpose: This keyword detects and corrects flaws in the mesh for the *rigid body* that models the tooling. Among its diagnostics are checks for duplicated elements, overlapping elements, skinny/long elements, degenerated elements, disconnected elements, and inconsistent element normal vectors.

This feature also automatically orients each tool's element normal vectors so that they face the blank. Additionally, an offset can be specified to create another tool (tool physical offset) based on the corrected tool meshes. Note that this keyword is distinct from *CONTROL_CHECK_SHELL, which checks and corrects mesh quality problems after trimming, to prepare the trimmed mesh for the next stamping process. This keyword only applies to shell elements.

The tool offset feature is now available in LS-PrePost 4.2 under Application → Metal-Forming → Easy Setup. The offset from Die button under Binder can be used to create offset tools.

Card 1	1	2	3	4	5	6	7	8
Variable	ICHECK	IGD	IOFFSET	IOUTPUT	IFSHARP			
Type	I	I	I	I	I			
Default	0	blank	0	blank	0			

VARIABLE	DESCRIPTION
ICHECK	Tool mesh checking/correcting flag: EQ.0: Do not activate mesh checking/correcting feature. EQ.1: Activate comprehensive mesh check and correct problematic tool meshes (see Figure 12-20). This option reduces the likelihood of unreasonable forming results and/or error termination. This is only for regular forming simulations. The calculation will continue after the tool mesh checking/correcting phase is completed. See Example 1. The corrected tool meshes can be viewed and recovered from the resulting d3plot files. If the termination time is set to "0.0" or the keyword *CONTROL_TERMINATION is absent all together, the simulation will terminate as soon

VARIABLE	DESCRIPTION
	as checking/correcting is completed, and corrected tool meshes can be extracted from the d3plot files.
IGD	Not used.
IOFFSET	Tool mesh offset flag. This variable works only when IOUTPUT is defined, and ICHECK is set to "1": EQ.0: Do not offset rigid tool mesh. The sheet blank does not need to be present. In this case the output files rigid_offset.inc and rigid_offset_before.inc will be identical. See Example 2. EQ.1: Perform rigid tool mesh offset using the variable SBST (see Figure 12-19) as specified on a *CONTACT_FORMING_… card. The blank must be defined and positioned completely above or below the rigid tool to be offset. Both part ID and part SID (SURFBTYP) can be used in defining SURFB. IOUTPUT must also be defined.
IOUTPUT	Output option flag: EQ.1: Output offset rigid tool meshes into a keyword file rigid_offset.inc, and terminate the simulation. EQ.2: Output offset rigid tool meshes as well as nodes used to define draw beads into a keyword file rigid_offset.inc, and terminate the simulation. See Example 4. EQ.3: Output checked/corrected tool as well as offset rigid tool meshes into two separate keyword files, rigid_offset_before.inc, and rigid_offset.inc, respectively, and terminate the simulation. See Example 3. EQ.4: Output checked/corrected tool meshes, offset rigid tool meshes as well as the nodes used to define draw beads into two separate keyword files, rigid_offset_before.inc, and rigid_offset.inc, respectively, and terminate the simulation. If not defined and ICHECK = 1, corrected and reoriented tool meshes can be viewed and recovered from d3plot files. See Example 1.
IFSHARP	Sharp edge checking option for those tool area without fillet radii: EQ.0: Check any sharp edges and delete the elements.

VARIABLE	DESCRIPTION
	EQ.1: Skip checking sharp edges.

Remarks:

In sheet metal forming, tools are typically modelled as rigid bodies, and their meshes are prepared from CAD (IGES or STEP) files according to the following procedure:

1. The user imports the CAD data into a preprocessor, such as LS-PrePost.

2. The preprocessor automatically generates a mesh. LS-PrePost features a streamlined GUI for this application.

3. Export the generated mesh to LS-DYNA input files. The LS-PrePost eZ-Setup user interface provides quick access to generate the necessary input files for metal forming applications.

Ideally, this process should produce a good mesh requiring no manual intervention. Often, though, such meshes that have been automatically generated from CAD data have flaws severe enough to prevent an accurate or complete calculation. This feature, *CONTROL_FORMING_AUTOCHECK, is intended to make LS-DYNA more robust with respect to tooling mesh quality.

This keyword *requires* that the tooling meshes represent rigid bodies. Also, when this keyword is used, a part ID or a part set ID, corresponding to SURFBTYP = 2 or 3 on the *CONTACT_FORMING_… card, may be used to define the SURFB side. Segment set ID input, SURFBTYP = 0, is not supported.

Some cases of incoming bad tooling meshes which can be corrected by this keyword are shown in Figure 12-20. This keyword can be inserted anywhere in the input deck. To include the corrected tooling mesh into the d3plot the ICHECK field must be defined. The corrected mesh is written to rigid_offset_before.inc file if IOFFSET and IOUTPUT are defined.

When IOFFSET = 1 and IOUTPUT is defined, the tool meshes will first be checked, corrected, and reoriented correctly towards the blank. Then the tool is offset by an amount of 0.5|SBST| either on the same or opposite side of the blank, depending on the signs of the SBST field on the *CONTACT_FORMING_… card (Figure 12-19). A new keyword file, "rigid_offset.inc" file, will be output as containing the corrected, reoriented, and offset tooling mesh.

Example 1 - Mesh checking/correction in a regular forming simulation:

The keyword can be inserted anywhere in a regular forming simulation input deck. A partial input example of checking, correcting the tool meshes, and reorienting all tools' normals is provided below. Note that although SBST is defined between blank and die contact interface, die meshes will not be offset, since IOFFSET is not defined. The simulation will continue if "&endtime" is not zero but will terminate as soon as the checking and correcting are done if "&endtime" is set to "0.0", or *CONTROL_TERMINATION is absent altogether. Corrected and reoriented tool meshes can be viewed and recovered from d3plot files.

Example 3 - Mesh checking/correction and tool offset (sheet blank required):

In addition to checking, correcting, and reorienting all tools' normals, the following partial input will offset the die meshes in toolmesh.k by 0.88 mm (using the SBST value defined for the die) on the opposite side of the blank, and output the offset tool meshes in the file rigid_offset.inc. The checked/corrected original die meshes will be written to rigid_offset_before.inc. The simulation will terminate as soon as the files are written, regardless of what the "&endtime" value is. In fact, the keyword *CONTROL_TERMINATION can be omitted all together.

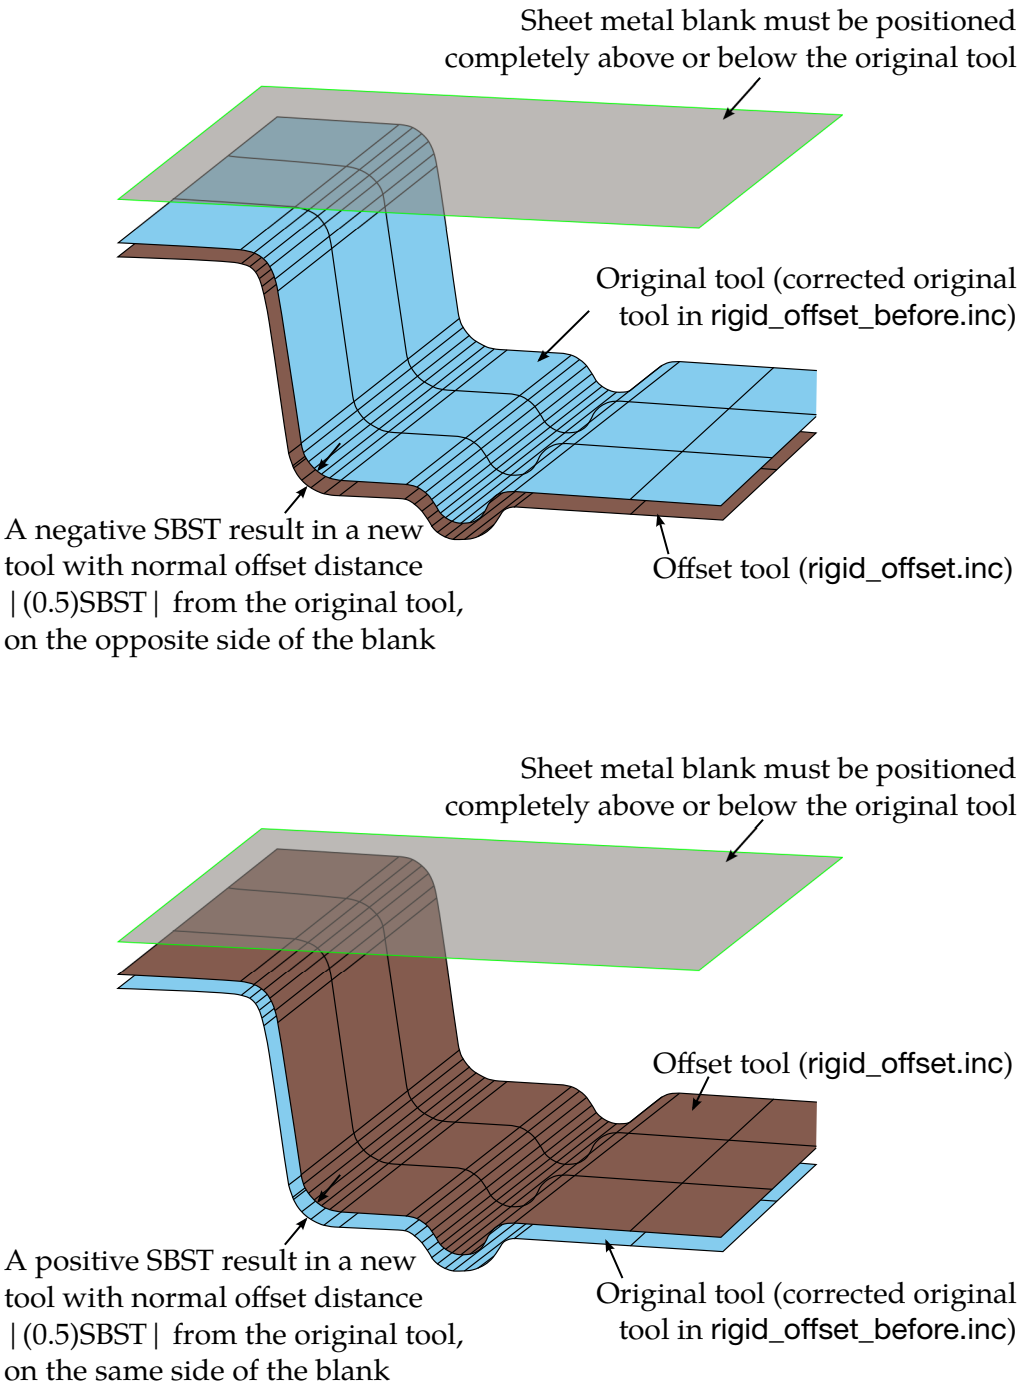

Figure 12-19. Offset using the SBST value defined in *CONTACT_FORMING_…

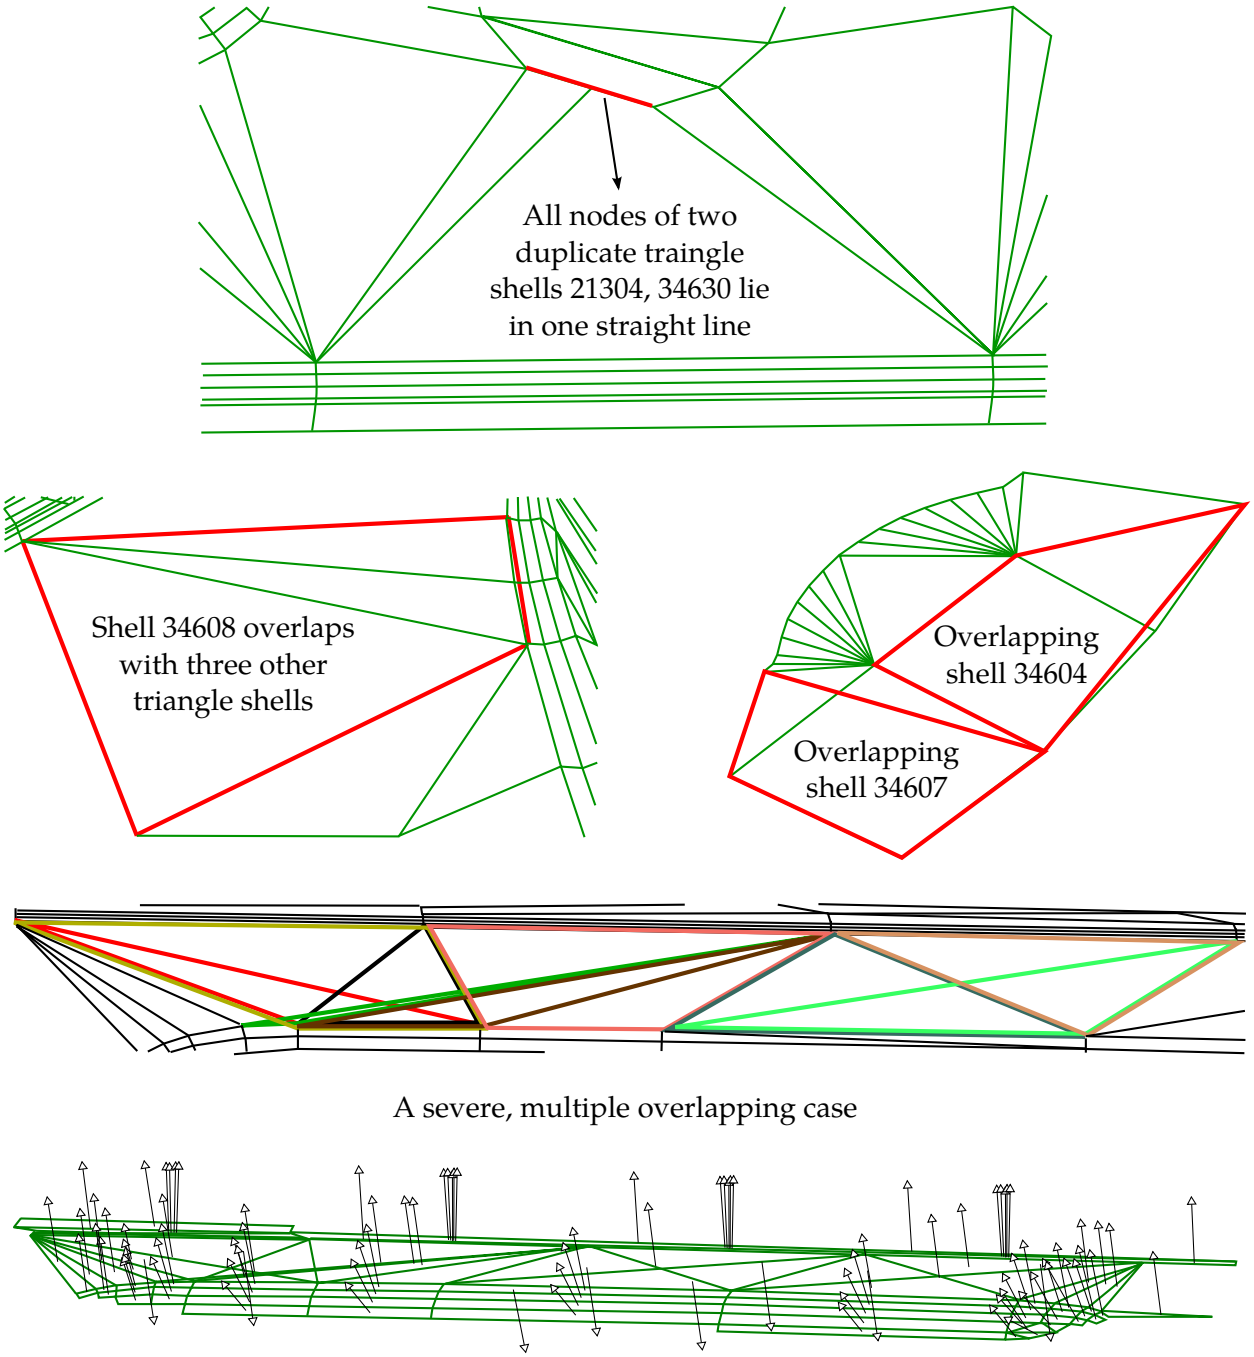

A severe, multiple overlapping case

A case of typical incoming, inconsistent shell normals

Figure 12-20. A few cases of the tooling mesh problems handled by this keyword.

*CONTROL_FORMING_AUTOPOSITION_PARAMETER_{OPTION1}_{OPTION2}

Available options for *OPTION1* include:

<BLANK>

SET

With SET, a set of parts will be repositioned together.

Available options for *OPTION2* include:

<BLANK>

POSITIVE

When *OPTION2* is set to POSITIVE, the calculated distance to reposition will always be a positive value.

Purpose: The purpose of this keyword is to *calculate* the minimum required separation distances among forming tools for initial tool and blank positioning in metal forming simulation. It is applicable to sheet blanks with shell and solid elements. It does not, actually, move the part; for that, see *PART_MOVE.

> **NOTE:** This keyword requires that the model begins in its home position. While processing this card, LS-DYNA moves the parts to match the auto-position results so that auto-position operations correctly compose. Upon completion of the auto-positioning phase, the parts are returned to their home positions.

Auto-Position Part Cards. Add one card for each part to be auto-positioned. The next keyword ("*") card terminates this input.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	CID	DIR	MPID	POSITION	PREMOVE	THICK	PORDER
Type	I	I	I	I	I	F	F	I/A
Default	none	global	none	none	0	0.0	0.0	none

VARIABLE	DESCRIPTION
PID	Part ID. This part will be moved based on the following controlling parameters. When the option SET is activated, PID becomes part set ID, defined by *SET_PART_LIST. This is useful in defining tailor-welded blanks, where two pieces of the blank must be moved simultaneously.
CID	Coordinate ID set with *DEFINE_COORDINATE_SYSTEM or *DEFINE_COORDINATE_VECTOR. The default is the global coordinate system. LT.0: |CID| is vector ID giving the direction the part will be moved.
DIR	Direction in which the part will be moved: EQ.1: x-direction, EQ.2: y-direction, EQ.3: z-direction.
MPID	Master part ID, whose position is to be referenced by PID for positioning. When the option SET is activated, MPID becomes part set ID, defined by *SET_PART_LIST.
POSITION	Definition of relative position between PID and MPID: EQ.1: PID is above MPID; EQ.-1: PID is below MPID. Definition of "above" is determined by the defined coordinate system. If PID is above MPID, it means PID has a larger z-coordinate. This definition is helpful in line-die simulations where the local coordinate system may be used.
PREMOVE	Move PID through distance PREMOVE *prior* to processing the other *CONTROL_FORMING_AUTOPOSITION cards. See Remark 4.
THICK	One half of this distance value (THICK) will be used to separate the tools and the blank. The same value must be used in *all* defined move operations under this keyword. The calculation error of the separation distance is one half of THICK.

VARIABLE	DESCRIPTION
PORDER	The name of the parameter without the ampersand "&," as defined in *PARAMETER, or the position or order of the parameter defined in the *PARAMETER list.

Background:

In a line-die (multi-stage) simulation, initial positioning of the tools and blank is one of the major issues preventing several die processes from being run automatically from a single job submission. The most basic method for running a line-die simulation is to chain a series of calculations together using the previous calculation's partially formed blank, written to a dynain file, as a part of the input for the next calculation.

Since the partial results are unknown until the preceding calculation completes, the tools need to be repositioned before the next calculation. Without this card the repositioning step must be done by hand using a preprocessor. With the combination of this card and the LS-DYNA case driver (see *CASE card) or a continuous run script (works for both Linux and Windows), the repositioning can be fully automated, enabling a complete line-die simulation to be performed with a single job submission.

Workflow:

This card requires that all parts start in their home (tool closed) position. It calculates how far the parts need to be moved to prevent initial penetration. The results are stored into the parameter listed in the PORDER field to be used for a part move operation.

1. For each defined move operation a *PARAMETER card *must* initialize the parameter referred to in the PORDER field.

2. All tools must start in home position including *desired final gaps*.

3. The required distance between each contact pair is calculated and stored in the initialized parameter named in the PORDER field. Starting with Revision 124103, if the separation distance cannot be found, such as when MPID is not found or is out of position, or DIR is not input correctly, the value of PREMOVE will be returned instead of a very large number.

4. The parts are repositioned through a distance based on the value written to the parameter PORDER using the *PART_MOVE card.

5. The *PARAMETER_EXPRESSION can be used to evaluate expressions depending on the move distances, such as times and tool move speeds.

6. The *CASE feature, can be used to chain together the sub-processes in a line die (process chain) simulation. Alternatively, a continuous run script (for both Linux and Windows environment) can be generated for an entire process chain simulation using the Metal Forming GUI starting in LS-PrePost 4.3.

Remarks:

1. **Order Dependence.** Input associated with this keyword is order sensitive. The following order should be observed:

   a) All model information *including* all elements and node

   b) Part definitions (see *PART)

   c) Part set definitions (see *SET_PART_LIST)

   d) *PARAMETER initialization

   e) This keyword

   f) *PARAMETER_EXPRESSION

   g) *PART_MOVE

2. **New Keyword Input with Positioned Model.** This keyword can also be used to generate a new keyword input (dynain) containing the fully positioned model (without actually running the entire simulation). This procedure is identical to a full calculation except that the *PARAMETER_EXPRESSION keyword, the *CONTROL_TERMINATION keyword, and tool kinematic definitions are omitted.

3. **Local Coordinate Systems and Computed Parameters.** When working in local coordinate systems, the sign of the computed parameter may not necessarily correspond to its intended use. In this case, the absolute value function, ABS, for the *PARAMETER_EXPRESSION keyword is especially useful.

4. **PREMOVE.** Cards with the PREMOVE field set are processed before *all* other *CONTROL_FORMING_AUTOPOSITON cards, regardless of their location in the input deck. The PREMOVE field serves to modify the initial state on which the calculations of the other AUTOPOSITON cards are based.

   For instance, when a binder is moved downward with the PREMOVE feature, it will be in its post-PREMOVE position for *all other* AUTOPOSITION calculations. But, as is the case with the other AUTOPOSITON cards, the model will be returned to its home position upon completion of the AUTOPOSITION phase. Note that the master part, MPID, and the POSITION fields are *ignored* when the

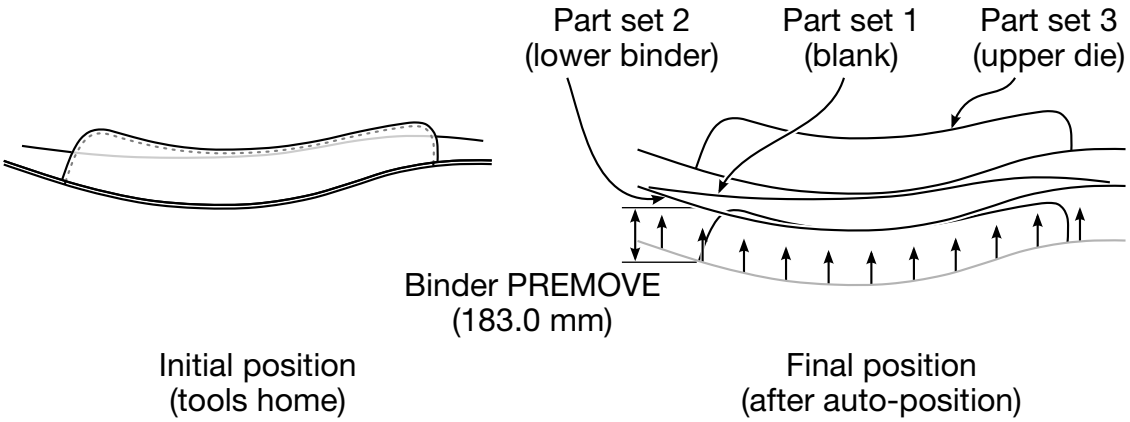

Figure 12-21. An example of using the variable PREMOVE

PREMOVE field is set, and that the PREMOVE value is copied into the PORDER parameter.

5. **CALCULATED MOVE DISTANCE.** Calculated move distance for each part will be displayed in the beginning of the messag file. All parameters (defined and calculated) can be found in the d3hsp file.

6. **LS-PrePost.** This feature is implemented starting in LS-PrePost4.0 eZSetup for metal forming in both explicit and implicit application.

Example 1:

An air draw process like the one shown in Figure 12-21 provides a clear illustration of how this card, and, in particular, the PREMOVE field is used to specify the lower binder's travel distance.

1. The card with the PREMOVE field set, the *third* AUTOPOSITON card, is processed first. It moves lower binder 183 mm upward from its home position, and it will form the base configuration for other AUTOPOSITION cards. It will also store this move into &bindmv. Note that although the POSITION and MPID fields are set, they are ignored.

2. The *first* autoposition card, which will be the *second* one processed, calculates the minimum offset distance (&blankmv) necessary for the blank (part set 1) to clear part set 9999, which consists of the lower binder (PID = 2), which is in its post-PREMOVE location, and of the lower punch (PID = &lpunid).

3. The next card determines the minimum offset (&updiemv) necessary to bring the upper die (part set 3) as close to the blank as possible without penetrating. *This calculation proceeds under the assumption that the blank part set has been moved through &blankmv.*

```

Example 2:

The following examples demonstrates the *PARAMETER_EXPRESSION card, which is used to derive new parameters from the value calculated during auto-positioning. In this example, the auto-positioned distance for binder, which is stored in the parameter, &bindmv, is used to define an additional parameter,

$$\&bindmv1 = \&bindmv - 30\ \text{mm}$$

The *PART_MOVE step uses &bindmv1 rather than &bindmv, to move both the lower binder and the draw beads.

*CONTROL_FORMING_BESTFIT

Available options include:

<BLANK>

VECTOR

Purpose: Rigidly move a part to the target using an iterative least-squares method so that they maximally coincide. This feature can be used to assess the accuracy of the spring-back prediction in sheet metal forming by translating and rotating a sprung part (source) to a scanned part (target). This keyword applies to shell elements only. The VECTOR option allows vector components of the normal distance from the target to the part node to be included in the output file, bestfit.out, under the keyword *NODE_TO_TARGET_-VECTOR.

This feature is available as of LS-PrePost 4.5 in *Metal Forming Application/eZ Setup*.

Card 1	1	2	3	4	5	6	7	8
Variable	IFIT	NSKIP	GAPONLY	IFAST	IFSET	NSETS	NSETT	
Type	I	I	I	I	I	I	I	
Default	0	-3	0	1	0	none	none	

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
IFIT	Best fit program activation flag: EQ.0: do not perform best-fit. EQ.1: activate the best-fit program.

VARIABLE	DESCRIPTION
NSKIP	Optional skipping scheme during bucket searching to aid the computational speed (zero is no skipping): GT.0: Number of nodes to skip in bucket searching. NSKIP set to 1 does not skip any nodes in searching, resulting in the slowest computing speed but the highest accuracy. Larger values of NSKIP speed up the calculation time with slightly deteriorating accuracies. Based on studies, a value of 5 is recommended with IFAST = 1, which balances the speed and accuracy. LT.0: Absolute value is the distance to skip in bucket searching. This scheme is faster compared to the previous method and therefore is recommended for computational efficiency and accuracy. A value of -5 is suggested.
GAPONLY	Separation distance calculation flag: EQ.0: after performing best-fit, calculate the separation between the two parts. EQ.1: no best-fit, just calculate separation between the two existing parts. EQ.2: the user is responsible for moving the parts closer together in both distance and orientation for the situation where the target and source are not similar in shape. Also see NSETS and NSETT (recommended method).
IFAST	Computing performance optimization flag: EQ.0: no computing speed optimization. EQ.1: activate computing speed optimization (default and recommended).
IFSET	Optional flag to define a node set to be included or excluded in the source mesh file for best fitting. The node set can be defined in a file together with the source mesh. EQ.0: All nodes in the source mesh file will be best fitted. GT.0: The input value is a node set ID; only the nodes in the set will be best fitted. LT.0: The absolute value is a node set ID; all nodes excluding those in the set will be best fitted.

VARIABLE	DESCRIPTION
NSETS	An optional node set ID of three nodes from the source mesh to help align the source to the target. See Remark 4. The nodes should be selected based on distinctive geometry features, such as, the center of an arc, the center of a dart, or the end node of a take-up bead (see Figure 12-23). The three nodes must not be aligned in one straight line. Define NSETS if the orientations of the source mesh and the target have a large deviation (> ~30 degrees in any direction). This method is recommended.
NSETT	An optional node set ID of three nodes from the target mesh that consists of nodes corresponding to the same geometry features as the source mesh to help align the source to the target. The three nodes should be input in the same order as those from the source mesh. Approximate locations are acceptable. See Remark 4. Define NSETT only if NSETS is defined. See Figure 12-23 for details. This method is recommended.
FILENAME	Target mesh file in keyword format, in which only *NODE and *ELEMENT_SHELL should be included. The target mesh is typically the scanned part.

Remarks:

1. **Source Mesh.** The source mesh can be included in the input file using *INCLUDE.

2. **Target Mesh Coarseness.** To reduce the computing time, the scan file (STL) mesh can be coarsened in a scan-processing software from a typically very dense mesh to a more reasonably sized mesh.

3. **Fit Evaluation.** The distances between corresponding portions of the two parts are calculated after they are fitted. The distance is given as a positive or negative value based on the target's normal directions. The distance vector points from the target to the corresponding portion on the source. If the projection of the distance vector onto the target's normal vector at this portion is in the direction of the target's normal direction, then the distance is "positive", otherwise it is "negative." For areas where no corresponding meshes can be found between the two parts, the distances are set to nearly zero. The fitting accuracy is within 0.02 mm.

   The distances are stored as thickness values in bestfit.out. They can be plotted in LS-PrePost using *COMP → Thickness*. By importing both bestfit.out and the

target mesh to LS-PrePost, the deviation on cut-sections can be evaluated using the *SPLANE* feature.

4. **Initial Orientation.** If the orientation of the source and target exceeds 30 degrees, the fit process becomes computationally costly. NSETS and NSETT can be used to initially align the source mesh to the target mesh before a full fitting is performed.

5. **Output.** The following information will be output to the results file bestfit.out. The summary gives a percentage of the source nodes that are between 0.0 and 6.0 mm of the target, with a 0.5 mm interval range, along with the maximum deviation value of the source from the target. A transformation matrix as well as the transformation given as a set of euler angles (radians) and a translation vector (in mm) are also output starting in Revision 140609. The transformation matrix can be used directly in the keyword *INCLUDE_STAMPED_PART_MATRIX to perform a validation or for other needs. The euler angle and translation vector form allows you to transform (note it is order sensitive) the source to the target in a more direct method, namely rotate in RZ first, followed by RY and RX, followed by translations in DX, DY, and DZ.

Example 1 – fitting with NSETS and NSETT (recommended):

In the following partial keyword example (meshes and results shown in Figure 12-23) a source mesh sourcemesh.k is being best-fitted to a target mesh targetmesh.k.

Node sets 1 and 2 are defined from nodes in the source and target meshes, respectively, to help with alignement. Node ID 1001 and 1 are both located at the center of a dart on the top surface of the hat-shaped part. Node ID 1002 and 2 are selected at the center of

an arc of a cutout hole. Lastly, node ID 1003 and 3 are at the center of a tangent line of a radius.

In this example, since the source and target meshes are exactly the same, the normal distance, as displayed by *thickness* is nearly zero everywhere.

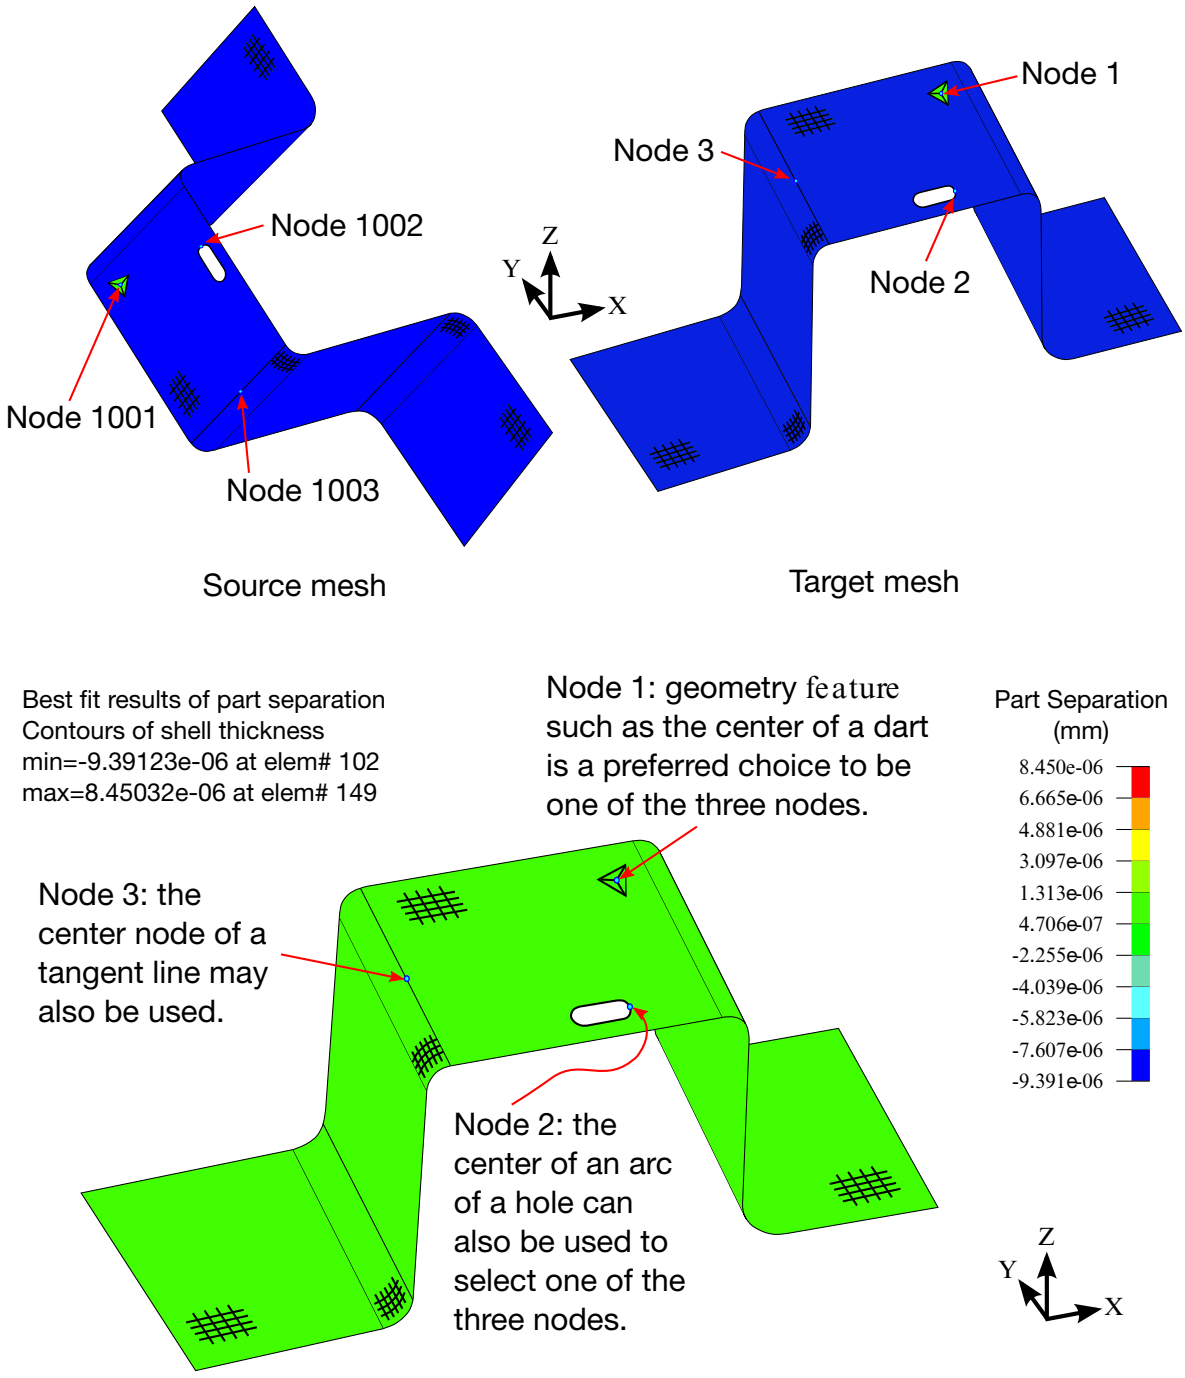
Revision information:

This feature is available starting from LS-DYNA Revision 96427 double precision SMP. The variable IFSET is available starting from Revision 96696. The variables NSETS, NSETT are available starting from Revision 99369. The VECTOR option is available starting from Revision 112655. A transformation matrix, and other transformation option in angles (in radians) and translation (in mm) are available starting in Revision 140609



Best fit results - color contour of part separation plotted with "thickness" from the output file "Bestfit.out"

Figure 12-23. Best fit of two meshes with an orientation difference of greater than 30 degrees.

*CONTROL_FORMING_HOME_GAP

Purpose: Calculate the minimum gap between the upper and lower tools. Gaps smaller than the blank thickness can lead to problems with the simulation. The gap is initially measured from the home position. Then the tools are incrementally moved to the starting position where the gap is again measured.

Card 1	1	2	3	4	5	6	7	8
Variable	PSIDU	PSIDL	GAP	MVINC	ISTOP			
Type	I	I	F	F	I			
Default	none	none	none	none	0			

VARIABLE	DESCRIPTION
PSIDU	Part set ID of the tools above the blank (upper tools)
PSIDL	Part set ID of the tools below the blank (lower tools)
GAP	Minimum gap allowed between the upper and lower tools
MVINC	Incremental movement of tools from home position to starting position to check the gap
ISTOP	How to proceed if the minimum gap found is less than GAP: EQ.0: Output a warning message. Job continues EQ.1: Terminate the job.

*CONTROL_FORMING_INITIAL_THICKNESS

Purpose: Specify a varying thickness field along a specific direction on a sheet blank (shell elements only) as a result of a metal forming process, such as a tailor-rolling, that will be used for an additional metal forming simulation. A related keyword is *ELEMENT_SHELL_THICKNESS.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	LCID	X0	Y0	Z0	VX	VY	VZ
Type	I	I	F	F	F/I	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
PID	Part ID of the sheet blank to be defined with varying thickness, as in *PART. Currently only 1 PID is allowed.
LCID	Load curve ID defining thickness (ordinate) as a function of distance (abscissa) starting from position coordinates (X0,Y0,Z0) and in the direction of the vector (VX,VY,VZ). See *DEFINE_CURVE.
X0, Y0, Z0	Starting position coordinates
VX, VY, VZ	Vector components defining the direction of the distance in the load curve

Background:

Tailor-rolling is a process used to vary the thickness of the blank. A judiciously designed and manufactured tailor-rolled blank will reduce the number of parts (reinforcements) involved in the stamping process, as well as the number tools needed to make them. By reducing the number of spot welds, tailor-rolled pieces also possess superior structural integrity.

Remarks:

1. **Thickness Curve.** Beyond the last data point LS-DYNA extrapolates the load curve specified in LCID as being constant.

2. **Overriding Set Thickness.** This card overrides thicknesses set with the *SECTION_SHELL keyword.

Application Example:

A reduced input deck containing a characteristic example of this keyword's application is given below. In this example the blank is part ID 1. The axis of the load curve starts at position $(-295, -607, -43)$ and the direction along which the load curve sets the thickness is given by $(524, 607, 0)$. For each of the load curve's abscissa values, t, the corresponding geometrical coordinate is given by:

$$\boldsymbol{r} = \begin{bmatrix} -295 \\ -607 \\ -43 \end{bmatrix} + \begin{bmatrix} 524 \\ 607 \\ 0 \end{bmatrix} t$$

For negative values along the load curve, $t < 0$, and values of $t > 101.0$, the thickness is extrapolated as a constant value of 0.8, and 0.9, respectively.

```

In Figure 12-24, a sheet blank is defined with a varying thickness across its surface in a vector direction pointed from the start to end point. The thickness variation as a function of the distance from starting point in section A-A is shown in Figure 12-25.

Revision information:

This feature is available in LS-DYNA starting in Revision 82990.

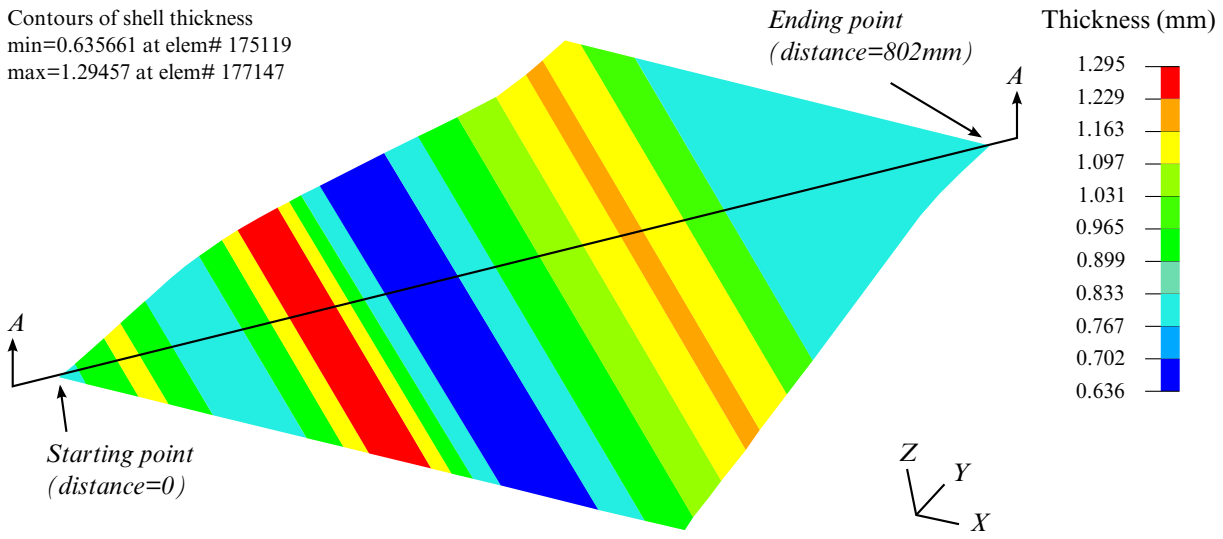

Figure 12-24. Define a varying thickness field across the sheet blank.

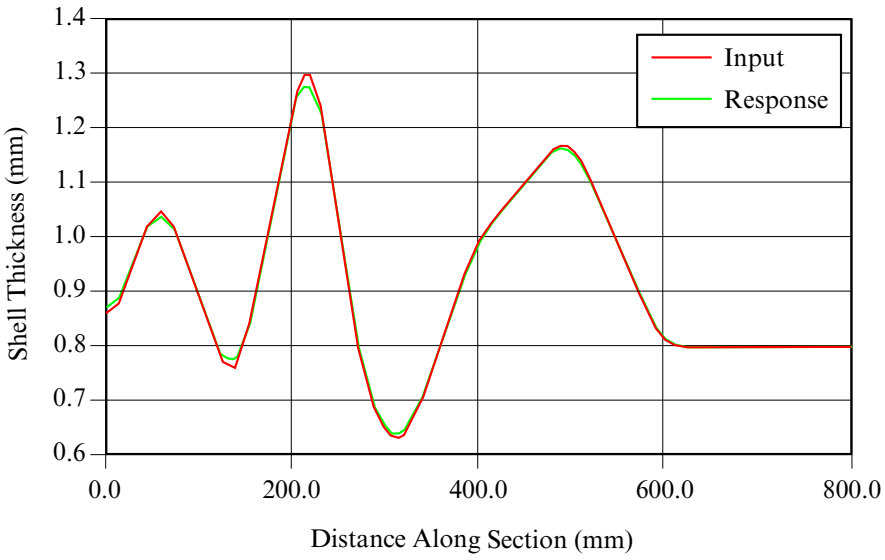

Figure 12-25. Thickness variation across section A-A

*CONTROL_FORMING_MAXID

Purpose: This card sets the node and element ID numbers for an adaptive sheet blank. The new node and element number of the adaptive mesh will start at the values specified on this card, typically greater than the last node and element number of all tools and blanks in the model. This keyword is often used in multi-stage sheet metal forming simulation. The *INCLUDE_AUTO_OFFSET keyword is related.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	MAXIDN	MAXIDE		I2DYNAIN			
Type	I	I	I		I			
Default	none	none	none		0			

VARIABLE	DESCRIPTION
PID	Part ID of the sheet blank, as in *PART.
MAXIDN	Node ID number from which adaptive node ID numbers will be created.
MAXIDE	Element ID number from which adaptive element ID numbers will be created.
I2DYNAIN	Setting I2DYNAIN to 1 will cause this keyword to be output to a dynain file with the updated maximum node and element IDs. This output simplifies post-processing for multi-step processes since it ensures that element and node IDs generated in subsequent steps are larger than those in previous steps. By default, this keyword is not output to a dynain file.

Remarks:

In a multi-stage automatic line die simulation the adaptivity feature may generate node and element IDs that collide with those of the tools used in the later stages of the process. Before the calculation begins, the set of IDs used by the tools is known. By setting MAXIDN to a value greater than the largest tool node ID and MAXIDE to a value greater than the largest tool element ID, it is guaranteed that refinement during the early stages will not lead to conflicts with tool IDs in the later stages.

The following example shows this feature applied in a 2D trimming simulation. Nodes and elements ID numbers generated from an adaptive trim simulation will be larger than the specified ID numbers of 5921980 and 8790292, respectively, for a sheet blank with part ID of 4.

*CONTROL_FORMING_ONESTEP_{OPTION}

Purpose: This keyword activates a one-step solution using the *total strain theory* approximation to plasticity (also known as deformation theory) to implement an inverse method. Given the *final* geometry, the one-step method uses LS-DYNA's implicit statics solver to compute an approximate solution for (1) the stresses and strains in the formed part, (2) the thickness of the formed part, and (3) the size of the initial blank (unfolded flat blank). This method, which is implemented only for SMP double precision, is useful for estimating the initial blank size with attendant material costs, and for augmenting crashworthiness models to account for metal forming effects, such as plastic strains and blank thickness in crash simulation.

NOTE: The entire input deck must contain a single *fully connected* surface consisting entirely of shells (nothing more nothing less). This surface specifies the *final* geometry. Isogeometric shells *are* supported.

The input may contain more than one *PART provided the parts share common boundary nodes (for instance to model a tailor-welded blank).

Adaptive mesh is not supported. Use *CONTROL_FORMING_REMOVE_ADAPTIVE_CONSTRAINTS if the part is a formed blank with adaptive mesh.

The keyword *DEFINE_FORMING_ONESTEP_PRIMARY can be used to model "patch welded" blanks.

Keywords associated with *CONTROL_FORMING_ONESTEP are:

*CONTROL_FORMING_UNFLANGING

*INTERFACE_BLANKSIZE_DEVELOPMENT

*DEFINE_FORMING_ONESTEP_PRIMARY

Available options include:

<BLANK>

AUTO_CONSTRAINT

DRAWBEAD

FRICTION

TRIA

QUAD

QUAD2 (default)

ORTHO

Summary of keyword options:

1. The AUTO_CONSTRAINT option excludes rigid body motion from the implicit solution by automatically adding nodal constraints. A deck with a *CONTROL_FORMING_ONESTEP card should contain at most one *CONTROL_FORMING_ONESTEP_AUTO_CONSTRIANT card. In addition, starting from Revision 91229, three nodes can be specified on the final part to position the unfolded blank for easier blank nesting, and for blank alignment in forming simulation.

2. The DRAWBEAD option is used to apply draw bead forces in addition to those provided by AUTOBD field in Card 1a.1. A deck containing a *CONTROL_FORMING_ONESTEP card may contain as many *CONTROL_FORMING_ONESTEP_DRAWBEAD cards as there are draw beads to be defined. See Remark 6.

3. The FRICTION option applies friction along the edge of the part based on the binder tonnage input by the user in the BDTON field of Card 1. A deck containing a *CONTROL_FORMING_ONESTEP card may contain as many *CONTROL_FORMING_ONESTEP_FRICTION cards as there are friction node sets to be defined.

4. When one-step forming method was first introduced back in 2011, all quadrilateral elements in the model were split into two triangular elements internally for calculation. As of Revision 112682, this original formulation (with no option) is set as option TRIA. A new option QUAD (Revision 112071) is now available supporting quadrilateral elements with improved algorithm in various areas, which leads to better results. In addition, this option greatly improves calculation speed under multiple CPUs in SMP mode. Another new option QUAD2 improves upon the option QUAD with enhanced element formulation, which further improves results in terms of thinning and plastic strain with slightly longer CPU times. Calculation speed comparisons among the three options can be found in the Performance Among Options TRIA, QUAD, and QUAD2 section. The option QUAD2 is set as a default as of Revision 112682 and is the recommended option.

Data Card Definitions:

Card 1 for no option (<BLANK>), TRIA, QUAD, and QUAD2.

Card 1a.1	1	2	3	4	5	6	7	8
Variable	OPTION	TSCLMAX	AUTOBD	TSCLMIN	EPSMAX		LCSDG	DMGEXP
Type	I	F	F	F	F		I	F
Default	6	0.0	0.0	0.0	1.0		none	none

Card 2 for no option (<BLANK>), TRIA, QUAD, and QUAD2.

Card 1a.2	1	2	3	4	5	6	7	8
Variable	FLATNAME							
Type	A							
Default	none							

VARIABLE	DESCRIPTION
OPTION	Options to invoke the one-step solution methods which account for undercut conditions in the formed part: EQ.6: One-step solution with unfolded blank (flat) provided by LS-PrePost (see Remark 3). Input to Card 1a.2 is required. EQ.7: One-step solution with blank automatically unfolded in LS-DYNA. Card 1a.2 must be included as a blank line. This option is recommended. L.T.0: If a negative sign precedes any of the above OPTIONs, the stress and strain output in the file onestepresult will be in a large format (E20.0), which leads to more accurate stress results. Card 1a.2 must be included as a blank line.
TSCLMAX	If not zero, it defines a thickness scale factor limiting the maximum thickness in the part. See Effects of TSCLMAX, TSCLMIN and EPSMAX. For example, if the maximum thickness allowed is 0.8 mm for a blank with initial thickness of 0.75 mm TSCLMAX can be set to 1.0667. All thicknesses that are computed as more than 0.8 mm in the sheet blank will be reset to 0.8 mm. The scale factor is useful in advance feasibility analysis where part design and stamping process have not been finalized and could potentially cause large splits or severe wrinkles during unfolding, rendering the forming results unusable for crash/safety simulation.
AUTOBD	Apply a fraction of a fully locked bead force along the entire periphery of the blank. The fully locked bead force is automatically calculated based on a material hardening curve input. AUTOBD can be increased to easily introduce more thinning and effective plastic strain in the part. See Remark 6.

VARIABLE	DESCRIPTION
	LT.0.0: Turns off the auto-bead feature. EQ.0.0: Automatically applies 30% of fully locked force. GT.0.0: Fraction input will be used to scale the fully locked force.
TSCLMIN	If not zero, defines a thickness scale factor limiting the maximum thickness reduction. See Effects of TSCLMAX, TSCLMIN and EPSMAX. For example, if the minimum thickness allowed is 0.6 mm for a blank with initial thickness of 0.75 mm TSCLMIN can be set to 0.8. All thicknesses that are computed as less than 0.6 mm in the sheet blank will be reset to 0.6 mm. The scale factor is useful in advance feasibility analysis where part design and stamping process have not been finalized and could potentially cause large splits or severe wrinkles during unfolding, rendering the forming results unusable for crash/safety simulation.
EPSMAX	If not zero, it defines the maximum effective plastic strain allowed. All computed effective plastic strains that are greater than this value in the blank will be set to this value. See Effects of TSCLMAX, TSCLMIN and EPSMAX.
LCSDG	Load curve ID defining equivalent plastic strain to failure as a function of stress triaxiality; see *MAT_ADD_EROSION.
DMGEXP	Exponent for nonlinear damage accumulation; see *MAT_ADD_EROSION. Damage accumulation is written as history variable #6 in the file onestepresult.
FLATNAME	File name of the initial unfolded blank by LS-PrePost (see Remark 3). This is needed only for the OPTION = 6. Leave a blank line for OPTION = 7.

Card 1 for option AUTO_CONSTRAINT.

Card 1b	1	2	3	4	5	6	7	8
Variable	ICON	NODE1	NODE2	NODE3				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
ICON	Automatic nodal constraining option to eliminate the rigid body motion (see Remark 8): EQ.1: Apply
NODE[1,2,3]	Node IDs for which the position is fixed during the unfolding. The position of these nodes in the calculated unfolded piece will coincide with the corresponding nodes in the input. The transformed and unfolded blank will be written in a keyword file repositioned.k. *When these fields are undefined, the orientation of the unfolded blank is arbitrary.* Starting in Revision118294, the file repositioned.k will always be output regardless if these fields are defined.

Card 1 for option DRAWBEAD.

Card 1c	1	2	3	4	5	6	7	8
Variable	NDSET	LCID	TH	PERCNT				
Type	I	I	F	F				
Default	none	none	0.0	0.0				

VARIABLE	DESCRIPTION
NDSET	Node set ID along the periphery of the part; see *SET_NODE_LIST.
LCID	Load curve ID that defines the material hardening curve.
TH	Thickness of the unformed sheet blank.

VARIABLE	DESCRIPTION
PERCNT	Draw bead lock force fraction of the fully locked bead force.

Card 1 for option FRICTION.

Card 1d	1	2	3	4	5	6	7	8
Variable	NDSET	BDTON	FRICT					
Type	I	F	F					
Default	none	0.0	0.12					

VARIABLE	DESCRIPTION
NDSET	Node set ID along the periphery of the part, as defined by keyword *SET_NODE_LIST.
BDTON	Binder tonnage used to calculate friction force. See Remark 7.
FRICT	Coefficient of friction

Card 1 for option ORTHO, for anisotropic material.

Card 1e	1	2	3	4	5	6	7	8
Variable	PID	NODE1	NODE2					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
PID	Part ID of the final formed blank mesh
NODE1	First node in the part to define the metal rolling direction
NODE2	Second node in the part to define the metal rolling direction

About One-Step Forming Solution:

One-step solution employs the total strain (or deformation) theory of plasticity in place of the more realistic incremental strain (or flow) theory. The total deformation theory expresses stress as a function of total strain; whereas the incremental strain theory requires that LS-DYNA compute a stress update at each time step (strain increment) from the deformation that occurred *during that time step*. Deformation theory results, therefore, do not depend on strain path, forming history, or the details of the stamping process.

When this card is included, the input must contain the *final geometry* from which LS-DYNA calculates the initial flat state using the inverse method. The one-step solution results can get close to the incremental results only when the forming process involves a linear strain path for which the deformation is either monotonically increasing or decreasing. In most cases total strain theory does not match incremental forming.

Path independence leads to several key simplifications:

1. Binder and addendum geometry are not required. There is no need to measure or model these geometries.

2. The solution is independent of stamping die processes (including part tipping).

3. There is no need for contact treatment since there are no tools and dies involved.

The one-step solution is mostly used for advance formability studies in which the user needs to quickly compare a wide range of different design alternatives. With this method the user can evaluate blank size, estimate material cost, and generate a first guess for blank size development (see also *CONTROL_FORMING_UNFLANGING, and *INTERFACE_BLANKSIZE_DEVELOPMENT). This method is also widely used to initialize forming stresses and strains in crash and occupant safety analysis.

Remarks:

1. **Mesh.** In addition to the usual material and physical property definitions, this method requires that the final part be fully meshed using shell elements. *No adaptive mesh is supported.* This mesh should look quite different from a formed blank going through an incremental forming. For example, along the part bend radius, there is no need to build six elements along the arc length as one would do for the punch/die radius in an incremental forming; two elements may be enough. A mesh consisting of uniformly distributed quadrilateral shell elements is ideal. *All elements in the mesh must also have normal consistency*.

   With LS-PrePost 4.0, this kind of mesh can be generated using *Mesh* → *AutoM* → *Size*. Since this method uses an implicit static solution scheme, the number of elements controls the computational cost; element size has no effect.

Furthermore, to obtain forming results that are similar to the incremental forming results, the part in the one-step input should be similar in size to the final formed blank shape in the incremental forming (before trimming).

Dynain files with *ELEMENT_SHELL_THICKNESS, *INITIAL_STRESS_SHELL and *INITIAL_STRAIN_SHELL are not supported.

2. **Holes.** Any trimmed-out holes can be filled (but not necessary). The filling can be done semi-automatically using LS-PrePost 4.0 by selecting *Mesh → EleGen → Shell → Shell by Fill_Holes → Auto Fill*. The filled area of the part can be saved in a different part, as multiple parts (PID) are allowed. The forming results will be more realistic with holes are filled, or left alone, based on the actual stamping process intent.

3. **Unfolding.** For OPTION = 6, the unfolded blank can be obtained from LS-PrePost using *EleTol → Morph → Type = Mesh_Unfolding → Unfold*. The unfolded mesh can be saved as a keyword file and used as input (see the FLATNAME field in Card 1a.2). With OPTION = 7, LS-DYNA unfolds the mesh itself.

4. **Element Formulation.** Shell elements of type 2 and 16 are supported. Since this feature uses the implicit method, type 16 is more convergent and computationally efficient than type 2; therefore, it is strongly recommended. Results are output on all integration points, as seen in the ELFORM and NIP variables in *SECTION_SHELL.

5. **Supported Materials.** *MAT_024, *MAT_036, *MAT_037, *MAT_112, *MAT_114, *MAT_123, *MAT_133, and *MAT_238 are supported. The user *must* provide a material hardening curve. For *MAT_024 the hardening curve must be specified with the LCSS field. It can be input as a table. Strain rate, however, is ignored for this material, even if the variables C and P are provided. For MAT_036 the hardening curve must be a load curve (HR = 3), and for *MAT_037 it must be specified with HLCID.

   For anisotropic material, the option ORTHO can be used to define the material rolling direction. Since there is no flat blank existing as an input, the only way to define the rolling direction is to use two existing nodes in the 3D formed part to meet the requirement.

6. **Boundary Conditions.** The primary boundary/loading condition for the one-step solution is the draw bead forces, which are set with the AUTOBD field or with the DRAWBEAD keyword option.

   a) With the DRAWBEAD option, draw bead forces are applied on a user defined node set (see NDSET). A fraction of the full lock force, determined by the tensile strength and sheet thickness, can be specified. The larger the

fraction, the less the metal will flow into the die resulting in more stretching and thinning.

b) Boundary conditions may also be set using the auto-beads feature (see the AUTOBD field) with which draw bead forces are automatically applied to all nodes along the part boundary. The users must specify the fraction of the fully locked bead force to be applied. The default value of 30% is sufficient for crash/occupant safety applications.

The last important, but often overlooked, boundary condition is the part's shape. For example, an oil pan with a larger flange area will experience greater thinning in the part wall, whereas having a smaller flange area will have the reverse effect. To obtain results that are closer to the incremental strain theory, additional materials may need to be added to the final part geometry in cases where the sheet blank is not fully developed, meaning no trimming is required to finish the part.

7. **Friction.** Friction effects can be included with the FRICTION option. The frictional force is based on an expected binder tonnage, and is a percentage of the input force. Note that the binder tonnage value (see BDTON) is used *exclusively* in calculating friction forces. The binder tonnage is not actually applied on the binder as a boundary condition.

8. **Rigid Body Motion.** LS-DYNA will automatically add nodal constraints to prevent rigid body motion when the AUTO_CONSTRAINT option is used and ICON is set to 1.

9. **Implicit Solver Options.** All other implicit cards, such as *CONTROL_IMPLICIT_GENERAL, *CONTROL_IMPLICIT_SOLUTION, *CONTROL_IMPLICIT_SOLVER, *CONTROL_IMPLICIT_AUTO, *CONTROL_IMPLICIT_TERMINATION, etc., are used to set the convergence tolerance, termination criterion, etc. The two most important variables controlling the solution convergence are DELTAU from *CONTROL_IMPLICIT_TERMINATION, and DCTOL from *CONTROL_IMPLICIT_SOULTION. Experience has shown that they should be set to 0.001 and 0.01, respectively, to obtain the most efficient solution with the best results. Typically, four implicit steps are sufficient, and DT0 in *CONTROL_IMPLICIT_GENERAL and ENDTIM in *CONTROL_TERMINATION should be set accordingly. For difficult parts, more steps maybe needed. For some parts, ILIMIT in *CONTROL_IMPLICIT_SOLUTION may need to be set to 1 for the full Newton iteration.

10. **Results.** Results are stored in an ASCII file named onestepresult using the dynain format. This file contains the forming thickness, the stress and the strain fields on the final part. It can be plotted with LS-PrePost. One quick and useful LS-PrePost plotting feature is the formability contour map, which colors the model to highlight various forming characteristics including cracks, severe

thinning, wrinkles, and good surfaces. The formability map feature is in *Post → FLD → Formability*.

The variable PSID in *INTERFACE_SPRINGBACK_LSDYNA can be used to control the output to onestepresult and dynain files, starting in Dev 138146.

11. **Final Estimated Blank Size.** Additionally, the final estimated blank size in its initial, flat state is stored in the d3plot files. The d3plot files also contain intermediate shapes from each implicit step. The final blank mesh in its flat state can be written to a keyword file using LS-PrePost by the following steps:

    a) Go to *Post → Output → Keyword*,

    b) Check the box to include *Element* and *Nodal Coordinates*

    c) Move the animation bar to the last state, and,

    d) Click on *Curr* and *Write.*

    In addition, blank outlines can be created by:

    e) Menu option *Curve → Spline → From Mesh (Method)*,

    f) Checking *Piecewise → byPart*,

    g) Select the blank,

    h) Click on *Apply*, and,

    i) Finally, save the curves in IGES format using the *File* menu at the upper left corner.

    The unformed blank mesh will be output into the file repositioned.k.

Effects of TSCLMAX, TSCLMIN and EPSMAX:

During the early stage of product design, the initial product specifications may lead to large strains and excessive thinning or thickening on the formed panel. The ensuing one-step results may not be suitable to be used in a crashworthiness simulation. However, these kinds of forming issues are certain to be fixed as a natural part of the design and stamping engineering process. The variables TSCLMAX, TSCLMIN and EPSMAX, thus, impose artificial limits on the excessive thickening (indication of wrinkles), excessive thinning, and plastic strains, respectively. These fields provide a convenient way to run a crash simulation with approximate and reasonable forming effects before the design is finalized. In the keyword below (which is a part of the firewall model with original thickness of 0.75 mm), TSCLMIN and EPSMAX are set to 0.8 and 0.3, respectively.

```
*CONTROL_FORMING_ONESTEP
$    OPTION    TSCLMAX     AUTODB    TSCLMIN     EPSMAX
         7                    0.5        0.8        0.3
```

The thickness and effective plastic strain plots for the firewall model are shown in Figures 12-30 and 12-31, respectively. The minimum value in the thickness contour plot and maximum value in the plastic strain contour plot as shown in the upper left corner correspond to the values specified in TSCLMIN and EPSMAX, respectively.

Similarly, TSCLMAX can be set to 1.0667 to limit the max thickening in the part to 0.8 mm:

```
*CONTROL_FORMING_ONESTEP
$    OPTION    TSCLMAX     AUTODB    TSCLMIN     EPSMAX
         7     1.0667        0.5        0.8        0.3
```

Repositioning the Unfolded Flat Blank:

Often the input to a one-step simulation is the final product part in a coordinate system that is useful for subsequent simulations. However, after the one-step simulation, the unfolded flat blank will be in a different orientation and position, requiring manual repositioning of the blank to its desired orientation and position. The variables NODE1, NODE2, and NODE3 allow users to specify three nodes so that the blank is transformed onto the final part (the input), superimposing the exact same three nodes in both parts. In the example shown in Figure 12-33, the three nodes (Nodes 197, 210 and 171) are defined near the edges of two holes. The transformed and unfolded flat blank (written to a keyword file repositioned.k) is seen superimposed onto the final part according to the three nodes specified (Figure 12-33 bottom). If these nodes are not defined, the simulation will result in the unfolded flat blank in a state shown in Figure 12-33 (top), which is undesirable to most users.

Damage Accumulation:

Damage accumulation D is calculated based on (see *MAT_ADD_EROSION):

$$D = \left(\frac{\varepsilon_p}{\varepsilon_f}\right)^{\text{DMGEXP}},$$

where ε_p is the equivalent plastic strain and ε_f is the equivalent plastic strain to failure.

In the example below, load curve 500 (LCSDG) gives plastic failure strain as a function stress triaxiality and DMGEXP is assumed to be 1.254. Since the damage accumulation is written into the file onestepresult as history variable #6, the variable NEIP in *DATABASE_EXTENT_BINARY should be set to at least 6.

```
*CONTROL_FORMING_ONESTEP
```

```
$   OPTION              AUTODB    TSCLMIN     EPSMAX               LCSDG     DMGEXP
         7                              0.8        0.3                 500      1.254

                   1                   2
```

The damage accumulation contour map from the file onestepresult can be plotted in LS-PrePost.

Effects of Unfilled Holes on Forming Results:

In Figure 12-32, a thickness contour plot of a one-step calculation on the NCAC Taurus firewall model with its holes unfilled is shown. The unfilled case will undergo slightly less thinning, since the holes will expand as material flows outward away from the hole. However, the thicknesses with holes filled are likely closer to reality, since the holes are mostly filled during forming on the draw panel and then trimmed off afterwards in a trim process. On the other hand, it is important to realize that not all the holes are filled in a draw panel. Some holes are cut inside the part in the scrap area (but not all the way to the trim line) during the draw process to allow material to flow into areas that are difficult to form which avoids splitting.

Example:

The following example provides a partial input file with typical control cards. It will iterate for four steps, with auto beads of 0% lock force applied around the part boundary, and with automatic nodal constraints.

```
*CONTROL_TERMINATION
$   ENDTIM
       1.0
*CONTROL_IMPLICIT_GENERAL
$   IMFLAG       DT0
          1     0.25
*CONTROL_FORMING_ONESTEP
$   OPTION              AUTODB
         7

*CONTROL_FORMING_ONESTEP_AUTO_CONSTRAINT
$     ICON
         1
*CONTROL_IMPLICIT_TERMINATION
$   DELTAU
     0.001
*CONTROL_IMPLICIT_SOLUTION
```

```
$  NSLOLVR    ILIMIT    MAXREF     DCTOL     ECTOL
         2        11      1200      0.01      1.00
*CONTROL_IMPLICIT_SOLVER
$   LSOLVR
         5
*CONTROL_IMPLICIT_AUTO
$    IAUTO    ITEOPT    ITEWIN     DTMIN     DTMAX
         0         0         0       0.0       0.0
```

Additional cards below specify extra bead forces of 45% and 30% applied to node sets 22 and 23 along the part periphery, respectively. Also, the friction forces are applied to the same node sets with a friction coefficient of 0.1 and a binder tonnage of 10000.0 N.

```
*CONTROL_FORMING_ONESTEP_DRAWBEAD
$   NDSET      LCID        TH    PERCNT
       22       200       1.6      0.45
*CONTROL_FORMING_ONESTEP_DRAWBEAD
       23       200       1.6      0.30
*CONTROL_FORMING_ONESTEP_FRICTION
$   NDSET     BDTON    FRICT
       22   10000.0      0.1
*CONTROL_FORMING_ONESTEP_FRICTION
$   NDSET     BDTON    FRICT
       23   10000.0      0.1
```

The one-step forming results for the NCAC Taurus model's firewall are shown in Figure 12-26. The average element size across the blank is 8 mm, and the trimmed part (with holes filled) consists of 15490 elements. *MAT_24 was used with BH210 material properties. On a 1 CPU Xeon E5520 Linux machine, it took 4 minutes to complete the run with a total of four steps. The thickness, the plastic strain, and the blank size prediction were reasonable, as shown in Figures 12-27, 12-28, and 12-29.

Performance Among Options TRIA, QUAD and QUAD2:

The following partial keyword input is an example of using the option QUAD. Note the draw bead force parameter AUTOBD is set at 0.5. Calculation speed comparison among options QUAD, QUAD2 and TRIA can be found in Table 12-1.

*CONTROL_FORMING_OUTPUT_{OPTION}

Available options include:

<BLANK>

INTFOR

Purpose: This card defines the times at which states are written to the d3plot and intfor files based on the tooling's distances from the home (final) position. When the INTFOR option is set, this keyword card controls when states are written to the intfor file, otherwise it controls the d3plot file. This feature may be combined with parameterized input and/or automatic positioning of the stamping tools using the *CONTROL_FORMING_-AUTOPOSITION_PARAMETER card.

> **NOTE:** When this card is present, no states are written except for those specified on this card. This card supersedes the *DATABASE_BINARY_D3PLOT card.

Forming Output Cards. Repeat as many times as needed to define additional outputs in separate tooling kinematics curves. The next keyword ("*") card terminates the input.

Card 1	1	2	3	4	5	6	7	8
Variable	CID	NOUT	TBEG	TEND	Y1/LCID	Y2/CIDT	Y3	Y4
Type	I	I	F	F	F/I	F/I	F	F
Default	none	0	0.0	none	Rem 3	Rem 3	Rem 3	Rem 3

VARIABLE	DESCRIPTION
CID	ID of a tooling kinematics curve. This curve is integrated so that the specified output distances can be mapped to times. For correct distance-to-time mapping CID must be applied to the tool of interest using a *BOUNDARY_PRESCRIBED_MOTION_-RIGID card. The ordinate scale factor SFO in the *DEFINE_-CURVE is supported in this keyword starting from Dev Revision 82755.
NOUT	Total number of states written to the d3plot or intfor databases for the tooling kinematics curve, CID, excluding the beginning and final states. If NOUT is larger than the number of states specified by either LCID or Y*i* fields (5 through 8), the remaining states are

VARIABLE	DESCRIPTION
	evenly distributed between TBEG and the time corresponding to the biggest Y*i* from the home position, as shown in Figure 12-34. If NOUT is left as blank or as "0", the total number of output states will be determined by either LCID or Y*i*'s. Starting in Dev Revision 124051, NOUT works alone, without the need to define LCID or Y*i*'s.
TBEG	Start time of the curve. This time should be consistent with the BIRTH in *BOUNDARY_PRESCRIBED_MOTION_RIGID.
TEND	End time of the curve. This time should be consistent with the DEATH in *BOUNDARY_PRESCRIBED_MOTION_RIGID. This time is automatically reset backward removing any idling time if the tool finishes traveling early, so output distances can start from the reset time. A state is written at TEND.
Y1/LCID, Y2, Y3, Y4	Y1/LCID.GT.0: All four variables (Y1, Y2, Y3, Y4) are taken to be the distances from the punch home, where d3plot files will be output. Y1/LCID.LT.0: The absolute value of Y1/LCID (must be an integer) is taken as a load curve ID (see *DEFINE_CURVE). Only the abscissas in the load curve, which are the distances to punch home, are used. These distances specify the states that are written to the d3plot files. Ordinates of the curve are ignored. This case accommodates more states than is possible with the four variables Y1, Y2, Y3, Y4. Furthermore, when Y1/LCID < 0, Y2, Y3, and Y4 are ignored. Available starting from Dev Revision 112604, the output will be skipped for any negative abscissa in the load curve. Note a curve with *only* negative abscissas is not allowed.
Y2/CIDT	Y2/CIDT.GT.0: The input is taken as the distance from the punch home, where a d3plot file will be output. Y2/CIDT.LT.0: The absolute value of Y2/CIDT (must be an integer) is taken as a load curve ID (see *DEFINE_CURVE). Only the abscissas in the load curve, which are the simulation times, are used. These times specify the states that are written to the d3plot files. Ordinates of the curve are ignored.

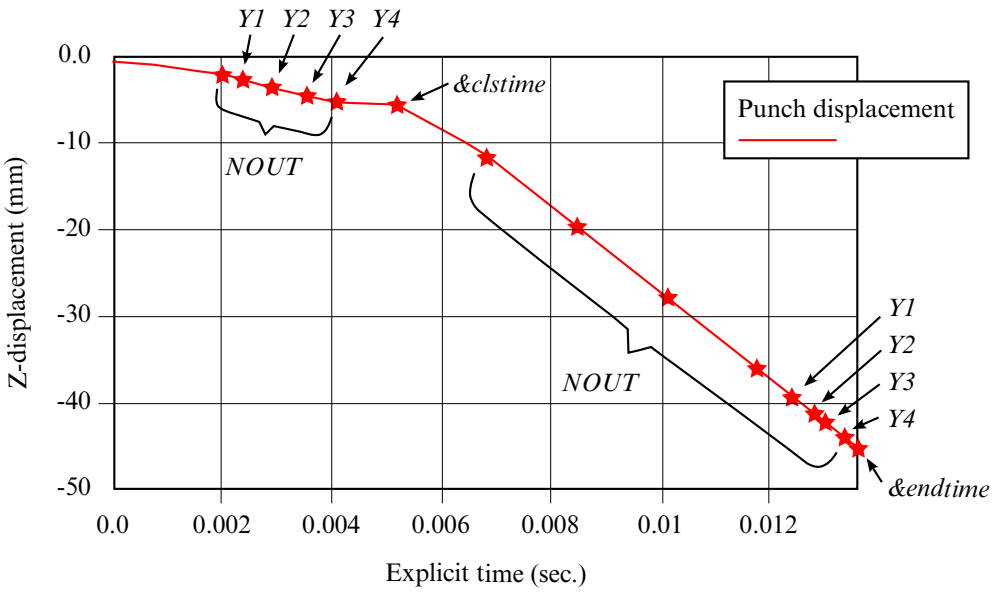

Figure 12-34. An output example for closing and drawing. See the example provided at the end of this section.

VARIABLE	DESCRIPTION
	Note this time-dependent load curve will output additional d3plot files on top of the d3plot files already written in case Y1/LCID < 0 (if specified). Furthermore, when Y2/CIDT < 0, Y3 and Y4 are ignored. See the example Using CIDT below.

Motivation:

In stamping simulations not all time steps are of equal interest to the analyst. This feature allows the user to save special states, usually those for which wrinkling and thinning conditions arise as the punch approaches its home position.

Remarks:

1. **Related Keywords.** Keywords *DATABASE_BINARY_D3PLOT and *DATABASE_BINARY_INTFOR are not required (ignored if present) to output d3plot and intfor files when this keyword is present.

2. **CID.** *CONTROL_FORMING_OUTPUT and *CONTROL_FORMING_OUTPUT_INTFOR can share the same CIDs.

3. **Output Distribution.** The following are rules for output distribution:

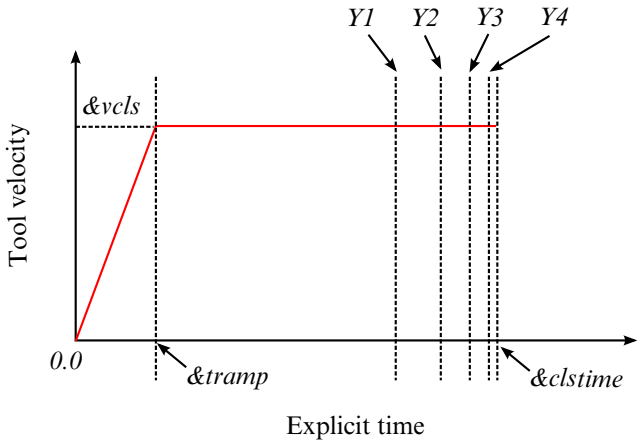

Figure 12-35. Specifying d3plot/intfor output at specific distances to punch home.

a) If columns 5 through 8 are left blank, output (NOUT) will be evenly distributed through the travel.

b) The variable NOUT has priority over the number of points on the LCID.

c) Distances input (in LCID) that are greater than the actual tool travel will be ignored.

d) Distance input (in LCID) does not necessarily have to be in a descending or ascending order.

Applicability:

Velocity must be the prescribed motion in *BOUNDARY_PRESCRIBED_MOTION_-RIGID (VAD = 0) for this keyword to apply. This keyword only works for explicit dynamics. Tooling kinematics profiles of various trapezoids (including right trapezoid) are all supported. Local coordinate systems are supported.

Air Draw Example:

In the sample keyword input below (air draw, referring to Figures 12-34 and 12-36), a total of five states will be output during a binder closing. The kinematics are specified by the curve of ID 1113, which defines tooling kinematics starting time 0.0 and ending at time `&clstime`.

Curve 1113 is used to associate the specified distances to the appropriate time step. In this example NOUT is set to 5. Of these five outputs states the last four will be output at upper die distance to closing of 3.0, 2.0, 1.0, and 0.5 mm according to the values specified in the Y1, Y2, Y3, and Y4 fields.

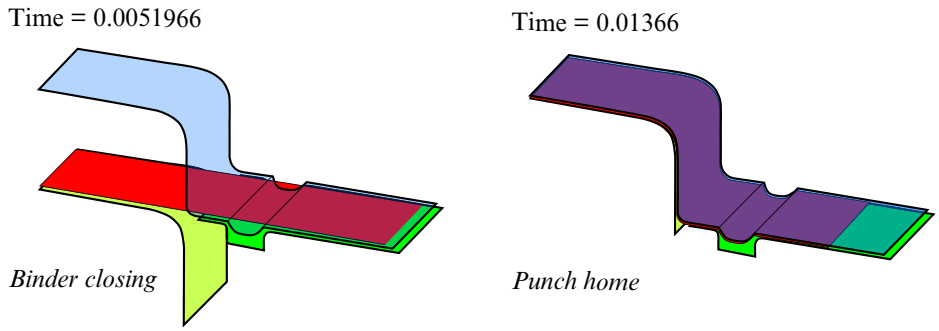

Figure 12-36. An air draw example with closing and drawing.

Similarly, a total of eight states will be written to the d3plot file made during draw forming according curve ID 1115, which defines tooling kinematics starting at time `&clstime`, and ending at time `&endtime`. Of the eight states the last four will be output at punch distance to draw home of 6.0, 4.0, 3.0, and 1.0 mm; the remaining four outputs will be evenly distributed between starting punch distance to home and punch distance of 6.0mm to home.

Likewise, for intfor, 15 states will be written before closing and 18 states after the closing. The d3plot and intfor files will always be output for the first and last states as a default; and at where the two curves meet at &clstime, only one d3plot and intfor will be output.

To output intfor, "S=*filename*" needs to be specified on the command line, and SAPR and SBPR need to be set to "1" on the *CONTACT_… cards.

Multiple Flanging Process Example:

Referring to Figure 12-37 and a partial keyword example listed below, flanging steels #1 through #4 are defined as parameters `&flg1pid` through `&flg4pid`, respectively, which are moving in their own local coordinate systems. The termination time `&endtime` is defined as pad closing time, `&clstime`, plus the maximum travel time of all four flanging

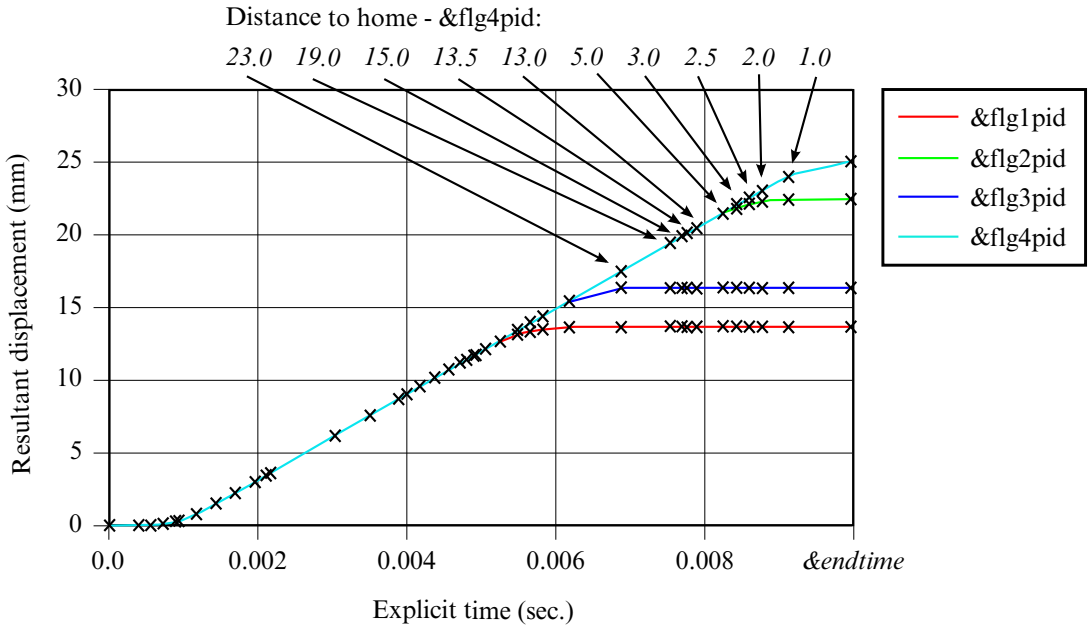

Figure 12-38. D3PLOT/INTFOR output in case of multiple flanging process.

steels. A total of ten d3plot states and ten intfor states are defined for each flanging steel using curve IDs 980 and 981, respectively. Curve values outside of the last 10 states (distances) are ignored; and reversed points are automatically adjusted.

In Figure 12-38, locations of d3plot states are indicated by "x" markers for each flanging steel move. Note that for flanging steels with longer travel distances, there may be additional d3plot states between the defined points, controlled by distance output defined for other flanging steels with shorter travels. The total number of d3plot (and intfor) states is the sum of all nout defined for each flanging steel so care should be taken to limit the total d3plot (and intfor) states, especially if large number of flanging steels are present.

*CONTROL_FORMING_PARAMETER_READ

Purpose: This feature allows for reading of a numerical number from an existing file to store in a defined parameter. The parameter can be used and referenced in the current simulation. The file to be read may be a result from a previous simulation. The file may also simply contain a list of numbers defined beforehand and to be used for the current simulation.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

Parameter Cards. Include one card for each parameter. The next keyword ("*") card terminates the input.

Card 2	1	2	3	4	5	6	7	8
Variable	PARNAME	METHOD	LINE #	BEGIN	END			
Type	C	I	I	I	I			
Default	none	0	0	0	0			

VARIABLE	DESCRIPTION
FILENAME	Name of the file to be read.
PARNAME	Parameter name. Maximum character length is 7.
METHOD	Read instruction: EQ.1: read, follow definition by LINE #, BEGIN and END definition
LINE #	Line number in the file.
BEGIN	Beginning column number in the line number defined above.
END	Ending column number in the line number defined above.

Remarks:

1. **Input Order.** Keyword input order is sensitive. Recommended order is to define variables in *PARAMETER first, followed with this keyword, using the defined variables.

2. **Multiple Variables.** Multiple variables can be defined with one such keyword, with the file name needed to be defined only once. If there are variables located in multiple files, the keyword needs to be repeated for each file.

Examples:

An example provided below shows that multiple PIDs for individual tools and blank are defined in files data.k and data1.k. In the main input file, sim.dyn, used for LS-DYNA execution, variables (integer) are first initialized for PIDS of all tools and blank with *PARAMETER. These variables are updated with integers read from files data.k and data1.k from respective line number and column number through the use of this keyword. In the *SET_PART_LIST definition, these PIDs are used to define the part set.

Below is file data.k, to be read into sim.dyn:

```
$$$$$$$$$$$$$$$$$$$$$$$$
$$$ define PIDs
$$$$$$$$$$$$$$$$$$$$$$$$
$---+----1----+----2----+----3----+----4----+----5----+----6----+----7----+--
upper die  pid:              3
lower post pid:              2
Below is file "data1.k", also to be read into "sim.dyn":
$$$$$$$$$$$$$$$$$$$$$$$$
$$$$$$$$$$$$$$$$$$$$$$$$
$$$$$$$$$$$$$$$$$$$$$$$$
$$$ define PIDs
$$$$$$$$$$$$$$$$$$$$$$$$
$---+----1----+----2----+----3----+----4----+----5----+----6----+----7----+--
lower binder pid:            4
blank pid:                   1
```

Below is partial input for the main input file sim.dyn:

```
$---+----1----+----2----+----3----+----4----+----5----+----6----+----7----+--

Revision Information:

This feature is available in LS-DYNA R5 Revision 55035 and later releases.

*CONTROL_FORMING_POSITION

Purpose: This keyword allows user to position tools and a blank in setting up a stamping process simulation. All tools must be pre-positioned at their home positions. For tools that are positioned above the sheet blank (or below the blank) and ready for forming, *CONTROL_FORMING_TRAVEL should be used. This keyword is used together with *CONTROL_FORMING_USER. One *CONTROL_FORMING_POSITION card may be needed for each part.

> **NOTE:** This option has been deprecated in favor of *CONTROL_FORMING_AUTOPOSITION_PARAMETER).

Positioning Cards. For each part to be positioned include an additional card. The next "*" card terminates the input.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	PREMOVE	TARGET					
Type	I	F	I					
Default	none	none	I					

VARIABLE	DESCRIPTION
PID	Part ID of a tool to be moved, as in *PART
PREMOV	The distance to pre-move the tool, in the reverse direction of forming.
TARGET	Target tool PID, as in *PART. The tool (PID) will be moved in the reverse direction of the forming and positioned to clear the interference with the blank, then traveled to its home position with a distance GAP (*CONTROL_FORMING_USER) away from the TARGET tool to complete the forming.

Remarks:

When this keyword is used, all stamping tools must be in their respective home positions, which is also the position of each tool at its maximum stroke. From the home position each tool will be moved to its start position, clearing interference between the blank and

tool yet maintaining the minimum separation needed to avoid initial penetration. Currently the tools can only be moved and travels in the direction of the global Z-axis.

A partial keyword example is provided in manual pages under *CONTROL_FORMING_USER.

Revision information:

This feature is available starting in Revision 24641.

*CONTROL_FORMING_PRE_BENDING_{OPTION}

Available options include:

<BLANK>

LOCAL

Purpose: Bend an initially flat sheet metal blank with a user-specified radius to control the blank's gravity loaded shape during sheet metal forming.

Card 1	1	2	3	4	5	6	7	8
Variable	PSET	RADIUS	VX	VY	VZ	XC	YC	ZC
Type	I	F	F	F	F	F	F	F
Default	none	none	none	none	none	↓	↓	↓

Local Coordinate System Card. This card is required if the option LOCAL is used.

Card 2	1	2	3	4	5	6	7	8
Variable	CID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PSET	Part set ID to be included in the pre-bending
RADIUS	Radius of the pre-bending: GT.0.0: bending center is on the same side as the element normal. LT.0.0: bending center is on the reverse side of the element normals. See Figure 12-39.

VARIABLE	DESCRIPTION
VX, VY, VZ	Vector components of an axis about which the flat blank will be bent
XC, YC, ZC	(X, Y, Z) coordinates of the center of most-bent location. If undefined, center of gravity of the blank will be used as a default.
CID	ID for a local coordinate system in which the blank will be bent

About Pre-Bending due to Gravity:

In some situations, gravity loading upon a flat blank will result in a "concave" shape in a die. This mostly happens in cases where there is little or no punch support in the middle of the die cavity and in large stamping dies. Although the gravity loaded blank shape is correct, the end result is undesirable. For example, buckles may result during the ensuing closing and forming simulations. In practice, a true flat blank rarely exists. Typically, the blank is either manipulated (shaking or bending) by die makers in the tryout stage or by suction cups in a stamping press to get an initial convex shape prior to the binder closing and punch forming. This keyword allows this bending to be performed.

Example:

A partial keyword example (NUMISHEET2002 fender outer) is provided below, where blank part set ID variable &BLKSID defined previously is to be bent with a radius value of -10000.0 mm with the Z-axis as the bending axis on the reverse side of the blank positive normal (see Figure 12-39). The bending is off the center of gravity at $(234.0, 161.0, 81.6)$ (to the right along positive X-axis). Only a slight pre-bending on the blank is needed to ensure a convex gravity-loaded shape. Note this keyword is input order sensitive and requires all model information to be placed ahead, therefore it is best to place the keyword at the end of an input deck.

```
*KEYWORD
⋮
*CONTROL_IMPLICIT_FORMING
1
*CONTROL_FORMING_PRE_BENDING
$     PSET    RADIUS        VX        VY        VZ        XC        YC        ZC
   &BLKSID   -10000.      0.00      0.00       1.0   234.000   161.000     81.60
...
*END
```

In Figures 12-40, initial blank shape without pre-bending is shown. Without pre-bending, the gravity loaded blank sags in the middle of the die cavity (see Figure 12-41) which is likely unrealistic and would lead to predictions of surface quality issues. With pre-bending applied (see Figure 12-42), the blank bends slightly into a convex shape before loading. This shape results in an overall convex shape after gravity completes loading

(see Figure 12-43), leading to a much shorter binder closing distance, and a more realistic surface quality assessment.

Bending in a local coordinate system:

A partial keyword example below bends the blank (part set ID 5) in local coordinate system #8, about an axis 45 degrees from both the local *X*- and *Y*- axes, and perpendicular to the local *Z*-axis, in a radius of 1000 mm. The bending center is located in the negative surface normal side of the blank.

Revision Information:

This feature is available in double precision starting in LS-DYNA DEV 66094. It is also available in LS-PrePost *eZ-Setup* for metal forming application (http://ftp.lstc.com/-anonymous/outgoing/lsprepost/). The option LOCAL is available starting in DEV 139260.

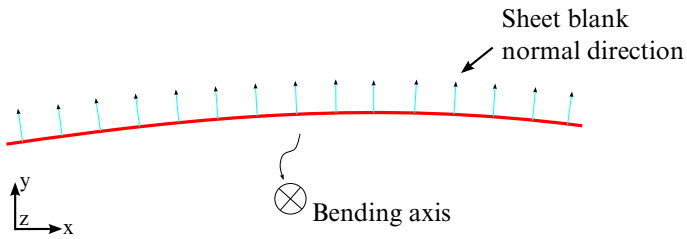

Figure 12-39. Negative "R" puts center of bending on the opposite side of the positive blank normal.

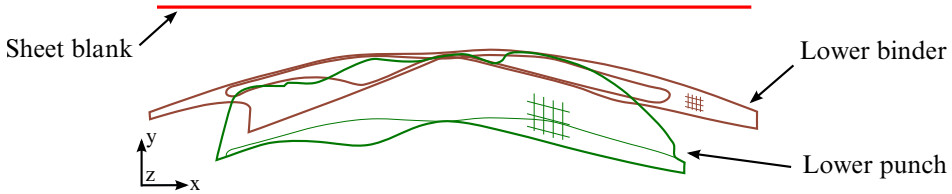

Figure 12-40. Initial model before auto-positioning.

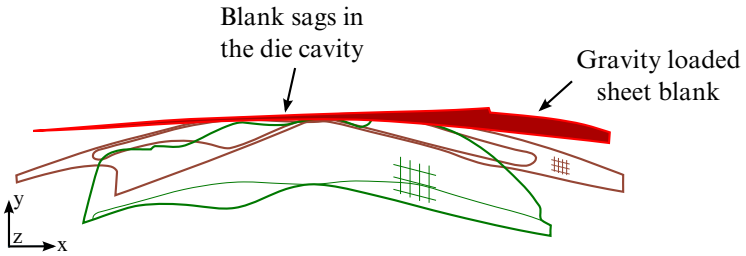

Figure 12-41. Gravity loaded blank without using this keyword.

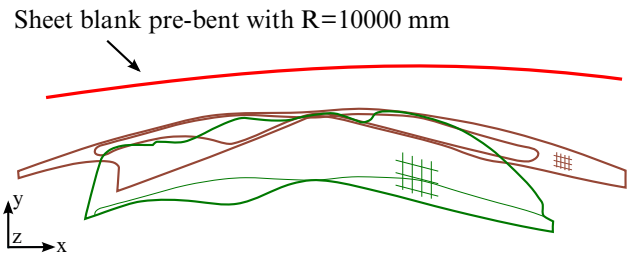

Figure 12-42. Pre-bending using this keyword (1st state in d3plot).

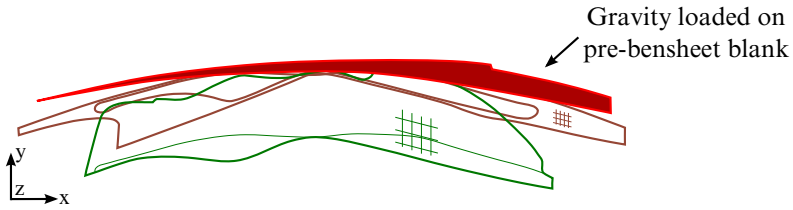

Figure 12-43. Gravity loaded shape (final state in d3plot) with convex shape.

*CONTROL_FORMING_PROJECTION

Purpose: Remove initial penetrations between the blank and the tooling (shell elements only) by projecting the penetrated blank nodes along a normal direction to the surface of the blank or to the surface of the tool with the specified gap between the node and the tooling surface. This is useful for line die simulations of a previously formed panel to reduce tool travel, therefore saving simulation time.

Define Projection Card. This card may not be repeated.

Card 1	1	2	3	4	5	6	7	8
Variable	PIDB	PIDT	GAP	NRBST	NRTST			
Type	I	I	F	I	I			

VARIABLE	DESCRIPTION
PIDB	Part ID of the blank
PIDT	Part ID for the tool
GAP	A distance, which defines the minimum gap required
NRBST	Specify whether the blank will move along its normal direction. If its moves along the normal of blank, then this flag also specifies the direction the normal is pointing with respect to the tool. EQ.0: Move the blank's nodes along the blank's normal. The normal to the surface of the blank is pointing towards the tool. EQ.1: Move the blank's nodes along the blank's normal. The normal to the surface of the blank is pointing away from the tool. EQ.2: Move the blank nodes along the tool's normal direction. This case is useful for contact between a guide pin and blank.
NRTST	Normal direction of the tool: EQ.0: The normal to the surface of the tool is pointing towards the blank. EQ.1: The normal to the surface of the tool is pointing away from blank.

Remarks:

This feature requires consistent normal vectors for both the rigid tooling surface and the blank surface.

*CONTROL_FORMING_REMOVE_ADAPTIVE_CONSTRAINTS

Purpose: Convert an adaptive mesh into a fully connected mesh. This feature removes adaptive constraints and connects the mesh with triangular elements.

Card 1	1	2	3	4	5	6	7	8
Variable	PID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PID	Part ID (see *PART) of the part whose adaptive mesh constraints are to be removed and its mesh converted into connected meshes.

Remarks:

In some applications of sheet metal forming, such as stoning or springback simulations, adaptive refinement of the sheet blank may affect the accuracy of the calculation. To avoid this problem, a non-adapted mesh is required. However, an adaptively refined mesh has the optimal mesh density that is tailored to the tooling geometry; the resulting mesh, in its initial shape, either flat or deformed, has fewer elements than a blank with non-adapted and uniformly-sized elements and thus is the most efficient for simulation. If the parameter IOFLAG in *CONTROL_ADAPTIVE is turned on, such a mesh adapt.msh will be generated at the end of each simulation, with its shape conforming to the initial input blank shape.

This keyword takes the adapted mesh, removes the adaptive constraints, and use triangular elements to connect the otherwise disconnected mesh. The resulting mesh is a fully connected mesh, with the optimal mesh density, to be used to re-run the simulation (without mesh adaptivity) for better accuracy.

Note that the original adapt.msh file from an LS-DYNA run will include not only the blank but the tooling mesh as well. For this keyword to be used, the original file can be read into LS-PrePost with the blank shown in active display only; the menu option *File* → *Save As* → *Save Active Keyword As* can be used to write out the adapted blank mesh only.

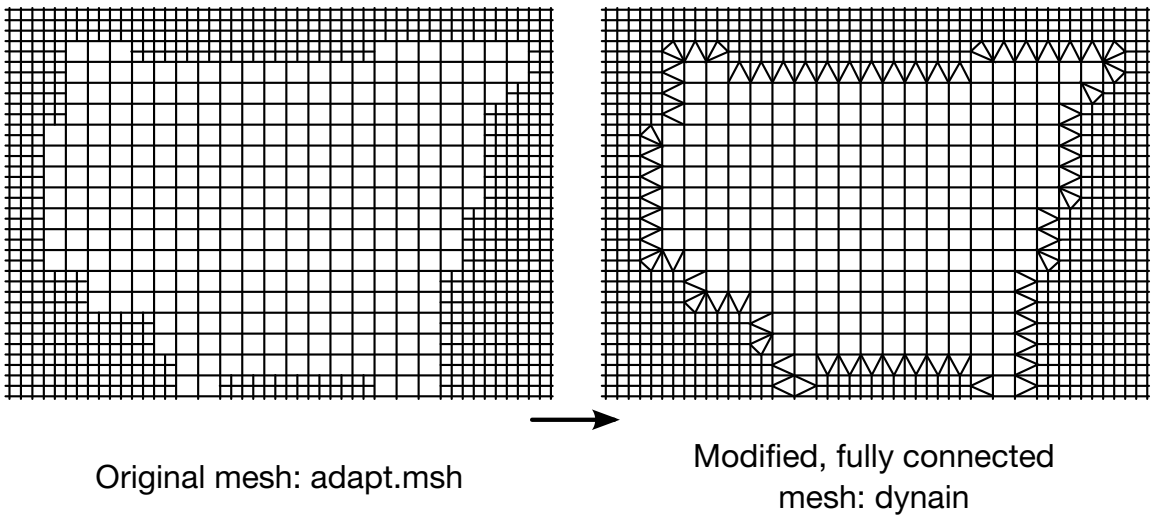

Figure 12-44. Converting an adaptive mesh to a fully connected mesh.

Example:

The following complete input file converts an adaptive mesh file blankadaptmsh.k (Figure 12-44 left) with the PID of 1 into a connected mesh (Figure 12-44 right). The resulting mesh will be in the dynain file.

*CONTROL_FORMING_SCRAP_FALL

Purpose: Direct and aerial trimming of a sheet metal part by trim steels in a trim die. According to the trim steels and trim vectors defined, the sheet metal part will be trimmed into a parent piece and multiple scrap pieces. The parent piece is defined as a fixed rigid body. Trimmed scraps (deformable shells) are constrained along trim edges until they come into contact with the trim steel; the edge constraints are gradually released as the trim steel's edge contacts the scrap piece, allowing for simulating contact-based scrap fall. This keyword applies to shell elements only.

Card Sets. Include Card 1 columns 1-6 only per each scrap piece for the *constraint release method* (see Remarks). For the *scrap trimming method* include one set of Cards 1, 2, and 3 per trim steel. The next keyword ("*") card terminates the input.

Default	none	↓	↓	↓	none	none	none	none

Card 3	1	2	3	4	5	6	7	8
Variable	NEWID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PID	Part ID of a scrap piece. This part ID becomes a dummy ID if all trimmed scrap pieces are defined by NEWID. See definition for NEWID and Figure 12-47.
VECTID	Vector ID for a trim steel movement, as defined by *DEFINE_VECTOR. If left undefined (blank), global *z*-direction is assumed.
NDSET	A node set consisting of all nodes along the cutting edge of the trim steel. Note that prior to Revision 90339 the nodes in the set must be defined in consecutive order. See Remarks (LS-PrePost) below on how to define a node set along a path in LS-PrePost. This node set, together with VECTID, is projected to the sheet metal to form a trim curve. To trim a scrap out of a parent piece involving a neighboring trim steel, which also serves as a scrap cutter, the node set needs to be defined for the scrap cutter portion only for the scrap, see Figure 12-47.
LCID	Load curve ID governing the trim steel kinematics, as defined by *DEFINE_CURVE. GT.0: velocity-controlled kinematics LT.0: displacement-controlled kinematics Example input decks are provided below.
DEPTH	A small penetrating distance between the cutting edge of the trim steel and the scrap piece, as shown in Figure 12-46. Nodes along the scrap edge are released from automatically added constraints at the simulation start and are free to move after this distance is reached.
DIST	A distance tolerance measured in the plane normal to the trim steel moving direction, between nodes along the cutting edge of the trim steel defined by NDSET and nodes along an edge of the scrap, as shown in Figure 12-45. This tolerance is used to determine if the constraints need to be added at the simulation start to the nodes along the trim edge of the scrap piece.
IDRGD	Part ID of a parent piece, which is the remaining sheet metal after the scrap is successfully trimmed out of a large sheet metal. Note the usual *PART needs to be defined somewhere in the input deck, along with *MAT_20 and totally fixed translational and rotational DOFs. See Figure 12-47.

VARIABLE	DESCRIPTION
IFSEED	A flag to indicate the location of the scrap piece. EQ.0: automatically determined. The trim steel defined will be responsible to trim as well as to push (have contact with) the scrap piece. EQ.1: automatically determined; however, the trim steel in definition will only be used to trim out the scrap, not to push (have contact with) the scrap piece. EQ.-1: user specified by defining SEEDX, SEEDY, and SEEDZ
NDBEAD	A node set to be excluded from initially imposed constraints after trimming. This node set typically consists of nodes in the scrap draw bead region where due to modeling problems the beads on the scrap initially interfere with the beads on the rigid tooling; it causes scrap to get stuck later in the simulation if left as is. See Figure 12-48.
SEEDX, SEEDY, SEEDZ	x, y, z coordinates of the seed node on the scrap side; define only when IFSEED is set to "-1". See Figure 12-47.
EFFSET	Scrap edge offset amount away from the trim steel edge, towards the scrap seed node side. This is useful to remove initial interference between the trimmed scrap (because of poorly modeled trim steel) and coarsely modeled lower trim post. See Figure 12-47.
GAP	Scrap piece offset amount from the part set defined by IPSET (e.g. top surfaces of the scrap cutters), in the direction of the element normals of the IPSET. This parameter makes it easier to remove initial interference between the scrap and other die components. See Figure 12-50.
IPSET	A part set ID from which the scrap will be offset to remove the initial interference; works together only with GAP. The part set ID should only include portions of tool parts that are directly underneath the scrap (top surface portion of the tools). The normals of the IPSET must point toward the scrap. The parts that should belong to IPSET are typically of those elements on the top surface of the scrap cutter; see Figure 12-50.
EXTEND	An amount to extend a trim steel's edge based on the NDSET defined, so it can form a continuous trim line together with a

VARIABLE	DESCRIPTION
	neighboring trim steel, whose edge may also be extended, to trim out the scrap piece. See Figure 12-47.
NEWID	New part ID of a scrap piece for the scrap area defined by the seed location. If this is not defined (left blank) or input as "0", the scrap piece will retain original PID as its part ID. See Figure 12-47. This is useful when one original scrap is trimmed into multiple smaller pieces, and contacts between these smaller pieces need to be defined.

Background:

Sheet metal trimming and the resulting scrap fall are top factors in affecting the efficiency of stamping plants worldwide. Difficult trimming conditions, such as those multiple direct trims, a mixture of direct and cam trims, and multiple cam trims involving bypass condition, can cause trimmed scraps to get stuck around and never separate from the trim edge of the upper trim steels or lower trim post. Inappropriate design of die structure and scrap chute can slow down or prevent scraps from tumbling out to the scrap collectors. Smaller scrap pieces (especially aluminum) can sometimes shoot straight up, and get stuck and gather in areas of the die structure. All these problems result in shutdowns of stamping presses, reducing stroke-per-minute (SPM) and causing hundreds of thousands of dollars in lost productivity.

With this keyword, engineers can consider the trimming details, manage the scrap trim and the drop energy, study different trimming sequences, explore better die structure and scrap chutes design and layout before a trim die is even built. This feature is developed in conjunction with the *Ford Motor Company*.

The constraint release method:

Prior to Revision 91471 (see Revision), simulating the scrap trim and fall uses the "constraint release" method, where only the scrap piece is modeled and defined.

As shown in Figure 12-45, the scrap piece is modeled as a deformable body and the trim steel and trim post as rigid shell elements, while the parent piece does not need to be modeled at all. Between the trim edge of the scrap piece and the post there should be a gap (indicated by GAP in the figure). The gap ensures that the contact interface (to be explained later) correctly accounts for the shell thickness along the edge. A gap that is too small may cause initial penetration between the scrap and the post which may manifest as unphysical adhesion between the scrap and the post.

The edge of the scrap piece should initially be flush with that of the trim post (perpendicular to the trim direction), just as exactly what happens in the production environment.

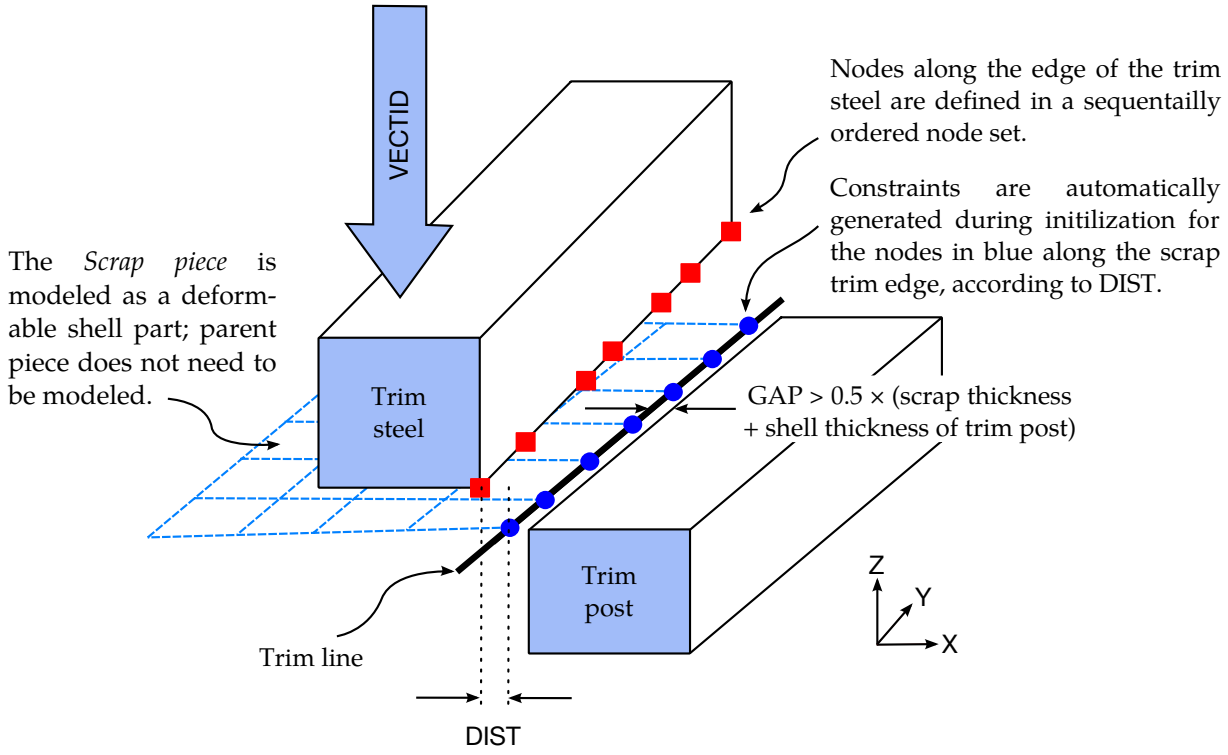

Figure 12-45. Modeling details of the constraint release method. *Drawing modified from the original sketches courtesy of the Ford Motor Company.*

If the scrap is unrealistically positioned above the trim post edge, the scrap may be permanently caught between the trim steel and the post under a combination of uncertain trimming forces as the trim steel moves down.

During initialization, constraints are added automatically on the nodes along the scrap trim edge corresponding to the node set (NDSET) along the trim steel, based on the supplied tolerance variable DIST and trim vector VECTID. Although the direction of the path is not important, prior to Revision 90339, the NDSET must be arranged so that the nodes are in a sequential order (*LS-PrePost 4.0* creating node set by *path*). As the edge of the trim steel comes within DEPTH distance of the trim line, the constraints are removed. The contact interfaces serve to project the motion of the trim steel onto the scrap piece, see Figure 12-46.

The scrap trimming method:

The original simplified method has the following drawbacks:

1. No scrap trimming – the scrap piece cannot be trimmed directly from a parent piece; an exact scrap piece after trimming must be modeled.

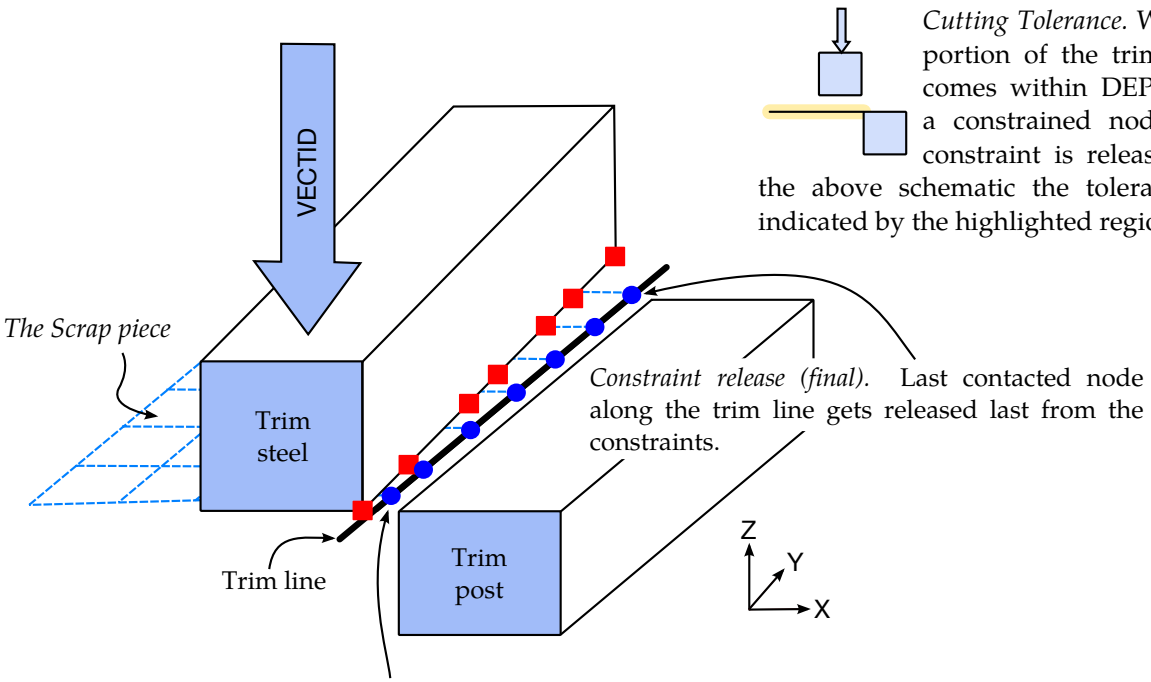

Figure 12-46. Contact-based separation and contact-driven kinematics and dynamics in the constraint release method. *Drawing modified from the original sketches courtesy of the Ford Motor Company.*

2. Poorly (or coarsely) modeled draw beads in the scrap piece do not fit properly in badly modeled draw beads on the tooling, resulting in initial interferences between the two and therefore affecting the simulation results.

3. For poorly (or coarsely) modeled scrap edges and trim posts, users have to manually modify the scrap trim edges to clear the initial interference with the trim posts.

4. Users must clear all other initial interferences (e.g. between scrap and scrap cutter) manually.

Based on users' feedback, a new method "scrap trimming" (after Revision 91471) has been developed to address the above issues and to, furthermore, reduce the effort involved in preparing the model. The new method (Figure 12-47) involves trimming scrap from an initially large piece of sheet metal, leaving the parent piece as a new fixed rigid body, defined by user (along with *SECTION_SHELL and *MAT_20). If one large piece of sheet metal is trimmed in many different places to form several scrap pieces, a new PID can be defined for each of the scrap pieces (NEWID), along with *SECTION_SHELL and *MAT_037, for example. The trim lines are obtained from the trim steel edge node set NDSET and the trim vector VECTID.

Note: The trim steel cannot have walls that are parallel to the trim direction; otherwise the scrap will not be trimmed properly from the parent piece. This is illustrated in Figure 12-49.

Parameters related to the constraint release method:

1. The value of DEPTH is typically set to one-half of the scrap thickness.

2. The initial gap separating the scrap from the post must be greater than the average of the scrap and post thickness values; see Figure 12-45.

3. The input parameter DIST should be set larger than the maximum distance between nodes along the trim steel edge and scrap edge in the view along the trim direction; see Figure 12-45.

Parameters related to the scrap trimming method:

1. Similar to DEPTH, EFFSET should be typically set to one-half of the scrap thickness, although it may be larger for some poorly modeled trim steels and trim posts.

Contact:

Only *CONTACT_FORMING contact interfaces are allowed for contact between the scrap piece and the trim steel. In particular, *CONTACT_FORMING_SURFACE_TO_SURFACE is recommended. A negative contact offset must be used; this is done typically by setting the variable SBST in *CONTACT_FORMING_SURFACE_TO_SURFACE to the negative thickness value of the scrap piece.

For contact between the scrap piece and the shell elements in all the other die structures, *CONTACT_AUTOMATIC_GENERAL should be used for the edge-to-edge contact frequently encountered during the fall of the scrap piece. All friction coefficients should be small. The explicit time integrator is recommended for the modeling of scrap trim and fall. Mass scaling is not recommended.

LS-PrePost:

The node set (NDSET) defined along the trim steel edge can be created with *LS-PrePost 4.0*, via *Model/CreEnt/Cre, Set Data, *SET_NODE, ByPath*, then select nodes along the trim edge continuously until finish and then hit *Apply.*

Keyword examples – the constraint release method:

A partial example of using the keyword below includes a node set ID 9991 along the trim steel (PID 2) edge used to release the constraints between the scrap piece with PID 1, and the parent piece. The LCID for the trim steel kinematics is (+)33 (load curve is controlled by velocity) moving in the $-z$ direction. The trimming velocity is defined as 1000 mm/s, and the retracting velocity is 4000 mm/s. The variables DEPTH and DIST are set to 0.01 and 2.5, respectively. The contact interface between the trim steel and scrap piece is defined using *CONTACT_FORMING_SURFACE_TO_SURFACE and contact between the scrap and all other die structures are defined using *CONTACT_AUTOMATIC_GENERAL.

For the negative option of LCID, displacement will be used as input to control the tool kinematics. A partial example is provided below, where LCID is defined as a negative integer of a load curve, controlling the trim steel kinematics. The trim steel is moving down for 27.6075 mm in 0.2 sec to trim, and moving up for the same distance to its original position in 0.3 sec to retract. Although this option is easier to use, the corresponding velocity from the input time and displacement must be realistic for a realistic simulation.

A keyword example – the scrap trimming method:

The keyword example below shows three scrap pieces, with part ID &spid1 (PID, also is the original blank to be trimmed) and new part IDs 1001 and 1002 (NEWID), being trimmed out of the original blank &spid1 (PID); the remaining parent piece is defined as a fixed rigid body with part ID 110 (IDRGD). Each scrap piece is indicated by a point location defined by SEEDX, SEEDY and SEEDZ. Each scrap is also to be trimmed by three different trim steels. For example, scrap piece &spid1 is to be trimmed by trim steels with part IDs 22, 23 and 24 (as referenced by *BOUNDARY_PRESCRIBED_MOTION_RIGID_LOCAL) in trim directions defined respectively by vector IDs (from VID in *DEFINE_VECTOR) &cord1, &cord2 and &cord3 (VECTID) and with trim kinematics defined respectively by load curve IDs 1800, 1801 and 1802 (LCID). The scrap pieces &spid1, 1001 and 1002 are each offset by 0.60mm (GAP), in the direction normal to the elements defined by part set IDs 887, 888, and 889 (IPSET), respectively. The trim edge offset is 0.90mm (EFFSET) away from the trim edge for all scraps. The draw bead node sets to be released are, 987, 988 and 989 for each scrap &spid1, 1001, and 1002, respectively.

Revision/Other information:

A graphical user interface capable of setting up a complete input deck for the original simplified method is now available in *LS-PrePost* under *APPLICATION/Scrap Trim* (http://ftp.lstc.com/anonymous/outgoing/lsprepost/). A reference paper regarding the development and application of this keyword for the constraint release method can be found in the *proceedings of the 12th International LS-DYNA User's Conference*. The following provides a list of revision history for the keyword:

1. The *constraint release method* is available between LS-DYNA Revision 63618 and 91471.

2. The *scrap trimming method* is available starting in Revision 91471.

3. The parameter NEWID is available starting in Revision 92578.

4. The restriction that NDSET must be defined in a consecutive order is lifted starting in Revision 90339.

*CONTROL_FORMING_SHELL_TO_TSHELL

Purpose: This keyword converts thin shell elements (*SECTION_SHELL) to thick shell elements (*SECTION_TSHELL). It generates segments on both the top and bottom sides of the thick shells for contact. Mesh adaptivity is also supported.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	THICK	MIDSF	IDSEGB	IDSEGT			
Type	I	I	I	I	I			
Default	none	none	0	Rem 4	Rem 4			

VARIABLE	DESCRIPTION
PID	Part ID of the thin shell elements.
THICK	Thickness of the thick shell elements (TSHELL).
MIDSF	TSHELL's mid-plane position definition (see Figure 12-51 and Remark 4): EQ.0: Mid-plane is at thin shell surface. EQ.1: Mid-plane is at one half of THICK above thin shell surface. EQ.-1: Mid-plane is at one half of THICK below thin shell surface.
IDSEGB	Set ID of the segments to be generated at the bottom layer of the TSHELLs, which can be used for segment-based contact. The bottom layer of the TSHELLs has an outward normal that points in the opposite direction to the positive normal side of thin shells; see Figure 12-51. Note the default normal of the generated segments are consistent with the thin shells' normal. To reverse this default normal, set the IDSEGB to a negative number. See Remark 2.
IDSEGT	Set ID of the segments to be generated at the top layer of the TSHELLs, which can be used for segment-based contact. The top side of a TSHELL has an outward normal that points in the same direction as the positive normal side of the thin shells; see Figure 12-51.

VARIABLE	DESCRIPTION
	The normal of the generated segments are consistent with the thin shells' normal. To reverse this default normal, set the IDSEGT to a negative number. See Remark 2.

Remarks:

1. **Node and Element Numbering**. Node IDs of the thick shell elements will be the same as those for the thin shells. Element IDs of the thick shell elements will start at 2 (so renumber element IDs of other parts accordingly). Only one layer of thick shells will be created.

2. **Contact.** For FORMING contacts, if the generated segments are used as a SURFA member in contact with a SURFB member of a rigid body, the normal vectors for the rigid body must be consistent and facing the SURFA segments. The normal vectors for the SURFA segments are not required to point at the rigid bodies, although they should be made consistent.

3. **Adaptivity.** New nodes generated adaptively from their parent nodes with *BOUNDARY_SPC are automatically constrained accordingly.

4. **Contact and Segment Sets.** If no contact for the TSHELLs is defined in the input deck, then the fields IDSEGB and IDSEGT are ignored and the field MIDSF will be set to 0, regardless of the user set value. See the first example.

Examples:

1. A standalone part of thin shell elements can be changed to thick shell elements with a simplified small input deck. The following will convert shell elements with PID 100 of thickness 1.5 mm to thick shell elements of PID 100 with thickness of 2.0 mm, with thick shell meshes stored in the file dynain.geo. Note that MIDSF, IDSEGB and IDSEGT are ignored in this case and do not need to be set.

2. The conversion can also be done in an input deck set up for a complete metal forming simulation with thin shell elements that are part of a sheet blank. The conversion happens at the beginning of the simulation, as shown in an example below. This partial deck is of a thin shell sheet blank with PID 1 that is to be converted to a thick shell sheet blank with thickness of 1.6 mm. The commented out keywords were originally for the thin shells but have been changed due to the conversion. For example, the *SECTION_TSHELL is defined instead of *SECTION_SHELL for the sheet blank. The corresponding material type for the sheet blank (*MAT_037) is also changed to a type that supports solid element simulations (*MAT_024). The mid-plane of the thick shells is one half of 1.6 mm below the thin shells' surface. Segment IDs 10 (IDSEGB) and 11 (IDSEGT) are created at the bottom and top side of the thick shells, respectively, as shown in Figure 12-51. Segment set 10 is defined to contact with the lower punch (part set ID 2), while segment set 11 is used for contact with the upper die cavity (part set ID 3).

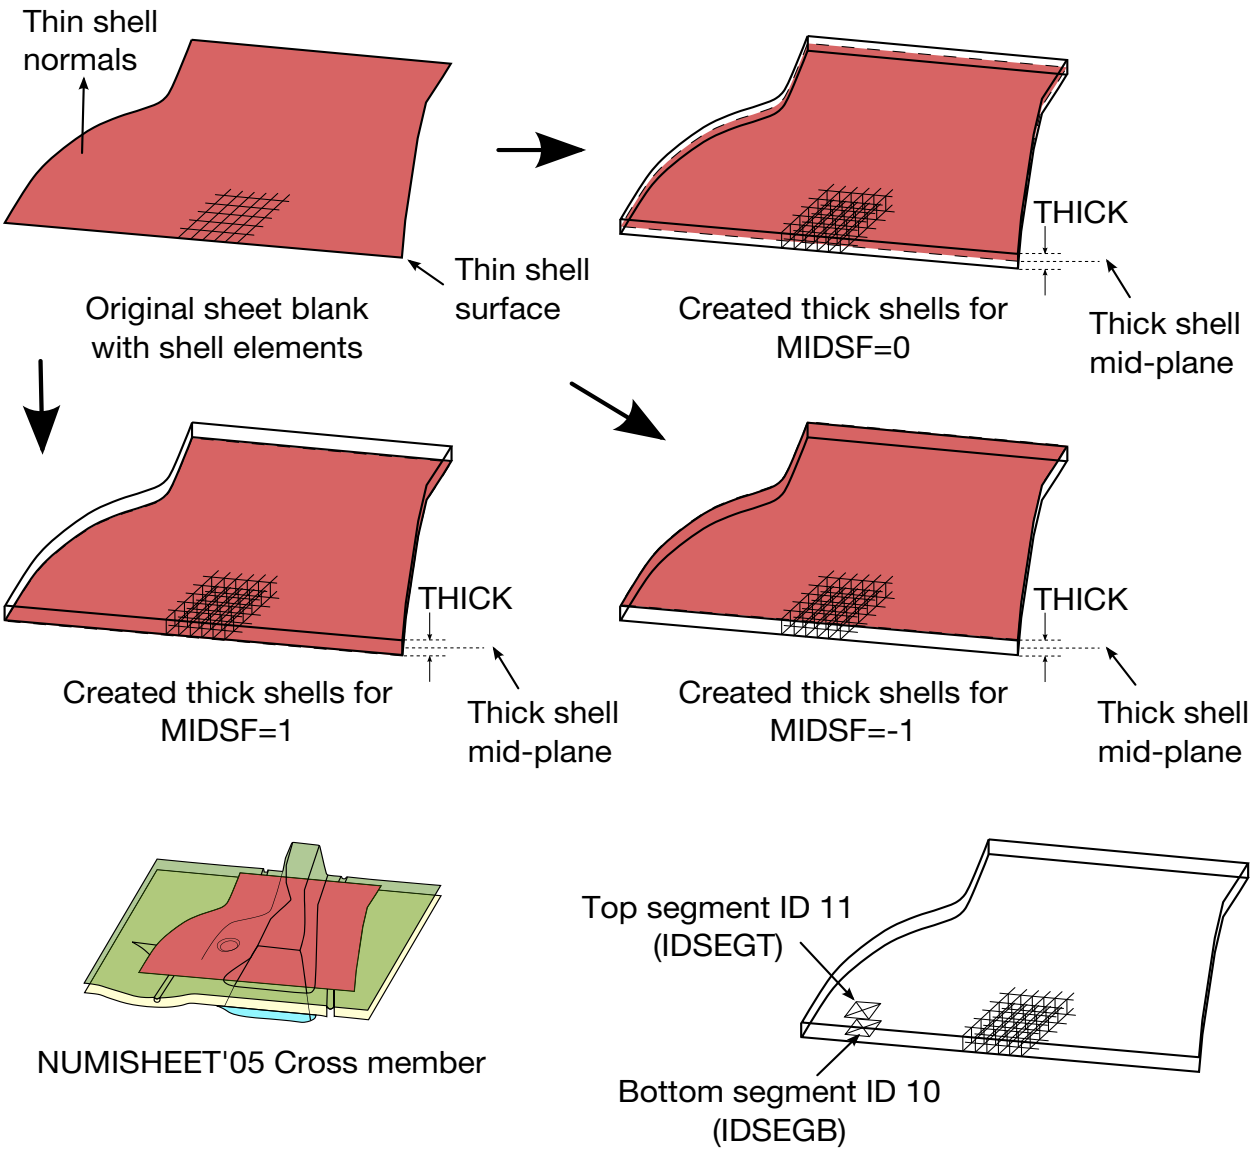

Figure 12-51. Converting thin shells to thick shells in sheet metal forming

*CONTROL_FORMING_STONING

Purpose: Detect surface lows or surface defects formed during metal stamping. This calculation is typically performed after a springback simulation. A curvature-based method is implemented with the feature. Users have the option to check an entire part or just a few local areas, defined by node set or shell element set. In each area, direction of the stoning action can be specified or the program can automatically determine the stoning direction.

Card 1	1	2	3	4	5	6	7	8
Variable	ISTONE	LENGTH	WIDTH	STEP	DIRECT	REVERSE	METHOD	
Type	I	F	F	F	F	I	I

VARIABLE	DESCRIPTION
ISTONE	Stoning calculation option. EQ.1: calculate panel surface quality using stoning method.
LENGTH	Length of the stone. See Remark 1.
WIDTH	Width of the stone. See Remark 1.
STEP	Stepping size of the moving stone. See Remark 1.
DIRECT	Number of automatically determined stoning direction(s). See Remark 2.

VARIABLE	DESCRIPTION
REVERSE	Surface normal reversing option (see Remark 3): EQ.0: do not reverse surface normals. EQ.1: reverse surface normals.
METHOD	Stoning method. EQ.0: curvature-based method.
NODE1	Tail node defining stoning moving direction. See Remark 2.
NODE2	Head node defining stoning moving direction. See Remark 2.
SID	Node or shell set ID.
ITYPE	Set type designation: EQ.1: node set EQ.2: element set
V1, V2, V3	Vector components defining stoning direction (optional). See Remark 2.

About Stoning:

Stoning is a quality checking process on class-A exterior stamping panels. Typically the long and wider surfaces of an oil stone of a brick shape are used to slide and scratch in a given direction against a localized area of concern on a stamped panel. Surface "lows" are shown where scratch marks are not visible and "highs" are shown in a form of scratch marks. This keyword is capable of predicting both the surface "lows" and "highs". Since stoning process is carried out after the stamping (either drawn or trimmed) panels are removed from the stamping dies, a springback simulation needs to be performed prior to conducting a stoning analysis.

Remarks:

1. **Stone Reference Sizes.** As a reference, typical stone length and width can be set at 150.0 and 30.0 mm, respectively. The step size of the moving stone is typically set about the same order of magnitude of the element length. The smallest element length can be selected as the step size.

2. **Stoning Direction.** Stoning direction can be set in three different ways:

a) The variables NODE1 and NODE2 are used to define a specific stoning direction. The stone is moved in the direction defined by NODE1 to NODE2.

b) Alternatively, one can leave NODE1 and NODE2 blank and define the number of automatically determined stoning directions by using the variable DIRECT. Any number can be selected but typically 2 is used. Although CPU time required for the stoning calculation is trivial, a larger DIRECT consumes more CPU time.

c) Furthermore, stoning direction can also be defined using a vector by defining the variables V1, V2, and V3.

3. **Element Normal Vectors.** Stoning is performed on the outward normal side of the mesh. Element normals must be consistent and oriented accordingly. Element normal can be automatically made consistent in LS-PrePost4.0 under *EleTol/Normal* menu. Alternatively, the variable REVERSE provides in the solver an easy way to reverse a part with consistent element normals before the computation.

4. **Region for Stoning Analysis.** The blank model intended for analysis can be included using keyword *INCLUDE. If nothing is defined for SID and ITYPE, then the entire blank model included will be used for stoning analysis.

   A large area mesh can be included in the input file. An ELSET may also be included, which defines a local area that requires stoning computation. Alternatively, an ELSET can define several local areas to be used for the computation. Furthermore, an ELSET should not include meshes that have reversed curvatures. An ELSET can be easily generated using LS-PrePost4.0, under *Model* → *CreEnt* → *Cre* → *Set_Data* → **SET_SHELL*.

5. **Modeling Guidelines.** Since stoning requires high level of accuracy in springback prediction, it is recommended that the SMOOTH option in keyword *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE to be used during the draw forming simulation. Not all areas require SMOOTH contact, only areas of interest may apply. In addition, meshes in the areas of concern need to be very fine, with average element size of 1 to 2 mm. Mesh adaptivity is not recommended in the SMOOTH/stoning areas. Also, mass scaling with DT2MS needs to be sufficiently small to reduce the dynamic effect during forming. For binder closing of large exterior panels, implicit static method using *CONTROL_IMPLICIT_FORMING type 2 is recommended, to further reduce potential buckles caused by the inertia effect.

6. **Stoning Output.** It is recommended that double precision version of LS-DYNA be used for this application. The output of the stoning simulation results is in a file named filename.output, where "filename" is the name of the LS-DYNA stoning input file containing this keyword, without the file extension. The stoning

results can be viewed using LS-PrePost4.0, under *MFPost* → *FCOMP* → *Shell_Thickness*.

Example:

An example of a stoning analysis on a Ford Econoline door outer panel is provided for reference. The original part model comes from National Crash Analysis Center at The George Washington University. The original part was modified heavily in LS-PrePost4.0 for demonstration purposes. Binder and addendum were created and sheet blank size was assumed. The blank is assigned 0.65 mm thickness and a BH210 properties with *MAT_037. Shell thickness contour plots for the drawn and trimmed panels are shown in Figures 12-52 and 12-53, respectively. Springback amount in the Z-direction is plotted in Figure 12-54. The complete input deck used for the stoning simulation is provided below for reference; where, a local area mesh of the door handle after springback simulation Doorhandle.k and an element set elset1.k are included in the deck. Locations of the ELSETs are defined for the upper right (Figure 12-55 left) and lower right corners (Figure 12-56 left) of the door handle, where "mouse ears" are expected.

*CONTROL_FORMING_STRAIN_RATIO_SMOOTH

Purpose: In explicit methods, the output strain path looks smooth, but the strain incremental ratio, β (= $d\epsilon 2/d\epsilon 1$) can oscillate significantly during each step and will result in significant error in formability prediction. This keyword uses a smoothing algorithm to smooth the beta value when calculating the Formability Index, which is designed to better calculate formability by considering a non-linear strain path.

This keyword must be used with the NLP option in *MAT_36, *MAT_37, *MAT_125, or *MAT_226 for shell elements only. It is jointly developed with Ford Motor Company.

Card 1	1	2	3	4	5	6	7	8
Variable	DT/CYCLE	WEIGHT						
Type	F	F						
Default	none	none						

VARIABLE	DESCRIPTION
DT/CYCLE	Flag for output option (time interval or cycle number). LT.0: the absolute value is the time interval between outputs. GT.0: number of cycles between outputs
WEIGHT	Coefficient α in equation below.

Remarks:

The incremental change of in-plane major and minor strains are smoothed according to the following formula:

$$\Delta\epsilon 1_{(n-1)} \times (1-\alpha) + d\epsilon 1_{(n)} \times \alpha$$
$$\Delta\epsilon 2_{(n-1)} \times (1-\alpha) + d\epsilon 2_{(n)} \times \alpha$$

where, $d\epsilon 1_{(n)}$ and $d\epsilon 2_{(n)}$ are incremental changes of $\epsilon 1$ and $\epsilon 2$ in the current time step n, $\Delta\epsilon 1_{(n-1)}$ and $\Delta\epsilon 2_{(n-1)}$ are incremental changes of $\epsilon 1$ and $\epsilon 2$ in the previous time step $n-1$. The weighting coefficient α regulates the smoothness of the incremental changes in $\epsilon 1$ and $\epsilon 2$.

With the smoothed incremental major and minor strains, β is:

$$\beta = \frac{\Delta\epsilon 2_{(n-1)} \times (1-\alpha) + d\epsilon 2_{(n)} \times \alpha}{\Delta\epsilon 1_{(n-1)} \times (1-\alpha) + d\epsilon 1_{(n)} \times \alpha} \ .$$

The lower limit of β is the minimum strain ratio defined in the FLD curve.

Note that β is stored in history variable #2.

A partial keyword deck that illustrates using this keyword is shown below. The material model is *MAT_36. Note NEIPS is set to 3 so three history variables that include formability index (F.I.), strain ratio β and effective plastic strain $\bar{\varepsilon}$ are output.

*CONTROL_FORMING_TEMPLATE

Purpose: This keyword is used to simplify the required input for sheet metal stamping simulations. With this keyword, five templates are given: three-piece air draw, three-piece toggle draw, four-piece stretch draw, trimming, and springback.

NOTE: This option has been deprecated in favor of *CONTROL_FORMING_AUTOPOSITION_PARAMETER.

Variable	LVLADA	SIZEADA	TIMSADA	D3PLT				
Type	I	F	I	I				
Default	1	none	20	10				

VARIABLE	DESCRIPTION
IDTEMP	Type of forming process (see About IDTEMP below): EQ.1: 3-piece air-draw (Figure 12-57) EQ.2: 3-piece Toggle-draw (Figure 12-58) EQ.3: 4-piece stretch draw (Figure 12-60) EQ.4: springback EQ.5: trimming
BLKID	Part or part set ID (see TYPE) that defines the blank.
DIEID	Part or part set ID that defines the die. See Figures 12-57, 12-58 and 12-60 for more information
PNCHID	Part or part set ID that defines the punch.
BNDUID	Part or part set ID that defines the upper binder.
BNDLID	Part or part set ID that defines the lower binder.
TYPE	Flag for part or part set ID used in the definition of BLKID, DIEID, PNCHID, BNDUID, and BNDLID: EQ.0: Part ID EQ.1: Part set ID
PREBD	"Pull-over" distance, for 4 piece stretch draw only. This is the travel distance of both upper and lower binder together after they are fully closed. Typically, this distance is below 50 mm. See Figure 12-60 for more information.
LCSS	If the material (*MAT_XXX) for the blank is not defined, this curve ID will define the stress-strain relationship; otherwise, this curve is ignored.
AL/FE	This parameter is used to define the Young's Modulus and density of the blank. If this parameter is defined, E and DENSITY will be defined in the units given by Table 12-59. EQ.A: the blank is aluminum EQ.F: the blank is steel (default)
R00, R45, R90	Material anisotropic parameters. For transversely anisotropy the R value is set to the average value of R00, R45, and R90.

VARIABLE	DESCRIPTION
E	Young's Modulus. If AL/FE is user defined, E is unnecessary.
DENSITY	Material density of blank. If AL/FE is user defined, this parameter is unnecessary.
PR	Poisson's ratio.
K	Strength coefficient for exponential hardening ($\overline{\sigma} = k\bar{\varepsilon}^n$). If LCSS is defined, or if a blank material is user defined by *MAT_XXX, this parameter is ignored.
N	Exponent for exponential hardening ($\overline{\sigma} = k\bar{\varepsilon}^n$). If LCSS is defined, or if a blank material user defined, this parameter is ignored.
MTYP	Only material models *MAT_036 and *MAT_037 are supported.
UNIT	Define a number between 1 and 10 (Table 12-59) to indicate the UNIT used in this simulation. This unit is used to obtain proper punch velocity, acceleration, time step, and material properties.
THICK	Blank thickness. If the blank thickness is already defined with *SECTION_SHELL, this parameter is ignored.
GAP	The gap between rigid tools at their home position. If *BOUNDARY_PRESCRIBED_RIGID_BODY is user defined, this parameter is ignored. The default is 1.1 x blank thickness.
FS	Friction coefficient (default is 0.10). If the contact (*CONTACT) is user defined, this parameter is ignored.
PATERN	Velocity profile of moving tool. If the velocity is user defined by *BOUNDARY_PRESCRIBED_RIGID_BODY, PATERN is ignored. EQ.1: Ramped velocity profile EQ.2: Smooth velocity curve
VX, VY, VZ	Vector components defining the direction of the punch movement. The default direction is defined by VID.
VID	Vector ID defining the direction of the punch movement. This variable overrides the vector components (VX,VY,VZ). If VID and (VX,VY,VZ) are undefined, the punch is assumed to move in the negative z-direction.
AMAX	The maximum allowable acceleration.

VARIABLE	DESCRIPTION
LVLADA	Maximum adaptive level.
SIZEADA	Minimum element size permitted in the adaptive mesh.
TIMSADA	Total number of adaptive steps during the forming simulation.
D3PLT	The total number of output states in the D3PLOT database.

Table 12-59. Available units for metal stamping simulation.

About IDTEMP:

When the variable IDTEMP is set to 1, it represents a 3-piece draw in air, as shown in Figure 12-57. When IDTEMP is set to 2, a 3-piece toggle draw is assumed, as in Figure 12-58. For IDTEMP of 1 or 2, LS-DYNA will automatically position the tools and minimize the punch travel (step a), calculate the binder and punch travel based on the blank thickness and the home gap (step b), set the termination time based on steps (a) and (b), define the rigid body motion of the tooling, establish all the contacts between the blank and rigid tools, and, select all necessary control parameters.

When IDTEMP is set to 3, a 4-piece stretch draw shown in Figure 12-60 will be followed. The die action goes as follows: after upper binder moves down to fully close with lower binder, both pieces move together down a certain distance (usually ~50 mm) to "pull" the blank "over" the lower die; then the upper punch closes with the lower die; and finally the binders move down together to their home position.

Both toggle draw and 4-piece stretch draw are called "double action" processes which suffer from a slower stamping speed. As the metric of "hits per minute" (or "parts per minute") becomes a stamping industry benchmark for efficiency, these types of draw are

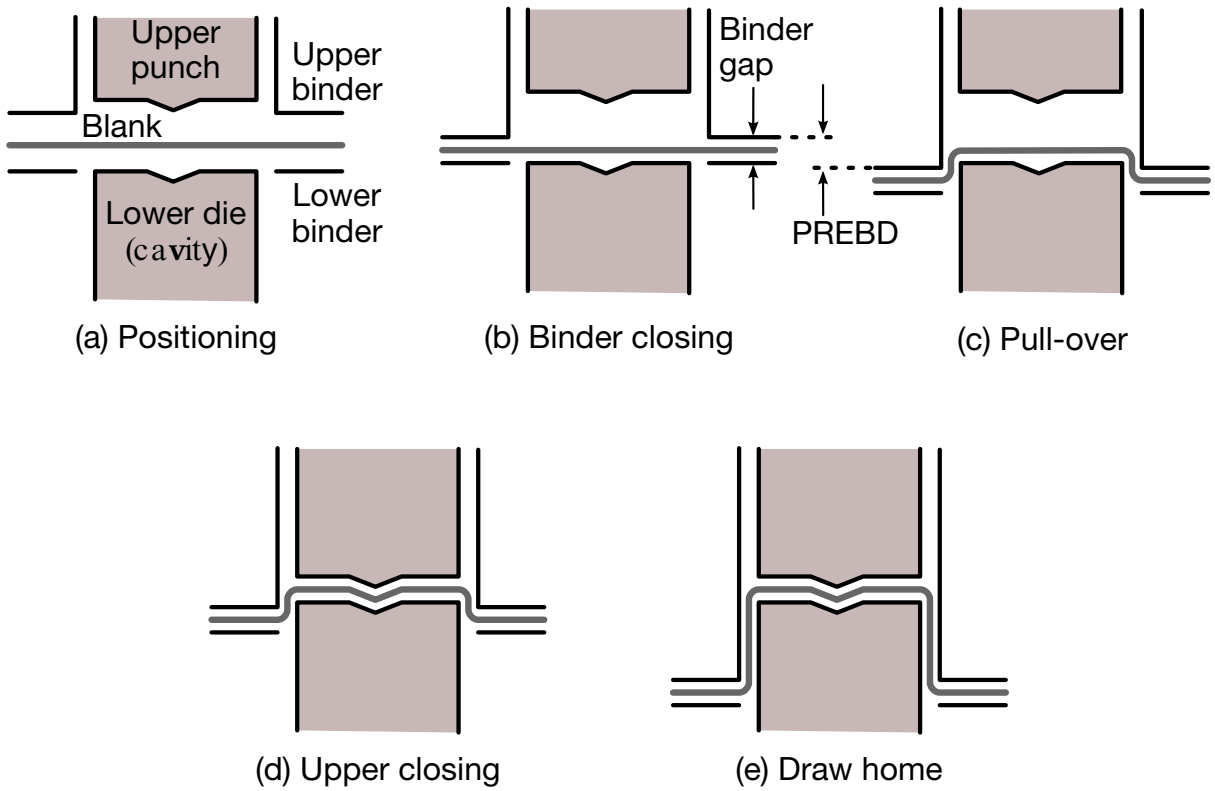

Figure 12-60. IDTEMP = 3: forming in 4-piece stretch draw.

becoming less popular (especially the 4-piece stretch draw). Nevertheless, they remain important stamping processes for controlling wrinkles in difficult-to-form panels such as lift gate inners, door inners and floor pans. These two processes are also used in situation where deep drawn panels require draw depth of over 250 mm, the usual limit for automatic transfer presses.

For all the above IDTEMP values, users do not need to define additional keywords, such as *PART, *CONTROL, *SECTION, *MAT_…, *CONTACT_… (drawbead definition is an exception), and *BOUNDARY_PRESCRIPTION_RIGID. If any such keyword is defined, automatic default settings will be overridden.

When IDTEMP is set to 4, a springback simulation will be conducted. The only additional keyword required is *BOUNDARY_SPC_… to specify the constraints in the input deck.

When IDTEMP is set to 5, a trimming operation will be performed. The only additional keyword required is *DEFINE_CURVE_TRIM to specify the trim curves in the input deck.

Revision information:

This feature is available starting in Revision 45901 and later releases.

*CONTROL_FORMING_TIPPING

Purpose: Reorient or reposition a part between the stamping dies. In a stamping line die simulation, panel tipping and translation between the die stations are frequently required. Typically, such transformations involve only a small rotation (less than 15 degrees) but a large translation. For example, a part may need to be tipped by an angle of 10 degrees along the *Y*-axis and translated 2000 mm along the *X*-axis between the current trimming die and next flanging die.

Card Summary:

Card Sets. For each rotated or translated part or set add one Card 1 (Tipping Card). If NMOVE ≠ -6, include NMOVE of Cards 2a and 2b combined. If NMOVE = -6, include Cards 2c.1 through 2c.6. The data set for this keyword ends at the next keyword ("*") card.

Card 1. This card is required.

PID/SID	ITYPE	ISTRAIN	IFSTRSS	NMOVE			

Card 2a. If NMOVE ≠ -6, this card may be included. It is recognized when the first field (ROT/TRAN) is 1. It defines a rotation transformation. Include a combination of this card and Card 2b to get NMOVE transformation cards.

ROT/TRAN	V11	V12	V13	X01	Y01	Z01	DISTA1

Card 2b. If NMOVE ≠ -6, this card may be included. It is recognized when the first field (ROT/TRAN) is 2. It defines a translation transformation. Include a combination of this card and Card 2a to get NMOVE transformation cards.

ROT/TRAN	DX	DY	DZ				

Card 2c.1. This card is included if and only if NMOVE = -6.

P1	X1	Y1	Z1			

Card 2c.2. This card is included if and only if NMOVE = -6.

P2	X2	Y2	Z2			

Card 2c.3. This card is included if and only if NMOVE = -6.

P4	X3	Y3	Z3			

Card 2c.4. This card is included if and only if NMOVE = -6.

P4	X4	Y4	Z4			

Card 2c.5. This card is included if and only if NMOVE = -6.

P5	X5	Y5	Z5			

Card 2c.6. This card is included if and only if NMOVE = -6.

P6	X6	Y6	Z6			

Data Card Definitions:

Tipping Card. Specify a part or set ID to be tipped.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/SID	ITYPE	ISTRAIN	IFSTRSS	NMOVE			
Type	I	I	I	I	I			
Default	none	none	0	0	0			

VARIABLE	DESCRIPTION
PID/SID	Part ID or part set ID of part(s) that requires tipping and/or translation.
ITYPE	Part ID or part set ID indicator: EQ.1: PID means part ID, EQ.2: PID/SID means part set ID.
ISTRAIN	Strain tensors inclusion option: EQ.1: include in tipping/translation.
ISTRESS	Stress tensors inclusion option: EQ.1: include in tipping/translation.
NMOVE	Total number of tipping and translation transformations intended for this part/part set. However, when NMOVE: EQ.-6: Transformation is done based on user-specified coordinates of 3 points on the source, and the corresponding point coordinates on the target.

Move Card 2a (Rotation). Include when first entry, ROT/TRAN, is set to 1.

Card 2a	1	2	3	4	5	6	7	8
Variable	ROT/TRAN	V11	V12	V13	X01	Y01	Z01	DISTA1
Type	I	F	F	F	F	F	F	F
Default	none	0.0	0.0	0.0	0.0	0.0	0.0	0.0

Move Card 2b (Translation). Include when first entry, ROT/TRAN, is set to 2.

Card 2b	1	2	3	4	5	6	7	8
Variable	ROT/TRAN	DX	DY	DZ				
Type	I	F	F	F				
Default	none	0.0	0.0	0.0				

VARIABLE	DESCRIPTION
ROT/TRAN	Transformation type: EQ.1: rotation, EQ.2: translation.
V11, V12, V13	Vector components of an axis about which tipping is performed.
X01, Y01, Z01	*X*, *Y*, and *Z* coordinates of a point through which the tipping axis passes.
DSITA	Tipping angle in degrees. See Remark 2.
DX, DY, DZ	Translation distances along global *X*-axis, *Y*-axis and *Z*-axis.

Move Card 2c.1 (3-point Transformation). Include when NMOVE is set to -6. (I8, 3E16.0)

Card 2c.1	1	2	3	4	5	6	7	8	9	10
Variable	P1	X1		Y1		Z1				
Type	I	F		F		F				
Default	none	0.0		0.0		0.0				

Move Card 2c.2 (3-point Transformation). Include when NMOVE is set to -6. (I8, 3E16.0)

Card 2c.2	1	2	3	4	5	6	7	8	9	10
Variable	P2	X2		Y2		Z2				
Type	I	F		F		F				
Default	none	0.0		0.0		0.0				

Move Card 2c.3 (3-point Transformation). Include when NMOVE is set to -6. (I8, 3E16.0)

Card 2c.3	1	2	3	4	5	6	7	8	9	10
Variable	P3	X3		Y3		Z3				
Type	I	F		F		F				
Default	none	0.0		0.0		0.0				

Move Card 2c.4 (3-point Transformation). Include when NMOVE is set to -6. (I8, 3E16.0)

Card 2c.4	1	2	3	4	5	6	7	8	9	10
Variable	P4	X4		Y4		Z4				
Type	I	F		F		F				
Default	none	0.0		0.0		0.0				

Move Card 2c.5 (3-point Transformation). Include when NMOVE is set to -6. (I8, 3E16.0)

Card 2c.5	1	2	3	4	5	6	7	8	9	10
Variable	P5	X5		Y5		Z5				
Type	I	F		F		F				
Default	none	0.0		0.0		0.0				

Move Card 2c.6 (3-point Transformation). Include when NMOVE is set to -6. (I8, 3E16.0)

Card 2c.6	1	2	3	4	5	6	7	8	9	10
Variable	P6	X6		Y6		Z6				
Type	I	F		F		F				
Default	none	0.0		0.0		0.0				

VARIABLE	DESCRIPTION
P1, P2, P3	Unique point IDs from the target, where it will be transformed to.
X1, Y1, Z1 X2, Y2, Z2 X3, Y3, Z3	X, Y, and X coordinates of the points P_1, P_2, and P_3 from the target, respectively.

VARIABLE	DESCRIPTION
P4, P5, P6	Unique point IDs from the source, where it will be transformed from.
X4, Y4, Z4 X5, Y5, Z5 X6, Y6, Z6	X, Y, and Z coordinates of the points P_4, P_5, and P_6 from the source, respectively. Note that points P_4, P_5, and P_6 correspond to points P_1, P_2, and P_3, respectively.

Remarks:

1. **Include Keyword.** Keyword *INCLUDE can be used to include the file to be tipped or translated.

2. **Tipping Angle.** Tipping angle DISTA1 is defined in degrees. Signs of the tipping angles follow the right-hand rule.

3. **NMOVE ≠ -6 Example.** The keyword input below tips a part by +23.0°, -31.0°, and +8.0° about the X-, Y-, and Z-axes that pass through the origin, respectively. The part also translates 12.0 mm, -6.0 mm and 91.0 mm along X-, Y-, and Z-axes, respectively.

Revision Information:

This feature is available starting in LS-DYNA Dev53448, with major updates from Dev80261. It is also available in LS-PrePost *eZ-Setup* for metal forming applications (http://ftp.lstc.com/anonymous/outgoing/lsprepost/). Transformations based on 3-points (NMOVE = -6) is available in Dev123450.

*CONTROL_FORMING_TRAVEL

Purpose: This keyword allows user to define tool travel for each phase in a stamping process simulation. The entire simulation process can be divided into multiple phases corresponding to the steps of an actual metal forming process. This keyword is to be used for tools that are pre-positioned above the sheet blank (or below the blank) and ready for forming. For tools that are pre-positioned at their home positions, *CONTROL_FORMING_TRAVEL should be used. This keyword is used together with *CONTROL_FORMING_USER.

> **NOTE:** This option has been deprecated in favor of *CONTROL_FORMING_AUTOPOSITION_PARAMETER).

Define Travel Cards. Repeat Card as many times as needed to define travels in multiple phases. The next "*" card terminates the input.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	VID	TRAVEL	TARGET	GAP	PHASE	FOLLOW	
Type	I	I	F	I	F	I	I	
Default	none	none	none	none	1.0t	none	none	

VARIABLE	DESCRIPTION
PID	Part ID of a stamping tool, as defined in *PART.
VID	Vector ID defining the direction of travel for the tool defined by the PID.
TRAVEL	The distance in which the tool will be traveled to complete forming in the direction specified by the VID. If TRAVEL is defined, it is unnecessary to define TARGET.
TARGET	Target tool PID, as defined in *PART. The tool (defined by PID) will be traveled to where the TARGET tool is to complete forming.
GAP	The minimum distance between the tool (PID) and TARGET tool at the home position (forming complete). The GAP is by default the sheet blank thickness "t".

VARIABLE	DESCRIPTION
PHASE	Phase number, starting sequentially from 1. For example, phase 1 is the binder closing, and phase 2 is the drawing operation.
FOLLOW	Part ID of a stamping tool to be followed by the tool (PID). When this variable is defined, the distance between the tool (PID) and part ID defined by FOLLOW, will remain constant during the phase.

Remarks:

FOLLOW can be used to reduce total simulation time. For example, in a toggle draw, the upper punch travels together with the upper binder during binder closing phase, thus reducing the upper travel distance during the draw, shortening the overall termination time.

An example is provided in manual pages under *CONTROL_FORMING_USER.

*CONTROL_FORMING_TRIM_MERGE

Purpose: This feature allows for automatic close of any open trim loop curve for a successful trimming simulation. Previously, sheet metal trimming would fail if a trim curve does not form a closed loop. This keyword is used together with *DEFINE_CURVE_TRIM, *ELEMENT_TRIM, *DEFINE_VECTOR, *CONTROL_ADAPTIVE_CURVE, and *CONTROL_CHECK_SHELL. It applies to shell elements only.

Card 1	1	2	3	4	5	6	7	8
Variable	IMERGE	GAPM						
Type	I	F						
Default	1	0.0						

VARIABLE	DESCRIPTION
IMERGE	Activation flag. Set to '1' (default) to activate this feature.
GAPM	Gap distance between two open ends of a trim loop curve in the model. If the gap is smaller than GAPM, the two open ends of a trim curve will be closed automatically.

Remarks:

If multiple open trim loop curves exist, GAPM should be set to a value larger than any of the gap distances of any trim curves in the trim model.

Example:

The example provided below includes two trim curves, a three-dimensional curve (#90905) with an open gap of 2.3 mm and a two-dimensional trim curve (#90907) with an open gap 2.38 mm. An automatic merge operation is being performed with the GAPM set at 2.39 mm. Since this set value is larger than both gaps in the model, trimming will automatically close the gap for both curves to form two closed-loop curves for a successful trim. In Figure 12-61, two different trimming results are illustrated with GAPM of 2.39 (successful) as well as 2.37 (fail).

Revisions:

This feature is available starting in LS-DYNA Revision 84098.

*CONTROL_FORMING_TRIM_SOLID_REFINEMENT

Purpose: Activate adaptive refinement along the trim curve for trimming a multi-layered sandwiched part.

Card 1	1	2	3	4	5	6	7	8
Variable	IREFINE	ILEVEL						
Type	I	I						
Default	1	0						

VARIABLE	DESCRIPTION
IREFINE	A flag to activate the adaptive trimming of a multi-layer sandwiched part. Currently setting this to either 0 or 1 will turn on the adaptive trimming. EQ.1: Activate the adaptive trimming.
ILEVEL	Adaptive refinement level. Currently setting this variable to any integer other than 0 will refine the mesh one level down along the trim curve. EQ.0: No refinement EQ.1: Refine one level down.

Example:

A partial keyword input example is shown below where the included file incoming.dynain is a sandwiched part (ITYP = 1). The part is to be trimmed with adaptive refinement one level down (IREFINE = 1, ILEVEL = 2) along a 2D trim curve in the global *X*-direction that is defined in trimcurves2d.iges.

Note that for sandwiched part trimming, the keyword *INCLUDE_TRIM (not *INCLUDE) *must* be used to include the dynain file to be trimmed.

Revision information:

1. This feature is available starting in Dev 134513, in SMP and MPP.

*CONTROL_FORMING_TRIMMING

Purpose: Define a part subset to be trimmed by *DEFINE_CURVE_TRIM. This feature is intended for metal forming simulations. Currently trimming is enabled for shell elements, solid elements, adaptive sandwiched parts (one layer of solid elements with top and bottom layers of shell elements), non-adaptive sandwiched parts (multiple layers of solid elements with top and bottom layers of shell elements), thick shell elements (TSHELL, 2D trimming only) and isogeometric shell elements (*ELEMENT_SHELL_-NURBS_PATCH, 3D trimming only). Note it is not applicable for axisymmetric solids or 2D plane strain/stress elements. For details, see *DEFINE_CURVE_TRIM.

NOTE: Before revision 87566 this card was called ELEMENT_TRIM.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID		ITYP					
Type	I		I					
Default	none		0					

VARIABLE	DESCRIPTION
PSID	Part set ID for trimming, see *SET_PART.
ITYP	Activation flag for sandwiched parts (laminates) trimming: EQ.0: Trimming for solid elements. EQ.1: Trimming for laminates.

Remarks:

This keyword is used together with *DEFINE_CURVE_TRIM to trim the parts defined in PSID at time zero, that is, before any stamping process simulation begins. Elements in the part set will be automatically trimmed in the defined direction if they intersect the trim curves. See examples in keyword section *DEFINE_CURVE_TRIM.

Note for solid element trimming, the keyword *INCLUDE_TRIM (not *INCLUDE) *must* be used to include the dynain blank to be trimmed.

Revision information:

1. Revision 87566: *ELEMENT_TRIM was changed to the current name *CONTROL_FORMING_TRIMMING.

2. Revision 95745: *CONTROL_FORMING_TRIMING was changed to *CONTROL_FORMING_TRIMMING.

3. Revision 92088: 2D trimming of solid elements is implemented.

4. Revision 92289: 2D and 3D trimming of laminates (ITYP) is added.

5. Revision 93467: 3D trimming of solid elements is added.

6. Latter Revisions may incorporate more improvements and are suggested to be used for trimming.

*CONTROL_FORMING_UNFLANGING_{OPTION}

Available options include:

<BLANK>

OUTPUT

Purpose: This keyword unfolds flanges of a deformable blank onto a rigid tooling mesh using an implicit statics solver. This is typically used in trim line unfolding during a stamping die development process. The option OUTPUT must be used together with *CONTROL_FORMING_UNFLANGING to get the modified trim curves. Other keywords related to blank size development are *CONTROL_FORMING_ONESTEP and *INTERFACE_BLANKSIZE_DEVELOPMENT. The feature is available in double precision for SMP.

Card Summary:

Card 1a.1. This card is included if no keyword option is used.

NOPTION	DVID	NUNBEND	STFBEND	STFCNT	IFLIMIT	DIST	ILINEAR

Card 1a.2. This card is included if no keyword option is used.

NB1	NB2	NB3	CHARLEN	NDOUTER			

Card 1b. This card is included if the keyword option OUTPUT is used.

THMX	THMN	EPSMX					

Data Cards:

Card 1a.1	1	2	3	4	5	6	7	8
Variable	NOPTION	DVID	NUNBEND	STFBEND	STFCNT	IFLIMIT	DIST	ILINEAR
Type	I	I	I	F	F	I	F	I
Default	none	N/A	none	none	none	none	↓	2

VARIABLE	DESCRIPTION
NOPTION	Flag to turn on an unfolding simulation: EQ.1: Activate the unfolding simulation program.
DVID	This variable is currently not being used.
NUNBEND	Estimated number of unbending, ranging from 10 to 100.
STFBEND	Unflanging stiffness, ranging from 0.1 to 10.0.
STFCNT	Normal stiffness, ranging from 0.1 to 10.0.
IFLIMIT	Iteration limit for the first phase of unfolding, typically ranging from 11 to 400.
DIST	Distance tolerance for auto-SPC along flange root. DIST (Figure 12-63) is usually slightly more than ½ of the flange thickness. *This field must be left blank for ILINEAR = 2.* Also, nodes along the root can be directly positioned on the rigid body surface (addendum), leaving a DIST of zero (Figure 12-63).
ILINEAR	Unfolding algorithm selection flag: EQ.0: Nonlinear unfolding. EQ.1: Linear unfolding. EQ.2: A hybrid unfolding method (Revision 87100 and later). The curved 3D meshes of the flange will first be mapped onto the tooling surface to be used as a starting porting for nonlinear iterations; unfolding completes when force balance is reached. (recommended).

Card 1a.2	1	2	3	4	5	6	7	8
Variable	NB1	NB2	NB3	CHARLEN	NDOUTER			
Type	I	I	I	F	I			
Default	none	↓	↓	150.0	none			

VARIABLE	DESCRIPTION
NB1	The start node ID (Figure 12-64) on a flange root boundary (fixed end of the flange, see Figures 12-63 and 12-64). For closed-loop flange root boundary, only this parameter needs to be defined; for open-loop flange root boundary, define this parameter as well as NB2 and NB3. The solver will automatically identify and automatically impose the necessary boundary constraints on all the nodes along the entire three-dimensional flange root boundary.
NB2	The ID of a node in the middle of the flange root boundary, see Figure 12-64. Define this parameter for open-loop flange root boundary only.
NB3	The end node ID on a flange root boundary. Define this parameter for open-loop flange root boundary only. The "path" formed by NB1, NB2 and NB3 can be in any direction, meaning NB1 and NB3 (Figure 12-64) can be interchangeable.
CHARLEN	Maximum flange height (Figure 12-64) to limit the search region for the boundary nodes along the flange root. This value should be set bigger than the longest width (height) of the flange; and it is needed in some cases. This parameter is now automatically calculated as of Revision 92860.
NDOUTER	A node ID on the outer flange (free end of the flange) boundary. This node helps search of nodes along the flange root, especially when holes are present in the flange area, see Figure 12-64.

Card 1b	1	2	3	4	5	6	7	8
Variable	THMX	THMN	EPSMX					
Type	I	I	I					
Default	10^{20}	0.0	10^{20}					

VARIABLE	DESCRIPTION
THMX	Maximum thickness beyond which elements are deleted; this is useful in removing wrinkling areas of the flange (shrink flange). Modified, unfolded flange outlines based on this parameter are stored in a file called trimcurve_upd.k, written using the *DEFINE_CURVE_TRIM_3D keyword. The modified flanges (before unfolding) are in a keyword file called mdfiedflangedpart.k, and the unmodified flange (unfolded) is in trimcurve_nmd.k, also written using keyword *DEFINE_CURVE_TRIM_3D. See Figure 12-64 for an explanation. Currently the modified flange and curves are not smooth, which will be improved in the future. To convert between *DEFINE_CURVE_TRIM_3D and IGES format refer to Figures in *INTERFACE_BLANKSIZE.
THMN	Minimum thickness below which elements are deleted; this is useful in removing overly thinned areas of the flange (stretch flange). Updated flange information based on this parameter is stored in files listed above.
EPSMX	Maximum effective plastic strain beyond which elements are deleted; this is useful in removing flange areas with high effective plastic strains (stretch flange). Updated flange information based on this parameter is stored in files listed above.

Introduction:

Unfolding of flanges is one of the first steps in a stamping die development process. Immediately after tipping, binder and addendums are built for unfolding of flanges. According to process considerations (trim conditions, draw depth, and material utilization, etc.), the addendums are built either in parallel or perpendicular to the draw die axis, tangentially off the main surface off the breakline (see Appendix T), or any combinations of the three scenarios. Trim lines are developed by unfolding the flanges in finished (hemmed or flanged) position onto these addendums. Addendum length in some areas may have to be adjusted to accommodate the unfolded trim lines. Trim line development is very critical in hard tool development. Inaccurate trim lines lead to trim die rework.

Inputs and Outputs:

The inputs for the keyword are:

1. blank or flanges in the finished configuration, and,
2. the draw die surface in mesh.

Meshes for flanges should be of a quality similar to the blank mesh one would build for a forming simulation. In LS-PrePost 4.0, this kind of mesh can be created using *Mesh* → *Automesh* → *Size*. Element formulation 16 with NIP set to 5 is recommended for the blank. The output results, in terms of unfolding steps and final unfolded flanges, are stored in the d3plot files. The unfolded flange/trim curves can be created from the unfolded flanges using *Curve* → *Spline* → *From Mesh* → *By part*. Since the program uses an implicit statics solver, the double precision version of LS-DYNA must be used.

Other Modeling Guidelines:

1. All addendum and flanges need to be oriented as if they are in a draw position, with the drawing axis parallel to the global *Z*-axis; specifically the flanges need to be on top of the addendum, as noted in Figures 12-62, 12-63 and 12-64.

2. Normals of the to-be-unfolded flange side and tool surface side must be consistent and must face toward each other when the flange is unfolded, see Figure 12-64.

3. Holes in the blank are allowed only for ILINEAR = 2.

4. Adaptive re-meshing is not supported.

5. To-be-unfolded flange and tool meshes must not share the same nodes. This can be easily done using the mesh detaching feature under *EleTol* → *DetEle* in LS-PrePost.

6. Meshes of the flange part and rigid tool can slightly overlap each other, but *large amounts of overlap* (area of flange already on addendum surface) *is not allowed*. In LS-PrePost the *EleTol* → *PtTrim* feature can trim off the overlapped flange portion. The curves used for the trimming can be obtained from the flange tangent curves on the addendum (which has a more regulated mesh pattern) using LS-PrePost's *Curve* → *Spline* → *Method From Mesh* → *By Edge* → *Prop* feature with appropriate angle definition. Furthermore, any holes are not allowed in the overlapping area.

7. *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE should be used for the contact between the blank and tool. Negative tool offsets on the *CONTACT_… keyword is *not* supported.

8. The rigid tool (total fixed in *MAT_020) must be larger than the unfolded flanges, especially along symmetric lines. This may be obvious, nevertheless it is sometimes overlooked.

9. Nodes along the flange root are automatically fixed by defining NB1, NB2 and NB3, as shown in Figure 12-64.

10. No "zigzag" along the flange root boundary, meaning that the boundary along the flange root must be smooth. This restriction is removed as of R10.0.

11. Symmetric boundary conditions are supported.

12. Thickness and effective plastic strain are stored in a file unflanginfo.out, which can be plotted in LS-PrePost 4.0; see Figure 12-64.

Application Examples:

A partial input deck is provided below for flange unfolding of a fender outer, modified from the original NCAC Taurus model. Shown in Figure 12-62 are the progressions of the unfolding process, where the finished flanges are to be unfolded onto the addendum (rigid body). A section view of the same unfolding before and after is found in Figure 12-63. ILINEAR is set at 2 while DIST is left blank. Total numbers of elements are 1251 on the blank and 6600 on the tooling. It took less than 3 minutes on an 8 CPU (SMP) machine. Note that additional keywords, such as *CONTROL_IMPLICIT_FORMING, etc. are used. Termination criterion is set using the variable DELTAU in *CONTROL_-IMPLICIT_TERMINATION. Termination is reached when the relative displacement ratio criterion is met, as indicated in the messag file. Termination time of 10.0 (steps) is sufficient for most cases, but may need to be extended in some cases to satisfy the DELTAU in some cases.

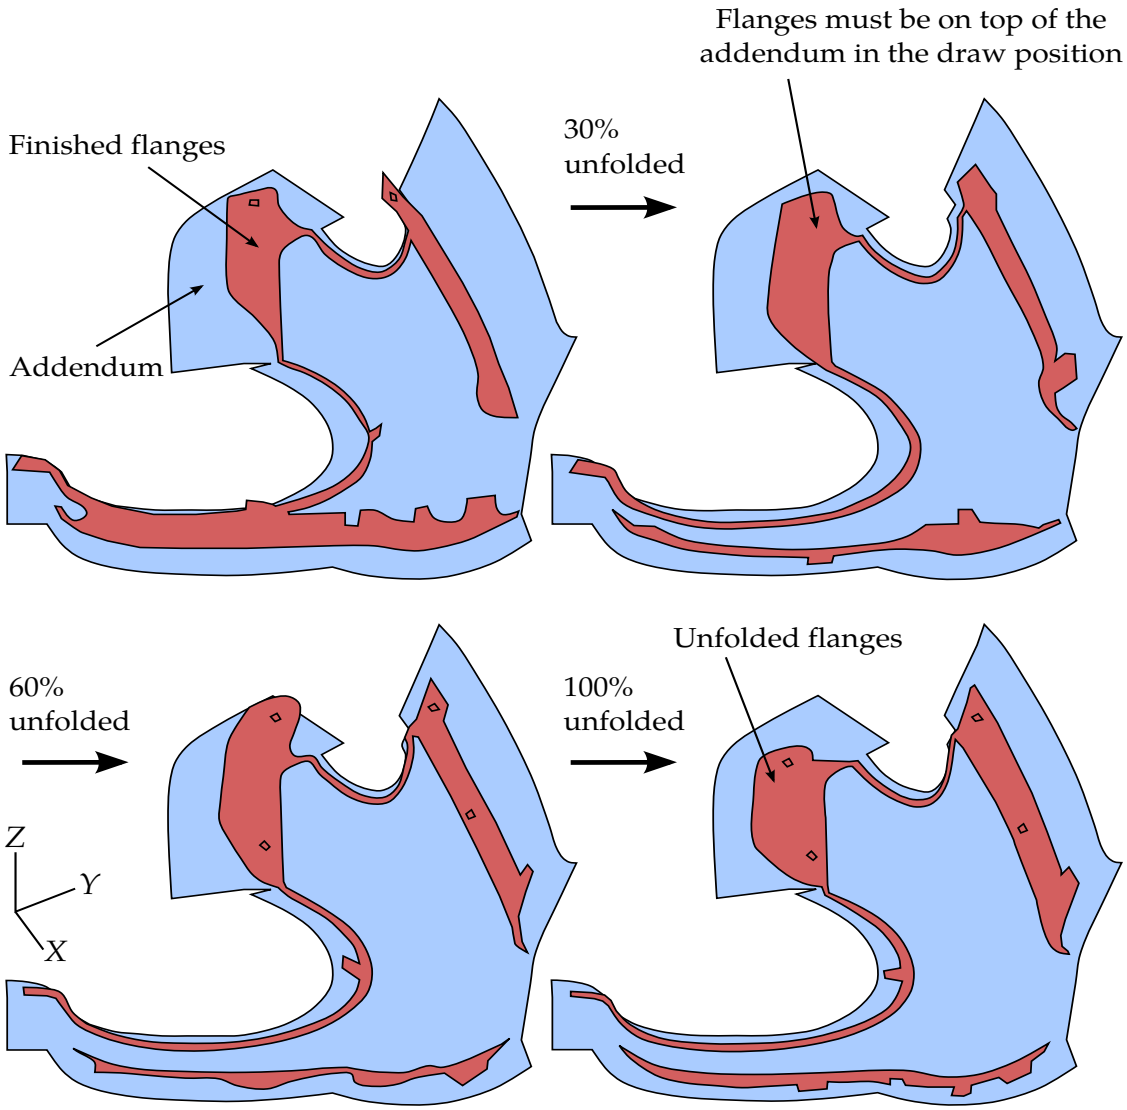

Figure 12-62. Flange unfolding progression of a fender outer (original model courtesy of NCAC at George Washington University).

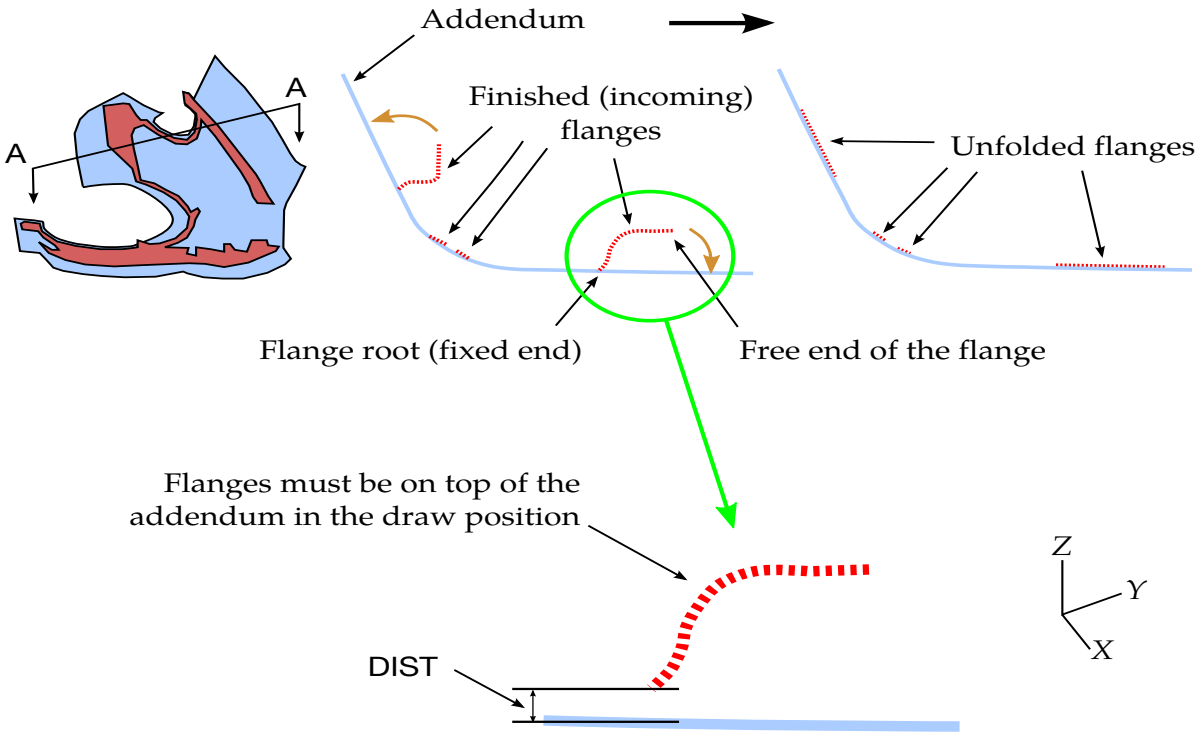

Figure 12-63. A section view showing flange unfolding before and after.

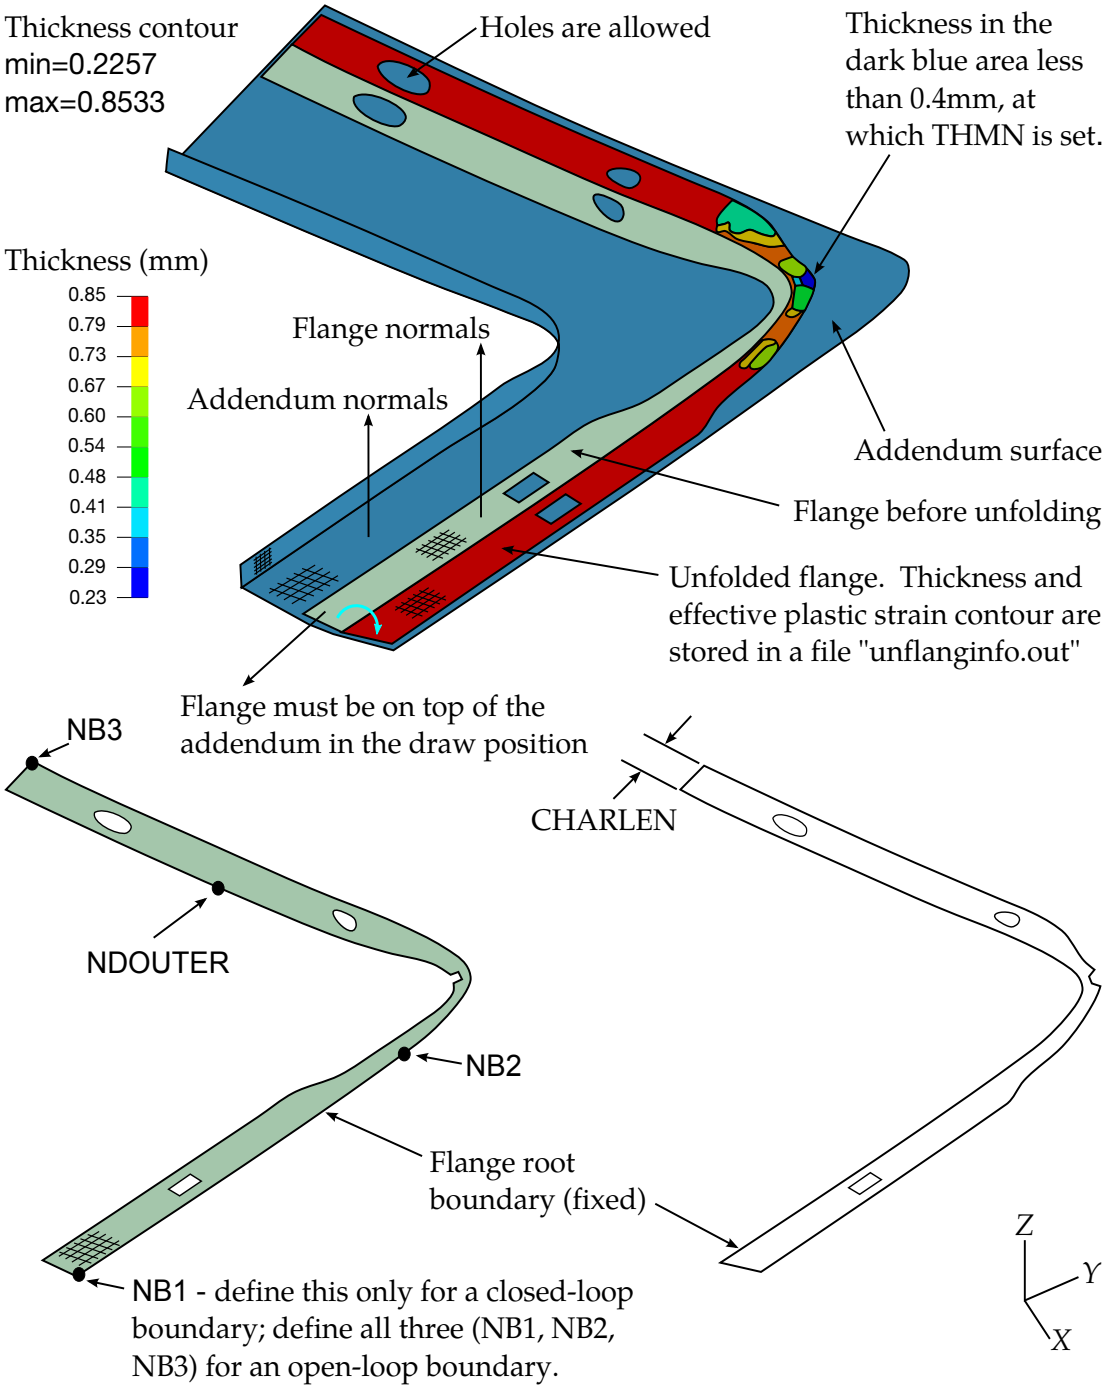

Original flange is modified based on THMN=0.4 and the mesh is stored in a file "mdfiedflangedpart.k". Boundary curves can be created using LSPP4.0 under Curve/Spline/From mesh/by part.

Modified boundary curves on unfolded flange are stored in a file "trimcurve_upd.k"; original boundary curves (without the corner cutout) is in "trimcurve_nmd.k".

Figure 12-64. Unfolding details and output files

*CONTROL_FORMING_USER

Purpose: This keyword, along with *CONTROL_FORMING_POSITION, or *CONTROL_FORMING_TRAVEL, allow user to set up a stamping process simulation. From this card various model parameters may be specified:

- material properties,
- material model,
- tooling kinematics,
- mesh adaptivity
- D3PLOT generation

NOTE: This option has been deprecated in favor of *CONTROL_FORMING_AUTOPOSITION_PARAMETER).

VARIABLE	DESCRIPTION
BLANK	PID of a sheet blank, as in *PART.
TYPE	Flag of part or part set ID for the blank: EQ.0: Part ID. EQ.1: Part set ID.
THICK	Thickness of the blank. This variable is ignored if the thickness is already defined in *SECTION_SHELL.
R00, R45, R90	Material anisotropic parameters. For transverse anisotropy the R value is set to the average value of R00, R45, and R90.
AL/FE	This parameter is used to define the Young's Modulus, E, and density, ρ, for the sheet blank. If this variable is defined, E and ρ will be found by using the proper unit, as listed in Table 8.1, under *CONTROL_FORMING_TEMPLATE. EQ.A: the blank is aluminum EQ.F: the blank is steel (default)
UNIT	Units adopted in this simulation. Define a number between 1 and 10. Table 8.1 is used to determine the value for UNIT. This unit is used to obtain proper values for punch velocity, acceleration, time step, and physical and material properties.
LCSS	If the material for the blank has not been defined, this curve will be used to define the stress-strain relation. Otherwise, this variable is ignored.
PREBD	"Pull-over" distance for the upper and lower binders after closing in a 4-piece stretch draw, as shown in Figure 12-60.

VARIABLE	DESCRIPTION
K	Strength coefficient for exponential hardening ($\overline{\sigma} = k\bar{\varepsilon}^n$). If LCSS is defined, or if a blank material is defined with *MAT_036 or *MAT_-037, this variable is ignored.
N	Exponent for exponential hardening ($\overline{\sigma} = k\bar{\varepsilon}^n$). If LCSS is defined, or if a blank material is defined with *MAT_036 or *MAT_037, this variable is ignored.
E	Young's Modulus. If AL/FE is user defined, E is unnecessary.
DENSITY	Material density of the blank. If AL/FE is defined, this variable is unnecessary.
PR	Poisson's ratio. If AL/FE is user defined, this variable is unnecessary.
FS	Coulomb friction coefficient. If contact is defined with *CONTACT_FORMING_..., this variable is ignored.
MTYP	Material model identification number, for example, 36 for *MAT_-036 and 37 for *MAT_037. Currently only material models 36 and 37 are supported.
PATERN	Velocity profile of the moving tool. If the velocity and the profile are defined by *BOUNDARY_PRESCRIBED_MOTION_RIGID, and *DEFINE_CURVE, this variable is ignored. EQ.1: Ramped velocity profile. EQ.2: Smooth velocity curve.
VMAX	The maximum allowable tool travel velocity.
AMAX	The maximum allowable tool acceleration.
LVLADA	Maximum mesh adaptive level.
SIZEADA	Minimum element size permitted during mesh adaptivity.
ADATIMS	Total number of adaptive steps during the simulation.
D3PLT	The total number of output states in the D3PLOT database.
GAP	Minimum gap between two closing tools at home position, in the travel direction of the moving tool. This variable will be used for *CONTROL_FORMING_POSITION.

Keyword examples:

A partial keyword example provided below is for tools in their home positions in a simple 2-piece crash forming die. A steel sheet blank PID 1, is assigned with a thickness of 0.76mm (UNIT = 1) and *MAT_037 with anisotropic values indicated, to follow hardening curve of 90903, form in a 'ramped' type of velocity profile with maximum velocity of 5000mm/s and acceleration of 500000.0 mm/s2, adapt mesh 5 levels with smallest adapted element size of 0.9 for a total of 20 adaptive steps, create a total of 15 post-processing states, and to finish forming with a final gap of 1.1mm between the tools (PID3 and 5) at home position. The upper tool with PID 3 is to be moved back in Z axis to clear the interference with the blank before close toward the lower tool of target PID 5.

```
*CONTROL_FORMING_USER
$     BLANK      TYPE     THICK       R00       R45       R90     AL/FE      UNIT
         1         0      0.76       1.5       1.6       1.4         F         1
$      LCSS         K         N         E   DENSITY        PR        FS     MTYPE
     90903                                                                    37
$   PATTERN      VMAX      AMAX    LVLADA   SIZEADA   ADATIMS     D3PLT       GAP

```

Revision information:

This keyword is available starting in LS-DYNA Revision 48319.

*CONTROL_FREQUENCY_DOMAIN

Purpose: Set global control flags and parameters for frequency domain analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	REFGEO	MPN	MCF					
Type	I	F	I					
Default	0	0.0	0					

VARIABLE	DESCRIPTION
REFGEO	Flag for reference geometry in acoustic eigenvalue analysis: EQ.0: use original geometry ($t = 0$), EQ.1: use deformed geometry at the end of transient analysis.
MPN	Large mass added per node to be used in large mass method for enforced motion.
MCF	Flag for writing out MCF (Modal Coefficient File) from SSD analysis, to be used in fatigue analysis with nCode Designlife: EQ.0: Don't write out MCF. EQ.1: Write out MCF.

Remarks:

1. **Deformed Geometry Eigenvalue Analysis.** For acoustic eigenvalue analysis (see keyword *FREQUENCY_DOMAIN_ACOUSTIC_ FEM_EIGENVALUE), sometimes it is desired to extract the eigenvalues at the end of transient analysis, based on the deformed geometry. This is useful to study the effect of loading history on acoustic eigenvalues. In this case, one can set REFGEO = 1 to use the deformed geometry at the end of transient analysis.

2. **Large Mass Method.** For enforced motion excitation (e.g. nodal acceleration, velocity, or displacement) in FRF, SSD, or random vibration analysis, one can use the large mass method to compute the response. With the large mass method, the user attaches a large mass to the nodes under excitation. LS-DYNA converts the enforced motion excitation to nodal force on the same nodes in the same direction to produce the desired enforced motion. MPN is the large mass

attached to each node under excitation (usually it is in the range of 10^5-10^7 times of the original mass of the entire structure). The large mass still needs to be applied to the nodes using the keyword *ELEMENT_MASS_*{OPTION}*.

The large nodal force p is computed as shown in the following table:

Nodal Motion	Nodal Force
Acceleration	$p = m_L \ddot{u}$
Velocity	$p = i\omega m_L \dot{u}$
Displacement	$p = -\omega^2 m_L u$

where ω is the round frequency, m_L is the large mass attached to each node (MPN), and $\ddot{u}$, $\dot{u}$ and u are the enforced acceleration, velocity and displacement, respectively.

*CONTROL_HOURGLASS_{OPTION}

Available options include:

<BLANK>

936

The "936" option switches the hourglass formulation for shells so that it is identical to that used in LS-DYNA version 936. The modification in the hourglass control from version 936 was to ensure that all components of the hourglass force vector are orthogonal to rigid body rotations. However, problems that run under version 936 sometimes lead to different results in versions 940 and later. This difference in results is primarily due to the modifications in the hourglass force vector. Versions released after 936 should be more accurate.

Purpose: Redefine the default values of hourglass control type and coefficient.

Card 1	1	2	3	4	5	6	7	8
Variable	IHQ	QH						
Type	I	F						
Default	Rem 1	0.1						
Remarks	1,2	3,4						

VARIABLE	DESCRIPTION
IHQ	Default hourglass control type: EQ.0: See Remark 1, EQ.1: Standard viscous form (may inhibit body rotation if solid element shapes are skewed), EQ.2: Viscous form, Flanagan-Belytschko integration for solid elements, EQ.3: Viscous form, Flanagan-Belytschko with exact volume integration for solid elements, EQ.4: Stiffness form of type 2 (Flanagan-Belytschko),

VARIABLE	DESCRIPTION
	EQ.5: Stiffness form of type 3 (Flanagan-Belytschko) for solid elements, EQ.6: Belytschko-Bindeman [1993] assumed strain co-rotational stiffness form for 2D and 3D solid elements, EQ.7: Linear total strain form of type 6 hourglass control. EQ.8: Activates full projection warping stiffness for shell formulations 9, 16 and -16. A speed penalty of 25% is common for this option. EQ.9: Puso [2000] enhanced assumed strain stiffness form for 3D hexahedral elements, EQ.10: Cosserat Point Element (CPE) developed by Jabareen and Rubin [2008] for 3D hexahedral elements and Jabareen et.al [2013] for 10-noded tetrahedral elements. See Remark 6.
QH	Default hourglass coefficient.

Remarks:

1. **Hourglass control types.** Hourglass control is viscosity or stiffness that is added to quadrilateral shell elements and hexahedral solid elements that use reduced integration. It also applies to formulation 1 tshells. Without hourglass control, these elements would have zero energy deformation modes which could grow large and destroy the solution. *CONTROL_HOURGLASS can be used to redefine the default values of the hourglass control type and coefficient. If omitted or if IHQ = 0, the default hourglass control types are as follows:

   a) For shells: viscous type for explicit; stiffness type for implicit.

   b) For solids: type 2 for explicit; type 6 for implicit.

   c) For tshell formulation 1: type 2.

   These default values are used unless HGID on *PART is used to point to *HOURGLASS data which overrides the default values for that part.

   For explicit analysis, shell elements can be used with viscous hourglass control, (IHQ = 1 = 2 = 3) or stiffness hourglass control (IHQ = 4 = 5). Only shell forms 9, 16 and -16 use the warping stiffness invoked by IHQ = 8. For implicit analysis, the viscous form is unavailable.

For explicit analysis, hexahedral elements can be used with any of the hourglass control types except IHQ = 8. For implicit analysis, only IHQ = 6, 7, 9, and 10 are available.

If IHQ is set to a value that is invalid for some elements in a model, then the hourglass control type for those elements is automatically reset to a valid value. For explicit analysis, if IHQ = 6, 7, 9, or 10, then shell elements will be switched to type 4 except for forms 16 and -16 shells that are switched to type 8. If IHQ = 8, then solid elements and shell elements that are not form 16 will be switched to type 4. For implicit analysis, if IHQ = 1-5, then solid elements will be switched to type 6, and if IHQ = 1, 2, 3, 6, 7, 9, or 10, then shell elements will be switched to type 4.

2. **Viscous hourglass control**. Viscous hourglass control has been used successfully with shell elements when the response with stiffness based hourglass control was overly stiff. As models have grown more detailed and are better able to capture deformation modes, there is less need for viscous forms. To maintain back compatibility, viscous hourglass control remains the default for explicit analysis, but there may be better choices, particularly the newer forms for bricks (6, 7, 9, and 10).

3. **Hourglass coefficient stability.** QH is a coefficient that scales the hourglass viscosity or stiffness. With IHQ = 1 through 5 and IHQ = 8, values of QH that exceed 0.15 may cause instabilities. Hourglass types 6, 7, 9, and 10 will remain stable with larger QH and can work well with QH = 1.0 for many materials. However, for plasticity models, a smaller value such as QH = 0.1 may work better since the hourglass stiffness is based on elastic properties.

4. **Hourglass control for hexahedral elements.** Hourglass types 6, 7, 9, and 10 for hexahedral elements are based on physical stabilization using an enhanced assumed strain method. When element meshes are not particularly skewed or distorted, their behavior may be very similar and all can produce accurate coarse mesh bending results for elastic material with QH = 1.0. However, form 9 gives more accurate results for distorted or skewed elements. In addition, for materials 3, 18 and 24 there is the option to use a negative value of QH. With this option, the hourglass stiffness is based on the current material properties, i.e., the plastic tangent modulus, and scaled by |QH|.

5. **IHQ type 7.** Hourglass type 7 is a variation on form 6. Instead of updating the hourglass forces incrementally using the current stiffness and an increment of deformations, the total hourglass deformation is evaluated each cycle. This ensures that elements always spring back to their initial geometry if the load is removed and the material has not undergone inelastic deformation. Hourglass type 7 is recommended for foams that employ *INITIAL_FOAM_REFER-

ENCE_GEOMETRY. However, the CPU time for type 7 is roughly double that for type 6, so it is only recommended when needed.

6. **IHQ type 10.** Hourglass type 10 for 1-point solid elements or 10-noded tetrahedron of type 16 are strucural elements based on Cosserat point theory that allows for accurate representation of elementary deformation modes (stretching, bending and torsion) for general element shapes and hyperelastic materials. To this end, the theory in Jabareen and Rubin [2008] and Jabareen et.al [2013] has been generalized in the implementation to account for any material response. The deformation is separated into a homogenous and an inhomogeneous part where the former is treated by the constitutive law and the latter by a hyperelastic formulation that is set up to match analytical results for the deformation modes mentioned above. Tests have shown that the element is giving more accurate results than other hexahedral elements for small deformation problems and more realistic behavior in general.

*CONTROL_IMPLICIT

LS-DYNA's implicit mode may be activated in two ways. Using the *CONTROL_IMPLICIT_GENERAL keyword, a simulation may be flagged to run entirely in implicit mode. Alternatively, an explicit simulation may be seamlessly switched into implicit mode at the termination time using the *INTERFACE_SPRINGBACK_SEAMLESS keyword. The seamless switching feature is intended to simplify metal forming springback calculations, where the forming phase can be run in explicit mode, followed immediately by an implicit static springback simulation. In case of difficulty, restart capability is supported.

Several control cards are available to support implicit analysis. Default values are carefully selected to minimize input necessary for most simulations. The implicit control cards follow:

*CONTROL_IMPLICIT_AUTO

*CONTROL_IMPLICIT_BUCKLE

*CONTROL_IMPLICIT_CONSISTENT_MASS

*CONTROL_IMPLICIT_DYNAMICS

*CONTROL_IMPLICIT_EIGENVALUE

*CONTROL_IMPLICIT_FORMING

*CONTROL_IMPLICIT_STABILIZATION

*CONTROL_IMPLICIT_STATIC_CONDENSATION

*CONTROL_IMPLICIT_TERMINATION

***CONTROL_IMPLICIT_AUTO**_*{OPTION}*

Available options for *OPTION* include:

<BLANK>

DYN

SPR

Purpose: Define parameters for automatic time step control during implicit analysis (see also *CONTROL_IMPLICIT_GENERAL). The DYN option allows setting controls specifically for the dynamic relaxation phase. The SPR option allows setting controls specifically for the springback phase.

Card 1	1	2	3	4	5	6	7	8
Variable	IAUTO	ITEOPT	ITEWIN	DTMIN	DTMAX	DTEXP	KFAIL	KCYCLE
Type	I	I	I	F	F	F		
Default	0	11	5	DT/1000.	DT×10.	none		

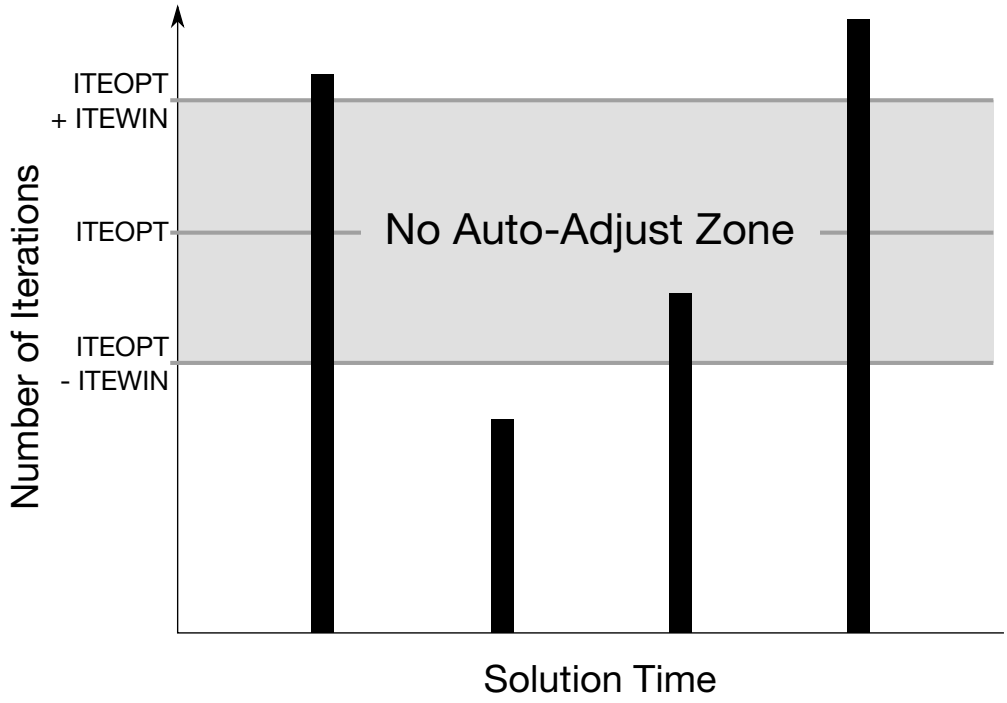

Figure 12-65. Iteration Window as defined by ITEOPT and ITEWIN.

Mid-Step Residual Optional Card. Define this card if and only if IAUTO.EQ.3

Card 2	1	2	3	4	5	6	7	8
Variable	HCMIN	HCMAX	HMMIN	HMMAX	HNTMAX	HNRMAX	HRTMAX	HRRMAX
Type	F	F	F	F	F	F	F	F
Default	2× RC-TOL	10× RC-TOL	2× RM-TOL	10× RM-TOL	Infinity	Infinity	Infinity	Infinity

VARIABLE	DESCRIPTION
IAUTO	Automatic time step control flag EQ.0: constant time step size EQ.1: automatically adjust time step size EQ.2: automatically adjust time step size and synchronize with thermal mechanical time step. EQ.3: same as 1, but accounting for mid step residual values with respect to parameters on card 2 and according to the Remark for IAUTO. LT.0: Curve ID = (-IAUTO) gives time step size as a function of time. If specified, DTMIN and DTMAX will still be applied.
ITEOPT	Optimum equilibrium iteration count per time step. See Figure 12-65.
ITEWIN	Allowable iteration window. If iteration count is within ITEWIN iterations of ITEOPT, step size will not be adjusted for the next step.
DTMIN	Minimum allowable time step size. Simulation stops with error termination if time step falls below DTMIN. LT.0: enable automatic key point generation. Minimum allowable time step is |DTMIN|.
DTMAX	Maximum allowable time step size. LT.0: curve ID = (-DTMAX) gives max step size as a function of time. Also, the step size is adjusted automatically so that the time value of each point in the curve is reached exactly (see Figures 12-66 and 0-3).
DTEXP	Time interval to run in explicit mode before returning to implicit mode. Applies only when automatic implicit-explicit switching is active (IMFLAG = 4 or 5 on *CONTROL_IMPLICIT_GENERAL). Also, see KCYCLE. EQ.0: defaults to the current implicit time step size. LT.0: curve ID = (-DTEXP) gives the time interval as a function of time.

VARIABLE	DESCRIPTION
KFAIL	Number of failed attempts to converge implicitly for the current time step before automatically switching to explicit time integration. Applies only when automatic implicit-explicit switching is active. The default is one attempt. If IAUTO = 0, any input value is reset to unity.
KCYCLE	Number of explicit cycles to run in explicit mode before returning to the implicit mode. The actual time interval that is used will be the maximum between DTEXP and KCYCLE*(latest estimate of the explicit time step size).
HCMIN, HCMAX	Mid-point relative Euclidian residual norm min and max tolerance, to be seen as a confidence interval, see Remark for IAUTO = 3. Only active if RCTOL on *CONTROL_IMPLICIT_SOLUTION is set.
HMMIN, HMMAX	Mid-point relative maximum residual norm min and max tolerance, to be seen as a confidence interval, see Remark for IAUTO = 3. Only active if RMTOL on *CONTROL_IMPLICIT_SOLUTION is set.
H*NT*MAX	Mid-point absolute *N*odal *T*ranslational norm tolerance, see Remark for IAUTO = 3. Only active if *NT*TOL on *CONTROL_IMPLICIT_SOLUTION is set.
H*NR*MAX	Mid-point absolute *N*odal *R*otational norm tolerance, see Remark for IAUTO = 3. Only active if *NR*TOL on *CONTROL_IMPLICIT_SOLUTION is set.
H*RT*MAX	Mid-point absolute *R*igid body *T*ranslational norm tolerance, see Remark for IAUTO = 3. Only active if *RT*TOL on *CONTROL_IMPLICIT_SOLUTION is set.
H*RR*MAX	Mid-point absolute *R*igid body *R*otational norm tolerance, see Remark for IAUTO = 3. Only active if *RR*TOL on *CONTROL_IMPLICIT_SOLUTION is set.

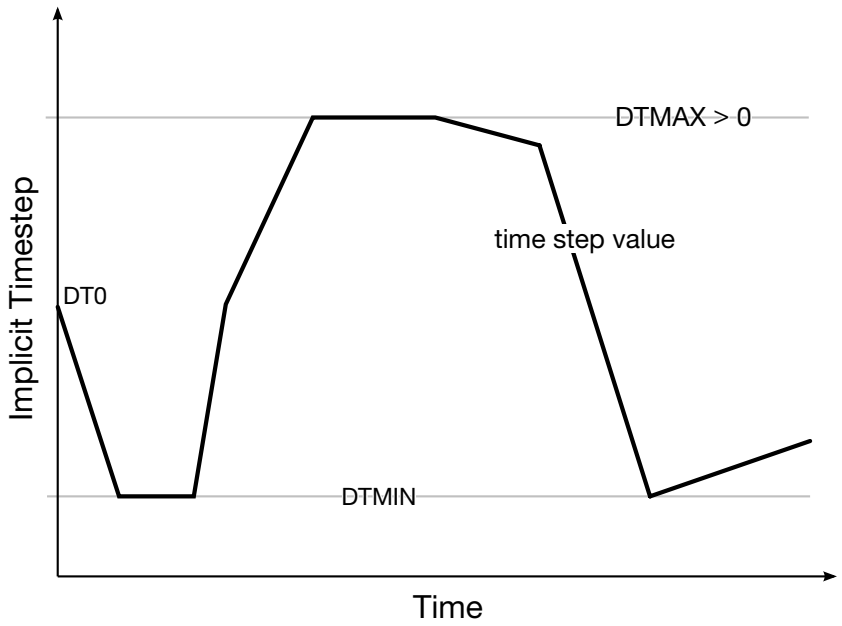

Figure 12-66. The implicit time step size changes continuously as a function of convergence within the bounds set by DTMIN and DTMAX

Remarks:

VARIABLE	REMARK
IAUTO	The default for IAUTO depends on the analysis type. For "spring-back" analysis, automatic time step control and artificial stabilization are activated by default. IAUTO = 3 accounts for the residual norm at the mid-point geometry between converged steps. We have included below a numbered set of conditions. These conditions are used to adjust the time step according to the following algorithm: 1. The time step is *increased* if either of the following criteria is met simultaneously: • 1b, 2b, 3, 4a, or • 1a, 2a, 3, 4b. 2. If the time step is not increased by these conditions, then it is decreased if any of the following above criteria is *violated* • 1b or • 2b or • 3 or

VARIABLE	REMARK

- 4b.

The Criteria Mentioned Above

1. The relative Euclidian residual norm at the mid-point is less than
   a) HCMIN
   b) HCMAX.
2. The relative maximum residual norm at the mid-point is less than
   a) HMMIN
   b) HMMAX.
3. At least one of the following conditions is satisfied at the midpoint
   a) The max norm of nodal translation < HNTMAX
   b) The max norm of nodal rotation < HNRMAX
   c) The max norm of rigid body translation < HRTMAX
   d) The max norm of rigid body rotation < HRRMAX
4. The number of iterations for convergence is
   a) less than ITEOPT − ITEWIN
   b) or equal to ITEOPT + ITEWIN.

Note

IAUTO = 1 is obtained as a special case for

$$\text{HCMIN} = \text{HMMIN} = 0$$

and

$$\text{HCMAX} = \text{HMMAX} = \text{HNTMAX} = \text{HNRMAX} = \text{HRTMAX} = \text{HRRMAX} = \infty$$

The remaining parameters below works the same way as for IAUTO = 1.

VARIABLE	REMARK
ITEOPT	With IAUTO = 1 or 2, the time step size is adjusted if convergence is reached in a number of iterations that falls outside the specified "iteration window", increasing after "easy" steps, and decreasing after "difficult" but successful steps. ITEOPT defines the midpoint of the iteration window. A value of ITEOPT = 30 or more can be more efficient for highly nonlinear simulations by allowing more iterations in each step, hence fewer total steps.
DTMIN	Often specific simulation times that are of special interest, such as when a peak load value occurs, require the simulation to be solved at exactly that time. The automatic key point generation feature attempts to automatically find such times by analyzing the load curves for stationary points in time. The keywords whose load curves are analyzed along with what type of curve value are shown below. •*INITIAL_AXIAL_FORCE_BEAM - global max •*INITIAL_STRESS_SECTION - global max •*LOAD_NODE_POINT - local min/max •*LOAD_NODE_SET - local min/max •*LOAD_SEGMENT - local min/max •*LOAD_SEGMENT_SET - local min/max •*LOAD_SHELL - local min/max •*LOAD_SHELL_SET - local min/max •*BOUNDARY_PRESCRIBED_MOTION_NODE - local min/max •*BOUNDARY_PRESCRIBED_MOTION_SET - local min/max For *CONTROL_IMPLICIT_DYNAMICS, the birth, death, and burial time are key points. For *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_-MORTAR MPAR1 is a key point when IGNORE = 3. The start time and end time of the simulation are also key points. To enable automatic key point generation, enter DTMIN negated.
DTMAX	To strike a particular simulation time exactly, create a key point curve (Figure 0-3) and enter DTMAX = -(curve ID). This is useful to guarantee that important simulation times, such as when peak load values occur, are reached exactly. A user defined key point curve can be used together with automatic key point generation. In that case all key points are merged into a compound list of key points.

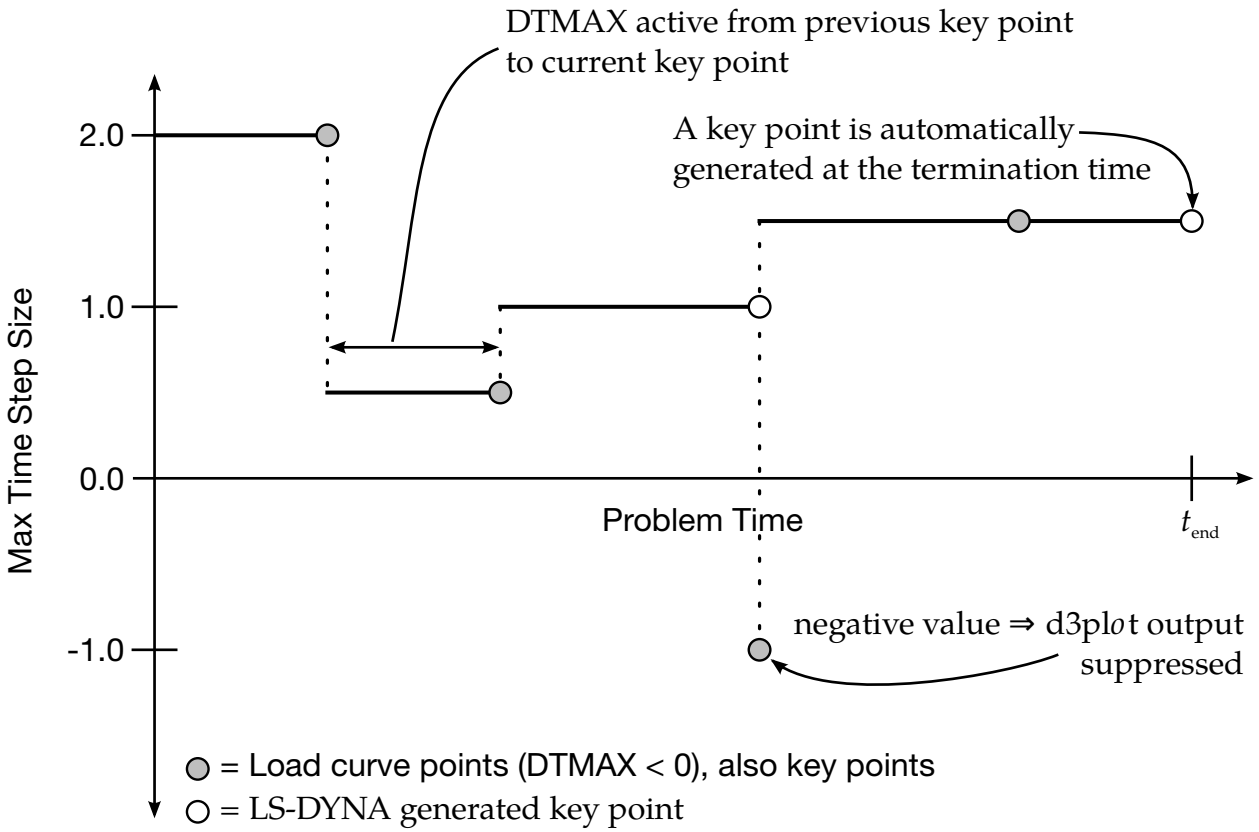

Figure 0-3. *DTMAX < 0.* The maximum time step is set by a load curve of LCID = −DTMAX interpolated using piecewise constants. The abscissa values of the load curve determine the set of *key points*. The *absolute value* of the ordinate values set the maximum time step size. *Key points* are special time values for which the integrator will adjust the time step so as to reach *exactly*. For each key point with a positive function value, LS-DYNA will write the state to the binary database.

VARIABLE	REMARK
DTEXP	When the automatic implicit-explicit switching option is activated (IMFLAG = 4 or 5 on *CONTROL_IMPLICIT_GENERAL), the solution method will begin as implicit, and if convergence of the equilibrium iterations fails, automatically switch to explicit for a time interval of DTEXP. A small value of DTEXP should be chosen so that significant dynamic effects do not develop during the explicit phase, since these can make recovery of nonlinear equilibrium difficult during the next implicit time step. A reasonable starting value of DTEXP may equal several hundred explicit time steps.

*CONTROL_IMPLICIT_BUCKLE

Purpose: Activate implicit buckling analysis when termination time is reached (see also *CONTROL_IMPLICIT_GENERAL). Optionally, buckling analyses are performed at intermittent times.

Card 1	1	2	3	4	5	6	7	8
Variable	NMODE	BCKMTH						
Type	I	I						
Default	0	↓						

VARIABLE	DESCRIPTION
NMODE	Number of buckling modes to compute: EQ.0: none (default) GT.0: compute n lowest buckling modes LT.0: curve ID = (-NEIG) used for intermittent buckling analysis
BCKMTH	Method used to extract buckling modes: EQ.1: Use Block Shift and Invert Lanczos. Default of all problems not using *CONTROL_IMPLICIT_INERTIA_RELIEF. EQ.2: Use Power Method. Only valid option for problems using *CONTROL_IMPLICIT_INERTIA_RELIEF. Optional for other problems. See Remarks.

Remarks:

1. **Buckling Eigenproblem.** Buckling analysis is performed at the end of a static implicit simulation or at specified times during the simulation. The simulation may be linear or nonlinear but must be implicit. After loads have been applied to the model, the buckling eigenproblem is solved:

$$[\mathbf{K}_M + \lambda \mathbf{K}_G]\{u\} = 0$$

where $\mathbf{K}_M$ is the material tangent stiffness matrix, and the geometric or initial stress stiffness matrix $\mathbf{K}_G$ is a function of internal stress in the model. The lowest

n eigenvalues and eigenvectors are computed. The eigenvalues, written to text file eigout, represent multipliers to the applied loads which give buckling loads. The eigenvectors, written to binary database d3eigv, represent buckling mode shapes. These modes can be viewed and animated using LS-PrePost.

2. **NMODE.** When NMODE > 0, eigenvalues will be computed at the termination time and LS-DYNA will terminate.

   When NMODE < 0, an intermittent buckling analysis will be performed. This is a transient simulation during which loads are applied, with buckling modes computed periodically during the simulation. Changes in geometry, stress, material, and contact conditions will affect the buckling modes. The transient simulation must be implicit. The curve ID = -NMODE indicates when to extract the buckling modes, and how many to extract. Define one curve point at each desired extraction time, with a function value equal to the number of buckling modes desired at that time. A d3plot database will be produced for the transient solution results. Consecutively numbered d3eigv and eigout databases will be produced for each intermittent extraction. The extraction time is indicated in each database's analysis title.

3. **Solver.** The buckling modes can be computed using either Block Shift and Invert Lanczos or the Power Method. It is strongly recommended that the Block Shift and Invert Lanczos method is used as it is a more powerful and robust algorithm. For problems using *CONTROL_IMPLICIT_INERTIA_RELIEF the Power Method must be used and any input value for BCKMTH will be overridden with the required value of 2. There may be some problems, which are not using *CONTROL_IMPLICIT_INERTIA_RELIEF, where the Power Method may be more efficient than Block Shift and Invert Lanczos. But the Power Method is not as robust and reliable as Lanczos and results should be verified. Furthermore convergence of the Power Method is better for buckling problems where the expected buckling mode is close to one in magnitude and the dominant mode is separated from the secondary modes. The number of modes extracted via the Power Method should be kept in the range of 1 to 5.

4. **Geometric Stiffness.** The geometric stiffness terms needed for buckling analysis will be automatically computed when the buckling analysis time is reached, regardless of the value of the geometric stiffness flag IGS on *CONTROL_IMPLICIT_GENERAL.

5. **Executable Precision.** A double precision executable should be used for best accuracy in buckling analysis.

6. **Applicable Parameters.** Parameters CENTER, LFLAG, LFTEND, RFLAG, RHTEND and SHFSCL from *CONTROL_IMPLICIT_EIGENVALUE are applicable to buckling analysis. For buckling analysis CENTER, LFTEND, RHTEND and SHFSCL are in units of the eigenvalue spectrum.

*CONTROL_IMPLICIT_CONSISTENT_MASS

Purpose: Use the consistent mass matrix in implicit dynamics and eigenvalue solutions.

Card 1	1	2	3	4	5	6	7	8
Variable	IFLAG							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
IFLAG	Consistent mass matrix flag EQ.0: Use the standard lumped mass formulation (DEFAULT) EQ.1: Use the consistent mass matrix.

Remarks:

The consistent mass matrix formulation is currently available for the three and four node shell elements, solid elements types 1, 2, 10, 15, 16, and 18 (See *SECTION_SOLID), all thick shell element types, and beam types 1, 2, 3, 4, and 5 (See *SECTION_BEAM). All other element types continue to use a lumped mass matrix.

***CONTROL_IMPLICIT_DYNAMICS**_*{OPTION}*

Default	none	90.0						

VARIABLE	DESCRIPTION
IMASS	Implicit analysis type: LT.0: -IMASS is a curve ID with ordinate values used to control the amount of implicit dynamic effects applied to the analysis. TDYBIR, TDYDTH and TDYBUR are ignored with this option. EQ.0: static analysis

VARIABLE	DESCRIPTION
	EQ.1: dynamic analysis using Newmark time integration. EQ.2: dynamic analysis by modal superposition following the solution of the eigenvalue problem EQ.3: dynamic analysis by modal superposition using the eigenvalue solution in the d3eigv files that are in the runtime directory.
GAMMA	Newmark time integration constant (see Remark 2).
BETA	Newmark time integration constant (see Remark 2).
TDYBIR	Birth time for application of dynamic terms. See Figure 12-67.
TDYDTH	Death time for application of dynamic terms.
TDYBUR	Burial time for application of dynamic terms.
IRATE	Rate effects switch: EQ.-1: rate effects are on in constitutive models even in implicit statics EQ.0: rate effects are on in constitutive models, except implicit statics EQ.1: rate effects are off in constitutive models EQ.2: rate effects are off in constitutive models for both explicit and implicit.
ALPHA	Composite time integration constant (see Remark 2): GT.0: Bathe composite scheme is activated. LT.0.AND.GT.-1: HHT scheme is activated, LE.-1: specify part sets for finite rotational dynamics.
PSID	Part set ID for a body undergoing rotational (spinning) motion
ANGLE	Target angle increment during a single time step in degrees

Remarks:

1. **Equilibrium Equations and Dynamic Terms.** For the dynamic problem, the linearized equilibrium equations may be written in the form

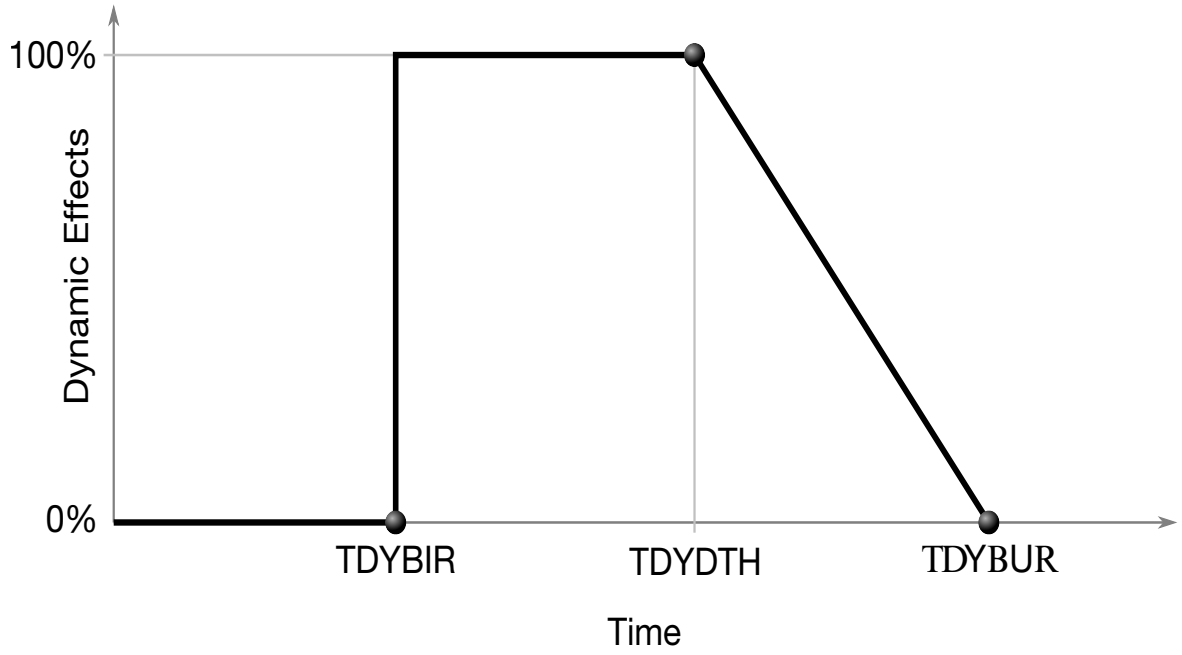

Figure 12-67. Birth, death, and burial time for implicit dynamics. The terms involving **M** and **D** are scaled by a factor ranging between 1 and 0 to include or exclude dynamical effects, respectively.

$$\mathbf{M}\ddot{\mathbf{u}}^{n+1} + \mathbf{D}\dot{\mathbf{u}}^{n+1} + \mathbf{K}_t(\mathbf{x}^n)\Delta\mathbf{u} = \mathbf{P}(\mathbf{x}^n)^{n+1} - \mathbf{F}(\mathbf{x}^n) \ ,$$

where

$$\begin{aligned} \mathbf{M} &= \text{lumped mass matrix} \\ \mathbf{D} &= \text{damping matrix} \\ \mathbf{u}^{n+1} = \mathbf{x}^{n+1} - \mathbf{x}^0 &= \text{nodal displacement vector} \\ \dot{\mathbf{u}}^{n+1} &= \text{nodal point velocities at time } n+1 \\ \ddot{\mathbf{u}}^{n+1} &= \text{nodal point acceleration at time } n+1 \end{aligned}$$

Between the birth and death times 100% of the dynamic terms, that is, the terms involving **M** and **D**, are applied. Between the death and burial time, the dynamic terms are decreased linearly with respect to time until 0% of the dynamic terms are applied after the burial time. This feature is useful for problems that are initially singular because the parts are not in contact initially such as in metal stamping. For these problems dynamics is required for stable convergence. When contact is established, the problem becomes well conditioned and the dynamic terms are no longer required for stable convergence. For such problems setting the death time to be after contact is established and the burial time for 2 or 3 time steps after the death time is recommended.

For problems with more extensive loading and unloading patterns the amount of dynamic effects added to the model can be controlled by using a load curve; see IMASS < 0. This curve should have ordinate values between 0.0 and 1.0. The user should use caution in ramping the load curve and the associated dynamic

effects from 1.0 to 0.0. Such a ramping down should take place over 2 or 3 implicit time steps.

2. **Time Integration.** The time integration is by default the unconditionally stable, one-step, Newmark-β time integration scheme

$$\begin{aligned}\ddot{\mathbf{u}}^{n+1} &= \frac{\Delta\mathbf{u}}{\beta\Delta t^2} - \frac{\dot{\mathbf{u}}^n}{\beta\Delta t} - \frac{1}{\beta}\left(\frac{1}{2}-\beta\right)\ddot{\mathbf{u}}^n \\ \dot{\mathbf{u}}^{n+1} &= \dot{\mathbf{u}}^n + \Delta t(1-\gamma)\ddot{\mathbf{u}}^n + \gamma\Delta t\ddot{\mathbf{u}}^{n+1} \\ \mathbf{x}^{n+1} &= \mathbf{x}^n + \Delta\mathbf{u}\end{aligned}$$

Here, Δt is the time step size, and β and γ are the free parameters of integration. For $\gamma = 1/2$ and $\beta = 1/4$, the method reduces to the trapezoidal rule and is energy conserving. If

$$\begin{aligned}\gamma &> \frac{1}{2} \\ \beta &> \frac{1}{4}\left(\frac{1}{2}+\gamma\right)^2,\end{aligned}$$

numerical damping is induced into the solution leading to a loss of energy and momentum.

The Newmark method, and the trapezoidal rule in particular, is known to lack the robustness required for simulating long term dynamic implicit problems. Even though numerical damping may improve the situation from this aspect, it is difficult to know how to set γ and β without deviating from desired physical properties of the system. In the literature, a vast number of *composite* time integration algorithms have been proposed to handle this, and a family of such methods is implemented and governed by the value of α (ALPHA, parameter 8 on Card 1).

For $\alpha > 0$, every other implicit time step is a three point backward Euler step given as

$$\begin{aligned}\ddot{\mathbf{u}}^{n+1} &= \frac{(1+\alpha)}{\Delta t}\left(\dot{\mathbf{u}}^{n+1} - \dot{\mathbf{u}}^n\right) - \frac{\alpha}{\Delta t_-}\left(\dot{\mathbf{u}}^n - \dot{\mathbf{u}}^{n-1}\right) \\ \dot{\mathbf{u}}^{n+1} &= \frac{(1+\alpha)}{\Delta t}\Delta\mathbf{u} - \frac{\alpha}{\Delta t_-}\Delta\mathbf{u}_-\end{aligned}$$

where $\Delta t_- = t^n - t^{n-1}$ and $\Delta\mathbf{u}_- = \mathbf{u}^n - \mathbf{u}^{n-1}$ are constants. Because of this three step procedure, the method is particularly suitable for nodes/bodies undergoing curved motion as it better accounts for curvature than the default Newmark step. For $\alpha = 1/2$, and default values of γ and β, the method defaults to the Bathe time integration scheme, Bathe [2007], and is reported to preserve energy and momentum to a reasonable degree. The improvement in stability over the Newmark method is primarily attributed to numerical dissipation, but fortunately this dissipation appears to mainly be due to damping of high frequency content

and the underlying physics is therefore not affected as such; see Bathe and Noh [2012].

For a negative value of ALPHA (strictly between −1 and 0), the HHT, Hilber-Hughes-Taylor [1977], scheme is activated. This scheme is similar to that of the Newmark method, but the equilibrium is sought at time step $n + 1 + \alpha$ instead of at $n + 1$. As a complement to the Newmark scheme above, we introduce

$$\dot{\mathbf{u}}^{\alpha} = -\alpha\dot{\mathbf{u}}^{n} + (1+\alpha)\dot{\mathbf{u}}^{n+1}$$
$$\mathbf{x}^{\alpha} = -\alpha\mathbf{x}^{n} + (1+\alpha)\mathbf{x}^{n+1}$$

and solve a modified system of equilibrium equations

$$\mathbf{M}\ddot{\mathbf{u}}^{n+1} + \mathbf{D}\dot{\mathbf{u}}^{\alpha} + \mathbf{F}(\mathbf{x}^{\alpha}) = \mathbf{P}(\mathbf{x}^{\alpha}).$$

This method is stable for $-1/3 \leq \alpha \leq 0$ and $\gamma = (1-2\alpha)/2$ and $\beta = (1-\alpha)^2/4$, which becomes the default values of γ and β if not explicitly set. Parameter α controls the amount of dissipation in the problem; for $\alpha = 0$ an undamped Newmark scheme is obtained, whereas $\alpha = -1/3$ introduces significant damping. From the literature, a value of $\alpha = -0.05$ appears to be a good choice.
Finite rotational dynamics can be activated for a part set by specifying a negative integer for ALPHA, the absolute value of ALPHA then indicates for how many rotating bodies this feature is activated. This option assumes that each body, meaning the parts within each part set PSID, is "almost" a rigid body in the sense that

- the assembly as a whole undergoes relatively large rigid body motion and small deformation in each step;
- the part set includes all parts that makes up the assembly;
- and the assembly is not merged to some other elements in the model by sharing nodes, that is, interaction with other parts should be through joints, contacts, and similar constraints.

The target angle, ANGLE, is meant to be used as a reasonable (in terms of accuracy and convergence) rotation angle for each time step and may vary depending on application. For relatively simple inputs a value of 90 may be ok while for advanced applications it may have to be reduced. The time step will be adjusted to not exceed this target angle. The intention with this option is to use Newmark time integration with large time steps while maintaining high accuracy and robustness and hence serves as an undamped alternative to the damped Bathe and HHT schemes.

3. **Modal Superposition.** When modal superposition is invoked, NEIGV on *CONTROL_IMPLICIT_EIGENVALUE indicates the number of modes to be used. With modal superposition, stresses are computed only for linear shell formulation 18.

*CONTROL_IMPLICIT_EIGENVALUE

Purpose: Activates implicit eigenvalue analysis and defines associated input parameters (see also *CONTROL_IMPLICIT_GENERAL). The available methods are Block Shift and Invert Lanczos, ARPACK for the nonsymmetric eigenvalue problem (see Remark 3), MCMS for problems requiring the computation of thousands of eigenmodes, LOBPCG for problems requiring a small number of eigenmodes, and Sectoral Symmetry for problems with sectoral (rotational) symmetry.

Card Summary:

Card 1. This card is required.

NEIG	CENTER	LFLAG	LFTEND	RFLAG	RHTEND	EIGMTH	SHFSCL

Card 2. Card 2 and beyond are optional. If Card 3a or 3b are included, then Card 2 must be included; Card 2 can be a blank line in this case, so default values are used.

ISOLID	IBEAM	ISHELL	ITSHELL	MSTRES	EVDUMP	MSTRSCL	

Card 3a. Card 3a is read only when EIGMTH = 101. It is optional.

IPARM1	IPARM2	IPARM3	IPARM4	RPARM1			

Card 3b. Card 3b is read only when EIGMTH = 102. It is optional.

IPARM1	IPARM2			RPARM1	RPARM2		

Card 3c. Card 3c is read only when EIGMTH = 111. It is optional.

IPARM1	IPARM2	IPARM3	IPARM4	IPARM5	IPARM6		

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	NEIG	CENTER	LFLAG	LFTEND	RFLAG	RHTEND	EIGMTH	SHFSCL
Type	I	F	I	F	I	F	I	F
Default	none	0.0	0	-infinity	0	+infinity	2	0.0

VARIABLE	DESCRIPTION
NEIG	Number of eigenvalues to extract. This must be specified. The other parameters below are optional. See Remark 1. LT.0: Curve ID = (-NEIG) used for intermittent eigenvalue analysis
CENTER	Center frequency. This option finds the nearest NEIG eigenvalues located about this value. See Remarks 2, 3, and 7.
LFLAG	Left end point finite flag (see Remarks 2 and 3): EQ.0: Left end point is -infinity. EQ.1: Left end point is LFTEND.
LFTEND	Left end point of interval. Only used when LFLAG = 1. See Remarks 2, 3 and 7.
RFLAG	Right end point finite flag (see Remarks 2 and 3): EQ.0: Right end point is +infinity. EQ.1: Right end point is RHTEND.
RHTEND	Right end point of interval. Only used when RFLAG = 1. See Remarks 2, 3, and 7.
EIGMTH	Eigenvalue extraction method (see Remark 3): EQ.2: Block Shift and Invert Lanczos (default). See Remark 2. EQ.3: Lanczos with [M] = [I] (for debugging only) EQ.5: Same as 3 but include Dynamic Terms EQ.6: Same as 2 but include Dynamic Terms EQ.101: MCMS. See Remark 4. EQ.102: LOBPCG. See Remark 5. EQ.111: Sectoral Symmetry. See Remark 10.
SHFSCL	Shift scale. Generally, not used. See Remarks 3, 6, and 7.

Card 2	1	2	3	4	5	6	7	8
Variable	ISOLID	IBEAM	ISHELL	ITSHELL	MSTRES	EVDUMP	MSTRSCL	
Type	I	I	I	I	I	I	F	
Default	0	0	0	0	0	0	0.001	

VARIABLE	DESCRIPTION
ISOLID	If nonzero, reset all solid element formulations to ISOLID for the implicit computations. Can be used for all implicit computations, not just eigenvalue computations.
IBEAM	If nonzero, reset all beam element formulations to IBEAM for the implicit computations. Can be used for all implicit computations, not just eigenvalue computations.
ISHELL	If nonzero, reset all shell element formulations to ISHELL for the implicit computations. Can be used for all implicit computations, not just eigenvalue computations.
ITSHELL	If nonzero, reset all thick shell element formulations to ITSHELL for the implicit computations. Can be used for all implicit computations, not just eigenvalue computations.
MSTRES	Flag for computing the stresses for the eigenmodes (see Remark 8): EQ.0: Do not compute the stresses. EQ.1: Compute the stresses.
EVDUMP	Flag for writing eigenvalues and eigenvectors to file Eigen_Vectors (SMP only; see Remark 8): EQ.0: Do not write eigenvalues and eigenvectors. GT.0: Write eigenvalues and eigenvectors using an ASCII format. LT.0: Write eigenvalues and eigenvectors using a binary format.
MSTRSCL	Scaling for computing the velocity based on the mode shape for the stress computation. See Remark 8.

MCMS Card. Omitted unless EIGTH = 101. Additional card for eigenvalue extraction method MCMS.

Card 3a	1	2	3	4	5	6	7	8
Variable	IPARM1	IPARM2	IPARM3	IPARM4	RPARM1			
Type	I	I	I	I	F			
Default	100	↓	{∅}	1500	4.0			

VARIABLE	DESCRIPTION
IPARM1	Minimum block size for the Cholesky factorization
IPARM2	Maximum block size for the Cholesky factorization. Default is the model size.
IPARM3	Node set ID specifying special nodes in the model where increased accuracy is desired. See Remark 4.
IPARM4	MCMS minimum group/substructure size. See Remark 4.
RPARM1	Eigenvalue expansion factor τ. See Remark 4.

LOBPCG Card. Omitted unless EIGMTH = 102. Additional card for eigenvalue extraction method LOBPCG.

Card 3b	1	2	3	4	5	6	7	8
Variable	IPARM1	IPARM2			RPARM1	RPARM2		
Type	I	I			F	F		
Default	100	100			10^{-12}	10^{-5}		

VARIABLE	DESCRIPTION
IPARM1	Maximum number of iterations
IPARM2	Block size
RPARM1	Convergence tolerance

VARIABLE	DESCRIPTION
RPARM2	BLR preconditioner tolerance

Sectoral Symmetry Card. Omitted unless EIGTH = 111. Additional card for eigenvalue extraction method MCMS.

Card 3c	1	2	3	4	5	6	7	8
Variable	IPARM1	IPARM2	IPARM3	IPARM4	IPARM5	IPARM6		
Type	I	I	I	I	I	I		
Default	none	0	none	none	none	0		

VARIABLE	DESCRIPTION
IPARM1	Node set ID for nodes on the left surface of the sector
IPARM2	Node set ID for nodes on the axis of rotation. EQ.0: No nodes on the axis of rotation (default)
IPARM3	Node set ID for nodes on the left surface of the sector
IPARM4	Number of sectors
IPARM5	Harmonic index
IPARM6	Vector ID for the axis of rotation. EQ.0: Axis of rotation is the global *z*-axis (default)

Remarks:

1. **Performing Eigenvalue Analysis.** To perform an eigenvalue analysis, activate the implicit method by selecting IMFLAG = 1 on *CONTROL_IMPLICIT_GENERAL, and indicate a nonzero value for NEIG above. By default, the lowest NEIG eigenvalues will be found. If a nonzero center frequency is specified, the NEIG eigenvalues nearest to CENTER will be found.

   When NEIG > 0, eigenvalues will be computed at time = 0 and LS-DYNA will terminate.

When NEIG < 0, an intermittent eigenvalue analysis will be performed, can be in both transient and dynamic relaxation (DR) phase. This is a transient/DR simulation during which loads are applied, with eigenvalues computed periodically during the simulation. Changes in geometry, stress, material, and contact conditions will affect the eigenvalues. The transient simulation can be either implicit or explicit according to IMFLAG = 1 or IMFLAG = 6, respectively, on *CONTROL_IMPLICIT_GENERAL. The curve ID = -NEIG indicates when to extract eigenvalues, and how many to extract. Define one curve point at each desired extraction time, with a function value equal to the number of eigenvalues desired at that time. If eigenvalues are desired during the dynamic relaxation phase, set SIDR = 2 in *DEFINE_CURVE, and then set the extraction time to a negative value which corresponds to the pseudo time during the dynamic phase. A d3plot database will be produced for the transient solution results. Consecutively numbered d3eigv and eigout databases will be produced for each intermittent extraction. The extraction time is indicated in each database's analysis title.

2. **Block Shift and Invert Lanczos Method.** The Block Shift and Invert Lanczos code is from BCSLIB-EXT, Boeing's Extreme Mathematical Library.

   When using Block Shift and Invert Lanczos, the user can specify a semifinite or finite interval region in which to compute eigenvalues. Setting LFLAG = 1 changes the left end point from -infinity to the value specified by LFTEND. Setting RFLAG = 1 changes the right end point from +infinity to the values given by RHTEND. If the interval includes CENTER (default value of 0.0) then the problem is to compute the NEIG eigenvalues nearest to CENTER. If the interval does not include CENTER, the problem is to compute the smallest in magnitude NEIG eigenvalues.

   If all of the eigenvalues are desired in an interval where both end points are finite just input a large number for NEIG. The software will automatically compute the number of eigenvalues in the interval and lower NEIG to that value. The most general problem specification is to compute NEIG eigenvalues nearest CENTER in the interval [LFTEND,RHTEND]. Computing the lowest NEIG eigenvalues is equivalent to computing the NEIG eigenvalues nearest 0.0.

3. **Nonsymmetric Eigenvalue Problems.** When the field LCPACK in *CONTROL_IMPICIT_SOLVER is set 3, the eigenvalue problem is assumed nonsymmetric. This feature allows you to compute the eigensolutions for problems with both nonsymmetric terms in the stiffness matrix and with damping terms. *Note that the fields CENTER, LFLAG, LFTEND, RFLAG, RHTEND, EIGMTH, and SHFSCL are ignored for the nonsymmetric eigenvalue problem.*

   By setting LCPACK to 3, ARPACK will automatically be chosen to solve the eigenvalue problem. All damping terms in the model will also be added to the

first order terms of the eigenvalue problem. Implicit Rotational Dynamics will also cause the use of ARPACK due to the added first order terms.

4. **MCMS Method.** MCMS is an implementation of the AMLS algorithm available as of LS-DYNA R11. The target application is automotive NVH models where thousands of approximate eigenmodes are computed for Frequency Response Analysis. MCMS computes all the eigenmodes with eigenvalues in the interval $[-\infty$,RHTEND]. NEIG must be positive to turn on the eigencomputation. If the number of eigenvalues in the interval is less than NEIG, then the next few eigenmodes will be included to reach NEIG. NEIG should not be too large compared to the expected number of eigenvalues in the interval as the accuracy of the eigenmodes past RHTEND will be less than that of the eigenmodes before RHTEND.

   Increasing the group/substructure size (IPARM4) and the eigenvalue expansion factor (RPARM1) improves the accuracy with the cost of increasing the time of the MCS eigen computation. To improve accuracy at a few nodes, such as the nodes of the mounting bracket for an automotive chassis, these nodes can be specified in a node set using IPARM3.

5. **LOBPCG Method.** LOBPCG is an iterative based eigensolver that is best used for computing a few eigenmodes because it requires less computer resources than LANCZOS. It is available as of LS-DYNA R11.

6. **Initial Shift.** For some problems it is useful to override the internal heuristic for picking a starting point for Lanczos shift strategy, that is the initial shift. In these rare cases, the user may specify the initial shift via the parameter SHFSCL. SHFSCL should be in the range of first few nonzero frequencies.

7. **Units.** Parameters CENTER, LFTEND, RHTEND, and SHFSCL are in units of Hertz for eigenvalue problems. These four parameters along with LFLAG and RFLAG are applicable for buckling problems. For buckling problems CENTER, LFTEND, RHTEND, and SHFSCL are in units of the eigenvalue spectrum.

8. **Output Files.** Eigenvectors are written to an auxiliary binary plot database named d3eigv, which is automatically created. These can be viewed using a postprocessor in the same way as a standard d3plot database. The time value associated with each eigenvector plot is the corresponding frequency in units of cycles per unit time. A summary table of eigenvalue results is printed to the eigout file. In addition to the eigenvalue results, modal participation factors and modal effective mass tables are written to the eigout" file. The user can export individual eigenvectors using LS-PrePost.

   The user can request stresses to be computed and written to d3eigv via MSTRES. A velocity is computed by dividing the displacements from the eigenmode by MSTRSCL. The element routine then computes the stresses based on this

velocity, but then those stresses are inversely scaled by MSTRSCL before being written to d3eigv. Thus MSTRSCL has no effect on results of linear element formulations. The strains associated with the stresses output using the MSTRES option can be obtained by setting the STRFLG on *DATABASE_EXTENT_BINARY.

Eigenvalues and eigenvectors can be written to file Eigen_Vectors by using a nonzero value for EVDUMP. If EVDUMP > 0, an ASCII file is used. If EVDUMP < 0, a simple binary format is used. The binary format is to reduce file space. The eigenvectors written to this file will be orthonormal with respect to the mass matrix. Eigenvector dumping is an SMP only feature.

9. **Solver Controls.** The print control parameter, LPRINT, and ordering method parameter, ORDER, from the *CONTROL_IMPLICIT_SOLVER keyword card also apply to the various eigensolvers.

10. **Sectoral Symmetry Method.** Sectoral symmetry makes use of the rotational symmetry of a model to reduce the model size to that of a sector but at the cost of performing many eigenvalue computations based on the harmonic index. The user must specify the nodes on the left surface of the sector, the nodes on the right surface of the sector, and any nodes on the in the sector on the axis of rotation. The default for the axis of rotation is the global *z*-axis. The axis is otherwise given by a vector ID from *DEFINE_VECTOR or *DEFINE_VECTOR_NODE. The model is checked to verify that the right nodes, properly rotated given the axis and number of sectors align with the left nodes.

    The eigenvalue problem is partitioned based on the left, center, right, and interior node sets. The boundary condition given by the harmonic index is solved.

    The user should note that only a subset of the eigenmodes are computed, those associated with a given harmonic index. To get the complete spectrum, multiple runs with harmonic indices varying from 0 to the number of sectors – 1 are required.

*CONTROL_IMPLICIT_FORMING_{OPTION}

Available options include:

<BLANK>

DYN

SPR

Purpose: This keyword is used to perform implicit static analysis, especially for metal forming processes, such as gravity loading, binder closing, flanging, and stamping sub-assembly simulation. A systematic study had been conducted to identify the key factors affecting implicit convergence, and the preferred values are automatically set with this keyword. In addition to forming application, this keyword can also be used in other applications, such as dummy loading and roof crush, etc. The DYN option allows setting controls specifically for the dynamic relaxation phase. The SPR option allows setting controls specifically for the springback phase.

A related keyword is *CONTACT_AUTO_MOVE, where an empty distance between the tool and blank can be automatically eliminated in a combined gravity and closing simulation for implicit static simulations.

Card 1	1	2	3	4	5	6	7	8
Variable	IOPTION	NSMIN	NSMAX	BIRTH	DEATH	PENCHK	DT0	
Type	I	I	I	F	F	F	F	
Default	1	↓	2	0.0	10^{20}	0.0	↓	

VARIABLE	DESCRIPTION
IOPTION	Solution type: EQ.1: Gravity loading simulation; see Remark 2 and examples: Gravity Loading, Flanging Simulation Using IOPTION = 1, and Switching between Implicit Dynamic and Implicit Static for Gravity Loading. EQ.2: Binder closing and flanging simulation; see Remark 2 and examples: Binder Closing, Binder Closing with Real Beads, and Flanging.
NSMIN	Minimum number of implicit steps for IOPTION = 2.

VARIABLE	DESCRIPTION
NSMAX	Maximum number of implicit steps for IOPTION = 2.
BIRTH	Birth time to activate this feature.
DEATH	Death time.
PENCHK	Relative allowed penetration with respect to the part thickness in contact for IOPTION = 2.
DT0	Initial time step size that overrides the DT0 field defined in *CONTROL_IMPLICIT_GENERAL

Remarks:

1. **Implicit Settings.** This keyword provides a simplified interface for implicit static analysis. If no other implicit cards are used, the stiffness matrix is reformed every iteration. Convergence tolerances (DCTOL, ECTOL, etc.) are automatically set and recommended not to be changed. In almost all cases, only two additional implicit control cards (*CONTROL_IMPLICIT_GENERAL and *CONTROL_IMPLICIT_AUTO) may be needed to control the time step size with fields DT0, DTMIN and DTMAX.

   If multiple steps are required for IOPTION = 1, *CONTROL_IMPLICIT_GENERAL must be placed *after* *CONTROL_IMPLICIT_FORMING with DT0 specified as a certain fraction of the ENDTIM (see *CONTROL_TERMINATION). Otherwise, even with DT0 specified as a fraction of the ENDTIM, only one step (with step size of ENDTIM) will be performed.

2. **Contact.** As always, the field IGAP should be set to "2" in *CONTACT_FORMING… cards for a more realistic contact simulation in forming. The contact type *CONTACT_FORMING_SURFACE_TO_SURFACE is recommended to be used with implicit analysis.

   Smaller penalty stiffness scale factor SLSFAC on *CONTROL_CONTACT produces a certain amount of contact penetration but yields faster simulation time, and therefore is recommended for gravity and closing (in case of no physical beads) simulation. Subsequent forming process is likely to follow and contact conditions will be reestablished there, where a tighter, default SLSFAC with a value of 0.1 should be used.

3. **Element Type.** It is recommended that the fully integrated element type 16 is to be used for all implicit calculations. For solids, type "-2" is recommended.

4. **Double Precision.** Executable with double precision is to be used for all implicit calculations.

5. **MPP.** MPP is more efficient for models with over 100,000 deformable elements.

Gravity Loading Example:

An example of the implicit gravity is provided below, where a blank is loaded with gravity into a toggle die. A total of five steps are used, controlled by the field DT0. The results are shown in Figure 12-68. If this binder closing is simulated with explicit dynamics, the inertia effects on the blank need to be reduced since contact with the upper binder only happens along the periphery and a large middle portion of the blank is not driven or supported by anything. With implicit static method, there is no inertia effect at all on the blank during the closing, and no tool speed, time step size, etc. to be concerned about.

The implicit gravity application for both air and toggle draw processes is available through LS-PrePost in Metal Forming Application → eZ Setup (http://ftp.lstc.com/-anonymous/outgoing/lsprepost/).

Binder Closing Example:

An example of binder closing and its progression is shown in Figures 12-69, 12-70, 12-71, and 12-72, using the NUMISHEET'05 deck lid inner, where a blank is being closed in a toggle die (modified). An adaptive level of three was used in the closing process. Gravity is and should be always applied at the same time, regardless of if a prior gravity loading simulation is performed or not, as listed at the end of the input deck. The presence of the gravity helps the blank establish an initial contact with the tool, thus improving the convergence rate. The upper binder is moved down by a closing distance (defined by a parameter &bindmv) using a displacement boundary condition (VAD = 2), with a simple linearly increased triangle-shaped load curve. The variable DT0 is set at 0.01, determined by the expected total deformation. The solver will automatically adjust based on the initial contact condition. The maximum step size is controlled by the variable DTMAX, and this value needs to be sufficiently small (<0.02) to avoid missing contact, but yet not too small causing a long running time. In some cases, this variable can be set to a larger value, but the current value works for most cases.

Binder Closing with Real Beads Example:

Binder closing with real beads can also be done with implicit static, and with adaptive mesh. An example is shown in Figure 12-73, where a hood outer is being closed implicitly. It is noted a small buckle can be seen near the draw bead region along the fender line. These kind of small forming effects can be more accurately detected with implicit static method.

The implicit static closing can now be set up in LS-PrePost Metal Forming Application → eZ Setup (http://ftp.lstc.com/anonymous/outgoing/lsprepost/).

Flanging Example:

An example flanging simulation using this feature is shown in Figures 12-74, 12-75 and 12-76, with NUMISHEET'02 fender outer, where flanging is conducted along the hood line. A partial input is provided below, where DTMAX is controlled by a load curve for

contact and speed; a load curve input for DTMAX is usually not necessary. Gravity, pad closing and flanging were set to 10%, 10% and 80% of the total step size, respectively. The pad travels a distance of &padtrav starting at 0.1, when it is to be automatically moved to close the gap with the blank due to gravity loading (*CONTACT_AUTO_MOVE), and finishing at 0.2 and held in that position until the end. Flanging steel travels a distance of '&flgtrav' starting at 0.2 and completing at 1.0. A detailed section view of the simulation follows in Figure 12-77.

Flanging Simulation Using IOPTION = 1:

IOPTION = 1 can also be used for closing and flanging simulation, or other applications in which there are large plastic strains or deformation. This is used when an equal step size throughout the simulation is desired and is done by specifying the equal step size in the variable DT0 in *CONTROL_IMPLICIT_GENERAL, as shown in the following partial keyword deck where DT0 of 0.014 is chosen. An application of this is shown in Figures 12-78 and 12-79.

Switching between Implicit Dynamic and Implicit Static for Gravity Loading:

For sheet blank gravity loading, it is now possible to start the simulation using implicit dynamic method and then switch to the implicit static method at a user defined time until completion. This feature is activated by setting the variable TDYDTH in *CONTROL_-IMPLICIT_DYNAMICS and was recently (Rev. 81400) linked together with *CON-TROL_IMPLICIT_FORMING. In a partial keyword example below, death time for the implicit dynamic is set at 0.55 second. The test model shown in Figure 12-80 (left) results in a gravity loaded blank shape in Figure 12-80 (right). Without the switch from dynamic to static, the blank at the end of the simulation will be as shown in Figure 12-81. The result with switching is more reasonable. The energy history in Figure 12-82 reveals that the kinetic energy dissipates completely at 0.60 second.

*CONTROL_IMPLICIT_GENERAL_{OPTION}

Available options include:

<BLANK>

DYN

SPR

Purpose: Activate implicit analysis and define associated control parameters. This keyword is required for all implicit analyses. The DYN option enables setting controls specifically for the dynamic relaxation phase. The SPR option enables setting controls specifically for the springback phase.

Card 1	1	2	3	4	5	6	7	8
Variable	IMFLAG	DT0	IMFORM	NSBS	IGS	CNSTN	FORM	ZERO_V
Type	I	F	I	I	I	I	I	I
Default	0	none	2	1	2	0	0	0

VARIABLE	DESCRIPTION
IMFLAG	Implicit/Explicit analysis type flag (see Remark 1): EQ.0: explicit analysis EQ.1: implicit analysis EQ.2: explicit followed by implicit, (seamless springback). *INTERFACE_SPRINGBACK_SEAMLESS is required to activate seamless springback. EQ.4: implicit with automatic implicit-explicit switching EQ.5: implicit with automatic switching and mandatory implicit finish EQ.6: explicit with intermittent eigenvalue extraction LT.0: curve ID = -IMFLAG specifies IMFLAG as a function of time.

VARIABLE	DESCRIPTION
DT0	Initial time step size for implicit analysis. See Remarks 2 and 5. LT.0: eliminate negative principal stresses in geometric (initial stress) stiffness. Initial time step is |DT0|.
IMFORM	Element formulation flag for seamless springback; see *INTERFACE_SPRINGBACK_SEAMLESS. See Remark 3. EQ.1: switch to fully integrated shell formulation for springback EQ.2: retain original element formulation (default)
NSBS	Number of implicit steps in seamless springback; see *INTERFACE_SPRINGBACK_SEAMLESS. See Remark 4.
IGS	Geometric (initial stress) stiffness flag (see Remark 5): EQ.1: include EQ.2: ignore LT.0: include on part set |IGS|
CNSTN	Indicator for consistent tangent stiffness (solid materials 3 & 115 only): EQ.0: do not use (default) EQ.1: use
FORM	Fully integrated element formulation (IMFLAG = 2 and IMFORM = 1 only). See Remark 3. EQ.0: type 16 EQ.1: type 6
ZERO_V	Zero out the velocity before switching from explicit to implicit. EQ.0: the velocities are not zeroed out. EQ.1: the velocities are set to zero.

Remarks:

1. **Analysis Types.** The default value 0 for IMFLAG indicates a standard explicit analysis will be performed. Using value 1 causes an entirely implicit analysis to be performed. Value 2 is automatically activated when the keyword *INTERFACE_SPRINGBACK_SEAMLESS is present, causing the analysis type to

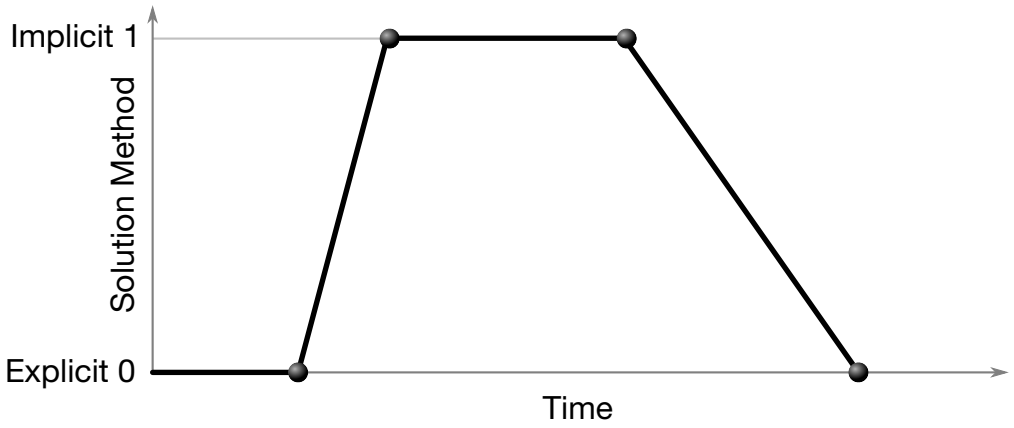

Figure 12-83. Solution method, implicit or explicit, controlled by a load curve.

switch from explicit to implicit when the termination time is reached. Other nonzero values for IMFLAG can also be used with *INTERFACE_SPRINGBACK_SEAMLESS. After this switch, the termination time is extended by NSBS × DT0 or reset to twice its original value if DT0 = 0.0. The implicit simulation then proceeds until the new termination time is reached. Contact interfaces are automatically disabled during the implicit phase of seamless springback analysis. Furthermore, implicit stabilization (*CONTROL_IMPLICIT_STABILIZATION) and automatic step size adjustment (*CONTROL_IMPLICIT_AUTO) are on by default for seamless springback.

When the automatic implicit-explicit switching option is activated (IMFLAG = 4 or 5), the solution method will begin as implicit. If convergence of the equilibrium iterations fails, the solution will automatically switch to explicit for a time interval of DTEXP (see *CONTROL_IMPLICIT_AUTO). After this time interval, the solution method will switch back to implicit and attempt to proceed. The implicit simulation may be either static or dynamic. When this feature is used in a static implicit job, simulation time is no longer arbitrary and must be chosen along with DTEXP in a realistic way to cause efficient execution of any explicit phases. Mass scaling may also be activated (see *CONTROL_TIMESTEP) and will apply only during the explicit phases of the calculation. In cases where much switching occurs, users must exercise caution to ensure that negligible dynamic effects are introduced by the explicit phases.

When IMFLAG = 5, the final step of the simulation must be implicit. The termination time will be extended automatically as necessary, until a successfully converged implicit step can be obtained. This is useful for example in difficult metal forming springback simulations.

When IMFLAG = 6, an explicit simulation will be performed. Eigenvalues will be extracted intermittently according to a curve indicated by curve -NEIG on *CONTROL_IMPLICIT_EIGENVALUE. Beware that dynamic stress oscillations which may occur in the explicit simulation will influence the geometric

(initial stress) stiffness terms used in the eigen solution, potentially producing misleading results and/or spurious modes. As an alternative, eigenvalues can also be extracted intermittently during an implicit analysis, using IMFLAG = 1 and curve -NEIG.

IMFLAG < 0 indicates a curve ID that gives the solution method as a function of time. Define a curve value of zero during explicit phases, and a value of one during implicit phases. Use steeply sloping sections between phases. An arbitrary number of formulation switches may be activated with this method. See Figure 12-83.

2. **Implicit Phase Initial Time Step Size.** DT0 selects the initial time step size for the implicit phase of a simulation. The step size may change during a multiple step simulation if the automatic time step size control feature is active (see *CONTROL_IMPLICIT_AUTO).

3. **Element Formulation Switching.** An adaptive mesh must be activated when using element formulation switching. For best springback accuracy, use of shell type 16 is recommended during the entire stamping and springback analysis, in spite of the increased cost of using this element during the explicit stamping phase.

4. **Seamless Springback.** The NSBS option allows a seamless springback analysis, invoked with *INTERFACE_SPRINGBACK_SEAMLESS, to use multiple unloading steps. Implicit seamless springback begins at time, t = ENDTIM and finishes at t = ENDTIM + NSBS × DT0 were ENDTIM is specified in *CONTROL_TERMINATION and DT0 is specified in *CONTROL_IMPLICIT_GENERAL.

5. **Geometric Stiffness.** The geometric stiffness (IGS) adds the effect of initial stress to the global stiffness matrix. This effect is seen in a piano string whose natural frequency changes with tension. Geometric stiffness does not always improve nonlinear convergence, especially when compressive stresses are present, so its inclusion is optional. Furthermore, the geometric stiffness may lead to convergence problems with incompressible, or nearly incompressible, materials. To eliminate compressive stresses in the geometric stiffness, set DT0 to a negative value.

*CONTROL_IMPLICIT_INERTIA_RELIEF

Purpose: Allows analysis of models that have rigid body modes by suppressing the rigid body motion. It can be used for implicit problems as well as implicit/explicit switching.

Card 1	1	2	3	4	5	6	7	8
Variable	IRFLAG	THRESH	IRCNT					
Type	I	F	I					
Default	0	0.1	0					

Additional Mode List Cards. This card should be included only when the user wants to specify the modes to use. Include as many cards as needed to provide all values. This input ends at the next keyword ("*") card. The mode numbers do not have to be consecutive.

Card 2	1	2	3	4	5	6	7	8
Variable	MODE1	MODE2	MODE3	MODE4	MODE5	MODE6	MODE7	MODE8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
IRFLAG	Inertia relief flag EQ.0: do not perform inertia relief EQ.1: do perform inertia relief and use for both implicit and explicit EQ.2: do perform inertia relief but only use for implicit time steps
THRESH	Threshold for what is a rigid body mode. The default is set to 0.1. Thus, the default threshold is 0.1 Hz when using seconds for the unit of time. If the unit of time is not seconds, you may need to adjust this parameter appropriately. For instance, a unit of time of ms means that the default is 0.1 kHz which leads to too many modes.

VARIABLE	DESCRIPTION
IRCNT	The user can specify to use the lowest IRCNT modes instead of using THRESH to determine the number of modes.
MODE*i*	Ignore THRESH and IRCNT and use a specific list of modes, skipping those that should not be used.

*CONTROL_IMPLICIT_JOINTS

Purpose: Specify penalty or constraint treatment of joints for implicit analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	ISPHER	IREVOL	ICYLIN					
Type	I	I	I					
Default	1	1	1					

VARIABLE	DESCRIPTION
ISPHER	Treatment of spherical joints EQ.1: use constraint method for all spherical joints (default) EQ.2: use penalty method for all spherical joints
IREVOL	Treatment of revolute joints EQ.1: use constraint method for all revolute joints (default) EQ.2: use penalty method for all revolute joints
ICYLIN	Treatment of cylindrical joints EQ.1: use constraint method for all cylindrical joints (default) EQ.2: use penalty method for all cylindrical joints

Remarks:

For most implicit applications one should use the constraint (default) method for the treatment of joints. When explicit-implicit switching is used the joint treatment should be consistent. This keyword allows the user to choose the appropriate treatment for their application.

*CONTROL_IMPLICIT_MODAL_DYNAMIC

Purpose: Activate implicit modal dynamic analysis. Eigenmodes are used to linearize the model by projecting the model onto the space defined by the eigenmodes. The eigenmodes can be computed or read from a file. All or some of the modes can be used in the linearization. Modal damping can be applied.

Card 1	1	2	3	4	5	6	7	8
Variable	MDFLAG	ZETA	MD_STRS	DTOUT	INTEG	NSID		
Type	I	F	I	F	I	I		
Default	0	0.0	0	0	1	{all}		

Eigenmodes Card. This card is optional if MDFLAG = 1, but it is required, even if blank, if MDFLAG = 2.

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							

Constraints Card. This card must be included if and only if MDFLAG = 2.

Card 3	1	2	3	4	5	6	7	8
Variable	FILENAME2							
Type	A80							

VARIABLE	DESCRIPTION
MDFLAG	Modal Dynamic flag: EQ.0: No modal dynamic analysis EQ.1: Perform modal dynamic analysis.

VARIABLE	DESCRIPTION
	EQ.2: Perform modal dynamic analysis with prescribed motion constraints on the constraint modes input with Card 3. See Remark 7.
ZETA	Modal Dynamic damping constant. See Remark 4.
MD_STRS	Modal dynamic stress flag: EQ.0: No modal stress calculated NE.0: Compute modal stresses for output to d3plot using the modal stresses from the d3eigv database. See Remark 3.
DTOUT	Modal dynamics output interval. LE.0: No modal variable output GT.0: Output modal displacement, velocity, and acceleration to file moddynout every DTOUT of simulation time.
INTEG	Integration method EQ.1: perform modal dynamic analysis with explicit time integration (default_. EQ.2: perform modal dynamic analysis with implicit time integration. See Remark 6.
NSID	The node set ID of the nodes in the modal model that are subjected to loads. If the set is not specified, then the forces are summed over all the nodes, and that is usually much more expensive than summing over only those subjected to a load.
FILENAME	If specified, the eigenmodes are read from the specified file. Otherwise the eigenmodes are computed as specified on *CONTROL_IMPLICIT_EIGENVALUE. See Remark 2.
FILENAME2	If specified, constraint modes are read from the specified file. Prescribed motion constraints can then be applied to the constraint modes. See Remark 7.

Remarks:

1. **Modal Dynamics.** Modal Dynamic uses the space spanned by the eigenmodes of the generalized eigenvalue problem

$$\mathbf{K}\boldsymbol{\phi}_i = \lambda_i \mathbf{M}\boldsymbol{\phi}_i.$$

The matrix of eigenmodes, $\mathbf{\Phi}$, diagonalizes $\mathbf{K}$ and $\mathbf{M}$

$$\mathbf{\Phi}^{\mathrm{T}}\mathbf{K}\mathbf{\Phi} = \mathbf{\Lambda}$$

and

$$\mathbf{\Phi}^{\mathrm{T}}\mathbf{M}\mathbf{\Phi} = \mathbf{I}.$$

Multiplication by $\mathbf{\Phi}$ changes coordinates from amplitude space to displacement space as

$$\mathbf{u} = \mathbf{\Phi a}\ ,$$

where $\mathbf{a}$ is a vector of modal amplitudes. The equations of motion,

$$\mathbf{M}\ddot{\mathbf{u}}^{n+1} + \mathbf{K}\Delta\mathbf{u} = \mathbf{F}(\mathbf{x}^n)\ ,$$

when multiplied on the left by $\boldsymbol{\phi}^{\mathrm{T}}$ and substituting $\mathbf{u} = \mathbf{\Phi a}$ become the linearized equations of motion in its spectral form as

$$\mathbf{I}\ddot{\mathbf{a}}^{n+1} + \mathbf{\Lambda}(\Delta\mathbf{a}) = \mathbf{\Phi}^{\mathrm{T}}\mathbf{F}(\mathbf{x}^n).$$

The modal damping features adds a velocity dependent damping term,

$$\mathbf{I}\ddot{\mathbf{a}}^{n+1} + 2\mathbf{Z}\dot{\mathbf{a}}^n + \mathbf{\Lambda}(\Delta\mathbf{a}) = \mathbf{\Phi}^{\mathrm{T}}\mathbf{F}(\mathbf{x}^n)\ ,$$

where $Z_{ii} = \zeta_i\omega_i$, $\omega_i = \sqrt{\lambda_i}$, and each ζ_i is a user specified damping coefficient.

The matrices in the reduced equations are diagonal and constant. So Modal Dynamics can quickly compute the acceleration of the amplitudes and hence the motion of the model. But the motion is restricted to the space spanned by the eigenmodes.

2. **Eigenmodes.** Eigenmodes are either computed based on *CONTROL_IMPLICIT_EIGENVALUE or read from file FILENAME. By default, all modes are used in the projection. Selected modes can be specified via *CONTROL_IMPLICIT_MODAL_DYNAMIC_MODE to reduce the size of the projection.

3. **Stress Output.** Stresses are computed only for linear shell formulation 18 and linear solid formulation 18.

4. **Modal Damping.** Modal damping on all modes can be specified using ZETA. More options for specifying modal damping can be found on *CONTROL_IMPLICIT_MODAL_DYNAMIC_DAMPING.

5. **Similar Keywords.** Using MDFLAG = 1, ZETA = 0.0, and FILENAME = " " is the same as using IMASS = 2 with *CONTROL_IMPLICIT_DYNAMICS. Using MDFLAG = 1, ZETA = 0.0 and FILENAME = d3eigv is the same as IMASS = 3. The new keywords *CONTROL_IMPLICIT_MODAL_DYNAMIC_MODE and *CONTROL_IMPLICIT_MODAL_DYNAMIC_DAMPING provide additional user options for mode selection and modal damping.

6. **Time Integration Method.** When INTEG is set to 2, the implicit Newmark time integration method is used instead of the explicit central difference method, and the time step size is taken from the *CONTROL_IMPLICIT_GENERAL input. The integration parameters are taken from the *CONTROL_IMPLICIT_DYNAMICS input. If they are not specified, the default values of GAMMA and BETA are used. This option permits a time steps size limited only by the accuracy requirements of the user.

7. **Prescribed Motion Constraints.** To apply prescribed motion constraints in global coordinates at specified nodes, the user must first use *CONTROL_IMPLICIT_MODES to compute constraint modes for these nodes for this model. The resulting d3mode file is then input as FILENAME2. The computation of the constraint modes must be performed separately from the computation of the eigenmodes specified in file FILENAME. The prescribed motion constraint (*BOUNDARY_PRESCRIBED_MOTION) should only be present in the execution with *CONTROL_IMPLICIT_MODAL_DYNAMIC and should not be present during the computation of the eigenmodes or the constraint modes. Any prescribed motion constraints on any node *not* in the constraint mode set will be ignored.

*CONTROL_IMPLICIT_MODAL_DYNAMIC_DAMPING_{OPTION}

Available options include:

<BLANK>

SPECIFIC

FREQUENCY_RANGE

Purpose: Define damping terms to be used in implicit modal dynamics.

Card Summary:

Card 1a. Include this card if and only if the keyword option is unused, that is, <BLANK>.

ZETA1							

Card 1b. Include this card if and only if the SPECIFIC keyword option is used. This input ends at the next keyword ("*") card.

MID1	ZETA1	MID2	ZETA2	MID3	ZETA3	MID4	ZETA4

Card 1c. Include this card if and only if the FREQUENCY_RANGE keyword option is used. This input ends at the next keyword ("*") card.

FREQ1	ZETA1	FREQ2	ZETA2	FREQ3	ZETA3	FREQ4	ZETA4

Data Card Definitions:

Damping Card. Card for option set to <BLANK>.

Card 1a	1	2	3	4	5	6	7	8
Variable	ZETA1							
Type	F				I			

Specific Damping Cards. Card for the SPECIFIC option. This input ends at the next keyword ("*") card.

Card 1b	1	2	3	4	5	6	7	8
Variable	MID1	ZETA1	MID2	ZETA2	MID3	ZETA3	MID4	ZETA4
Type	I	F	I	F	I	F	I	F

Frequency Range Damping Cards. Card for FREQUENCY_RANGE option. This input ends at the next keyword ("*") card.

Card 1c	1	2	3	4	5	6	7	8
Variable	FREQ1	ZETA1	FREQ2	ZETA2	FREQ3	ZETA3	FREQ4	ZETA4
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
ZETA*n*	Modal Dynamic damping coefficient *n*.
MID*n*	Mode ID *n*.
FREQ*n*	Frequency value *n*.

Remarks:

1. **No Keyword Option.** If no option is specified, the value of ZETA1 becomes the damping coefficient for all modes involved in implicit modal dynamic analysis. This value overrides the value on *CONTROL_IMPLICIT_MODAL_DYNAMIC.

2. **SPECIFIC Keyword Option.** If option SPECIFIC is specified, the integers MID*n* indicate which modes involved in *CONTROL_IMPLICIT_MODAL_DYNAMIC will have modal damping applied to them. The associated value ZETA*n* will be the modal damping coefficient for that mode.

3. **FREQUENCY_RANGE Keyword Option.** If option FREQUENCY_RANGE is specified, all modes involve will have modal damping applied. The damping coefficient will be computed by linear interpolation of the pairs (FREQ*i*,ZETA*i*). If the modal frequency is less than FREQ1, then the modal damping coefficient will be ZETA1. If the modal frequency is greater than FREQ*n*, then the modal

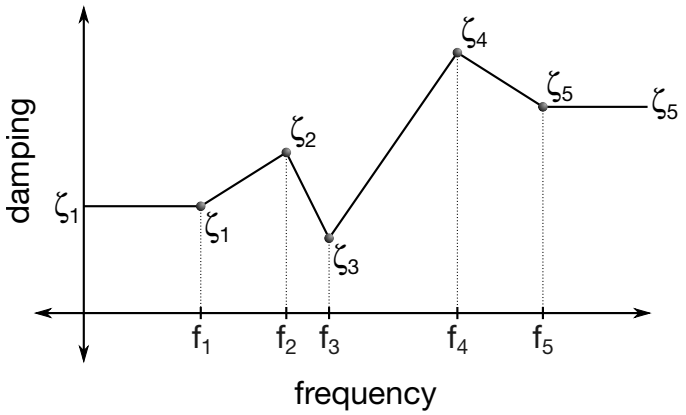

Figure 12-84. Schematic illustration of frequency range damping.

damping coefficient will be ZETA*n*. The values of FREQ*i* must be specified in ascending order.

CONTROL_IMPLICIT_MODAL_DYNAMIC_MODE_*OPTION

Available options include:

LIST

GENERATE

Purpose: Define vibration modes to be used in implicit modal dynamic.

Mode ID Cards. Card 1 for the LIST keyword option. Set one value per mode. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 1a	1	2	3	4	5	6	7	8
Variable	MID1	MID2	MID3	MID4	MID5	MID6	MID7	MID8
Type	I	I	I	I	I	I	I	I

Mode Range Cards. Card 1 for the GENERATE keyword option. Set one pair of M*n*BEG and M*n*END values per block of modes. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 1b	1	2	3	4	5	6	7	8
Variable	M1BEG	M1END	M2BEG	M2END	M3BEG	M3END	M4BEG	M4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
MID*n*	Mode ID *n*.
M*n*BEG	First mode ID in block *n*.
M*n*END	Last mode ID in block *n*. All mode IDs between and including M*n*BEG and M*n*END are added to the list.

Remarks:

1. **Related Keywords.** This keyword may be used with *CONTROL_IMPLICIT_-MODAL_DYNAMIC if some of the vibration modes have less contribution to

the total structural response and can be removed from the implicit modal dynamic analysis.

***CONTROL_IMPLICIT_MODES**_{OPTION}_

Available options include:

<BLANK>

BINARY

Purpose: Request calculation of constraint, attachment, and/or eigenmodes for later use in modal analysis using *PART_MODES (see also *CONTROL_IMPLICIT_GENERAL) or *ELEMENT_DIRECT_MATRIX_INPUT.

Card Summary:

Card 1. This card is required.

NSIDC	NSIDA	NEIG	IBASE	SE_MASS	SE_DAMP	SE_STIFF	SE_INERT

Card 1.1. This card is included if and only if at least one of SE_MASS, SE_DAMP, SE_-STIFF, or SE_INERT is not blank.

SE_FILENAME

Card 2. This card is optional.

IRESVEC	ISTRESS	ID3MODE					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	NSIDC	NSIDA	NEIG	IBASE	SE_MASS	SE_DAMP	SE_STIFF	SE_INERT
Type	I	I	I	I	A	A	A	A
Default	{∅}	{∅}	0	0	blank	blank	blank	blank

Card 1.1	1	2	3	4	5	6	7	8
Variable	SE_FILENAME							
Type	A							

Card 2	1	2	3	4	5	6	7	8
Variable	IRESVEC	ISTRESS	ID3MODE					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
NSIDC	Node set ID for constraint modes. See Remark 2. EQ.0: No constraint modes will be generated
NSIDA	Node set ID for attachment modes. See Remark 2. EQ.0: No attachment modes will be generated
NEIG	Number of eigenmodes (normal modes). See Remark 2. EQ.0: No eigenmodes will be generated.
IBASE	Offset for numbering of the generalized internal degrees of freedom for the superelement
SE_MASS	Name of the superelement mass matrix. If left blank, it is not generated.
SE_DAMP	Name of the superelement damping matrix. If left blank, it is not generated.
SE_STIFF	Name of the superelement stiffness matrix. If left blank, it is not generated.
SE_INERT	Name of the superelement inertia matrix, required for gravity loading applications of the superelement. If left blank, it is not generated.

VARIABLE	DESCRIPTION
SE_FILENAME	If any of SE_MASS, SE_DAMP, SE_STIFF, or SE_INERT are not blank, then the second line is required and contains the filename for the superelement. See Remark 3.
IRESVEC	Converting the attachment modes to residual vectors flag (see Remark 4): EQ.0: No conversion EQ.1: Conversion by orthogonalizing them to the eigenvectors.
ISTRESS	Flag to compute stresses: EQ.0: No stresses are computed. EQ.1: Stresses are computed for the mode shapes and added to the d3mode database.
ID3MODE	Write d3mode file flag: EQ.0: Write the d3mode file. EQ.1: Do not write the d3mode file. This is useful when *CONTROL_IMPLICIT_MODES is being used to create superelement matrices and you do not care about the contents of the d3mode file.

Remarks:

1. **Input and output files.** To use this feature, an implicit analysis must be requested using IMFLAG = 1 on *CONTROL_IMPLICIT_GENERAL, and a nonzero termination time must be specified on *CONTROL_TERMINATION. A double precision version of LS-DYNA should be used for best accuracy. Care must be taken to apply a sufficient number of constraints to the model to eliminate static rigid body motion. Computed modes are written to binary output file d3mode, with the order of output being constraint modes, followed by attachment modes, and then eigenmodes. The modes can be viewed by reading d3mode into LS-PrePost. Eigenmodes are also written to binary output file d3eigv.

2. **Modes.** Constraint and attachment modes are generated by applying unit displacements and unit forces, respectively, to each specified degree of freedom. By default, modes are computed for all degrees of freedom for each node in sets NSIDC and NSIDA. The first and second node set attribute parameters can be

optionally used to restrict the translational and rotational degrees of freedom for which modes are requested, respectively, according to the following syntax:

a) Node set attribute parameters DA1 and A1: translational degree of freedom codes

b) Node set attribute parameters DA2 and A2: rotational degree of freedom codes

code	modes computed
0	(See note below.)
1	X degree of freedom only
2	Y degree of freedom only
3	Z degree of freedom only
4	X, Y degrees of freedom only
5	Y, Z degrees of freedom only
6	X, Z degrees of freedom only
7	X, Y, Z degrees of freedom

Setting both node set attributes to zero is equivalent to setting both node set attributes to 7 (X, Y, and Z for translational and rotational degrees of freedom).

If one node set attribute is nonzero (codes 1 to 7) and the other node set attribute is zero, then the zero attribute means NO degrees of freedom are considered. For example, if DA1 = 2 and DA2 = 0, then only the Y-translational degree of freedom modes are calculated.

Eigenmodes are generated for the model with single point constraints applied on the constraint modes. The number of eigenmodes is specified here. If the user wants to compute eigenmodes other than the lowest ones, the controls on *CONTROL_IMPLICIT_EIGENVALUE can be used.

The combination of constraint modes and eigenmodes form the Hurty-Craig-Bampton linearization for a model. Using only constraint modes is the same as static condensation.

Some broad guidelines for appropriate selection of constraint modes, attachment modes, and eigenmodes include:

c) Use constraint modes for the nodal degrees-of-freedom that are to be "constrained" with SPCs or prescribed motion.

d) Use attachment modes for nodal degrees-of-freedom that are under the influence of point loads.

e) Use eigenmodes in the construction of the superelement to capture the reaction of the part being modeled by the superelement and the associated feedback to the rest of the model.

Note: This node set should only contain deformable nodes, using a node that is part of a rigid body will result in errors.

3. **Superelements.** When the superelement is created, an internal numbering must be applied to the attachment and eigenmodes. This numbering starts at IBASE+1.

   The user can create the superelement representation of the reduced model by specifying the SE_MASS, SE_DAMP, SE_STIFF, SE_INERT and SE_FILENAME fields. The inertia matrix is necessary if body forces, such as gravity loads, are applied to the superelement. The file, by default, is written in the Nastran DMIG file format and can be used as input to *ELEMENT_DIRECT_MATRIX_INPUT. The BINARY keyword option can be used to create a binary representation for the superelement which can be used with *ELEMENT_DIRECT_MATRIX_INPUT_BINARY to reduce the file size.

4. **Residual vectors.** For some applications residual vectors may be desired. These are attachment modes (response of the model to a unit force) orthogonalized to the eigenmodes. To do this, set IRESVEC to 1.

*CONTROL_IMPLICIT_ORDERING

Purpose: Provide user control for ordering algorithms used by implicit linear algebra.

Card 1	1	2	3	4	5	6	7	8
Variable	ORDER	NMETIS						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
ORDER	Ordering option (see Remarks 1 and 2): EQ.0: Method set automatically by LS-DYNA EQ.1: MMD (Multiple Minimum Degree) EQ.2: METIS EQ.3: ParMETIS EQ.4: LS-GPart
NMETIS	Number of times to use METIS on each compute node for MPP. See Remark 2.

Remarks:

1. **Ordering Option.** The system of linear equations is reordered to optimize the sparsity of the factorization when using direct methods. Reordering is a hard problem, and there is no one best algorithm for all problems. LS-DYNA offers four different methods:

   a) *MMD (Multiple Minimum Degree)*. This reordering method is inexpensive but should only be used for small problems.

   b) *METIS.* METIS is from the University of Minnesota. It is the default method for most problems. It is very effective for large problems. METIS, however, is a serial algorithm. For large problems in MPP, however, a bottleneck in both time and memory will occur. Thus, for a large number of MPP processes, you might want to use one of the two parallel algorithms mentioned next.

c) *ParMETIS.* ParMETIS is also from the University of Minnesota. It is the MPP version of METIS. For a large number of processes, it should run much faster than METIS, but there might be some variation in the factorization cost (storage and number of operations). It is available as of R14.

d) *LS-GPart.* LS-GPart is an MPP algorithm developed by Ansys and available as of R11. For a large number of processes, it should run faster than METIS. Quality (in terms of factorization cost) compared to METIS or ParMETIS will depend on the problem.

Reordering cost is included in the symbolic factorization phase of the linear solver. For large models, if this cost exceeds 20% of the numeric factorization cost, it may be more efficient to select the MMD method.

Note that the value of ORDER also affects the eigensolution software. That is ORDER from this keyword card is applicable to eigensolution.

2. **METIS in MPP.** In MPP LS-DYNA will run METIS on each compute node based on the estimate of required storage for METIS and the amount of free storage. The estimate is usually an overestimate. If insufficient storage is available, then MMD is used instead of METIS, usually leading to a more expensive solution. You can force the use of METIS with NMETIS > 0. However, a memory error and fatal termination of LS-DYNA may result in this case. If you do choose to try this option, NMETIS = 1 is recommended.

*CONTROL_IMPLICIT_RESIDUAL_VECTOR

Purpose: Activate and control the computations of residual vectors. Residual vectors are the linear response of a model to a specified load which is then orthogonalized to a set of eigenmodes and any previously computed residual vectors. The eigenmodes can be computed during the execution or read from an input file. The computation of residual vectors is the same as multi-step linear (see NSOLVR = -1 on *CONTROL_IMPLICIT_SOLUTION) but has the additional step of orthogonalization.

Card Summary:

Card 1a. Include this card if NEIG > 0.

IRESVEC	NEIG	IFORMAT					

Card 1a.1. Include this card if IFORMAT ≠ 0.

RV_FILENAME

Card 1b. Include this card if NEIG = 0.

IRESVEC	NEIG	IFORMAT					

Card 1b.1. Include this card if IRESVEC ≠ 0.

RV_FILENAME

Data Card Definitions:

Compute Eigenmodes Card. This card is included if and only if NEIG > 0.

Card 1a	1	2	3	4	5	6	7	8
Variable	IRESVEC	NEIG	IFORMAT					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
IRESVEC	Residual vector control flag: EQ.0: Do not compute residual vectors.

VARIABLE	DESCRIPTION
	GT.0: Compute residual vectors.
NEIG	Number of eigenmodes to compute to orthogonalize the computed load (NEIG > 0)
IFORMAT	Format for processing eigenmodes (NEIG > 0): EQ.0: Do not dump the computed eigenmodes. LT.0: Dump the computed eigenmodes in binary format. GT.0: Dump the computed eignemodes in ASCII format.

Eigenmodes File Card. This card is included if and only if IFORMAT ≠ 0.

Card 1a.1	1	2	3	4	5	6	7	8
Variable	RV_FILENAME							
Type	A80							

VARIABLE	DESCRIPTION
RV_FILENAME	Name of the file for dumping the eigenvector

Read Eigenmodes Card. This card is included if and only if NEIG = 0.

Card 1b	1	2	3	4	5	6	7	8
Variable	IRESVEC	NEIG	IFORMAT					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
IRESVEC	Residual vector control flag: EQ.0: Do not compute residual vectors. GT.0: Compute residual vectors.

VARIABLE	DESCRIPTION
NEIG	Read the eigenmodes from the file RV_FILENAME (if IRESVEC ≠ 0), which is the file used for dumping eigenvectors; see EVDUMP on *CONTROL_IMPLICIT_EIGENVALUE.
IFORMAT	Format for processing eigenmodes read from RV_FILENAME when NEIG = 0 (if IRESVEC > 0): LT.0: File is in binary format. GT.0: File is in ASCII format. If IRSEVEC > 0 and NEIG = 0, IFORMAT = 0 is not allowed.

Eigenmodes File Card. This card is included if and only if IRESVEC ≠ 0.

Card 1b.1	1	2	3	4	5	6	7	8
Variable	RV_FILENAME							
Type	A80							

VARIABLE	DESCRIPTION
RV_FILENAME	Name of the file read to obtain the eigenvectors. See EVDUMP on *CONTROL_IMPLICIT_EIGENVALUE.

Remarks:

For each load step, LS-DYNA resets the geometry to the original geometry and computes the response for the given load. This feature is similar to multi-step linear (NSOLVR = -1 for *CONTROL_IMPLICIT_SOLUTION). Then, the algorithm orthogonalizes the response with respect to the eigenmodes using the mass matrix norm and with respect to any previously computed residual vectors. Finally, LS-DYNA normalizes the residual vector with respect to the mass matrix.

LS-DYNA reads the eigenmodes from an eigenvector dump file or computes them depending on the values of NEIG. RV_FILENAME gives the file name.

LS-DYNA creates an LSDA database named residual_vectors to hold the results of these computations. For each load step, the database includes the following:

- the specified load
- the residual vector, **v**

- the residual frequency ($\mathbf{v}^T\mathbf{K}\mathbf{v}/\mathbf{v}^T\mathbf{M}\mathbf{v}$)

Please contact Technical Support for instructions for reading this database.

In addition, LS-DYNA writes a binary database d3resvec, which LS-PrePost can read to animate residual vectors.

*CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS

Purpose: This keyword is used to model rotational dynamics using the implicit time integrator. Applications for this feature include the transient and vibration analysis of rotating parts, such as turbine blades, propellers in aircraft, and rotating disks in hard disk drives. This feature requires the use of a double precision executable. For transient simulations (NOMEG = 0) both SMP and MPP are supported. The MPP implementation of the eigenvalue computations (NOMEG > 0) is not yet available.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	STYPE	OMEGA	VID	NOMEG	IREF	OMEGADR	ISTFNS
Type	I	I	F	I	I	I	F	I
Default	none	0	none	none	0	0	0.0	3

Additional Rotational Speed Cards. This card should be included only when NOMEG > 0. Include as many cards as needed to provide all NOMEG values. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	OMEG1	OMEG2	OMEG3	OMEG4	OMEG5	OMEG6	OMEG7	OMEG8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
SID	Set ID of the rotational components
STYPE	Set type: EQ.0: Part EQ.1: Part set
OMEGA	Rotating speed in units of radians/(time unit). GT.0: Rotating speed LT.0: Curve ID = |OMEGA| gives rotating speed as a function of time.

VARIABLE	DESCRIPTION
VID	Vector ID to define the rotating axis. It can be defined by *DEFINE_VECTOR and *DEFINE_VECTOR_NODES. The tail of the vector should be set as the rotating center.
NOMEG	Number of rotating speeds. This feature is intended to automatically perform parameter studies with respect to the rotation speed. The keyword *CONTROL_IMPLICIT_EIGENVALUE must be included if NOMEG > 0.
IREF	Reference frame (see Remark 7): EQ.0: Rotating coordinate system. Rotating parts will not rotate in the visualization. Solid element and thick shell element will use IREF = 0. EQ.1: Fixed coordinate system. Using rotational dynamics will add Coriolis and spin softening terms to the matrices but will not rotate the structures. EQ.2: Rotating coordinate system, only rotate rotating parts for visualization purpose.
OMEGADR	Rotating speed defined in dynamic relaxation. GT.0: Rotating speed defined in dynamic relaxation. LT.0: Curve ID = |OMEGADR| gives rotating speed as a function of time.
ISTFNS	Flag for adding spin softening and gyroscopic stiffness terms: EQ.1: Add no stiffness for rotational dynamics effects. EQ.2: Add only the spin softening stiffness terms which keep the stiffness matrix symmetric. EQ.3: Add both the spin softening and gyroscopic stiffness terms which make the stiffness matrix nonsymmetric.
OMEG*n*	The *n*th rotating speed

Remarks:

1. **Equilibrium Equation.** The equilibrium equations depend on the reference frame. For the rotating coordinate system, the linearized equilibrium equation is given by

$$\mathbf{M}\ddot{\mathbf{u}} + (\mathbf{D} + 2\Omega\mathbf{C})\dot{\mathbf{u}} + \left(\mathbf{K} - \Omega^2\mathbf{K}_G\right)\mathbf{u} = \mathbf{F}\,.$$

Whereas, in a fixed coordinate system, the linearized equilibrium equation is

$$\mathbf{M}\ddot{\mathbf{u}} + (\mathbf{D} + \Omega\mathbf{C})\dot{\mathbf{u}} + \mathbf{K}\mathbf{u} = \mathbf{F}$$

with

$\mathbf{M}$ = lumped mass matrix
$\mathbf{D}$ = damping matrix
$\mathbf{K}$ = stiffness matrix
$\mathbf{C}$ = gyroscopic matrix
$\mathbf{K}_G$ = centrifugal stiffness matrix
$\mathbf{u}$ = nodal displacement vector
$\dot{\mathbf{u}}$ = nodal point velocities at time
$\ddot{\mathbf{u}}$ = nodal point acceleration at time
Ω = rotating speed

The chief difference between the equations for the rotating and fixed frames is the inclusion of the centrifugal stiffness matrices $\mathbf{K}_g$. Additionally, the coefficient on the gyroscopic matrix, $\mathbf{C}$, as well as its content are modified in the rotating-frame case. Specifically, the rotating system includes an additional Coriolis contribution to $\mathbf{C}$.

2. **Spin Softening and Gyroscopic Effects.** Rotational Dynamics generates additional terms of spin softening and gyroscopic effects. For transient simulations adding both terms makes the stiffness matrix nonsymmetric which doubles the storage and cost for the numerical factorization. For large problems the user might consider using ISTFNS = 2 which adds only the spin softening terms. This feature maintains the symmetry of the stiffness matrix, hence, avoiding the doubling of the cost of the numerical factorization. No matter the value of ISTFNS, all the effects of rotational dynamics are included in the force computation.

3. **Eigen-Frequencies.** In many applications of rotational dynamics, the critical speed – the theoretical angular velocity that excites the natural frequency of a rotating object – is of particular concern. Therefore, the study of mode frequency response with the change of the rotating speed is very important. The Campbell diagram, which is defined to represent a system's eigen-frequencies as a function of rotating speeds, is introduced for this purpose. In order to do this, the user needs to define a set of rotating speeds on Card 2, and LS-DYNA will do modal analysis for each of these speeds. NOMEG should be defined as the number of rotating speeds specified in Card 2. A keyword file example in this application can be set as follows:

```
*KEYWORD
*CONTROL_TERMINATION...
*CONTROL_IMPLICIT_EIGENVALUE
         5

*CONTROL_IMPLICIT_GENERAL
         1      0.05
*CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS
$#     SID     STYPE     OMEGA       VID    NOMEGA      IREF
         1         0       0.0         1         4         1
$#   OMEG1     OMEG2     OMEG3     OMEG4
```

```
      50.0     100.0     150.0     200.0

         1       0.0       0.0       0.0       1.0       0.0       0.0
*DATABASE_...
*PART...
*SECTION...
*MAT...
*ELEMENT...
*NODE...
*END
```

5. **Limitations.** The rotational dynamics effects are currently not available for solid and thick shell elements in a fixed coordinate system (IREF = 1), so the Campbell diagram in fixed coordinate only shows horizontal lines for these two element types. You may use IREF = 0 to see the rotational dynamics effects. The rotational effects are available for other element types, such as shells and beams, in both fixed (IREF = 1) and rotating (IREF = 0) coordinate systems.

6. **Plotting Campbell Diagrams in LS-PrePost.** To plot a Campbell diagram (frequency as a function of rotating speed) using LS-PrePost, select Post → ASCII → eigout → Load → Frequency → (select modes of interest) → Plot.

7. **Choosing the Reference Frame.** The following table indicates how to choose the reference frame:

Fixed Coordinate System	Rotating Coordinate System
Structure must be axisymmetric about the spin axis.	Structure need not be axisymmetric about the spin axis.
Rotating structure can be part of a stationary structure.	Rotating structure must be the only part of an analysis model.

8. **Comparison to Similar Keywords.** The following table compares the capabilities for keywords *LOAD_BODY, *LOAD_BODY_GENERALIZED and *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS:

Feature	*LOAD_BODY	*LOAD_BODY_GENERALIZED	*CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS

*CONTROL_IMPLICIT_SOLUTION_{OPTION}

Available options include:

<BLANK>

DYN

SPR

Purpose: These optional cards apply to implicit calculations. Use these cards to specify whether a linear or nonlinear solution is desired. Parameters are also available to control the implicit nonlinear and arc length solution methods (see also *CONTROL_IMPLICIT_GENERAL). The DYN option allows setting controls specifically for the dynamic relaxation phase. The SPR option allows setting controls specifically for the springback phase.

Card Summary:

Card 1. This card is required.

NSOLVR	ILIMIT	MAXREF	DCTOL	ECTOL	RCTOL	LSTOL	ABSTOL

Card 2. Card 2 and beyond are optional.

DNORM	DIVERG	ISTIF	NLPRINT	NLNORM	D3ITCTL	CPCHK	

Card 2.1. Card 2.1 is read if DNORM is less than 0.

DMTOL	EMTOL	RMTOL		NTTOL	NRTOL	RTTOL	RRTOL

Card 3. The contents of this card are ignored unless an arc-length method is activated ($6 \le$ NSOLVR ≤ 9, or NSOLVR = 12 and ARCMTH = 3).

ARCCTL	ARCDIR	ARCLEN	ARCMTH	ARCDMP	ARCPSI	ARCALF	ARCTIM

Card 4. This card is optional.

LSMTD	LSDIR	IRAD	SRAD	AWGT	SRED		

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	NSOLVR	ILIMIT	MAXREF	DCTOL	ECTOL	RCTOL	LSTOL	ABSTOL
Type	I	I	I	F/I	F/I	F/I	F	F
Default	12	11	15	0.001	0.01	10^{10}	0.90	10^{-10}

VARIABLE	DESCRIPTION
NSOLVR	Solution method for implicit analysis: EQ.-1: Multistep linear (see Remark 1) EQ.1: Linear (see Remark 1) EQ.12: Nonlinear with BFGS updates (default). This solver incorporates different line search and integration schemes as compared to obsolete NSOLVR = 2. Inclusion of an arc length method is optional and is invoked by setting ARCMTH = 3. EQ.6: Nonlinear with BFGS updates + arc length (see Remark 2) EQ.7: Nonlinear with Broyden updates + arc length (see Remark 2) EQ.8: Nonlinear with DFP updates + arc length (see Remark 2) EQ.9: Nonlinear with Davidon updates + arc length (see Remark 2)
ILIMIT	Iteration limit between automatic stiffness reformations (see Remark 3). LT.0: -ILIMIT references a curve that defines reformation limit as a function of time.
MAXREF	Stiffness reformation limit per time step. LT.0: If |MAXREF| matrix reformations occur, convergence for that time step is forced; see Remark 4.
DCTOL	Displacement relative convergence tolerance (see Remark 5).

LT.0: -DCTOL references a curve that defines tolerance as a function of time.

ECTOL Energy relative convergence tolerance (see Remark 5).

LT.0: -ECTOL references a curve that defines tolerance as a function of time.

RCTOL Residual (force) relative convergence tolerance (see Remark 5).

LT.0: -RCTOL references a curve that defines tolerance as a function of time.

LSTOL Line search convergence tolerance; see Remark 6.

LT.0: -LSTOL is the line search tolerance, but this option activates an alternate strategy where line search acts only on the independent degrees of freedom. This is opposed to the default strategy, where prescribed motions on nodes and rigid bodies are also incorporated, sometimes leading to unnecessarily small time steps because of the requirement of fulfilling these boundary conditions.

ABSTOL Absolute convergence tolerance.

LT.0: Convergence detected when the residual norm is less than |ABSTOL|. Note: To drive convergence based on |ABSTOL|, set DCTOL and ECTOL to 10^{-20}.

Card 2	1	2	3	4	5	6	7	8
Variable	DNORM	DIVERG	ISTIF	NLPRINT	NLNORM	D3ITCTL	CPCHK	
Type	I	I	I	I	F/I	I	I	
Default	2	1	1	0	2	0	0	

Strict Tolerances Optional Card. Define this card if DNORM is less than 0.

Card 2.1	1	2	3	4	5	6	7	8
Variable	DMTOL	EMTOL	RMTOL		NTTOL	NRTOL	RTTOL	RRTOL
Type	F	F	F		F	F	F	F
Default	0.0	0.0	0.0		0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
DNORM	Displacement norm for convergence test (see Remark 5): EQ.1: Increment as a function of displacement over current step EQ.2: Increment as a function of total displacement (default) LT.0: |DNORM|; also activates reading of optional Card 2.1.
DIVERG	Divergence flag (force imbalance increases during equilibrium iterations): EQ.1: Reform stiffness if divergence detected (default) EQ.2: Ignore divergence (see Remark 3)
ISTIF	Initial stiffness formation flag (see Remark 3): EQ.1: Reform stiffness at start of each step (default) EQ.n: Reform stiffness at start of every n^{th} step LT.0: Curve ID = (-ISTIF) gives the number of steps to wait before reforming the stiffness as a function of time.
NLPRINT	Nonlinear solver print flag (see Remark 5): EQ.1: Print iteration information to screen, message, d3hsp files (default) EQ.2: Print extra norm information (NLNORM = 1) EQ.3: Same as 2, but also print information from line search NOTE: during execution, interactive commands can be used: interactive command — response <ctrl-c> **diag**nostic — toggle NLPRINT between 1 and 2 <ctrl-c> **infor**mation — set NLPRINT = 2 for one iteration

VARIABLE	DESCRIPTION
NLNORM	Nonlinear convergence norm type (see Remark 5; input is an integer if ≥ 0 and a float if < 0): LT.0: Same as 4, but rotational degrees of freedom are scaled with characteristic length |NLNORM| to account for units. EQ.1: Consider translational and rotational degrees of freedom EQ.2: Consider translational degrees of freedom only (default) EQ.4: Consider sum of translational and rotational degrees of freedom, that is, no separate treatment.
D3ITCTL	Control d3iter database. If nonzero, the search directions for the nonlinear implicit solution are written to the d3iter database. To reduce the size of the d3iter database, the database is reset every D3ITCTL time steps.
CPCHK	Contact penetration check flag. This flag does not apply to mortar contacts. EQ.0: No contact penetration check is performed (default). EQ.1: Check for contact penetration during the nonlinear solution procedure. If such penetration is found, modify the line search to prevent unnecessary penetration.
DMTOL	Maximum displacement convergence tolerance; convergence is detected when the *relative* maximum nodal or rigid body displacement is less than this value. See Remark 5.
EMTOL	Maximum energy convergence tolerance; convergence is detected when the *relative* maximum nodal or rigid body energy increment is less than this value. See Remark 5.
RMTOL	Maximum residual convergence tolerance; convergence is detected when the *relative* maximum nodal or rigid body residual is less than this value. See Remark 5.
NTTOL	Nodal translational convergence tolerance; convergence is detected when the *absolute* maximum nodal translational residual is less than this value. See Remark 5.
NRTOL	Nodal rotational convergence tolerance; convergence is detected when the *absolute* maximum nodal rotational residual is less than this value. See Remark 5.

VARIABLE	DESCRIPTION
RTTOL	Rigid body translational convergence tolerance; convergence is detected when the *absolute* maximum rigid body translational residual is less than this value. See Remark 5.
RRTOL	Rigid body rotational convergence tolerance; convergence is detected when the *absolute* maximum rigid body rotational residual is less than this value. See Remark 5.

Arc Length Optional Card. The contents of this card are ignored unless an arc-length method is activated (6 ≤ NSOLVR ≤ 9, or NSOLVR = 12 and ARCMTH = 3).

Card 3	1	2	3	4	5	6	7	8
Variable	ARCCTL	ARCDIR	ARCLEN	ARCMTH	ARCDMP	ARCPSI	ARCALF	ARCTIM
Type	I	I	F	I	I	F	F	F
Default	0	↓	0.	1	2	0.	0.	0.

VARIABLE	DESCRIPTION
ARCCTL	Arc length controlling node ID (see Remark 7). EQ.0: Generalized arc length method
ARCDIR	Arc length controlling node direction (ignored if ARCCTL = 0 above; see Remark 7): EQ.1: Global x-translation EQ.2: Global y-translation EQ.3: Global z-translation
ARCLEN	Relative arc length size. See Remark 7. LE.0.0: Use automatic size. GT.0.0: Use ARCLEN × (automatic step size).
ARCMTH	Arc length method (see Remark 7): EQ.1: Crisfield (default) EQ.2: Ramm

VARIABLE	DESCRIPTION
	EQ.3: Modified Crisfield (used with NSOLVR = 12 only) **Note**: When using the arc-length method, termination should be based on some criteria using *TERMINATION_OPTION keyword.
ARCDMP	Arc length damping option (see Remark 7): EQ.2: Off (default) EQ.1: On. Oscillations in the static solution are suppressed.
ARCPSI	Relative influence of load/time parameter in spherical arclength constraint; default value is 0 which corresponds to a cylindrical arclength constraint. Applies to ARCMTH = 3.
ARCALF	Relative influence of predictor step direction for positioning of the arc center; default is 0 which means that the center is at the origin. Applies to ARCMTH = 3.
ARCTIM	Optional time when arclength method is initiated. Applies to ARCMTH = 3.

Line Search Parameter Optional Card.

Card 4	1	2	3	4	5	6	7	8
Variable	LSMTD	LSDIR	IRAD	SRAD	AWGT	SRED		
Type	I	I	F	F	F	F		
Default	4	2	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
LSMTD	Line search convergence method (see Remark 6): EQ.1: Energy method using only translational variables EQ.2: Residual method EQ.3: Energy method using both translational and rotational variables

VARIABLE	DESCRIPTION
	EQ.4: Energy method using sum of translational and rotational degrees of freedom (default), that is, no separate treatment
	EQ.5: Same as 4, but account for residual norm growth to be extra conservative in step length
	EQ.6: Same as 5, but minimizes the residual norm whenever convenient
LSDIR	Line search direction method (see Remark 6):
	EQ.1: Search on all variables (traditional approach used in versions prior to 971)
	EQ.2: Search only on the independent (unconstrained) variables
	EQ.3: Use adaptive line search (see AWGT, SRED)
	EQ.4: Use curved line search (see IRAD, SRAD)
IRAD	Normalized curvature factor for curved line search, where 0 indicates a straight line search and 1 indicates full curved line search. See Remark 6.
SRAD	Radius of influence for determining curve in curved line search. For each independent node, all nodes within this radius are used for determining the curve. If 0, then all nodes connected to the same element as the independent node are used. See Remark 6.
AWGT	Adaptive line search weight factor between 0 and 1. A high value tends to restrict the motion of oscillating nodes during the implicit process. See Remark 6.
SRED	Initial step reduction between 0 and 1 for adaptive line search; use large number for conservative start in implicit procedure. See Remark 6.

Remarks:

1. **Linear Solution Methods.** NSOLVR = 1 invokes a linear analysis for a user specified number of time steps. The results are cumulative for those time steps. NSOLVR = -1 resets the geometry back to the initial state for each time step. With this method, a linear analysis for several different loading cases with only one stiffness matrix formation and factorization can be done. If a linear analysis is selected, equilibrium checking and iterations are not performed.

2. **Unmaintained Nonlinear Solution Methods.** The nonlinear solution methods 6-9 are not being maintained. NSOLVR = 12 with ARCMTH = 3 is the suggested method for arc length solvers.

3. **Stiffness Matrix Reformation.** In the default BFGS method, the global stiffness matrix is only reformed every ILIMIT iterations. Otherwise, an inexpensive stiffness update is applied. By setting ILIMIT = 1, a stiffness reformation is performed every iteration which is equivalent to the Full Newton method (with line search). A higher value of ILIMIT (20-25) can reduce the number of stiffness matrix reformations and factorizations which may lead to a significant reduction in cost. However, increasing the value of ILIMIT may increase the number of iterations. Note that the storage requirements for implicit include storing two vectors per iteration. Therefore, large values of ILIMIT will cause a substantial increase in storage requirements. By using a negative ILIMIIT, it is possible to switch between Full Newton and various degrees of BFGS methods, if for instance nonlinearity varies significantly during the simulation.

   By default, a new stiffness matrix is formed whenever divergence (growing out-of-balance force) is detected. The DIVERG flag can be used to suppress this stiffness reformation. Also, by default, a new stiffness matrix is formed at the start of every time step. Suppressing this stiffness reformation by changing the value of ISTIF can decrease the cost of simulations which have many tiny steps that are mostly linear, such as transient dynamics.

4. **MAXREF.** The nonlinear equilibrium search will continue until the stiffness matrix has been reformed |MAXREF| times, with ILIMIT iterations between each reformation. If equilibrium has not been found and MAXREF > 0, control will be passed to the automatic time step controller if it is activated. If the automatic time step controller is not active, error termination will result. When the auto time step controller is active, it is often efficient to choose MAXREF = 5 and try another stepsize quickly, rather than wasting too many iterations on a difficult step.

   When MAXREF < 0 and |MAXREF| matrix reformations have occurred, convergence for the current time step is declared, with a warning, and the simulation moves to the next time step. This option should be used with caution as the results for that particular time step may be wrong.

5. **Convergence Criteria.** For convergence criteria DCTOL, ECTOL, and RCTOL, the conditions are satisfied when the displacement norm ratio, energy norm ratio, and residual norm ratio are reduced below DCTOL, ECTOL, and RCTOL, respectively. Smaller tolerances lead to a stricter determination of equilibrium, but also result in more iterations and higher costs. By default, residual norm ratio (RCTOL) criterion is effectively disabled (RCTOL = 10^{10}).

When computing the displacement ratio, the norm of the incremental displacement vector is divided by the norm of "total" displacement. This "total" displacement may be either the total over the current step, or the total over the entire simulation. The latter tends to be more lax and can be poor at the end of simulations where large motions develop. For these problems, an effective combination is DNORM = 1 and DCTOL = 0.01 or larger.

For all nonzero values of the strict tolerance fields in optional Card 2.1, the associated criterion must be satisfied *in addition* to the ones defined through DCTOL, ECTOL, and RCTOL. These criteria are based on the maximum norm, which is regarded as stronger than the Euclidian norm used for the other parameters; using these criteria will likely result in higher accuracy at the price of more iterations. For NLPRINT greater than or equal to 2, a table is listed in the messag and d3hsp files for each iteration, providing the values associated with all the criteria activated. The first three (DMTOL, EMTOL and RMTOL) of these extra fields are unitless and honor the meaning of both DNORM and NLNORM. The last four (NTTOL, NRTOL, RTTOL and RRTOL) are to be given in units of force, torque, force, and torque, respectively, and the values used should account for the representative loads in the problem as well as the discretization size.

By default, only translational degrees of freedom are used when evaluating convergence norms. NLNORM can be set to include rotational degrees of freedom or to make additional data available for diagnosing convergence problems. This additional data includes the worst offending node and degree of freedom contributing to each norm.

By setting NLNORM to 1, rotational degrees of freedom can be considered independently from the translational degrees of freedom, meaning that two separate scalar products are used for evaluating norms, $\langle \mathbf{u}, \mathbf{v} \rangle_\mathrm{t} = \mathbf{u}^\mathrm{T} \mathbf{J}_\mathrm{t} \mathbf{v}$ and $\langle \mathbf{u}, \mathbf{v} \rangle_\mathrm{r} = \mathbf{u}^\mathrm{T} \mathbf{J}_\mathrm{r} \mathbf{v}$. Here $\mathbf{J}_\mathrm{t}$ and $\mathbf{J}_\mathrm{r}$ are diagonal matrices with ones on the diagonal to extract the translational and rotational degrees of freedom, respectively. In this case, the convergence criteria must be satisfied for both translational and rotational degrees of freedom simultaneously.

Alternatively they can be included by defining the single scalar product $\langle \mathbf{u}, \mathbf{v} \rangle = \langle \mathbf{u}, \mathbf{v} \rangle_\mathrm{t} + \lambda_u \lambda_v \langle \mathbf{u}, \mathbf{v} \rangle_\mathrm{r}$, where λ_u and λ_v are scale factors to account for different units of the rotational degrees of freedom. For NLNORM = 4 these scale factors are equal to a characteristic element size that is calculated internally. But for NLNORM < 0 λ_u is equal to |NLNORM| if $\mathbf{u}$ is a displacement vector and $|\mathrm{NLNORM}|^{-1}$ if it is a force vector; the same goes for the pair λ_v and $\mathbf{v}$. So |NLNORM| is a characteristic length that appropriately weighs translational and rotational degrees of freedom together. For NLNORM = 4 the internally calculated size is echoed to the screen, d3hsp and messag files for observation and based on this NLNORM < 0 can be used if another scale factor is more suitable.

6. **Line Search.** A line search is performed on stiffening systems to guard against divergence of Newton-based nonlinear solvers. With the Full Newton method, it is sometimes helpful to define a large value of LSTOL (LSTOL = 9999.0) to effectively disable line search.

   The default method for determining convergence of the nonlinear line search is to find the minimum of the energy. LMSTD allows choosing the energy on only the translational variables, energy of both the translational and rotational variables, or for minimizing the residual (forces). The effect of using a residual based line search is not always positive; sometimes it is too restrictive and stops convergence. But it is a more conservative approach than using the energy based method since it explicitly controls the norm of the residual. It should not be seen as a better strategy than the energy method but as an alternative to try in cases when the default method seems to be working poorly. Line search methods 5 and 6 are conservative line search methods to be used for highly nonlinear problems; these should not be used as default but as final resorts to potentially resolve convergence issues. The rule of thumb is that the LSMTD = 5 is slow but robust and LSMTD = 6 is even slower but more robust.

   In Version 971 of LS-DYNA, new line search options were added. The traditional approach (LSDIR = 1) computes the line search direction using all variables. The new (default) approach of LSIDR = 2 computes the line search direction only on the unconstrained variables. It has proven to be both robust and more efficient. We have also included two new approaches to try for problems where the default and traditional approach fail, and the user is using Full Newton (ILIMIT = 1). These methods are described below:

   a) *Curve Line Search.* The parameters IRAD and SRAD are for the curved line search (LSDIR = 4). The first parameter is a switch (0 or 1) to invoke this line search; an intermediate value is interpreted as weighted combination of a straight and curved line search (the curvature radius is decreased with increasing IRAD). A value of unit is recommended in situations with rather smooth responses, such as springback. Also, IRAD = 1 seems to work best with full Newton iterations. The SRAD parameter should be equal to 0 for most cases; this means that the search curve for a node is determined from the search direction of nodes connected to the same elements as that node. SRAD > 0 is interpreted as a radius of influence, meaning that the search curve for a node is determined from the search direction of nodes within a distance SRAD of this node. This option was introduced as an experiment to see if this had a smoothing and stabilizing effect. A value of 0.0 is currently recommended.

   b) *Adaptive Line Search.* The parameters AWGT and SRED are for the adaptive line search. The intention is to improve robustness for problems that have tendencies to oscillate or diverge, indicated by the dnorm and enorm

parameter outputs in the iterations (stdout). A value of 0.5 is recommended for AWGT as a starting point. With a nonzero value the motions of individual nodes are tracked. For nodes that are oscillating (going back and forth in space), the maximum step size for the next iteration is reduced in proportion to the parameter AWGT, and for nodes that are not oscillating but going nicely along a straight path, the maximum step size for the next iteration is increased in proportion to 1-AWGT.

In test problems, the introduction of the adaptive line search has stabilized the implicit procedure in the sense that the dnorm and enorm values are more monotonically decreasing until convergence with virtually no oscillations. If a problem is still oscillating or diverging, the user should try to increase the AWGT parameter since this is a more restrictive approach but probably gives a slower convergence rate. An option for nasty problems is also to use SRED > 0 which is the initial step reduction factor (less than 1). This means that the initial step size is reduced by this value but the maximum step size will increase by an amount that is determined by the success in the iterative procedure; eventually it will reach unity. It can never decrease. Also here, it is intended to be used with full Newton method.

7. **Arc Length Methods.** In the neighborhood of limit points the Newton based iteration schemes often fail. The arc length method of Riks and Wempner (combined here with the BFGS method) adds a constraint equation to limit the load step to a constant "arc length" in load-displacement space. This method is frequently used to solve snap through buckling problems. *When applying the arc-length method, the curves that define the loading should contain only two points, and the first point should be at the origin* (0,0). LS-DYNA will extrapolate, if necessary, to determine the load. In this way, time and load magnitude are related by a constant. It is possible that time can become negative in case of load reversal. The arc length method cannot be used in a dynamic analysis.

In many cases the arc length method has difficulty tracking the load displacement curve through critical regions. Using 0 < ARCLEN < 1 will reduce the step size to assist tracking the load-displacement curve with more accuracy. Use of ARCLEN < 1 will cause more steps to be taken. Suggested values are 1.0 (the default), 0.5, 0.25, and 0.10.

The arc length method can be controlled based on the displacement of a single node in the model using ARCCTL. For example, in dome reversal problems the node at the center of the dome can be used. By default, the generalized arc length method is used, where the norm of the global displacement vector controls the solution. This includes all nodes.

Some static problems exhibit oscillatory response near instability points. AR-CDMP numerically suppresses these oscillations and may improve the convergence behavior of the post-buckling solution.

***CONTROL_IMPLICIT_SOLVER**_*{OPTION}*

Available options include:

<BLANK>

DYN

SPR

Purpose: These optional cards apply to implicit calculations. The linear equation solver performs the CPU-intensive stiffness matrix solution (see also *CONTROL_IMPLICIT_-GENERAL). The DYN option allows setting controls specifically for the dynamic relaxation phase. The SPR option allows setting controls specifically for the springback phase.

Card 1	1	2	3	4	5	6	7	8
Variable	LSOLVR	LPRINT	NEGEV	ORDER	DRCM	DRCPRM	AUTOSPC	AUTOTOL
Type	I	I	I	I	I	F	I	F
Default	7	0	2	0	4	↓	1	↓

Card 2 is optional.

Card 2	1	2	3	4	5	6	7	8
Variable	LCPACK	MTXDMP	IPARM1	RPARM1	RPARM2			RPARM5
Type	I	I	I	F	F			F
Default	2	0	↓	↓	↓			↓

Card 3 is optional.

Card 3	1	2	3	4	5	6	7	8
Variable	EMXDMP	RDCMEM	ABSMEM					
Type	I	F	F					
Default	0	0.85	optional					

VARIABLE	DESCRIPTION
LSOLVR	Linear equation solver method (see Remark 1). EQ.2: Parallel multi-frontal sparse solver (deprecated) EQ.7: Parallel multi-frontal sparse solver (default) EQ.22: Iterative, CG with diagonal preconditioner EQ.23: Iterative, CG with local Symmetric Gauss-Seidel (SGS) preconditioner EQ.24: Iterative, CG with local Symmetric Successive Over-Relaxation (SSOR) preconditioner EQ.25: Iterative, CG with local 0-fill incomplete factorization (ILDLT0) preconditioner EQ.26: Iterative, CG with local 0-fill incomplete factorization (ILDLT0) preconditioner that requires extra storage EQ.30: Parallel direct/hybrid solver MUMPS (see Remark 2) EQ.90: User Supplied Linear Equation Solver (see Remark 3) SMP only: EQ.6: BCSLIB-EXT, direct, sparse, double precision
LPRINT	Linear solver print flag controls screen and message file output (see Remarks 4 and 6). EQ.0: No printing EQ.1: Output summary statistics on memory, cpu requirements EQ.2: More statistics EQ.3: Even more statistics and debug checking During execution, use the interactive command "<ctrl-c> lprint" to toggle this print flag between 0 and 1.

VARIABLE	DESCRIPTION
NEGEV	Negative eigenvalue flag. Selects procedure when negative eigenvalues are detected during stiffness matrix inversion (see Remark 5). EQ.1: Stop, or retry step if auto step control is active EQ.2: Print warning message, try to continue (default)
ORDER	Ordering option (see Remark 6): EQ.0: Method set automatically by LS-DYNA EQ.1: MMD, Multiple Minimum Degree EQ.2: METIS EQ.3: ParMETIS EQ.4: LS-GPart
DRCM	Drilling rotation constraint method for shells (see Remark 7): EQ.1: Add drilling stiffness (old Version 970 method) EQ.2: Same as 4 below EQ.3: Add no drilling stiffness EQ.4: Add drilling stiffness (improved method) (default)
DRCPRM	Drilling rotation constraint parameter for shells. This parameter scales the drilling stiffness. For the old method (DRCM = 1) the default value of DRCPRM is 1.0 for linear analysis, 100.0 for nonlinear implicit analysis, and either 10^{-12} or 10^{-8} for eigenvalue analysis depending on the shell element type. For eigenvalue analysis, the input value for DRCPRM is ignored. For the improved method (default, DRCM = 4), the default value of DRCPRM is as described above for the old method except default DRCPRM is 1.0 for nonlinear implicit analysis.
AUTOSPC	Automatic Constraint Scan flag EQ.1: Scan the assembled stiffness matrix looking for unconstrained, unattached degrees of freedom. Generate additional constraints as necessary to avoid negative eigenvalues. EQ.2: Do not add constraints.

VARIABLE	DESCRIPTION
AUTOTOL	AUTOSPC tolerance. The test for singularity is the ratio of the smallest singular value and the largest singular value. If this ratio is less than AUTOTOL, then the triple of columns is declared singular and a constraint is generated. Default values in single and double precision are 10^{-4} and 10^{-8}, respectively.
LCPACK	Matrix assembly package: EQ.2: Default. EQ.3: Same as 2, but incorporates a nonsymmetric linear solver; see Remark 8.
MTXDMP	Matrix and right-hand-side dumping. LS-DYNA has the option of dumping the globally assembled stiffness matrix and right-hand-side vectors files in Harwell-Boeing sparse matrix format. Such output may be useful for comparing to other linear equation solution packages. EQ.0: No dumping GT.0: Dump all matrices and right-hand-side vectors every MTXDMP time steps. The first dump occurs at the first time step, then at time step MTXDUMP+1, 2*MTXDUMP+1, and so on. Output is written as ASCII text and the involved filenames are of the following form: K_*xxxx*_*yyy*.mtx.rb This file contains the stiffness matrix at step *xxxx*, iteration *yyy*. M_*xxxx*_*yyy*.mtx.rb This file contains the mass matrix at step *xxxx*, iteration *yyy*. Only for eigenvalue analysis. W_*xxxx*_*yyy*.mtx.rb This file contains the damping matrix at step *xxxx*, iteration *yyy*. Only for simulations with damping. K_*xxxx*_*yyy*_*zzz*.rhs.rb This file contains the right hand side at step *xxxx*, iteration *yyy*, where *yyy* is the iteration at which a stiffness matrix is formed; and *zzz* is the cumulative iteration number for the step. The values of *yyy* and *zzz* don't always coincide because the stiffness matrix is not necessarily reformed every iteration.

VARIABLE	DESCRIPTION
	Node_Data *xxxx yyy* This file maps stiffness matrix to nodes and provides nodal coordinates. LT.0: Like positive values of MTXDMP but dumped data is binary. EQ.|9999|: Simulation is terminated after dumping matrices and right hand side prior to factorization.
IPARM1	For 22 ≤ LSOLVR ≤ 26 only, maximum number of iterations. Default is 10000.
RPARM1	For 22 ≤ LSOLVR ≤ 26 only, absolute tolerance for convergence. Default is 10^{-12}.
RPARM2	For 22 ≤ LSOLVR ≤ 26 only, relative tolerance for convergence. Default is 10^{-8}.
RPARM5	For LSOLVR = 30 only, compression tolerance used to compute a low-rank factorization with the MUMPS solver (see Remark 2). Default is 0.0.
EMXDMP	Flag for dumping elemental stiffness and mass matrices: EQ.0: No dumping GT.0: Dump all elemental matrices every EMXDMP time steps. Output is written as ASCII text and the involved filenames are of the following form: ElmStfMtx *xxxx yyy* This file contains the elemental stiffness matrix at step *xxxx*, iteration *yyy*. ElmMssMtx *xxxx yyy* This file contains the elemental mass matrix at step *xxxx*, iteration *yyy*. LT.0: Like positive values of MTXDMP but dumped data is binary. EQ.|9999|: Simulation is terminated after dumping matrices and right hand side prior to factorization.

VARIABLE	DESCRIPTION
RDCMEM	Starting with LS-DYNA R11, the memory for linear algebra has been moved from static memory allocation to dynamic memory allocation. For implicit applications we have found that some operating systems are not "robust" when queried about how much dynamic memory is free. This factor caps the amount of dynamic memory requested for linear algebra applications to RDCMEM times the amount that the operating system declares available. 0.85 seems to work well for most systems. If you are using a workstation and starting up other applications while running LS-DYNA, you may need to use a number like 0.50.
ABSMEM	Absolute upper bound for the dynamic memory allocated for factorization. The allocated memory will be bounded above by the min(RDCMEM × NWORDS, ABSMEM) where NWORDS is the number of available words as determined by the operating system. If the predicted amount of required memory is less than this value, then less memory than this bound may be allocated. Note that the memory can be specified in this input in the same way as memory is specified on the command line. For instance, an allocation of 3.5 Gwords can be input as 3.5G or 3.5e+9 for ABSMEM.

Remarks:

1. **Direct versus Iterative Solvers.** The linear solver is used to compute the inverse of the global stiffness matrix, which is a costly procedure both in memory and CPU time. Direct solvers apply Gaussian elimination, while iterative solvers successively improve "guesses" at the correct solution. Iterative solvers require far less memory than direct solvers, but may suffer from convergence problems. Generally, iterative solvers are poor for automotive applications, but can be superior for large brick element models, such as solid models in civil engineering.

2. **MUMPS Solver.** Starting with R11.1, we have coupled the external sparse linear solver MUMPS with LS-DYNA. MUMPS can be used either as a direct solver (similar to LSOLVR = 2) with RPARM5 = 0 or as a hybrid direct-iterative solver when RPARM5 > 0. When RPARM5 > 0, an approximate factorization is computed using RPARM5 as a compression threshold used for Block Low-Rank approximations. The approximate factorization is then used as a preconditioner inside a Conjugate Gradient solver; IPARM1, RPARM1, and RPARM2 are used to drive the Conjugate Gradient solver as described above.

Using MUMPS as the linear solver in LS-DYNA is a new feature which should only be used in conjunction with LS-DYNA Implicit Staff.

MUMPS is the property of CERFACS, CNRS, ENS Lyon, INP Toulouse, Inria, Mumps Technologies, and University of Bordeaux.

[1] P. R. Amestoy, I. S. Duff, J. Koster and J.-Y. L'Excellent, A fully asynchronous multifrontal solver using distributed dynamic scheduling, SIAM Journal on Matrix Analysis and Applications, Vol 23, No 1, pp 15-41 (2001).

[2] P. R. Amestoy, A. Buttari, J.-Y. L'Excellent and T. Mary, Performance and scalability of the block low-rank multifrontal factorization on multicore architectures, ACM Transactions on Mathematical Software, Vol 45, Issue 1, pp 2:1-2:26 (2019).

3. **User Supplied Solver.** Starting with R11, we have added a capability for a user supplied solver. Users can follow the template in the file UserLE.F90 to supply their own linear equation solver. Some examples are available in the usermat delivery and are available from Technical Support.

4. **Solver Print Flag.** Select printing of the timing and storage information (LPRINT = 1) if you are comparing performance of linear equation solvers, or if you are running out of memory for large models. Minimum memory requirements for in-core and out-of-core solution are printed. This flag can also be toggled using sense switch "<ctrl-c> lprint". *For best performance, increase available memory using "memory= " on the command line until an IN-CORE solution is indicated.*

   When using solver option 6, LPRINT = 2 and 3 will cause increased printed output of statistics and performance information.

5. **Negative Eigenvalues.** Negative eigenvalues result from underconstrained models (rigid body modes), severely deformed elements, or non-physical material properties. The NEGEV flag allows control to be passed directly to the automatic time step controller when negative eigenvalues are detected. Otherwise, significant numerical roundoff error is likely to occur during factorization, and equilibrium iterations may fail (see *CONTROL_IMPLICIT_AUTO).

6. **Ordering Algorithms and Cost.** The system of linear equations is reordered to optimize the sparsity of the factorization when using direct methods. Reordering is a hard problem, and there is no one best algorithm for all problems. LS-DYNA offers four different methods:

   a) *MMD (Multiple Minimum Degree)*. This reordering method is inexpensive but should only be used for small problems.

b) *METIS.* METIS is from the University of Minnesota. It is the default method for most problems. It is very effective for large problems. METIS, however, is a serial algorithm. Thus, for a large number of MPP processes, you might want to use one of the two parallel algorithms mentioned next.

c) *ParMETIS.* ParMETIS is also from the University of Minnesota. It is the MPP version of METIS. For a large number of processes, it should run much faster than METIS, but there might be some variation in the factorization cost (storage and number of operations). It is available as of R14.

d) *LS-GPart.* LS-GPart is an MPP algorithm developed by Ansys and available as of R11. For a large number of processes, it should run faster than METIS. Quality (in terms of factorization cost) compared to METIS or ParMETIS will depend on the problem.

Reordering cost is included in the symbolic factorization phase of the linear solver (LPRINT ≥ 1). For large models, if this cost exceeds 20% of the numeric factorization cost, it may be more efficient to select the MMD method.

Note that the values of LPRINT and ORDER also affect the eigensolution software. That is, LPRINT and ORDER from this keyword card is applicable to the eigensolution.

Please refer to *CONTROL_IMPLICIT_ORDERING for additional parameters for ordering methods.

7. **Drilling Degree of Freedom.** To avoid a singular stiffness matrix for the implicit analysis of flat shell topologies, some constraint on the drilling degree of freedom is needed. The default method of applying this constraint, DRCM = 4, adds the consistent force vector for consistency and improved convergence as compared to the old method, DRCM = 1.

   In explicit analysis, an unconstrained drilling degree of freedom is usually not a concern since a stiffness matrix is not used. However, special situations may arise in which the user wishes to include additional resisting rotational force in the drilling degree of freedom for improved robustness and/or accuracy. To activate the consistent drilling constraint in explicit analysis, use the input variables DRCPSID and DRCPRM for *CONTROL_SHELL.

8. **NonSymmetric Matrix Solver.** Certain features may break the symmetry of the stiffness matrix. Unless LCPACK is set to 3, these contributions are suppressed or symmetrized by the default symmetric linear solver. However, when LCPACK is set to 3, a more general linear solver lifting the symmetry requirement is used. The solver for nonsymmetric matrices is more computationally expensive.

For eigenvalue analysis, LCPACK = 3 is only implemented in SMP. For static and dynamic implicit analyses, LCPACK = 3 is implemented for both SMP and MPP.

Keywords for which the nonsymmetric contribution is included when LCPACK = 3 are listed below. If none of these features are included in the model, setting LCPACK = 3 offers no benefit but will nevertheless incur additional computational cost.

***CONTACT_..._MORTAR:**

The mortar contact accounts for frictional nonsymmetry in the resulting tangent stiffness matrix; the effects on convergence characteristics have not yet shown to be significant.

***LOAD_SEGMENT_NONUNIFORM:**

The nonsymmetric contribution may be significant for the follower load option, LCID < 0.

***LOAD_SEGMENT_SET_NONUNIFORM:**

The nonsymmetric contribution may be significant for the follower load option, LCID < 0.

***MAT_FABRIC_MAP:**

This stress map fabric model accounts for nonsymmetry in the material tangent modulus, representing the non-linear Poisson effect due to complex interaction of yarns.

***SECTION_SHELL, *SECTION_SOLID:**

Solid element formulation 2, -1, -2 and user defined resultant elements (ELFORM = 101, 102, 103, 104, 105 with NIP = 0) support the assembly and solution of nonsymmetric element matrices.

***SECTION_BEAM:**

Belytschko-Schwer beam (ELFORM = 2) nonsymmetric geometric stiffness contribution is supported.

9. **Constraints.** Explicit treats all the constraints in sequence, which introduces the limitation of applying several constraints on the same DOF. Implicit (with LCPACK), on the other hand, treats all constraints simultaneously, which precludes (circumvents) the limitation on applying multiple constraints on the same nodes or DOFs, as long as they are not in conflict.

*CONTROL_IMPLICIT_SSD_DIRECT

Purpose: Request a direct complex solution to steady state vibration. Currently, this keyword has limited loading and damping capabilities. It is only available for the double precision, SMP versions. Refer to Appendix W for a list of keywords this feature supports.

Card 1	1	2	3	4	5	6	7	8
Variable	ISSFLG	FMIN	FMAX	NFREQ	LOSS	FSPACE	FRACTN	
Type	I	F	F	I	F	I	I	
Default	0	none	FMIN	1	0.0	0	1	

VARIABLE	DESCRIPTION
ISSFLG	Complex steady state vibration flag: EQ.0: Off EQ.1: On
FMIN	Minimum frequency in the solution. Units are Hertz.
FMAX	Maximum frequency in the solution. Units are Hertz.
NFREQ	Number of frequencies in the solution
LOSS	Structural loss factor
FSPACE	Solution frequency assignment strategy: EQ.0: The frequency is interpolated linearly between FMIN and FMAX. This is the default strategy. EQ.1: The frequency is interpolated on a log scale between FMIN and FMAX, so they are biased to lower frequencies. EQ.2: The frequency is interpolated on a fractional octave scale starting with FMIN. Integer FRACTN is the octave fraction. The formula for the active frequency in Hertz is $\text{FACTIVE} = \text{FMIN}\left(2.0^{1/\text{FRACTN}}\right)^{(\text{IFREQ}-1)}$. IFREQ is the i^{th} frequency in the solution. FMAX is ignored.

VARIABLE	DESCRIPTION
	LT.0: |FSPACE| is a load curve ID for assigning active frequencies. The abscissa is frequencies in the solution and the ordinate is the active frequency in Hertz. FMIN and FMAX are ignored.
FRACTN	Octave fraction. For example, FRACTN = 3 means 1/3 octave spacing.

Remarks:

1. **Plot Files.** The complex solution is written to file d3ssd at every solution step. If *DATABASE_BINARY_PLOT output is also requested, then the real part of the solution is written to the d3plot file.

2. **Structural Loading.** Currently, the structural loads are identified with *LOAD_... keywords and limited to zero phase angle.

3. **Acoustics.** Acoustic elements (ELFORMs 8 and 14 on *SECTION_SOLID) with *MAT_ACOUSTIC as the material model are supported for *CONTROL_IMPLICIT_SSD_DIRECT analyses. The coupling of the acoustic fluid and the structural elements is achieved with *BOUNDARY_ACOUSTIC_COUPLING_MISMATCH or by merging acoustic and structural nodes with compatible element faces.

*CONTROL_IMPLICIT_STABILIZATION_{OPTION}

Available options include:

<BLANK>

DYN

SPR

Purpose: This optional card applies to implicit calculations. Artificial stabilization is required for multi-step unloading in implicit springback analysis (see also *CONTROL_IMPLICIT_GENERAL). The DYN option allows setting controls specifically for the dynamic relaxation phase. The SPR option allows setting controls specifically for the springback phase.

Card 1	1	2	3	4	5	6	7	8
Variable	IAS	SCALE	TSTART	TEND				
Type	I	F	F	F				
Default	2	1.0	↓	↓				

VARIABLE	DESCRIPTION
IAS	Artificial Stabilization flag (see Remark 2): EQ.1: active EQ.2: inactive (default)
SCALE	Scale factor for artificial stabilization (see Remark 3). For flexible parts with large springback, like outer body panels, a value of 0.001 may be required. EQ.-n: curve ID = n gives SCALE as a function of time
TSTART	Start time. (Default: immediately upon entering implicit mode)
TEND	End time. (Default: termination time)

Remarks:

1. **Artificial Stabilization.** Artificial stabilization allows springback to occur over several steps. This is often necessary to obtain convergence during equilibrium iterations on problems with large springback deformation. Stabilization is introduced at the start time TSTART, and slowly removed as the end time TEND is approached. Intermediate results are not accurate representations of the fully unloaded state. The end time TEND must be reached exactly for total springback to be predicted accurately.

2. **IAS Defaults.** The default for IAS depends on the analysis type in *CONTROL_IMPLICIT_GENERAL. For "seamless" springback analysis, automatic time step control and artificial stabilization are activated by default. Otherwise, IAS is inactive by default.

3. **Scale Factor.** SCALE is a penalty scale factor similar to that used in contact interfaces. If modified, it should be changed in order-of-magnitude increments at first. Large values suppress springback deformation until very near the termination time, making convergence during the first few steps easy. Small values may not stabilize the solution enough to allow equilibrium iterations to converge.

*CONTROL_IMPLICIT_STATIC_CONDENSATION_{OPTION}

Available options include:

<BLANK>

BINARY

Purpose: Request static condensation of a part to build a reduced linearized model for later computation with *ELEMENT_DIRECT_MATRIX_INPUT. Optionally the analysis can continue using the linearization for the current analysis.

Note: Implicit Static Condensation is not supported in MPP. Please use *CONTROL_IMPLICIT_MODES.

Card Summary:

Card 1. This card is required.

SC_FLAG	SC_NSID	SC_PSID	SE_MASS	SE_STIFF	SE_INERT		

Card 1.1. This card is included if and only if at least one of SE_MASS, SE_STIFF, or SE_INERT is not blank.

SE_FILENAME

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SC_FLAG	SC_NSID	SC_PSID	SE_MASS	SE_STIFF	SE_INERT		
Type	I	I	I	A10	A10	A10		
Default	0	0	0	↓	↓	↓		

Card 1.1	1	2	3	4	5	6	7	8
Variable	SE_FILENAME							
Type	A80							

VARIABLE	DESCRIPTION
SC_FLAG	Static Condensation Control Flag: EQ.0: No static condensation will be performed. EQ.1: Create superelement representation based on static condensation. EQ.2: Use static condensation to build a linearized representation for a part and use that linearized representation in the following analysis.
SC_NSID	Node set ID for nodes to be preserved in the static condensation procedure. Required when SC_FLAG = 1.
SC_PSID	Part set ID for parts to be included in the static condensation procedure. When SC_FLAG = 1, SC_PSID can be used to specify a subset of the model with the default being the entire model. When SC_FLAG = 2, SC_PSID is required. SC_PSID = 0 implies that the entire model is condensed.
SE_MASS	Name of the superelement mass matrix. If left blank, it is not generated.
SE_STIFF	Name of the superelement stiffness matrix. If left blank, it is not generated.
SE_INERT	Name of the superelement inertia matrix, required for gravity loading applications of the superelement. If left blank, it is not generated.
SE_FILENAME	If any of SE_MASS, SE_STIFF, or SE_INERT is blank, then the second line is required and contains the file name for the superelement.

Remarks:

1. **Input and Output Files.** To use this feature, an implicit analysis must be requested using IMFLAG = 1 on *CONTROL_IMPLICIT_GENERAL, and a nonzero termination time must be specified on *CONTROL_TERMINATION. A double precision version of LS-DYNA should be used for best accuracy. The superelement model is written to file SE_FILENAME.

2. **Modes.** Static condensation is the reduction of the global stiffness and mass matrices to a specified set of rows and columns associated with the nodes in the node set SC_NSID. The first and second node set attribute parameters can be optionally used to restrict the translational and rotational degrees of freedom for which modes are requested, respectively, according to the following syntax:

   a) Node set attribute parameters DA1 and A1: translational degree of freedom codes

   b) Node set attribute parameters DA2 and A2: rotational degree of freedom codes

Code	Modes Computed
0	(See note below.)
1	X degree of freedom only
2	Y degree of freedom only
3	Z degree of freedom only
4	X, Y degrees of freedom only
5	Y, Z degrees of freedom only
6	X, Z degrees of freedom only
7	X, Y, Z degrees of freedom

   Setting both node set attributes to zero is equivalent to setting both node set attributes to 7 (X, Y, and Z for translational and rotational degrees of freedom).

   If one node set attribute is nonzero (codes 1 to 7) and the other node set attribute is zero, then the zero attribute means NO degrees of freedom are considered. For example, if DA1 = 2 and DA2 = 0, then only the Y-translational degree of freedom modes are calculated.

3. **Superelements.** The user can create the superelement representation of the reduced model by specifying the SE_MASS, SE_STIFF, SE_INERT and SE_FILENAME fields. This implementation does not include SE_DAMP. The file, by default is written in the Nastran DMIG file format and can be used as input to *ELEMENT_DIRECT_MATRIX_INPUT. The keyword option BINARY can be used to create a binary representation for the superelement which can be used with *ELEMENT_DIRECT_MATRIX_INPUT_BINARY to reduce the file size.

4. **Comparison to *CONTROL_IMPLICIT_MODES.** Static Condensation is equivalent to using only constraint modes with *CONTROL_IMPLICIT_MODES. Static Condensation does have the ability to continue the analysis using the linear representation for a part set.

*CONTROL_IMPLICIT_TERMINATION

Purpose: Specify termination criteria for implicit transient simulations.

Card 1	1	2	3	4	5	6	7	8
Variable	DELTAU	DELTA1	KETOL	IETOL	TETOL	NSTEP	ABSTOL	
Type	F	F	F	F	F	I	F	
Default	0.0	0.0	0.0	0.0	0.0	3	0.0	

VARIABLE	DESCRIPTION
DELTAU	Terminate based on relative total displacement in the Euclidean norm. GT.0.0: terminate when displacement in the Euclidean norm for last time step relative to the total displacement in the Euclidean norm is less than DELTAU.
DELTA1	Terminate based on relative total displacement in the max norm. GT.0.0: terminate when displacement in the max norm for last time step relative to the total displacement in the max norm is less than DELTAU.
KETOL	Terminate based on kinetic energy GT.0.0: terminate when kinetic energy drops below KETOL for NSTEP consecutive implicit time steps.
IETOL	Terminate based on internal energy GT.0.0: terminate when internal energy drops below IETOL for NSTEP consecutive implicit time steps.
TETOL	Terminate based on total energy GT.0.0: terminate when total energy drops below TETOL for NSTEP consecutive implicit time steps.
NSTEP	Number of steps used in the early termination tests for kinetic, internal, and total energy.

VARIABLE	DESCRIPTION
ABSTOL	Terminate based on absolute total displacement in the Euclidean norm. GT.0.0: terminate when displacement in the Euclidean norm for last time step is less than ABSTOL.

Remarks:

For some implicit applications it is useful to terminate when there is no change in displacement or low energy. This keyword provides the ability to specify such a stopping criteria to terminate the simulation prior to ENDTIM.

*CONTROL_LSDA

This keyword is used to globally control data present in included dynain.lsda files generated by *INTERFACE_SPRINGBACK_LSDYNA with FTYPE = 3. The primary function is to provide the flexibility of not having to know *a priori* how to define *INTERFACE_-SPRINGBACK but be able to modify this *a posteriori* without having to rerun the first simulation. For examples, see remarks.

Card 1	1	2	3	4	5	6	7	8
Variable	NPEXCL							
Type	I							
Default	0							

Excluded Parts Card. If NPEXCL ≠ 0, include as many of this card as required to exclude NPEXCL part IDs.

Card 1.1	1	2	3	4	5	6	7	8
Variable	P1	P2	P3	P4	P5	P6	P7	P8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
NPEXCL	Number of parts to exclude from the dynain.lsda files
P1 - P8	Part IDs to exclude from dynain.lsda

Remarks:

1. **Excluding Parts Example.** Assume a forming simulation is performed with 2 deformable parts (say part 1 and part 2) and both are for some reason included in the resulting dynain.lsda. In a later stage, a springback of only part 1 is desired without the need of part 2. Instead of rerunning the forming simulation and outputting only part 1 to dynain.lsda, the springback can be performed by excluding part 2 from the springback simulation. This is done through NPEXCL = 1 and P1 = 2.

*CONTROL_MAT

Purpose: Define global control parameters for material model related properties.

Card 1	1	2	3	4	5	6	7	8
Variable	MAEF		UMCHK					
Type	I		I					
Default	0		0					

VARIABLE	DESCRIPTION
MAEF	Failure options: EQ.0: all *MAT_ADD_EROSION, *MAT_ADD_DAMAGE_-DIEM, and *MAT_ADD_DAMAGE_GISSMO definitions are active. EQ.1: switch off all *MAT_ADD_EROSION, *MAT_ADD_-DAMAGE_DIEM, and *MAT_ADD_DAMAGE_GISSMO definitions globally. This feature is useful for larger models where removing those cards is inconvenient.
UMCHK	User material check. In the first calculation cycle, LS-DYNA checks if user-defined material models are applied or whether only the default, unmodified subroutines already present in the native dyn21 files are called. EQ.0: Warning is issued if only unmodified subroutines are called. EQ.1: Error termination occurs if only unmodified subroutines are called.

*CONTROL_MPP

Purpose: Set control parameters for MPP specific features.

*CONTROL_MPP_CONTACT_GROUPABLE

*CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS

*CONTROL_MPP_DECOMPOSITION_AUTOMATIC

*CONTROL_MPP_DECOMPOSITION_BAGREF

*CONTROL_MPP_DECOMPOSITION_CHECK_SPEED

*CONTROL_MPP_DECOMPOSITION_CONTACT_DISTRIBUTE

*CONTROL_MPP_DECOMPOSITION_CONTACT_ISOLATE

*CONTROL_MPP_DECOMPOSITION_DEFORMED_GEOMETRY

*CONTROL_MPP_DECOMPOSITION_DISABLE_UNREF_CURVES

*CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_ALE_ELEMENTS

*CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_SPH_ELEMENTS

*CONTROL_MPP_DECOMPOSITION_ELCOST

*CONTROL_MPP_DECOMPOSITION_FILE

*CONTROL_MPP_DECOMPOSITION_FLAG_STRESS_STRAIN_CURVE

*CONTROL_MPP_DECOMPOSITION_METHOD

*CONTROL_MPP_DECOMPOSITION_NODISTRIBUT_DES_ELEMENTS

*CONTROL_MPP_DECOMPOSITION_NUMPROC

*CONTROL_MPP_DECOMPOSITION_OUTDECOMP

*CONTROL_MPP_DECOMPOSITION_PARTS_DISTRIBUTE

*CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE

*CONTROL_MPP_DECOMPOSITION_RCBLOG

*CONTROL_MPP_DECOMPOSITION_REDECOMPOSITION

*CONTROL_MPP_DECOMPOSITION_SCALE_CONTACT_COST

*CONTROL_MPP_DECOMPOSITION_SCALE_FACTOR_SPH

*CONTROL_MPP_DECOMPOSITION_SHOW

*CONTROL_MPP_DECOMPOSITION_TRANSFORMATION

*CONTROL_MPP_IO_LSTC_REDUCE

*CONTROL_MPP_IO_NOBEAMOUT

*CONTROL_MPP_IO_NOD3DUMP

*CONTROL_MPP_IO_NODUMP

*CONTROL_MPP_IO_NOFULL

*CONTROL_MPP_IO_SWAPBYTES

*CONTROL_MPP_MATERIAL_MODEL_DRIVER

*CONTROL_MPP_PFILE

*CONTROL_MPP_REBALANCE

*CONTROL_MPP_CONTACT_GROUPABLE

Purpose: Allow for global specification that the GROUPABLE algorithm should be enabled/disabled for contacts when running MPP.

Card 1	1	2	3	4	5	6	7	8
Variable	GRP							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
GRP	The sum of these available options (in any combination that makes sense): 1: Turn on GROUPABLE for all non-tied contacts 2: Turn on GROUPABLE for all tied contacts 4: Turn off GROUPABLE for all non-tied contacts 8: Turn off GROUPABLE for all tied contacts

Remarks:

The GROUPABLE algorithm is an alternate MPP communication algorithm for various single surface (including AUTOMATIC_GENERAL), nodes_to_surface, surface_to_surface, ERODING, and option SOFT = 2 contacts. This groupable algorithm does not support all contact options, including MORTAR, and is still under development. It can be significantly faster and scale better than the normal algorithm when there are more than two or three applicable contact types defined in the model. Its intent is to speed up the contact processing but not to change the behavior of the contact.

This keyword will override any setting of the GRPABLE parameter on the *CONTACT_…_MPP card and is intended as a way to quickly experiment with this feature. The equivalent pfile option is "contact { groupable GRP }" where GRP is an integer as described above.

*CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS_{OPTION}

Purpose: Allow users to distribute certain part(s) to all processors or to isolate certain part(s) in a single processor. This keyword supports multiple entries. Each entry is be processed as a separate region for decomposition.

When this keyword is part of an included file and the LOCAL option is given, the decomposition will be done in the coordinate system of the included file, which may be different from the global system if the file is included using the *INCLUDE_TRANSFORM keyword.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYPE	NPROC	FRSTP	NPTOT			
Type	I	I	I	I	I			
Default	none	none	none	none	0			

VARIABLE	DESCRIPTION
ID	Part ID/part set ID
TYPE	EQ.0: part ID to be distributed to all processors EQ.1: part set ID to be distributed to all processors EQ.10: part ID to be lumped into one processor EQ.11: part Set ID to be lumped into one processor EQ.20: part ID to be lumped into one processor with MPP load balanced EQ.21: part set ID to be lumped into one processor with MPP load balanced.
NPROC	Used only for TYPE equal to 0 or 1. Number of processors that will be used for decomposition. This part ID/part set ID will be distributed to NPROC of the processors.
FRSTP	Used only for TYPE equal to 0 or 1. Starting MPP rank ID (rank starts from 0).

VARIABLE	DESCRIPTION
NPTOT	Total number of processors for (NPROC, FRSTP): EQ.0: use current numproc. GT.0: if max(numproc,numproc_dc) is different than NPTOT, (NPROC, FRSTP) will be rescaled by NPTOT. This feature allows the same input to be used with changing computing resources.

Remarks:

Since this keyword supports multiple entries, each line will be treated as a region for the decomposition. Therefore, the equivalent method using a pfile will be different depending on TYPE and whether entity being decomposed is a part or parts set as shown in the table below.

TYPE	PFILE EQUIVALENT
0	region { parts PID nproc NPROC FRSTP }
1	region { partsets PSID nproc NPROC FRSTP }
10	region { parts PID lumped }
11	region { partsets PSID lumped }
20	region { parts PID together }
21	region { partsets PSID together }

*CONTROL_MPP_DECOMPOSITION_AUTOMATIC

Purpose: Instructs the program to apply a simple heuristic to try to determine the proper decomposition for the simulation.

There are no input parameters. The existence of this keyword triggers the automated decomposition. This option should not be used if there is more than one occurrence of any of the following options in the model:

*INITIAL_VELOCITY

*CHANGE_VELOCITY

*BOUNDARY_PRESCRIBED_MOTION

And the following control card must not be used:

*CONTROL_MPP_DECOMPOSITION_TRANSFORMATION

For the general case, it is recommended that you specify the proper decomposition using the command *CONTROL_MPP_DECOMPOSITION_TRANSFORMATION instead.

*CONTROL_MPP_DECOMPOSITION_BAGREF

Purpose: With this card LS-DYNA performs decomposition according to the airbag's reference geometry, rather than the folded geometry.

Other than BAGID values this card takes no input parameters. The initial geometry may lead to a poor decomposition once the bag is deployed. This option will improve load balancing for the fully deployed geometry.

Optional card(s) for selected reference geometry ID

Card 1	1	2	3	4	5	6	7	8
Variable	BAGID1	BAGID2	BAGID3	BAGID4	BAGID5	BAGID6	BAGID7	BAGID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
BAGID*i*	ID defined in *AIRBAG_REFERENCE_GEOMETRY_ID or *AIRBAG_SHELL_REFERENCE_GEOMETRY_ID

Bags specified in the optional cards will be decomposed based on the reference geometry. If there is no card given, *all* bags will be decomposed by their reference geometry.

Remarks:

Command in partition file (pfile): BAGREF. The option for selecting particular airbags is only available when using keyword input.

*CONTROL_MPP_DECOMPOSITION_CHECK_SPEED

Purpose: Modifies the decomposition depending on the relative speed of the processors involved.

There are no input parameters. Use of this keyword activates a short floating point timing routine to be executed on each processor. The information gathered is used during the decomposition, with faster processors being given a relatively larger portion of the problem. This option is not recommended on homogeneous systems.

*CONTROL_MPP_DECOMPOSITION_CONTACT_DISTRIBUTE_{OPTION}

Purpose: Ensures that the indicated contact interfaces are distributed across all processors, which can lead to better load balance for large contact interfaces. If this appears in an included file and the LOCAL option is used, the decomposition will be done in the coordinate system of the included file, which may be different from the global system if the file is included through *INCLUDE_TRANSFORM.

Card 1	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5			
Type	I	I	I	I	I			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
ID1	First contact interface ID to distribute. If no contact ID's are specified, the number given here corresponds to the order of the interfaces as they appear in the input, with the first being 1.
ID2, ID3, ID4, ID5	Remaining interfaces ID's to distribute.

Remarks:

Up to 5 contact interface ID's can be specified. The decomposition is modified as follows: First, all the elements involved in the first contact interface are decomposed across all the processors. Then all the elements involved in the second contact interface (excluding any already assigned to processors) are distributed, and so on. After all the contact interfaces given are processed, the rest of the input is decomposed in the normal manner. This will result in each processor having possibly several disjoint portions of the input assigned to it, which will increase communications somewhat. However, this can be offset by improved load balance for the contact. It is generally recommended that at most one or two interfaces be specified, and then only if they are of substantial size relative to the whole problem.

*CONTROL_MPP_DECOMPOSITION_CONTACT_ISOLATE

Purpose: Ensures that the indicated contact interfaces are isolated on a single processor, which can lead to decreased communication.

Card 1	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5			
Type	I	I	I	I	I			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
ID1	First contact interface ID to isolate. If no contact ID's are specified, the number given here corresponds to the order of the interfaces as they appear in the input, with the first being 1.
ID2, ID3, ID4, ID5	Remaining interfaces ID's to isolate.

Remarks:

Up to 5 contact interfaces can be specified. The decomposition is modified as follows: First, all the elements involved in the first contact interface ID are assigned to the first processor. Then all the elements involved in the second contact interface ID (excluding any already assigned to processors) are assigned to the next processor, and so on. After all the contact interfaces given are processed, the rest of the input is decomposed in the normal manner. This will result in each of the interfaces being processed on a single processor. For small contact interfaces this can result in better parallelism and decreased communication.

*CONTROL_MPP_DECOMPOSITION_DEFORMED_GEOMETRY

Purpose: Because of distortion due to deformation or changing contacts due to rotation, a new decomposition of the deformed geometry may need to be performed during a full deck restart for better load balancing. This option causes the new load balance. This feature may be useful, for instance, with bird strike since the contacts change as the fan blades rotate.

SPH Card. This card is optional.

Card 1	1	2	3	4	5	6	7	8
Variable	SPH							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
SPH	Flag for inclusion of inactive SPH elements: EQ.0: Exclude inactive SPH elements in the new decomposition (default). EQ.1: Include inactive SPH elements in the new decomposition.

Remarks:

Command in partition file (pfile): decomposition { defgeo } or decomposition { defgeo 1 }.

*CONTROL_MPP_DECOMPOSITION_DISABLE_UNREF_CURVES

Purpose: Disable unreferenced time dependent load curves for the following keywords:

*BOUNDARY_PRESCRIBED_MOTION_NODE

*LOAD_NODE

*LOAD_SHELL_ELEMENT

*LOAD_THERMAL_VARIABLE_NODE

The details of this operation are reported in each processor's scratch scr#### file. This will skip the curve evaluation on each cycle, and improve the parallel efficiency.

Remarks:

Command in partition file (pfile): DUNREFLC.

*CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_ALE_ELEMENTS

Purpose: Ensures ALE elements are evenly distributed to all processors.

There are no input parameters and the card below is optional. ALE elements usually have a larger computational cost than other element types, and it is better to distribute them to all CPUs for better load balance. This keyword causes DYNA/MPP to extract ALE parts from the input and then evenly distribute them to all the processors.

FSI/ALE Mesh Card. This card is optional.

Card 1	1	2	3	4	5	6	7	8
Variable	OVERLAP							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
OVERLAP	For FSI models where structures are inside ALE meshes (see *CONSTRAINED_LAGRANGE_IN_SOLID), flag to decompose the structure and ALE domains together instead of first the structure and then the ALE (see Remark 2). EQ.0: Off EQ.1: On

Remarks:

1. **Partition File.** Command in partition file (pfile): ALEDIST.

2. **ALE/FSI Overlap.** Most of the processors will have to deal with MPP subdomains from the structure and ALE meshes: a portion of the ALE computational domain and a portion of the structure meshes. The default decomposition (first divide the structures, then ALE) does not always overlap these subdomains. The more they overlap, the less the MPP communications due to the coupling cost. Cutting the ALE and structure meshes together allows their MPP subdomains to be as inclusive as possible.

*CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_SPH_ELEMENTS

Purpose: Ensures SPH elements are evenly distributed to all processors

There are no input parameters. SPH elements usually have higher computational cost than other type of elements and it is better to distribute them to all CPU for better load balance. The existence of this keyword causes DYNA/MPP to extract SPH parts from input and then evenly distributed to all processors.

Remarks:

Command in partition file (pfile): SPHDIST.

*CONTROL_MPP_DECOMPOSITION_ELCOST

Purpose: Instructs the program to use a hardware specific element cost weighting for the decomposition

Card 1	1	2	3	4	5	6	7	8
Variable	ITYPE							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
ITYPE	Hardware specific cost profile. EQ.1: Fujitsu PrimePower EQ.2: Intel IA 64, AMD Opteron EQ.3: Intel Xeon 64 EQ.4: General profile

Remarks:

Command in partition file (pfile): elcost itype.

*CONTROL_MPP_DECOMPOSITION_FILE_{OPTION}

Purpose: Allow for pre-decomposition and a subsequent run or runs without having to do the decomposition.

OPTION specifies the action type. The following options are accepted:

<BLANK>

READ

WRITE

When the keyword option READ is used, LS-DYNA expects you to have placed the pre-decomposition file in the working directory. The job will be terminated if the file is not there. When WRITE is used, LS-DYNA will create the file. The job will be terminated if the pre-decomposition file is in the working directory.

Card 1	1	2	3	4	5	6	7	8
Variable	NAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
NAME	Name of a file containing (or to contain) a decomposition record.

Remarks:

If the indicated file does not exist, it is created with a copy of the decomposition information from this run. If the file exists, it is read and the decomposition steps can be skipped. The original run that created the file must be for a number of processors that is a multiple of the number of processors currently being used. Thus, a problem can be decomposed once for, say, 48 processors. Subsequent runs are then possible on any number that divides 48: 1, 2, 3, 4, 6, etc. Since the decomposition phase generally requires more memory than execution, this allows large models to be decomposed on one system and run on another (provided the systems have compatible binary formats).

*CONTROL_MPP_DECOMPOSITION_FLAG_STRESS_STRAIN_CURVE

Purpose: Flag to skip evaluating non-time dependent stress strain curves on every cycle to save CPU time. The stress strain curves will only be evaluated as needed in the material routines. Currently, this keyword only affects curves used with *MAT_024.

Remarks:

Command in partition file (pfile): SORTSSLC.

*CONTROL_MPP_DECOMPOSITION_METHOD

Purpose: Specify the decomposition method to use.

Card 1	1	2	3	4	5	6	7	8
Variable	NAME							
Type	A80							
Default	RCB							

VARIABLE	DESCRIPTION
NAME	Name of the decomposition method to use. There are currently two options: EQ."RCB": recursive coordinate bisection EQ."GREEDY": a simple heuristic method In almost all cases the RCB method is superior and should be used.

*CONTROL_MPP_DECOMPOSITION_NODISTRIBUTE_DES_ELEMENTS

Purpose: By default, DES elements are treated as a single region and distributed to all processors. For traditional MPP execution in which LS-DYNA performs a single decomposition at the beginning of the run, the default treatment of distributing to all processors yields better load balancing. For MPP that includes repartition of the model during execution with *CONTROL_MPP_DECOMPOSITION_REDECOMPOSITION, putting DES elements and couple FE elements on the same processor leads to better performance. This keyword is for the second case. It disables the default distribution and causes current geometry to be used for decomposition.

There are no input parameters.

Remarks:

Command in partition file (pfile): DESNODIST.

*CONTROL_MPP_DECOMPOSITION_NUMPROC

Purpose: Specify the number of processors for decomposition.

Card 1	1	2	3	4	5	6	7	8
Variable	N							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
N	Number of processors for decomposition.

Remarks:

This is used in conjunction with the CONTROL_MPP_DECOMPOSITION_FILE command to allow for later runs on different numbers of processors. By default, the decomposition is performed for the number of processors currently being used. However, a different value can be specified here. If N > 1 and only one processor is currently being used, the decomposition is done and then the program terminates. If N is *not* a multiple of the current number of processors, then it is ignored the execution proceeds with the current number of processors. Otherwise, the decomposition is performed for N processors, and the execution continues using the current number of processors.

*CONTROL_MPP_DECOMPOSITION_OUTDECOMP

Purpose: Instructs the program to output element's ownership data to file for post-processor to show state data from different processors.

Card 1	1	2	3	4	5	6	7	8
Variable	TYPE							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
ITYPE	Sets the format for the output file. EQ.1: database in LS-PrePost format: decomp_parts.lsprepost EQ.2: database in animator format: decomp_parts.ses EQ.3: database in LS-PrePost format with d3plot state number. This file allows LS-PrePost to show the matching d3plot with the decomposition for *CONTROL_MPP_DECOMPOSITION_REDECOMPOSITION decomp_parts.lsprepost_s######

Remarks:

1. **PFILE.** Command in partition file (pfile): OUTDECOMP ITYPE.

2. **LS-PrePost.** When ITYPE is set to 1, the elements assigned to any particular core can be viewed and animated by LS-PrePost by (1) reading the d3plot data, and then (2) selecting *Models* → *Views* → *MPP* → *Load* → *decomp_parts.lsprepost*.

*CONTROL_MPP_DECOMPOSITION_PARTS_DISTRIBUTE_{OPTION}

Purpose: Distribute the parts given by this keyword to all processors before the decomposition for the rest of the model is performed.

If this appears in an included file and the **LOCAL** option is used, the decomposition will be done in the coordinate system of the included file, which may be different from the global system if the file is included via *INCLUDE_TRANSFORM.

Card 1	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
ID1, ID2, ID3, …	For each ID: GT.0: ID is a part number. LT.0: |ID| is a part set number. All parts defined in this card will be treated as a single region to be decomposed.

Remarks:

1. **Decomposition.** Up to 1000 parts/part sets can be specified. The decomposition is modified as follows: the elements involved in the given parts are put into a separate domain from rest of the model and then distributed to all processors to balance their computational cost. Then the remainder of the model will be distributed in the usual way.

2. **PFILE.** This is equivalent to the pfile command (for example, if ID1 - ID3 are part IDs and ID4 - ID6 are part set IDs):

   ```
   decomp { region { parts ID1 ID2 ID3 or partsets ID4 ID5 ID6 } }
   ```

   The part set IDs, however, are positive when used in the pfile.

CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE_*{OPTION}

Purpose: Distribute the part sets given in this option to all processors before the decomposition for the remainder of the model is performed.

If this appears in an included file and the **LOCAL** option is given, the decomposition will be done in the coordinate system of the included file, which may be different from the global system if the file is included via *INCLUDE_TRANSFORM.

Card 1	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
ID1, ID2, ID3, …	Part Set ID to be distributed. All parts in ID1 will be shared across all processors. Then all parts in ID2 will be distributed, and so on.

Remarks:

Any number of part sets can be specified. Each part set is distributed across all processors, in the order given. The order may be significant if, in particular, a part ID is in more than one set. Distribution of these parts is done before any decomposition specifications given in the pfile.

*CONTROL_MPP_DECOMPOSITION_RCBLOG

Purpose: Causes the program to record decomposition information in the indicated file, for use in subsequent analyses.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	Name of output file where decomposition history will be recorded. This file can be used as the pfile for later analyses.

Remarks:

Command in parallel option file (pfile): rcblog filename.

*CONTROL_MPP_DECOMPOSITION_REDECOMPOSITION_{OPTION}

Available options are:

<BLANK>

ONCE

ONCE causes this keyword to be disabled after the model has been redecomposed based on information collected from the initial step.

Purpose: Redecompose a model at a given time interval. Other decomposition directives given in a pfile or defined using *CONTROL_MPP_DECOMPOSITION_*OPTION* remain in effect for each redecomposition. Redecomposition is intended to improve computational efficiency in simulations where large relative displacements between nodes develop and change as the simulation progresses.

Redecomposition relies on LS-DYNA's full deck restart capability and therefore will work correctly only to the extent that a full deck restart works correctly. We advise examining results carefully to ensure that history variable values, such as stress values, present before redecomposition are present after redecomposition.

Card 1	1	2	3	4	5	6	7	8
Variable	FREQ	DEFGEO	WEIGHT	REMSPH	STIME	SAMPT		
Type	F	I	F	I	F	F		
Default	none	1	1.0	0	0.0	None		

VARIABLE	DESCRIPTION
FREQ	Determines the number of redecompositions during the solution: LT.0: |FREQ| rounded to the nearest integer is the number of redecompositions during the solution. GT.0: FREQ is the time interval between redecompositions.
DEFGEO	Geometry for decomposition: EQ.1: Use current geometry for decomposition. When applied to a model containing SPH, deactivated SPH elements are not considered in the partition. This will give

VARIABLE	DESCRIPTION
	better load balancing if SPH elements are deleted during the simulation. EQ.2: Use current geometry for decomposition (same as 1 if applied to a non-SPH model). When applied to a model containing SPH, all SPH elements are considered in the partition. This will give better load balancing if SPH elements are reactivated during the simulation.
WEIGHT	Element cost scale factor for an element in contact or an element that has undergone plastic strain. If the element is under contact and has plastic strain, the weight will be doubled. Since the element cost is measured from calculated quantities, the results will remain consistent between runs with the same input and decomposition unlike using SAMPT below.
REMSPH	Flag to remove deactivated SPH particles: EQ.0: Keep deactivated particles. EQ.1: Remove deactivated particles. EQ.2: Remove deactivated particles. Also, particles generated by the *DEFINE_SPH_MESH_BOX keyword are fragmented and added to the input file as needed during each redecomposition phase.
STIME	Start time for redecomposition
SAMPT	Time interval for collecting element cost profile to use in the next REDECOMP step. Since the cost profile is based on the measurement of elapsed time, the timing profile may change between runs. It may produce different numerical results from multiple runs using identical input. GT.0: Sampling from beginning of each redecomposition for length SAMPT (t to t + SAMPT). If SAMPT ≥ FREQ, then the sampling will occur for the entire time interval, FREQ. LT.0: Sampling from before ending of each redecomposition through to the next redecomposition (t + FREQ − SAMPT to t + FREQ)

*CONTROL_MPP_DECOMPOSITION_SCALE_CONTACT_COST

Purpose: Instructs the program to apply a scale factor to the list of contacts to change the partition weight for the decomposition.

Card 1	1	2	3	4	5	6	7	8
Variable	SF	ID1	ID2	ID3	ID4	ID5	ID6	ID7
Type	F	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
SF	Scale factor for the contact segments listed in the interface ID.
ID1, ID2, …	interfaces ID's to be considered for scaling. Include second card if necessary.

Remarks:

Up to 15 contact interfaces ID can be specified. The decomposition is modified by applying this scale factor to the default computational cost of elements for the given contact interface ID.

Command in partition file (pfile): CTCOST ID1, ID2, …, SF.

*CONTROL_MPP_DECOMPOSITION_SCALE_FACTOR_SPH

Purpose: Instructs the program to apply a scale factor to SPH elements to change the partition weight for the decomposition.

Card 1	1	2	3	4	5	6	7	8
Variable	SF							
Type	F							
Default	none							

VARIABLE	DESCRIPTION
SF	Scale factor

Remarks:

Command in partition file (pfile): SPHSF SF.

*CONTROL_MPP_DECOMPOSITION_SHOW

Purpose: The keyword writes the final decomposition to the d3plot database. There are no input parameters.

This keyword causes MPP LS-DYNA to terminate immediately after the decomposition phase without performing an analysis. The resulting d3plot database is designed to allow visualization of the decomposition by making each part correspond to the group of solids, shells, beams, thick shells, or SPH particles assigned to a particular processor. For example, in a model that includes various element types including solids, part 1 corresponds to the solid elements assigned to processor 1, part 2 corresponds to the solid elements assigned to processor 2, and so on.

This command can be used in conjunction with the *CONTROL_MPP_DECOMPOSITION_NUMPROC command to run on one processor and produce a d3plot file to visualize the resulting decomposition for the number of processors specified in *CONTROL_MPP_DECOMPOSITION_NUMPROC.

*CONTROL_MPP_DECOMPOSITION_TRANSFORMATION

Purpose: Specifies transformations to apply to modify the decomposition.

There are 10 different kinds of decomposition transformations available. For a detailed description of each, see Appendix O the LS-DYNA MPP user guide.

The data cards for this keyword consist of transformation operations. Each operation, depending on its type, involves either one or two additional cards. The input deck may include an arbitrary number of transformations with the next keyword, "*" card, terminating this input.

Transformation Card 1. For each transformation this card is required.

Card 1	1	2	3	4	5	6	7	8
Variable	TYPE	V1	V2	V3	V4	V5	V6	
Type	A10	F	F	F	F	F	F	
Default	none	0.0	0.0	0.0	0.0	0.0	0.0	

Transformation Card 2. Additional card for TYPE set to one of VEC3, C2R, S2R, MAT.

Card 2	1	2	3	4	5	6	7	8
Variable	V7	V8	V9					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
TYPE	Which transformation to apply. The allowed values are RX, RY, RZ, SX, SY, SZ, VEC3, C2R, S2R, and MAT.
V1 - V9	For type set to either RX, RY, RZ, SX, SY, or SZ: The parameter V1 gives either the angle of rotation (RX, RY, RZ) or the magnitude for the scaling (SX, SY, SZ). The remaining parameters are ignored.

VARIABLE	DESCRIPTION
	For type set to either VEC3, C2R, S2R, or MAT: All parameters are used. See the appendix for the "pfile."

Remarks:

When using scale factors (SX, SY, SZ), specify a non-zero scale factor; if left blank, it will be set to use 0.0.

*CONTROL_MPP_IO_LSTC_REDUCE

Purpose: Use LST's own reduce routine to consistently sum floating point data among processors. There are no input parameters.

Remarks:

1. **PFILE.** The related command in the partition file (pfile) is: lstc_reduce.

2. **Motivation behind this Keyword.** LS-DYNA/MPP uses the Recursive Coordinates Bisection (RCB) algorithm to divide the model element-wise into sub-domains; each sub-domain (group of elements) will be executed in its own CPU core. For shared nodes with data on more than one processor, both internal and external forces must be added across the processors to determine the correct loading; this is called the "REDUCE" operation in MPI.

   Adding up the values across processors uses the standard MPI interface provided by different vendors, such as Platform MPI, Intel MPI, Open MPI, etc. Each vendor has its own algorithm for better communication. Therefore, the order of summation for shared nodes varies depending on the vendor's algorithm as well as hardware differences, namely, the number of cores per socket. This numerical noise triggers undesired bifurcation for explicit analysis with lots of integration cycles.

   LSTC_REDUCE ensures a deterministic summation order to provide numerical consistency. This keyword gives identical results while using the same decomposition and core counts but different MPI algorithms.

*CONTROL_MPP_IO_NOBEAMOUT

Purpose: Suppress beam, shell, and solid element failure messages in the d3hsp and message files. There are no parameters for this keyword.

Remarks:

Command in parallel option file (pfile): nobeamout.

*CONTROL_MPP_IO_NOD3DUMP

Purpose: Suppresses the output of the d3dump and runrsf files.

There are no input parameters for this keyword.

*CONTROL_MPP_IO_NODUMP

Purpose: Suppresses the output of all dump files and full deck restart files.

There are no input parameters. The existence of this keyword causes the d3dump and runrsf file output routines to be skipped. It also suppresses output of the full deck restart files d3full and runfull.

*CONTROL_MPP_IO_NOFULL

Purpose: Suppresses the output of the full deck restart files.

There are no input parameters. The existence of this keyword suppresses the output of the full deck restart files d3full and runfull.

*CONTROL_MPP_IO_SWAPBYTES

Purpose: Swap bytes on some of the output files.

There are no input parameters. The existence of this keyword causes the d3plot file and the "interface component analysis" file to be output with bytes swapped. This is to allow further processing of data on a different machine that has big endian vs. little endian incompatibilities compared to the system on which the analysis is running.

*CONTROL_MPP_MATERIAL_MODEL_DRIVER

Purpose: Enable this feature in MPP mode. To allow MPP reader to pass the input phase even without any nodes and elements but using only one processor.

*CONTROL_MPP_PFILE

Purpose: Provide keyword support for the MPP "p=" pfile options

All lines of input up to the next keyword card will be copied to a temporary file which is effectively pre-pended to the "p=" file given on the command line (even if no such file is given). This allows all options available via the "p=" file to be specified in the keyword input. The only restriction is that pfile directives in the "directory" section are not available, as those must be processed before the keyword input file is read. See the "LS-DYNA MPP User Guide" in the appendix for details of the available pfile commands and their syntax.

*CONTROL_MPP_REBALANCE

Purpose: Specify parameters associated with dynamic load balancing

Card 1	1	2	3	4	5	6	7	8
Variable	NCYCLE	ICOOR	ICOST	THRES				
Type	I	I	I	F				
Default	optional	0	0	1.0				

VARIABLE	DESCRIPTION
NCYCLE	Number of cycles between rebalance steps
ICOOR	Coordinates used in rebalance: EQ.0: Current coordinates NE.0: Coordinates at $t = 0$
ICOST	Element costs used in rebalance: EQ.0: Time costs EQ.1: Original
THRES	Percent threshold for rebalancing when performing in-core adaptivity (see Remark 1). For in-core adaptivity, only include this field.

Remarks:

1. **In-Core Adaptivity Threshold.** After each adaptive step, the percent increase in the number of shell elements since the last rebalance is computed on each processor. If the maximum of these values minus the minimum exceeds this threshold, then a rebalance is performed.

2. **Supported Features.** This keyword is supported for the features listed below. Models that contain features not included in this list will have unpredictable results.

   - Nodes
   - Shells, solids, beams, thick shells, and discrete elements

- Seatbelt features (sliprings, retractors, etc.)
- Contact except SOFT = 2, CONSTRAINT, and beam
- Control volumes
- Velocity boundary conditions
- Nodal SPCs
- Files: d3plot, elout, nodout, bndout, glstat, abstat, deforc, jntforce, rcforc. sbtout, and sleout
- Adaptive constraints
- In-core adaptivity
- Rigid walls
- Joints
- Nodal rigid bodies
- Pressure loads
- Loads applied to nodes
- Lumped masses
- Cross sections
- Constrained sets (welds)

*CONTROL_NONLOCAL

Purpose: Allocate additional memory for *MAT_NONLOCAL option.

Card 1	1	2	3	4	5	6	7	8
Variable	MEM							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
MEM	This parameter is no longer used and any value input will be ignored. Memory is allocated dynamically as needed.

*CONTROL_OUTPUT

Purpose: Set miscellaneous output parameters.

Card Summary:

Card 1. This card is required.

NPOPT	NEECHO	NREFUP	IACCOP	OPIFS	IPNINT	IKEDIT	IFLUSH

Card 2. This card and all remaining cards are optional.

IPRTF	IERODE	TET10S8	MSGMAX	IPCURV	GMDT	IP1DBLT	EOCS

Card 3. This card and all remaining cards are optional.

TOLEV	NEWLEG	FRFREQ	MINFO	SOLSIG	MSGFLG	CDETOL	IGEOM

Card 4. This card and all remaining cards are optional.

PHSCHNG	DEMDEN	ICRFILE	SPC2BND	PENOUT	SHLSIG	HISNOUT	ENGOUT

Card 5. This card is optional.

INSF	ISOLSF	IBSF	ISSF	MLKBAG			

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	NPOPT	NEECHO	NREFUP	IACCOP	OPIFS	IPNINT	IKEDIT	IFLUSH
Type	I	I	I	I	F	I	I	I
Default	0	0	0	0	0.	0	100	5000

VARIABLE	DESCRIPTION
NPOPT	Print suppression during input phase flag for the d3hsp file: EQ.0: No suppression, EQ.1: Nodal coordinates, element connectivities, rigid wall definitions, nodal SPCs, initial velocities, initial strains,

VARIABLE	DESCRIPTION
	adaptive constraints, and SPR2/SPR3 constraints are not printed.
NEECHO	Print suppression during input phase flag for echo file: EQ.0: All data printed, EQ.1: Nodal printing is suppressed, EQ.2: Element printing is suppressed, EQ.3: Both nodal and element printing is suppressed.
NREFUP	Flag to update reference node coordinates for beam formulations 1, 2, and 11. This option requires that each reference node is unique to the beam: EQ.0: Do not update reference node. EQ.1: Update reference node. This update is required for proper visualization of the beam cross-section orientation in LS-PrePost beyond the initial (t = 0.0) plot state. NREFUP does not affect the internal updating of the beam cross-section orientation in LS-DYNA.
IACCOP	Flag to average or filter nodal accelerations output to file nodout and the time history database d3thdt: EQ.0: No average (default), EQ.1: Averaged between output intervals, EQ.2: Accelerations for each time step are stored internally and then filtered over each output interval using a filter from General Motors [Sala, Neal, and Wang, 2004] based on a low-pass Butterworth frequency filter. See also [Neal, Lin, and Wang, 2004]. DT2MS in *CONTROL_TIMESTEP must be set to a negative value when IACCOP = 2 so that the maximum possible number of time steps for an output interval is known and adequate memory can be allocated.
OPIFS	Output time interval for interface file written per *INTERFACE_COMPONENT_*OPTION*.
IPNINT	Flag controlling output of initial time step sizes for elements to d3hsp: EQ.0: 100 elements with the smallest time step sizes are printed.

VARIABLE	DESCRIPTION
	EQ.1: Time step sizes for all elements are printed. GT.1: IPNINT elements with the smallest time step sizes are printed.
IKEDIT	Problem status report interval steps to the d3hsp file. This flag is ignored if the glstat file is written; see *DATABASE_GLSTAT.
IFLUSH	Number of time steps interval for flushing I/O buffers. The default value is 5000. If the I/O buffers are not emptied and an abnormal termination occurs, the output files can be incomplete. The I/O buffers for restart files are emptied automatically whenever a restart file is written so these files are not affected by this option.

This card is optional.

Card 2	1	2	3	4	5	6	7	8
Variable	IPRTF	IERODE	TET10S8	MSGMAX	IPCURV	GMDT	IP1DBLT	EOCS
Type	I	I	I	I	I	F	I	I
Default	0	0	2	50	0	0.	0	0

VARIABLE	DESCRIPTION
IPRTF	Default print flag for rbdout and matsum files. This flag defines the default value for the print flag which can be defined in the part definition section; see *PART. This option is meant to reduce the file sizes by eliminating data which is not of interest. EQ.0: Write part data into both matsum and rbdout EQ.1: Write data into rbdout file only EQ.2: Write data into matsum file only EQ.3: Do not write data into rbdout and matsum
IERODE	Output eroded internal and kinetic energy into the matsum file. Also, (1) under the heading of part ID 0 in matsum, output the kinetic energy from nonstructural mass, lumped mass elements, and lumped inertia elements; and (2) under the heading of part ID -1in matsum, output the kinetic energy associated with distributed

VARIABLE	DESCRIPTION
	mass from *ELEMENT_MASS_PART. EQ.0: Do not output extra data. EQ.1: Output the eroded internal and kinetic energy.
TET10S8	Output ten connectivity nodes for the 10-node solid tetrahedral (solid formulations 16/17) and the eight connectivity nodes for the 8-node shell (shell formulation 23) into the d3plot, d3part, d3eigv, and d3mode databases. The current default is set to 2 since this change in the databases may make the data unreadable for many popular post-processors and older versions of LS-PrePost. EQ.1: Write the full node connectivity into the databases EQ.2: Write only the corner nodes of the elements into the databases
MSGMAX	Maximum number of each error/warning message: GT.0: Number of messages to screen output; all messages written to d3hsp/messag LE.0: Number of messages to screen output and d3hsp/messag EQ.0: Default, 50
IPCURV	Flag to output digitized curve data to messag and d3hsp files: EQ.0: Off EQ.1: On
GMDT	Output interval for recorded motions from *INTERFACE_SSI_AUX
IP1DBLT	Output information of 1D (bar-type) seatbelt created for 2D (shell-type) seatbelt to sbtout. EQ.0: The analysis results of internally created 1D seatbelts are extracted and processed to yield the 2D belt information. The 2D belt information is stored in sbtout. EQ.1: The analysis results of internally created 1D retractors and slip rings are stored in sbtout. Belt load can be yielded by *DATABASE_CROSS_SECTION. This might lead to different results from that of IP1DBLT = 0 in MPP if the model is not robust.

VARIABLE	DESCRIPTION
	EQ.2: Same as IP1DBLT = 1, but the model is decomposed in the same way as IP1DBLT = 0 in MPP and, therefore, guarantees result consistency.
EOCS	elout Coordinate System: controls the coordinate system to be used when writing out shell data to the elout file. EOCS has no effect on eloutdet. EOCS has no effect on elout if OPTION2 in *DATABASE_ELOUT is greater than zero. EQ.0: Default (local element coordinate system, or if an orthotropic material model and CMPFLG = 1, then material coordinate system) EQ.1: Local element coordinate system EQ.2: Global coordinate system

This card is optional.

Card 3	1	2	3	4	5	6	7	8
Variable	TOLEV	NEWLEG	FRFREQ	MINFO	SOLSIG	MSGFLG	CDETOL	IGEOM
Type	I	I	I	I	I	I	F	I
Default	2	0	1	0	0	0	10.0	1

VARIABLE	DESCRIPTION
TOLEV	Timing Output Levels: controls the number of levels output in the timing summary at termination. The default is 2.
NEWLEG	New Legends: controls the format of the LEGEND section of various ASCII output files. EQ.0: Use the normal format EQ.1: Use the optional format with extra fields.
FRFREQ	Output frequency for failed element report in cycles. The default is to report the summary every cycle in which an element fails. If > 1, the summary will be reported every FRFREQ cycles whether an element fails that cycle or not, provided some element has failed since the last summary report. Individual element failure is still

VARIABLE	DESCRIPTION
	reported as it occurs.
MINFO	Output penetration information for mortar contact after each implicit step, not applicable in explicit analysis. See remarks on mortar contact on *CONTACT card. EQ.0: No information EQ.1: Penetrations reported for each contact interface.
SOLSIG	Flag to extrapolate stresses and other history variables for multi-integration point solids from integration points to nodes. These extrapolated nodal values replace the integration point values normally stored in d3plot. When a nonzero SOLSIG is invoked, NINTSLD in *DATABASE_EXTENT_BINARY should be set to 8 as any other value of NINTSLD will result in only one value being reported for each element. Supported solid formulations are: -1, -2, 2, 3, 4, 16, 17, -18, 18, 23, and 62. EQ.0: No extrapolation. EQ.1: Extrapolate the stress for linear materials only. EQ.2: Extrapolate the stress if plastic strain is zero. EQ.3: Extrapolate the stress always. EQ.4: Extrapolate all history variables. **NOTE:** Do not use "Setting – Extrapolate" in LS-PrePost when this field, SOLSIG, is nonzero.
MSGFLG	Flag for writing detailed error/warning message to d3msg. MSGFLG has no effect on output of standard length error/warning messages; such messages are written to messag or mes****. NOTE: Most errors/warnings offer only standard length messages. Only a few also offer optional, detailed messages. EQ.0: Do not write detailed messages to d3msg. EQ.1: Write detailed messages to d3msg at the conclusion of the run. Each detailed message is written only once even in cases where the associated error or warning occurs multiple times. A detailed message written to d3msg should only be used to help interpret the standard length message better. The information in d3msg could contain fictitious IDs and names.

VARIABLE	DESCRIPTION
CDETOL	Tolerance for output of *DEFINE_CURVE discretization warnings. After each curve is discretized, the resulting curve is evaluated at each of the original definition points, and the values compared. A warning will be issued for any curve where this comparison results in an error of more than CDETOL/100 × M, where the curve specific value M is computed as the median of the absolute values of the non-zero curve values.
IGEOM	Flag to control whether nodal coordinates or displacements for the nodes in the mesh are output to d3plot, d3part, and d3drlf: EQ.1: Nodal coordinates (default) EQ.2: Displacements. IGEOM = 2 is useful when the precision of the binary files is insufficient for accurately calculating the displacements from the coordinates in post-processing. This problem arises when the displacements are very small relative to the coordinate values. Note that IGEOM = 2 is supported for post-processing in LS-PrePost 4.10 and later.

This card is optional.

Card 4	1	2	3	4	5	6	7	8
Variable	PHSCHNG	DEMDEN	ICRFILE	SPC2BND	PENOUT	SHLSIG	HISNOUT	ENGOUT
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
PHSCHNG	Message to messag file when materials 216, 217, and 218 change phase. EQ.0: No message (default). EQ.1: The time and element ID are written.
DEMDEN	Output DEM density data to d3plot database. EQ.0: No output (default).

VARIABLE	DESCRIPTION
	EQ.1: Output data. EQ.2: Output data with modification of the boundary density calculation to avoid the low-density distribution near the DES domain boundary.
ICRFILE	Flag to output node sets and element sets used in computing secforc data; see *DATABASE_CROSS_SECTION_*OPTION* and *DATABASE_SECFORC. These sets are written in keyword format (*SET_...) and thus can be displayed using LS-PrePost. The assigned set IDs are the same as the ID of the cross-section. EQ.0: Do not write sets (default). EQ.1: Write a separate file for each cross-section called cross_section_# where # is the cross-section ID. EQ.2: Write sets for all cross-sections to a file called cross_sections.
SPC2BND	Flag to convert constraints on rigid bodies (see CMO/CON1/CON2 on *MAT_RIGID and *CONSTRAINED_NODAL_RIGID_BODY_SPC) to equivalent *BOUNDARY_PRESCRIBED_MOTION_RIGID motion. The purpose of this field is to obtain reaction forces in bndout, without changing the results of the simulation. EQ.0: Not active EQ.1: Active
PENOUT	Flag to output contact penetration to sleout (binout format only) and d3plot for Mortar contact. In sleout the maximum absolute and/or relative penetration per interface is output, in magnitude only. In d3plot a nodal vector field is output for absolute and/or relative penetration, respectively, each giving the maximum penetration (magnitude and direction) for all nodes in any sliding interface. See also NPEN on *DATABASE_EXTENT_INTFOR. EQ.0: Do not output. EQ.1: Output absolute penetration. EQ.2: Output absolute and relative penetration.
SHLSIG	Flag to extrapolate stresses for shells with 8 integration points to nodes. These extrapolated nodal values replace the integration point values normally stored in d3plot. When a nonzero SHLSIG

VARIABLE	DESCRIPTION
	is invoked, MAXINT in *DATABASE_EXTENT_BINARY should be set to -2 to indicate 4 in-plane integration points and 2 in the thickness direction. Supported shell formulations are: 16, 20, and 21. EQ.0: No extrapolation EQ.1: Extrapolate the stress for linear materials only.
HISNOUT	Flag to invoke output of extra history variable names. Usually, the extra history variables of material models are given as just numbers. The corresponding meaning of these variables can be determined, for example, using this website: www.dynasupport.com/howtos/material/history-variables. As an alternative, this option allows the output of the history variable names, listed for each part separately, to d3hsp. In addition, XML files that can be read by a post-processor can be output. Currently, two XML files are available: • hisnames.xml (read by LS-PrePost and GS Animator), which lists the history variable names in each part (as with d3hsp), and • d3labels.xml (read by LS-PrePost), which is similar to hisnames.xml but contains additional information regarding history variable names for each element and integration point when necessary (such as in the case of composites). The number of supported material models is continuously increasing. EQ.0: No output (default) EQ.1: Information written to d3hsp EQ.2: Information written to d3hsp and XML file hisnames.xml EQ.3: Information written to d3hsp and XML file d3labels.xml (and hisnames.xml).
ENGOUT	Flag to output contact sliding energy densities to d3plot for Mortar contact. If set to 1, a nodal scalar field is output giving the minimum sliding energy density for each node in any sliding interface. See also NENG on *DATABASE_EXTENT_INTFOR.

Card 5	1	2	3	4	5	6	7	8
Variable	INSF	ISOLSF	IBSF	ISSF	MLKBAG			
Type	I	I	I	I	I			
Default	0	0	0	0	0			

VARIABLE	DESCRIPTION
INSF	Flag to invoke output of *SET_NODE data: EQ.0: No output (default) EQ.1: Information written to file. See Remark 1.
ISOLSF	Flag to invoke output of *SET_SOLID data: EQ.0: No output (default) EQ.1: Information written to file. See Remark 1.
IBSF	Flag to invoke output of *SET_BEAM data: EQ.0: No output (default) EQ.1: Information written to file. See Remark 1.
ISSF	Flag to invoke output of *SET_SHELL data: EQ.0: No output (default) EQ.1: Information written to file. See Remark 1.
MLKBAG	Flag to invoke output of accumulated airbag mass leakage in AB-STAT: EQ.0: Airbag mass leakage rate is output (default). EQ.1: Accumulated airbag mass leakage is output.

Remarks:

1. **Set Output Format.** Set data is written to an output file based on the type of set (see table below). Note that the output file will have the job ID as a prefix.

Set Type	Output Filename	Set Prefix(ID) in the file
node	nodeset_file	SetN
solid	solidset_file	SetH
beam	beanset_file	SetB
shell	shellset_file	SetS

*CONTROL_PARALLEL

Purpose: Control parallel processing usage by defining the number of processors and invoking the optional consistency of the global vector assembly. This command applies only to shared memory parallel (SMP) LS-DYNA. It does not apply to distributed memory parallel (MPP) LS-DYNA.

Card 1	1	2	3	4	5	6	7	8
Variable	NCPU	NUMRHS	CONST	PARA				
Type	I	I	I	I				
Default	1	0	2	0				
Remarks		1	2	3				

VARIABLE	DESCRIPTION
NCPU	Number of cpus used. (This parameter is disabled in 971 R5 and later versions. Set number of cpus using "ncpu =" on the execution line — see Execution Syntax section of Getting Started — or on the *KEYWORD line of the input.)
NUMRHS	Number of right-hand sides allocated in memory: EQ.0: Same as NCPU, always recommended, EQ.1: Allocate only one.
CONST	Consistency flag. (Including "ncpu = *n*" on the execution line or on the *KEYWORD line of input overrides CONST. The algebraic sign of *n* determines the consistency setting.) EQ.1 or $n < 0$: on (recommended) EQ.2 or $n > 0$: off, for a faster solution (default).
PARA	Flag for parallel force assembly if CONST = 1. (Including "para =" on the execution line overrides PARA.) EQ.0: Off EQ.1: On (see Remark 3)

VARIABLE	DESCRIPTION
	EQ.2: On (see Remark 3)

Remarks:

1. **NUMHRS.** It is recommended to always set NUMRHS = NCPU because then the force assembly is done in parallel which greatly improves the parallel performance. Setting NUMRHS to one reduces storage by one right-hand side vector for each additional processor after the first. If the consistency flag is active, that is, CONST = 1, NUMRHS defaults to unity.

2. **Consistency.** For any given problem with the consistency option off, i.e., CONST = 2, slight differences in results are seen when running the same job multiple times with the same number of processors and also when varying the number of processors. Comparisons of nodal accelerations often show wide discrepancies; however, it is worth noting that the results of accelerometers often show insignificant variations due to the smoothing effect of the accelerometers which are generally attached to nodal rigid bodies.

   The accuracy issues are not new and are inherent in numerical simulations of automotive crash and impact problems where structural bifurcations under compressive loads are common. This problem can be easily demonstrated by using a perfectly square thin-walled tubular beam of uniform cross section under a compressive load. Typically, every run on one processor that includes a minor input change (i.e., element or hourglass formulation) will produces dramatically different results in terms of the final shape, and, likewise, if the same problem is again run on a different brand of computer. If the same problem is run on multiple processors the results can vary dramatically from run to run WITH NO INPUT CHANGE. The problem here is due to the randomness of numerical round-off which acts as a trigger in a "perfect" beam.

   Since summations will (CONST = 2) occur in a different order from run to run, the round-off is also random. The consistency flag, CONST = 1, provides for identical results (or nearly so) whether one, two, or more processors are used while running in the shared memory parallel (SMP) mode. This is done by requiring that all contributions to global vectors be summed in a precise order independently of the number of processors used. When checking for consistent results, nodal displacements or element stresses should be compared. The NODOUT and ELOUT files should be digit to digit identical. However, the GLSTAT, SECFORC, and many of the other ASCII files will not be identical since the quantities in these files are summed in parallel for efficiency reasons and the ordering of summation operations are not enforced. The biggest drawback of this option is the CPU cost penalty which is at least 15 percent if PARA = 0 and is much less if PARA = 1 and 2 or more processors are used. Unless the PARA flag is on (for

non-vector processors), parallel scaling is adversely affected. The consistency flag does not apply to MPP parallel.

3. **PARA.** The PARA flag set to 1 or 2 will cause the force assembly for the consistency option to be performed in parallel for the SMP version, so better scaling will be obtained. However, PARA = 1 will increase memory usage while PARA = 2 will not. This flag does not apply to the MPP version. If PARA = 0, CONST = 0, and NUMRHS = NCPU, the force assembly by default is done in parallel, but without consistency. The value of the flag may also be given by including "para = <value>" on the execution line, and the value given in this manner will override the value of PARA in *CONTROL_PARALLEL.

*CONTROL_PORE_AIR

Purpose: Set parameters for pore air pressure calculations.

Card 1	1	2	3	4	5	6	7	8
Variable	AIR_RHO	AIR_P	ETERM	ANAMSG				
Type	F	F	F	I				
Default	none	none	endtim	0				

VARIABLE	DESCRIPTION
AIR_RHO	Density of atmospheric air, = 1.184 kg/m^3 at 25°C
AIR_P	Pressure of atmospheric air, = 101.325 kPa at 25°C
ETERM	Event termination time, default to ENDTIME of *CONTROL_TERMINATION
ANAMSG	Flag to turn off the printing of pore air analysis status message, including the analysis time, the node with the highest pressure change. EQ.0: Status messages are printed, the default value. EQ.1: Status messages are not printed

*CONTROL_PORE_FLUID

Purpose: Set parameters for pore water pressure calculations.

This control card is intended for soil analysis but is also applicable to any other materials containing pore fluid. The pore-pressure capabilities invoked by this card are available for explicit analysis only, not for implicit, and are restricted to solid element formulations 1, 2, 10, and 15 and thick shell formulations 1, 2, 3, 5, 6 and 7.

LS-DYNA uses Terzaghi's Effective Stress to model materials with pore pressure. The pore fluid and soil skeleton are assumed to occupy the same volume and to carry loads in parallel. Thus, the total stress in an element is the sum of the "effective stress" in the soil skeleton, plus the pressure in the pore fluid. LS-DYNA calculates the "effective stress" with standard material models. The pore fluid treatment, then, is independent of material model. The pore pressure is calculated at nodes and interpolated onto the elements. The pore fluid's hydrostatic stress is equal to the negative of the element pore pressure.

Card 1	1	2	3	4	5	6	7	8

Card 3 is optional

Card 3	1	2	3	4	5	6	7	8
Variable	ETFLAG							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
ATYPE	Analysis type for pore water pressure calculations (see Analysis Types): EQ.0: No pore water pressure calculation EQ.1: Undrained analysis EQ.2: Drained analysis EQ.3: Time dependent consolidation (coupled) EQ.4: Consolidate to steady state (uncoupled) EQ.5: Drained in dynamic relaxation, undrained in transient EQ.6: Same as 4 but do not check convergence, continue to end time
WTABLE	Default z-coordinate of water table (where pore pressure is zero)
PF_RHO	Default density for pore water
GRAV	Gravitational acceleration used to calculate hydrostatic pore water pressure
PF_BULK	Default bulk modulus of pore fluid (stress units)
OUTPUT	Flag controlling stresses output to d3plot, d3thdt, and elout: EQ.0: Total stresses are output. EQ.1: Effective stresses are output; see Output section below.
TMF	Initial Time Magnification Factor for seepage (ATYPE = 3 and 4 only):

VARIABLE	DESCRIPTION
	GT.0: Factor (can be used with automatic control, see TARG, FMIN, FMAX) LT.0: Load curve ID (see *DEFINE_CURVE) giving Time Magnification Factor as a function of analysis time
TARG	Target for maximum change of excess pore pressure head at any node, per timestep. Head is defined in Remark 2. If the actual change falls below the target, the time factor for the seepage calculation will be increased (see Time Factoring). If zero, the constant value of TMF is used. If non-zero, TMF is taken as the initial factor.
FMIN	Minimum time factor for seepage calculation
FMAX	Maximum time factor for seepage calculation
FTIED	Analysis type for pore water pressure calculations (see Remark 1): EQ.0.0: Tied contacts act as impermeable membranes, EQ.1.0: Fluid may flow freely through tied contacts.
CONV	Convergence tolerance for ATYPE = 4. Maximum head change per time step at any node. See Remark 2 below for the definition of "head".
CONMAX	Maximum factor on permeability for ATYPE = 4
ETERM	Event time termination (ATYPE = 3)
THERM	Thermal expansion: Volumetric strain per degree increase for undrained soil.
ETFLAG	Flag for interpretation of time (see Time Factoring): EQ.0: Time means analysis time. EQ.1: Time means event time.

Analysis Types (see ATYPE):

1. **Undrained.** For analyses of the "undrained" type the pore fluid is trapped within the material. Volume changes result in pore pressure changes. This approximation is used to simulate the effect of rapidly applied loads on relatively impermeable soil.

2. **Drained.** For analyses of the "drained" type the pore fluid is free to move within the material such that the user-defined pressure as a function of z-coordinate relationship is always maintained. This approximation is used to model high-permeability soils.

3. **Time-Dependent Consolidation.** For the analysis type "time dependent consolidation" pressure gradients cause pore fluid to flow through the material according to Darcy's law:

$$\mathbf{v} = \kappa \nabla (p + z)$$

where

$\mathbf{v}$ = fluid seepage velocity vector
κ = permeability
p = pressure head
z = z-coordinate.

The seepage velocity is defined as fluid volume flow rate per unit cross-sectional area. Net inflow or outflow at a node leads to a theoretical volume gain or loss. The analysis is coupled, that is, any difference between actual and theoretical volume leads to pore pressure change, which in turn affects the fluid flow. The result is a prediction of response as a function of time.

4. **Steady-State Consolidation.** For the analysis type "steady-state consolidation" an iterative method is used to calculate the steady-state pore pressure. The analysis is uncoupled, that is, only the final state is meaningful, not the response as a function of time.

Time Factoring:

Consolidation occurs over time intervals of days, weeks, or months. To simulate this process using explicit time integration, a time factor is used. The permeability of the soil is increased by the time factor so that consolidation occurs more quickly. The output times in d3plot, d3thdt, and the ascii files are modified to reflect the time factor. The factored time ("Event Time") is intended to represent the time taken in the real-life consolidation process and will usually be much larger than the analysis time (the analysis time is the sum of the LS-DYNA timesteps). The time factor may be chosen explicitly (using TMF), but we recommend using automatic factoring instead. The automatic scheme adjusts the time factor according to how quickly the pore pressure is changing. Usually at the start of consolidation the pore pressure changes quickly, and the time factor is low. The time factor increases gradually as the rate of pore pressure change reduces. Automatic time factoring is input by setting TARG (the target pore pressure head change per timestep) and maximum and minimum allowable time factors; for example, TARG = 0.001 to 0.01 m head, FMIN = 1.0, and FMAX = 10^6. Optimum settings for these are model-dependent.

Loading, other input data from load curves, and output time-intervals on *DATABASE cards use the analysis time by default (for example, the *x*-axis of a load curve used for pressure loading is analysis time). When performing consolidation with automatic time-factoring, the relationship between analysis time and event time is unpredictable. Termination based on event time may be input using ETERM.

It may also be desired to apply loads as functions of event time rather than analysis time, since the event time is representative of the real-life process. By setting ETFLAG = 2, the time axis of all load curves used for any type of input as a function of time, and output intervals on *DATABASE cards, will be interpreted as event time. This method also allows consolidation to be used as part of a staged construction sequence – when ETFLAG = 2, the stages begin and end at the "real time" stage limits and input curves of pore pressure analysis type as a function of time may be used to enforce, for example, consolidation in some stages and undrained behavior in others.

Output:

Five extra variables for solid elements are automatically written to the d3plot and d3thdt files when the model contains *CONTROL_PORE_FLUID, in addition to the NEIPH variables requested on *DATABASE_EXTENT_BINARY. The first of the five is the pore pressure in stress units; the second is the excess pore pressure, meaning actual minus hydrostatic pressure. These follow the NEIPH extra variables requested by the user, so for example if NEIPH = 3 then there will be a total of 8 extra variables in the d3plot and d3thdt files of which the fourth is pore pressure. Even if NEIPH = 0, the d3plot and d3thdt files will still contain the five extra variables related to pore pressure. The same five extra variables are also written to the elout file, but only if OPTION1 > 0 on *DATABASE_ELOUT.

Further optional output to d3plot, d3thdt, and nodout files is available for nodal pore pressure variables; see *DATABASE_PWP_OUTPUT.

For time-dependent and steady-state consolidation, information on the progress of the analysis is written to d3hsp file.

Remarks:

1. **Tied Contacts.** By default, the mesh discontinuity at a tied contact will act as a barrier to fluid flow. If the flag FTIED is set to 1.0, then pore fluid will be transmitted across tied nodes in tied contacts (*CONTACT_TIED_SURFACE_TO_SURFACE and *CONTACT_TIED_NODES_TO_SURFACE, including OFFSET and non-OFFSET types). This algorithm has an effect only when the analysis type of at least one of the contacting parts is 3, 4 or 6.

2. **Pressure and Head.** The term "head" means pressure, defined in terms of the height of fluid needed to generate that pressure hydrostatically. Head is given in length units. Head relates to pressure measured in stress units as follows:

$$h = \frac{p}{\rho g}$$

where h is head (in length units), p is pressure (in stress units), ρ is pore fluid density (PF_RHO), and g is gravitational acceleration (GRAV).

3. **See also *BOUNDARY_PORE_FLUID.** Only the parts for which *BOUNDARY_PORE_FLUID is defined will be treated as containing pore fluid. Parts not included in a *BOUNDARY_PORE_FLUID definition will be treated as dry, meaning they do not have pore fluid; the settings on *CONTROL_PORE_FLUID will not affect them. Pore fluid properties, water table and analysis type are input on a per part basis on *BOUNDARY_-PORE_FLUID. Nonzero values given on *BOUNDARY_PORE_FLUID override those on *CONTROL_PORE_FLUID for that particular part.

4. **Material Properties and Density.** For parts containing pore fluid, the properties given on the *MAT card determine the effective stresses. For example, the bulk modulus on the *MAT card should not include the bulk stiffness of the pore water. The only material property on the *MAT card that relates to the soil/water mixture (as opposed to the soil skeleton) is the density, RO, for which the density of saturated soil should be input. This is somewhat higher than the density of dry soil. The mass and weight of the soil are determined solely from the RO on the *MAT card, and not from the pore fluid density PF_RHO given on *CONTROL_PORE_FLUID or *BOUNDARY_PORE_FLUID.

5. **Part Associativity.** Pore pressure is a nodal variable, but analysis type and other pore pressure related inputs are properties of parts. When a node is shared by elements of different parts, and those parts have different pore pressure inputs, the following rules are followed to determine which part's properties should be applied to the node.

   a) Dry parts (meaning parts without a *BOUNDARY_PORE_FLUID card) will never be used (lowest priority).

   b) If a part is initially dormant (due to staged construction inputs), it has next-lowest priority.

   c) Parts with analysis type set to drained have highest priority.

   d) Next, higher permeability gives higher priority.

   e) If two or more parts have equal-highest priority at a node, the part with lowest ID will win.

6. **Related Keywords.** The following are cards related to this keyword:

*BOUNDARY_PORE_FLUID

BOUNDARY_PWP_*OPTION

*DATABASE_PWP_OUTPUT

*DATABASE_PWP_FLOW

*MAT_ADD_PERMEABILITY

*CONTROL_PZELECTRIC

Purpose: Set solver options for a piezoelectric material; see *MAT_ADD_PZELECTRIC.

Card 1	1	2	3	4	5	6	7	8
Variable	SOLVER	MSGITR	MAXITR	ABSTOL	RELTOL	NDTRFK	EPZMSG	
Type	I	I	I	F	I	I	I	
Default	11	0	500	10^{-20}	10^{-10}	1	0	

VARIABLE	DESCRIPTION
SOLVER	Piezoelectric solver type: EQ.11: Direct solver EQ.12: Diagonal scaling conjugate gradient iterative, recommended for MPP for better scalability
MSGITR	Output iteration message level for SOLVER = 12: EQ.0: No output (default) EQ.1: Summary information
MAXITR	Maximum number of iterations for SOLVER = 12. EQ.0: Use default value 100.
ABSTOL	Absolute convergence tolerance, for SOLVER = 12. EQ.0.0: Use default value 10^{-20}.
RELTOL	Relative convergence tolerance, for SOLVER = 12. EQ.0.0: Use default value 10^{-10}.
NDTRFK	Reform the dielectric stiffness matrix every NDTRFK time steps. LT.0: Curve |NDTRFK| defines the stiffness reformation time step as a function of time.
EPZMSG	Flag to determine if electric flux and electric field at the element center of piezoelectric material is output to d3plot: EQ.0: No electric flux or electric field output to d3plot

VARIABLE	DESCRIPTION
	EQ.1: x, y, and z strain slots in d3plot store the electric flux along the x, y, and z directions, respectively. xy, yz, and zx strain slots in d3plot store the electric field along the x, y, and z directions, respectively.

*CONTROL_REFERENCE_CONFIGURATION_{OPTION}

Available options include:

<BLANK>

ITER

Purpose: Find an approximate reference geometry given a measured/known deformed geometry. A solution to this inverse problem is found iteratively by means of an optimization method. This keyword needs to be in the main keyword file, not in any of the include files. case must be used on the command line (see Remark 2).

Card 1	1	2	3	4	5	6	7	8
Variable	MAXITER	TARGETFILE						
Type	I	A70						
Default	none	none						

Card 2	1	2	3	4	5	6	7	8
Variable	METHOD	STEP	TOL					
Type	I	F	F					
Default	0	1.0	0.0					

Optional card for the ITER keyword option.

Card 3	1	2	3	4	5	6	7	8
Variable	ITERFILE							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
MAXITER	Maximum number of iterations. See Remark 1.
TARGET-FILE	File containing all nodes of the target geometry. See Remark 2.
METHOD	Iterative method: EQ.1: Sellier's method EQ.2: Rausch's method EQ.3: Rausch's method with an additional line search.
STEP	Step size used in the iterations to update the current approximate reference geometry for Sellier's method. It must be > 0. See Remark 1.
TOL	Tolerance used to determining convergence of the iterative method. This is given in the unit of length. See Remark 1.
ITERFILE	Base name of two files for the ITER keyword option. These files are used to start, or restart, the iterative method. ITERFILE.guess gives an initial guess of the approximate stress free reference geometry. It has the same format as the TARGET file. The second file, ITERFILE.algo, gives algorithmic parameters and uses an internal format. ITERFILE is optional. If ITERFILE is not supplied, TARGET is used as an initial guess. See Remark 2 and 3 for details.

Remarks:

1. **Iterative Method.** The implemented iterative method is a backward displacement method of either Sellier [1] (METHOD = 1) or Rausch et.al. [2] (METHOD = 2 or 3). It attempts to solve the inverse problem by a sequence of so-called forward solves. In each forward solve the underlying mechanical problem is solved. The reference geometry is then adjusted by subtracting a suitable amount of the obtained displacement.

   Let $\boldsymbol{x}^*$ be the target geometry specified by TARGETFILE. Then we want to find the unknown reference geometry $\boldsymbol{X}^*$. We can state the inverse problem as a minimization of the difference $\mathfrak{I}(\boldsymbol{X}) = \|\boldsymbol{x} - \boldsymbol{x}^*\|$ under the constraint that $\boldsymbol{x}$ must be in equilibrium with respect to the applied load. In iteration n of the optimization method, we have a guess of the reference geometry, $\boldsymbol{X}_n$. For $n = 0$ this geometry is given by ITERFILE.guess if specified; otherwise it is given by TARGETFILE.

The stated problem provides the solution x_n as the resulting deformed geometry when applying the prescribed load. It can be shown that an approximate descent direction for $\mathfrak{I}$ yields the update $\boldsymbol{X}_{n+1} = \boldsymbol{X}_n - \alpha_n(\boldsymbol{x}_n - \boldsymbol{x}^*)$. α_n is the step size STEP for Sellier's method, while for Rausch's method it is given as

$$\alpha_n = \alpha_{n-1} \times \frac{(\boldsymbol{x}_{n-1} - \boldsymbol{x}^*)^T(\boldsymbol{x}_n - \boldsymbol{x}_{n-1})}{(\boldsymbol{x}_n - \boldsymbol{x}_{n-1})^T(\boldsymbol{x}_n - \boldsymbol{x}_{n-1})} \ .$$

For METHOD = 3, a line search is also attempted if the error $\boldsymbol{x}_n - \boldsymbol{x}^*$ does not decrease at iteration n. It amounts to bisecting the step at iteration n into $\alpha_n/2^k$ and re-solving with $k = 1,2,3,\ldots$ until either the error decreases or $k = 5$.

For all METHOD types, the iterations continue until $\mathfrak{I}(\boldsymbol{X}_n)$ is smaller than the tolerance TOL, or until the maximum number of iterations MAXITER is exceeded. In the implementation, $\boldsymbol{x}$ and $\boldsymbol{X}$ are vectors of nodal positions.

2. **Iteration using Cases.** The overall iterative structure is based on the *CASE construct. Starting from a main keyword file (*.key, *.k, *.dyn) which acts as a template, the iterates are automatically generated by parsing this input file. Each iterate is a "case" with a corresponding *.inp file containing the necessary keywords. The input for iterate number n is named jobid.iter{n}.inp, where jobid is an optional job ID. This is essentially a copy of the main keyword file, but with minor modifications reflecting input that is unique to iterate n.

   You must have *CONTROL_REFERENCE_CONFIGURATION in the main keyword file. For disk space reasons we recommend reducing the size of the main keyword file to a minimum. The modifications to the main keyword file chiefly pertain to change of node coordinates for the current iterate and associated iteration parameters. At the end of the iteration jobid.iter{$n+1$}.guess and jobid.iter{$n+1$}.algo are written with the updated (reference) geometry and algorithmic parameters, respectively. These files are used as starting guess in the next iterate, $n+1$.

3. **Node Files.** The TARGETFILE and ITERFILE.guess files both contain the nodes subjected to optimization and have the same simple structure

```
*KEYWORD
*NODE
$#   nid               x               y               z
       1         -11.776         -23.849          14.234
…
*END
```

   The ITERFILE.algo files have an internal format whose description is currently omitted.

Example 1:

Below is a sketch of a main file showing the use of the *CONTROL_REFERENCE_CONFIGURATION keyword. To run it, the syntax on the command line should be: lsdyna case i=main.k

*CONTROL_REFINE_ALE

Purpose: Refine ALE hexahedral solid elements locally. Each parent element is replaced by 8 child elements with a volume equal to $1/8^{th}$ the parent volume. If only the 1^{st} card is defined, the refinement occurs during the initialization. The 2^{nd} card defines a criterion CRITRF to automatically refine the elements during the run. If the 3^{rd} card is defined, the refinement can be removed if a criterion CRITRM is reached, that is, the child elements can be replaced by their parents.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYPE	NLVL	MMSID	IBOX	IELOUT		
Type	I	I	I	I	I	I		
Default	none	0	1	0	0	0		

Remaining cards are optional.†

Automatic refinement card. Optional card for activating automatic refinement whereby each element satisfying certain criteria is replaced by a cluster of 8 child elements (2 × 2 × 2 elements)

Card 2	1	2	3	4	5	6	7	8
Variable	NTOTRF	NCYCRF	CRITRF	VALRF	BEGRF	ENDRF	LAYRF	DELAYRF

VARIABLE	DESCRIPTION
ID	Set ID.
TYPE	Set type: EQ.0: ALE part set EQ.1: ALE part EQ.2: Lagrangian part set coupled to ALE (see Remarks 1 and 2) EQ.3: Lagrangian part coupled to ALE (see Remarks 1 and 2) EQ.4: Lagrangian shell set coupled to ALE (see Remarks 1 and 2) EQ.5: ALE solid set
NLVL	Number of refinement levels (see Remark 3).
MMSID	Multi-Material Set ID (see Remark 4): LT.0: only ALE elements with all the multi-material groups listed in *SET_MULTI-MATERIAL_GROUP_LIST can be refined (or removed otherwise) GT.0: ALE elements with at least one of the multi-material groups can be refined (or removed)
IBOX	Box ID (See *DEFINE_BOX) defining a region in which the ALE elements are refined. The options LOCAL and ADAPTIVE for *DEFINE_BOX are supported.
IELOUT	Flag to handle child data in elout (see Remark 9).

VARIABLE	DESCRIPTION
NTOTRF	Total number of ALE elements to refine (see Remark 5): GT.0: number of elements to refine EQ.0: number of solid elements in IBOX (see Remark 2) EQ.-1: add clusters of 8 solids for the refinement during the run as needed. LT.-1: |NTOTRF| is the ID of *CONTROL_REFINE_MPP_DISTRIBUTION that computes the number of extra elements required by the processors.
NCYCRF	Number of cycles between each refinement. LT.0: |NCYCRF| is the time interval.
CRITRF	Refinement criterion: EQ.-3: volume fraction < VALRF EQ.-2: relative volume (V/V_0) > VALRF EQ.-1: pressure < VALRF EQ.0: static refinement (as if only Card 1 is defined) EQ.1: pressure > VALRF EQ.2: relative volume (V/V_0) < VALRF EQ.3: volume fraction > VALRF EQ.5: user defined criterion: The fortran routine alerfn_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat.
VALRF	Criterion value to reach for the refinement
BEGRF	Time to begin the refinement
ENDRF	Time to end the refinement
LAYRF	Number of element layers to refine around an element satisfying the refinement criterion (see Remark 6).
DELAYRF	Period of time after removing the refinement of an element, during which this element will not be refined again.

VARIABLE	DESCRIPTION
MAXRM	Maximum number of child clusters (2 × 2 × 2 child elements) to remove (see Remark 8): LT.0: for the whole run GT.0: every NCYCRM cycles
NCYCRM	Number of cycles between each check for refinement removal. LT.0: |NCYCRM| is the time interval.
CRITRM	Criterion for refinement removal (a negative CRITRM reverses the conditions below): EQ.-3: volume fraction > VALRM EQ.-2: relative volume (V/V_0) < VALRM EQ.-1: pressure > VALRM EQ.0: no refinement removal (as if only Cards 1 and 2 are defined) EQ.1: pressure < VALRM EQ.2: relative volume (V/V_0) > VALRM EQ.3: volume fraction < VALRM EQ.5: user defined criterion: The fortran routine alermv_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat.
VALRM	Criterion value to reach in each child element of a cluster for its removal (child elements replaced by parent element).
BEGRM	Time to begin the check for refinement removal. LT.0: |BEGRM| represents a critical percent of NTOTRF below which the check for refinement removal should begin (0.0 < |BEGRM| < 1.0). See Remark 7.
ENDRM	Time to end the check for refinement removal
MMSRM	Multi-Material Set ID for the refinement removal. See Remark 4. LT.0: |MMSRM| represents the radius of a sphere centered on a newly refined element, in which the refinement can not be removed.

VARIABLE	DESCRIPTION
DELAYRM	Period of time after refining an element, during which this refinement will not be removed

Remarks:

1. **First Card Definition Only and TYPE.** If only the 1st card is defined, only TYPE = 0, 1, and 5 can be defined.

2. **Lagrangian Coupling.** *CONSTRAINED_LAGRANGE_IN_SOLID needs to be defined for TYPE = 2, 3, and 4. If an ALE element has at least one coupling point (see NQUAD in *CONSTRAINED_LAGRANGE_IN_SOLID), this element will be selected to be refined (or removed). The number of elements to refine is computed during the initialization. NTOTRF can be zero. Otherwise it can be used to add more elements.

3. **Refinement Levels.** If NLVL = 1, there is only one level of refinement: the ALE elements in *ELEMENT_SOLID are the only ones to be replaced by clusters of 8 child elements. If NLVL > 1, there are several levels of refinement; not only the initial ALE elements in *ELEMENT_SOLID are refined but also their child elements.

4. **Multi-Material Groups.** If only Card 1 is defined, a multi-material set ID is not used. It can be left as zero. For Cards 2 and 3, MMSID is the ID of *SET_MULTI-MATERIAL_GROUP_LIST in which the multi-material group IDs (as defined in *ALE_MULTI-MATERIAL_GROUP) are listed to select the ALE elements to be refined (or removed). If MMSID < 0, only mixed ALE elements containing all the multi-material groups can be refined. Otherwise clusters of 8 elements without a mix of the listed multi-material groups can be removed.

   If MMSRM = 0, all the child clusters meeting the removal criteria can be deleted. If MMSRM is defined, only ALE child clusters fully filled by the multi-material groups listed by the set MMSRM can be removed (if the refinement removal criterion is reached).

5. **Number of ALE Elements to be Refined.** NTOTRF defines the total number of ALE elements to be refined. For example, NTOTRF = 100 with NLVL = 1 means that only 100 ALE elements can be replaced by 800 finer ALE elements (or 100 clusters of 8 child elements). For NLVL = 2, these 800 elements can be replaced by 6400 finer elements.

6. **Neighbor Element Refinement.** If an element is refined, the neighbor elements can be refined as well. LAYRF defines the number of neighbor layers to refine. For example:

a) with LAYRF = 1 an element that meets the refinement criterion at the center of a block of 3 × 3 × 3 elements will cause the refinement of these 27 elements.

b) with LAYRF = 2 an element that meets the refinement criterion at the center of a block of 5 × 5 × 5 elements will cause the refinement of these 125 elements.

c) with LAYRF = 3 an element that meets the refinement criterion at the center of a block of 7 × 7 × 7 elements will cause the refinement of these 343 elements.

7. **Refinement Removal Activation.** If BEGRM < 0, the check for refinement removal is activated when the number of 8 element clusters for the refinement is below a limit defined by |BEGRM| × NTOTRF. If |BEGRM| = 0.1, then the check for refinement removal starts when 90% of the stock of clusters is used for the refinement.

8. **Number of Child Clusters to Remove.** MAXRM < 0 defines a total number of child clusters to remove for the whole run. If positive, MAXRM defines an upper limit for the number of child clusters to remove every NCYCRM cycles.

9. **Output Child Element Data.** If only Card 1 is defined, the child data is always output in elout, that is, IELOUT is always activated. Since the refinement occurs during the initialization, every refined element is replaced by its 8 children in the set defined for *DATABASE_ELOUT.

   If the optional cards are included, the child data is output in elout if the IELOUT flag is set to 1. Since the refinement occurs during the run, the parent IDs in the set defined for *DATABASE_ELOUT are duplicated 8^{NLVL} times. The points of integration in the elout file are incremented to differentiate the child contributions to the database.

*CONTROL_REFINE_ALE2D

Purpose: Refine ALE quadrilateral shell elements locally. Each parent element is replaced by 4 child elements with a volume equal to $1/4^{th}$ the parent volume. If only the 1^{st} card is defined, the refinement occurs during the initialization. The 2^{nd} card defines a criterion CRITRF to automatically refine the elements during the run. If the 3^{rd} card is defined, the refinement can be removed if a criterion CRITRM is reached, that is, the child elements can be replaced by their parents.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYPE	NLVL	MMSID	IBOX	IELOUT		
Type	I	I	I	I	I	I		
Default	none	0	1	0	0	0		

Remaining cards are optional.†

Automatic refinement card. Optional card for activating automatic refinement whereby each element satisfying certain criteria is replaced by a cluster of 4 child elements (2 × 2 child elements)

Type	I	F	I	F	F	F	I	
Default	0	0.0	0	0.0	0.0	0.0	0	

Automatic Refinement Remove Card. Optional card for activating automatic refinement removal whereby, when, for a cluster of 4 child elements, certain criteria are satisfied the cluster (2 × 2 child elements) is replaced by its parent.

Card 3	1	2	3	4	5	6	7	8
Variable	MAXRM	NCYCRM	CRITRM	VALRM	BEGRM	ENDRM	MMSRM	
Type	I	F	I	F	F	F	I	
Default	0	0.0	0	0.0	0.0	0.0	0	

VARIABLE	DESCRIPTION
ID	Set ID
TYPE	Set type: EQ.0: ALE part set EQ.1: ALE part EQ.2: Lagrangian part set coupled to ALE (see Remarks 1 and 2) EQ.3: Lagrangian part coupled to ALE (see Remarks 1 and 2) EQ.4: Lagrangian beam set coupled to ALE (see Remarks 1 and 2) EQ.5: ALE shell set
NLVL	Number of refinement levels (see Remark 3)
MMSID	Multi-Material Set ID (see Remark 4): LT.0: only ALE elements with all the multi-material groups listed in *SET_MULTI-MATERIAL_GROUP_LIST can be refined (or removed otherwise) GT.0: ALE elements with at least one of the multi-material groups can be refined (or removed)
IBOX	Box ID (See *DEFINE_BOX) defining a region in which the ALE elements are refined. The options LOCAL and ADAPTIVE for *DEFINE_BOX are supported.
IELOUT	Flag to handle child data in elout (see Remark 9)

VARIABLE	DESCRIPTION
NTOTRF	Total number of ALE elements to refine (see Remark 5): GT.0: number of elements to refine EQ.0: number of shell elements in IBOX (see Remark 2) EQ.-1: add clusters of 4 shells for the refinement during the run as needed
NCYCRF	Number of cycles between each refinement. LT.0: -NCYCRF is the time interval.
CRITRF	Refinement criterion: EQ.-3: volume fraction < VALRF EQ.-2: relative volume (V/V_0) > VALRF EQ.-1: pressure < VALRF EQ.0: static refinement (as if only the 1st card is defined) EQ.1: pressure > VALRF EQ.2: relative volume (V/V_0) < VALRF EQ.3: volume fraction > VALRF EQ.5: user defined criterion. The fortran routine al2rfn_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat.
VALRF	Criterion value to reach for the refinement
BEGRF	Time to begin the refinement
ENDRF	Time to end the refinement
LAYRF	Number of element layers to refine around an element that has satisfied the refinement criterion (see Remark 6)
MAXRM	Maximum number of child clusters (cluster is 2 × 2 child elements) to remove (see Remark 8): LT.0: for the whole run GT.0: every NCYCRM cycles

VARIABLE	DESCRIPTION
NCYCRM	Number of cycles between each check for refinement removal. LT.0: |NCYCRM| is the time interval.
CRITRM	Criterion for refinement removal (a negative CRITRM reverses the conditions below): EQ.3: volume fraction > VALRM EQ.2: relative volume (V/V_0) < VALRM EQ.1: pressure > VALRM EQ.0: no refinement removal (as if only Cards 1 and 2 are defined) EQ.1: pressure < VALRM EQ.2: relative volume (V/V_0) > VALRM EQ.3: volume fraction < VALRM EQ.5: user defined criterion. The fortran routine al2rmv_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat.
VALRM	Criterion value to reach in each child element of a cluster for its removal (child elements of a cluster replaced by parent element)
BEGRM	Time to begin the check for refinement removal. LT.0: |BEGRM| represents a critical percent of NTOTRF below which the check for refinement removal should begin (0.0 < |BEGRM| < 1.0). See Remark 6.
ENDRM	Time to end the check for refinement removal
MMSRM	Multi-Material Set ID for the refinement removal. See Remark 4.

Remarks:

1. **First Card Definition Only and TYPE.** If only the 1st card is defined, only TYPE = 0, 1, and 5 can be defined.

2. **Lagrangian Coupling.** *CONSTRAINED_LAGRANGE_IN_SOLID needs to be defined for TYPE = 2, 3, and 4. If an ALE element has at least one coupling point (see NQUAD in *CONSTRAINED_LAGRANGE_IN_SOLID), this element will be selected to be refined (or removed).

3. **Refinement Levels.** If NLVL = 1, there is only one level of refinement; the ALE elements in *ELEMENT_SHELL are the only ones to be replaced by clusters of 4 child elements. If NLVL > 1, there are several levels of refinement; not only the initial ALE elements in *ELEMENT_SHELL are refined but also their child elements. If NLVL = 2, for example, an initial ALE element can be replaced by a cluster of 16 child elements.

4. **Multi-Material Groups.** If only Card 1 is defined, a multi-material set ID is not used. It can be left as zero. For the Cards 2 and 3, MMSID is the ID of *SET_MULTI-MATERIAL_GROUP_LIST in which the multi-material group IDs (as defined in *ALE_MULTI-MATERIAL_GROUP) are listed to select the ALE elements to be refined (or removed). If MMSID < 0, only mixed ALE elements containing all the multi-material groups can be refined. Otherwise clusters of 4 elements without a mix of the listed multi-material groups can be removed.

   If MMSRM = 0, all the child clusters meeting the removal criterion can be deleted. If MMSRM is defined, only ALE child elements fully filled by the multi-material groups listed by the set MMSRM can be removed (if the refinement removal criterion is reached).

5. **Number of ALE Elements to be Refined.** NTOTRF defines the total number of ALE elements to be refined. For example, NTOTRF = 100 means that only 100 ALE elements will be replaced by 400 ALE finer elements (or 100 clusters of 4 child elements). For NLVL = 2, these 400 elements can be replaced by 1600 finer elements.

6. **Neighbor Element Refinement.** If an element is refined, neighbor elements can be refined as well. LAYRF defines the number of neighbor layers to refine. For example:

   a) with LAYRF = 1 an element that meets the refinement criterion at the center of a block of 3 × 3 elements will cause the refinement of these 9 elements.

   b) with LAYRF = 2 an element that meets the refinement criterion at the center of a block of 5 × 5 elements will cause the refinement of these 25 elements.

   c) with LAYRF = 3 an element that meets the refinement criterion at the center of a block of 7 × 7 elements will cause the refinement of these 49 elements

7. **Refinement Removal Activation.** If BEGRM < 0, the check for refinement removal is activated when the number of four element clusters for the refinement is below a limit defined by |BEGRM| ×*NTOTRF. If |BEGRM| = 0.1, then the check for refinement removal starts when 90% of the stock of clusters is used for the refinement.

8. **Number of Child Clusters to Remove.** MAXRM < 0 is the exact opposite of NTOTRF > 0; it defines a total number of child clusters to remove for the whole run. If positive, MAXRM defines an upper limit for the number of child clusters to remove every NCYCRM cycles

9. **Output Child Element Data.** If only Card 1 is defined, the child data is output in elout, that is, IELOUT is always activated. Since the refinement occurs during the initialization, every refined element is replaced by its 4 children in the set defined for *DATABASE_ELOUT.

   If the optional cards are included, the child data is output in elout if the IELOUT is set to 1. Since the refinement occurs during the run, the parent IDs in the set defined for *DATABASE_ELOUT are duplicated 4^{NLVL} times. The points of integration in the elout file are incremented to differentiate the child contributions to the database.

*CONTROL_REFINE_MPP_DISTRIBUTION

Purpose: Distribute the elements for the refinement over the MPP processes. This keyword addresses the following situation:

> If TYPE = 2, 3, or 4 in *CONTROL_REFINE_ALE, the refinement occurs around a structure. The number of elements for this refinement is computed for each process according the initial position of the structure in each MPP subdomain (after the MPP decomposition of the ALE mesh during phase 3 of the initialization, each process has a subdomain that is a portion of the ALE mesh). If the structure is not in a subdomain, the related process receives no extra element for the refinement. If the structure moves into this subdomain during the computation, the refinement around the structure can not occur. To avoid this problem, the structure can be considered within a box (the structure maxima and minima give the box dimensions and positions). This box moves and expands during the computation to keep the structure inside. An estimation of the maximal displacement and expansion will allow the code to evaluate which subdomains the structure will likely cross and how many extra elements a process may need to carry out the refinement.

The computation of the number of extra elements per process occurs in 2 steps:

- If a file called refine_mpp_distribution does not exist in the working directory, it will be created to list the number of elements by process. Each line in this file matches a process rank (starting from 0). After phase 3 of the MPP decomposition, the run terminates as if *CONTROL_MPP_DECOMPOSITION_SHOW was activated.
- The model can be run again and the file refine_mpp_distribution will be read to allocate the memory for the extra elements and distribute them across the processes.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	DX	DY	DZ	EX	EY	EZ	
Type	I	F	F	F	F	F	F	
Default	none	0.0	0.0	0.0	1.0	1.0	1.0	

VARIABLE	DESCRIPTION
ID	ID = -NTOTRF in *CONTROL_REFINE_ALE

VARIABLE	DESCRIPTION
DX	Dimensionless x-displacement of the box. (see Remark 1).
DY	Dimensionless y-displacement of the box. (see Remark 1).
DZ	Dimensionless z-displacement of the box. (see Remark 1).
EX	Dimensionless x-expansion of the box. (see Remark 2).
EY	Dimensionless y-expansion of the box. (see Remark 2).
EZ	Dimensionless z-expansion of the box. (see Remark 2).

Remarks:

1. **Box Displacements.** DX, DY and DZ are the maximal displacements of the box center. These displacements are ratio of the box dimensions. If, for example, the largest length of the structure in the x-direction is 10 m and the maximal displacement in this direction is 2 m, DX should be equal to 0.2.

2. **Maximal Box Dilations.** EX, EY and EZ represent the maximal dilatations of the box in each direction. These expansions are the ratio of the box dimensions. The box expands around its center. If, for example, the maximal thickness of a structure along the z-direction is 1 cm and the structure deforms 30 times the thickness in z-direction, EZ should be equal to 30, and DZ = 15 accounts for the box center motion. The xy-plane is a plane of symmetry for this deformation; DZ can be zero.

*CONTROL_REFINE_SHELL

Purpose: Refine quadrilateral shell elements locally. Each parent element is replaced by 4 child elements, each with a volume equal to 1/4 the parent volume.

Card Summary:

Card 1. This card is required. If only this card is defined, the refinement occurs during the initialization.

ID	TYPE	NLVL	IBOX	IELOUT			

Card 2. This card is optional. If defined, this card sets a criterion, CRITRF, to automatically refine the elements during the run.

NTOTRF	NCYCRF	CRITRF	VALRF	BEGRF	ENDRF	LAYRF	

Card 3. This card is optional. If defined, this card sets a criterion, CRITRM, for which the refinement can be removed; that is, the child elements can be replaced by their parents.

MAXRM	NCYCRM	CRITRM	VALRM	BEGRM	ENDRM		

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYPE	NLVL	IBOX	IELOUT

VARIABLE	DESCRIPTION
NTOTRF	Total number of elements to refine (see Remark 2): GT.0: number of elements to refine EQ.0: number of shell elements in IBOX EQ.-1: add clusters of 4 shells for the refinement during the run.
NCYCRF	Number of cycles between each refinement. LT.0: |NCYCRF| is the time interval.
CRITRF	Refinement criterion: EQ.-4: criterion similar to ADPTYP = 4 in *CONTROL_ADAPTIVE with VALRF replacing ADPTOL (VALRF = ADPTOL), except refinement occurs when the shell error in the energy norm is less than VALRF/100 times the mean energy norm within the part

VARIABLE	DESCRIPTION
	EQ.-3: von Mises stress < VALRF EQ.-1: pressure < VALRF EQ.0: static refinement (as if only the 1st card is defined) EQ.1: pressure > VALRF EQ.2: undefined EQ.3: von Mises stress > VALRF EQ.4: criterion similar to ADPTYP = 4 in *CONTROL_ADAPTIVE with VALRF replacing ADPTOL (VALRF = ADPTOL) EQ.5: user defined criterion. The fortran routine shlrfn_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat.
VALRF	Criterion value to reach for the refinement
BEGRF	Time to begin the refinement
ENDRF	Time to end the refinement
LAYRF	Number of element layers to refine around an element reaching the refinement criterion (see Remark 3)

Automatic Refinement Remove Card. Optional card for activating automatic refinement removal whereby, when, for a cluster of 4 child elements, certain criteria are satisfied the clusters is replaced by its parent.

Card 3	1	2	3	4	5	6	7	8
Variable	MAXRM	NCYCRM	CRITRM	VALRM	BEGRM	ENDRM		
Type	I	F	I	F	F	F		
Default	0	0.0	0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
MAXRM	Maximum number of child clusters to remove: LT.0: |MAXRM| is the total number of child clusters to be removed for the whole run, GT.0: max number removed every NCYCRM cycles
NCYCRM	Number of cycles between each check for refinement removal: LT.0: |NCYCRM| is the time interval.
CRITRM	Criterion for refinement removal: EQ.-4: criterion similar to ADPTYP = 4 in *CONTROL_ADAPTIVE with VALRM replacing ADPTOL (VALRM = ADPTOL) EQ.-3: von Mises stress > VALRM EQ.-1: pressure > VALRM EQ.0: no refinement removal (as if only the 1st and 2nd cards are defined) EQ.1: pressure < VALRM EQ.2: undefined EQ.3: von Mises stress < VALRM EQ.4: criterion similar to ADPTYP = 4 in *CONTROL_ADAPTIVE with VALRM replacing ADPTOL (VALRM = ADPTOL), except refinement occurs when the shell error in the energy norm is less than VALRM/100 times the mean energy norm within the part EQ.5: user defined criterion. The fortran routine shlrmv_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat.
VALRM	Criterion value to reach in each child elements of a cluster for its removal (child elements replaced by parent element)
BEGRM	Time to begin the check for refinement removal. LT.0: |BEGRM| represents a critical percent of NTOTRF below which the check for refinement removal should begin (0.0 < |BEGRM| < 1.0). See Remark 4.

VARIABLE	DESCRIPTION
ENDRM	Time to end the check for refinement removal

Remarks:

1. **Refinement Level.** If NLVL = 1, there is only one level of refinement; the elements in *ELEMENT_SHELL are the only ones to be replaced by clusters of 4 child elements. If NLVL > 1, there are several levels of refinement; not only the initial elements in *ELEMENT_SHELL are refined but also their child elements. If NLVL = 2 for example, the initial elements can be replaced by clusters of 16 child elements.

2. **Number of Parent Elements.** NTOTRF > 0 defines the total number of elements to be refined. For example, NTOTRF = 100 with NLVL = 1 means that only 100 elements can be replaced by 400 finer elements (or 100 clusters of 4 child elements). For NLVL = 2, these 400 elements can be replaced by 1600 finer elements.

3. **Neighboring Element Refinement.** If an element is refined, neighboring elements may be refined as well. LAYRF defines the number of neighbor layers to refine. For example:

   a) with LAYRF = 1 an element that meets the refinement criterion at the center of a block of 3 × 3 elements will cause the refinement of these 9 elements.

   b) with LAYRF = 2 an element that meets the refinement criterion at the center of a block of 5 × 5 elements will cause the refinement of these 25 elements.

   c) with LAYRF = 3 an element that meets the refinement criterion at the center of a block of 7 × 7 elements will cause the refinement of these 49 elements

4. **Refinement Removal Activation.** If BEGRM < 0, the check for refinement removal is activated when the number of 4-element clusters for the refinement is below a limit defined by |BEGRM| × NTOTRF. If |BEGRM| = 0.1, the check for refinement removal starts when 90% of the stock of clusters is used for the refinement.

5. **IELOUT.** If only the 1st card is defined, the code for IELOUT is always activated. Since the refinement occurs during the initialization, every refined element is replaced by its 4 children in the set defined for *DATABASE_ELOUT.

   If more than the 1st card is defined, the code for IELOUT is activated if the flag is equal to 1. Since the refinement occurs during the run, the parent IDs in the set defined for *DATABASE_ELOUT are duplicated 4^{NLVL} times. The points of

integration in the elout file are incremented to differentiate the child contributions to the database.

*CONTROL_REFINE_SOLID

Purpose: Refine hexahedral solid elements locally. Each parent element meeting the refinement criterion is replaced by 8 child elements with a volume equal to $1/8^{th}$ the parent volume. If only the 1^{st} card is defined, the refinement occurs during the initialization. The 2^{nd} card defines a criterion CRITRF to automatically refine the elements during the run. If the 3^{rd} card is defined, the refinement can be removed if a criterion CRITRM is reached: the child elements can be replaced by their parents.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYPE	NLVL	IBOX	IELOUT			
Type	I	I	I	I	I			
Default	none	0	1	0	0			

Remaining cards are optional.†

Automatic refinement card. Optional card for activating automatic refinement whereby each element satisfying certain criteria is replaced by a cluster of 8 child elements

Card 2	1	2	3	4	5	6	7	8
Variable	NTOTRF	NCYCRF	CRITRF	VALRF	BEGRF	ENDRF	LAYRF	
Type	I	F	I	F	F	F	I	
Default	0	0.0	0	0.0	0.0	0.0	0	

Automatic Refinement Remove Card. Optional card for activating automatic refinement removal whereby, when, for a cluster of 8 child elements, certain criteria are satisfied the clusters is replaced by its parent.

Card 3	1	2	3	4	5	6	7	8
Variable	MAXRM	NCYCRM	CRITRM	VALRM	BEGRM	ENDRM		
Type	I	F	I	F	F	F		
Default	0	0.0	0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
ID	Set ID. LT.0: parent elements can be hidden in LS-PrePost as they are replaced by their children.
TYPE	Set type: EQ.0: part set EQ.1: part EQ.2: solid set
NLVL	Number of refinement levels. See Remark 1.
IBOX	Box ID (see *DEFINE_BOX) defining a region in which the elements are refined. The keyword options LOCAL and ADAPTIVE for *DEFINE_BOX a re supported.
IELOUT	Flag to handle child data in elout. See Remarks 6 and 7.
NTOTRF	Total number of elements to refine. See Remark 2. GT.0: number of elements to refine EQ.0: NTOTRF = number of solid elements in IBOX EQ.-1: add clusters of 8 solids for the refinement during the run.
NCYCRF	Number of cycles between each refinement. LT.0: |NCYCRF| is the time interval.

VARIABLE	DESCRIPTION
CRITRF	Refinement criterion: EQ.-5: user defined criterion as defined in subroutine sldrfn_criteria5 in the file dynrfn_user.f, which is included in the general usermat package. "Effective plastic strain" < VALRF is the criterion if sldrfn_criteria5 is not modified by the user. EQ.-3: von Mises stress < VALRF EQ.-1: pressure < VALRF EQ.0: static refinement as if only the 1st card is defined EQ.1: pressure > VALRF EQ.2: no refinement occurs. EQ.3: von Mises stress > VALRF EQ.5: user defined criterion as defined in subroutine sldrfn_criteria5 in the file dynrfn_user.f, which is included in the general usermat package. "Effective plastic strain" > VALRF is the criterion if sldrfn_criteria5 is not modified by the user.
VALRF	Value of the refinement criterion that triggers refinement
BEGRF	Time to begin the refinement
ENDRF	Time to end the refinement
LAYRF	Number of element layers to refine around an element reaching the refinement criterion. See Remark 3.
MAXRM	Maximum number of child clusters to remove. See Remark 5. LT.0: for the whole run GT.0: every NCYCRM cycles
NCYCRM	Number of cycles between each check for refinement removal: LT.0: |NCYCRM| is the time interval.
CRITRM	Criterion for removal of refinement: EQ.-3: von Mises stress > VALRM EQ.-1: pressure > VALRM

VARIABLE	DESCRIPTION
	EQ.0: no removal of refinement as if only the 1st and 2nd cards are defined. EQ.1: pressure < VALRM EQ.2: same effect as CRITRM = 0 EQ.3: von Mises stress < VALRM EQ.5: user defined criterion as defined in subroutine sldrmv_criteria5 in the file dynrfn_user.f.
VALRM	Criterion value to reach in each child element of a cluster for its removal (replace child elements with parent element)
BEGRM	Time to begin check for refinement removal: LT.0: |BEGRM| represents a critical percent of NTOTRF below which the check for refinement removal should begin (0.0 < |BEGRM| < 1.0). See Remark 4.
ENDRM	Time to end the check for refinement removal

Remarks:

1. **Number of Refinement Levels.** If NLVL = 1, there is only one level of refinement: the elements in *ELEMENT_SOLID are the only ones to be replaced by clusters of 8 child elements. If NLVL > 1, there are several levels of refinement: not only the initial elements in *ELEMENT_SOLID are refined but also their child elements. If NLVL = 2 for example, the initial elements can be replaced by clusters of 64 child elements.

2. **Maximum Number of Elements to Refine.** NTOTRF defines the total number of elements to be refined. For example, NTOTRF = 100 with NLVL = 1 means that only 100 elements can be replaced by 800 finer elements (or 100 clusters of 8 child elements). For NLVL = 2, these 800 elements can be replaced by 6400 finer elements.

3. **Number of Layers to Refine.** If an element is refined, it is possible to refine the neighbor elements as well. LAYRF defines the number of neighbor layers to refine. For example:

   a) with LAYRF = 1 an element that meets the refinement criterion at the center of a block of 3 × 3 × 3 elements will cause the refinement of these 27 elements.

b) with LAYRF = 2 an element that meets the refinement criterion at the center of a block of 5 × 5 × 5 elements will cause the refinement of these 125 elements.

c) with LAYRF = 3 an element that meets the refinement criterion at the center of a block of 7 × 7 × 7 elements will cause the refinement of these 343 elements.

4. **Onset of Refinement Removal.** If BEGRM < 0, the check for refinement removal is activated when the number of 8-element clusters for the refinement is below a limit defined by |BEGRM| × NTOTRF. If |BEGRM| = 0.1, it means that the check for refinement removal starts when 90% of the stock of clusters are used for the refinement.

5. **Maximum Refinement Removal.** MAXRM < 0 defines a total number of child clusters to remove for the whole run. If positive, MAXRM defines an upper limit for the number of child clusters to remove every NCYCRM cycles.

6. **The elout Database and Initial Refinement.** If only the 1st card is defined, the code for IELOUT is always activated. Since the refinement occurs during the initialization, every refined element is replaced by its 8 children in the set defined for *DATABASE_ELOUT.

7. **The elout Database and Refinement at Run Time.** If there is more than 1 line, the code for IELOUT is activated if the flag is equal to 1. Since the refinement occurs during the run, the parent IDs in the set defined for *DATABASE_ELOUT are duplicated 8^{NLVL} times. The points of integration in the elout file are incremented to differentiate the child contributions to the database.

8. **Contact.** When a refined part involves a contact that is not *CONTACT_ERODING_SINGLE_SURFACE with SOFT = 2, that contact is automatically replaced with *CONTACT_ERODING_SINGLE_SURFACE with SOFT = 2.

***CONTROL_REMESHING**_*{OPTION}*

Available options include:

<BLANK>

EFG

Purpose: Provide control over the adaptive remeshing of solids. See also *CONTROL_-ADAPTIVE and the variable ADPOPT in *PART.

There are two different types of 3D solid adaptivity affected by *CONTROL_REMESH-ING.

1. Tetrahedral adaptivity is invoked by ADPOPT = 2 in *PART. The initial mesh must be comprised of only tetrahedrons. We recommend FEM solid formulations 10 and 13 and EFG solid formulation 42 (see details in *SECTION_SOLID). When adaptivity is triggered by any of several available criteria (volume loss, minimum time step, etc.), the surface mesh consisting of triangles is first improved, subject to the element size criteria set forth in *CONTROL_REMESH-ING. Then, the automatic remesher creates the tetrahedral elements of the new mesh starting from the improved surface mesh. When the EFG option is included, additional adaptivity criteria may be invoked using Card 2 and, optionally, Card 3.

2. Axisymmetric adaptivity, sometimes called orbital adaptivity, in which remeshing is done with hexahedral and pentahedral elements, is invoked by AD-POPT = 3 in *PART. Only the variables RMIN, RMAX, CID, and SEGANG are used in this type of adaptivity. Though EFG solid formulation 41 is permissible, the EFG option of *CONTROL_REMESHING does not apply for this type of adaptivity.

Card 1	1	2	3	4	5	6	7	8
Variable	RMIN	RMAX	VF_LOSS	MFRAC	DT_MIN	ICURV	CID	SEGANG
Type	F	F	F	F	F	I	I	F
Default	none	none	1.0	0.0	0.	4	0	0.0

Additional card for EFG option or FEM tetrahedral adaptivity. With FEM tetrahedral adaptivity, only MM option is available.

Card 2	1	2	3	4	5	6	7	8
Variable	IVT	IAT	IAAT		MM			
Type	I	I	I		I			
Default	1	0	0		0			

Second additional card for EFG option. This card is optional.

Card 3	1	2	3	4	5	6	7	8
Variable	IAT1	IAT2	IAT3					
Type	F	F	F					
Default	10^{20}	10^{20}	10^{20}					

VARIABLE	DESCRIPTION
RMIN	Minimum edge length for the surface mesh surrounding the parts which should be remeshed. See Remark 1.
RMAX	Maximum edge length for the surface mesh surrounding the parts which should be remeshed. See Remark 1.
VF_LOSS	Volume fraction loss required in a type 10/13 tetrahedral elements to trigger a remesh. For the type 13 solid elements, the pressures are computed at the nodal points; therefore, it is possible for overall volume to be conserved but for individual tetrahedrons to experience a significant volume loss or gain. The volume loss can lead to numerical problems. Recommended values for VF_LOSS in the range of 0.10 to 0.30 may be reasonable.
MFRAC	Mass ratio gain during mass scaling required for triggering a remesh. For a one percent increase in mass, set MFAC = 0.010. This variable applies to both to general three-dimensional tetrahedral remeshing and to three dimensional axisymmetric remeshing.

VARIABLE	DESCRIPTION
DT_MIN	Time step size required for triggering a remesh. This option applies only to general three-dimensional tetrahedral remeshing and is checked before mass scaling is applied and the time step size reset.
ICURV	Define number of elements along the radius in the adaptivity. See Remark 3.
CID	Coordinate system ID for three dimensional axisymmetric remeshing. The z-axis in the defined coordinate system is the orbital axis and must be parallel to the global z-axis in the current axisymmetric remesher. EQ.0: Use global coordinate, and the global z-axis is the orbital axis (default)
SEGANG	*For axisymmetric 3D remeshing.* Angular element size in degrees. *For general (tet) 3D remeshing.* Critical angle specified in radians needed to preserve feature lines.
IVT	Internal variable transfer in adaptive EFG (see Remark 4): EQ.1: Moving least square approximation with Kronecker-delta property (recommended in general case) EQ.-1: Moving least square approximation without Kronecker-delta property EQ.2: Partition of unity approximation with Kronecker-delta property EQ.-2: Partition of unity approximation without Kronecker-delta property EQ.-3: Finite element approximation
IAT	Flag for interactive adaptivity (see Remark 2): EQ.0: No interactive adaptivity EQ.1: Interactive adaptivity combined with predefined adaptivity. EQ.2: Purely interactive adaptivity. The time interval between two successive adaptive steps is bounded by ADPFREQ. EQ.3: Purely interactive adaptivity

VARIABLE	DESCRIPTION
IAAT	Interactive adaptivity adjustable tolerance: EQ.0: The tolerance to trigger interactive adaptivity is not adjusted. EQ.1: The tolerance is adjusted in run-time to avoid over-activation.
MM	Adaptive remeshing with monotonic resizing for either EFG or FEM: EQ.1: The adaptive remeshing cannot coarsen a mesh. The current implementation only supports IAT = 1, 2, 3 for EFG. It is available for FEM tetrahedral remeshing too.
IAT1	Shear strain tolerance for interactive adaptivity. If the shear strain in any formulation 42 EFG tetrahedral element exceeds IAT1, remeshing is triggered. (0.1 ~ 0.5 is recommended).
IAT2	$L_{\max}/L_{\min}$ tolerance where $L_{\max}$ and $L_{\min}$ are the maximum and minimum edge lengths of any given formulation 42 EFG tetrahedral element. If this ratio in any element exceeds IAT2, remeshing is triggered. (RMAX/RMIN is recommended.)
IAT3	Volume change tolerance. If the normalized change in volume of any formulation 42 tetrahedral element, defined as $\|v_1 - v_0\|/\|v_0\|$ where v_1 is the current element volume and v_0 is the element volume immediately after the most recent remeshing, exceeds IAT3, remeshing is triggered. (0.5 is recommended.)

Remarks:

1. **Edge Length.** The value of RMIN and RMAX should be of the same order. The value of RMAX can be set to 2-5 times greater than RMIN. RMIN and RMAX may be superseded in specific regions of the part being adapted; see the variables PID, BRMIN, and BRMAX in *DEFINE_BOX_ADAPTIVE.

2. **Interactive Adaptivity.** Interactive adaptivity is only supported for the adaptive 4-noded mesh-free (EFG) solid formulation (ELFORM = 42 in *SECTION_SOLID_EFG). When interactive adaptivity is invoked (IAT > 0), even if none of the tolerances IAT1, IAT2, and IAT3 for the three respective indicators (shear strain, edge length ratio, normalized volume change) are exceeded, remeshing will still be triggered if any of the three indicators over a single explicit time step changes by more than 50%, that is, if

$$\frac{|[\text{value}]_n - [\text{value}]_{n-1}|}{|[\text{value}]_{n-1}|} > 0.5$$

where $[\text{value}]_n$ denotes value of indicator in n^{th} (current) time step and $[\text{value}]_{n-1}$ denotes value of indicator in previous time step. This condition is checked only if $[\text{value}]_{n-1}$ is nonzero.

3. **ICURV.** ICURV represents a number of elements and applies only when ADPENE > 0 in *CONTROL_ADAPTIVE. The "desired element size" at each point on the SURFA contact surface is computed based on the tooling radius of curvature (see the description of ADPENE in *CONTROL_ADAPTIVE), so that ICURV elements would be used to resolve a hypothetical 90 degree arc at the tooling radius of curvature. The value of ICURV is (internally) limited to be ≥ 2 and ≤ 12. The final adapted element size is adjusted as necessary to fall within the size range set forth by RMIN and RMAX.

4. **IVT.** IVT defines different remapping schemes for the adaptive 4-noded meshfree (EFG) solid formulation (ELFORM = 42 in *SECTION_SOLID_EFG). The finite element approximation (IVT = -3) is the most efficient one in terms of computational cost. The moving least square approximation (IVT = 1 or -1) can significantly reduce the remapping error when there are many adaptive steps and the solution fields have local features, such as a high gradient. But this option has a high CPU and memory cost. The partition of unity approximation (IVT = 2 or -2) is slightly more accurate than the finite element approximation (IVT = -3).

*CONTROL_REQUIRE_REVISION

Purpose: To prevent the model from being run in old versions of LS-DYNA. This might be desirable due to known improvements in the program, required capability, etc.

Card 1	1	2	3	4	5	6	7	8
Variable	RELEASE	SVNREV	GITREV					
Type	C	I	I					
Default	Rem 2	none	none					

VARIABLE	DESCRIPTION
RELEASE	The release of code required. This should be a string such as "R6.1.0" or "R7.0"
SVNREV	The minimum SVN revision required (ignored by executables made after our move to git). This corresponds to the "SVN Version" field in the d3hsp file for versions of LS-DYNA prior to our move to git for version control. R12.0 was the last release version made while we were using SVN for version control.
GITREV	The minimum git revision required corresponding to the release of code (ignored by executables made prior to our move to git). This corresponds to part of the git hash given in the "Revision" field in the d3hsp file for versions of LS-DYNA after our move to git for version control. In d3hsp, the last string is "R[Release #]-[number]-[alphanumeric]". If RELEASE is given, LS-DYNA compares GITREV to that [number]. If RELEASE is not given, see Remark 2. R11.2 was the first release version made when we moved to git.

Remarks:

1. **Number of Lines.** Any number of lines can appear, indicating for example that a particular feature was introduced in different release branches at different times.

2. **RELEASE.** If the RELEASE field is left empty, then any executable whose development split from the main SVN or git trunk after the given SVNREV or GITREV, respectively, will be allowed.

Example:

```
*CONTROL_REQUIRE_REVISION
R6.1    79315
R7.0    78310
        78304
```

The above example would prevent execution by any R6.1 executable before r79315, any R7.0 before r78310, and all other executables whose development split from the main trunk before r78304. Note that no versions of R6.0, R6.0.0, or R6.1.0 are allowed: R6.1 does NOT imply R6.1.0, no matter what the revision of R6.1.0 – R6.1.0 would have to be explicitly listed. Similarly, R7.0.0 would not be allowed because it is not listed, and it split from the trunk in r76398. Any future R8.X executable would be allowed, since it will have split from the trunk after r78304.

*CONTROL_RIGID

Purpose: Special control options related to rigid bodies and to linearized flexible bodies; see *PART_MODES.

Card 1	1	2	3	4	5	6	7	8
Variable	LMF	JNTF	ORTHMD	PARTM	SPARSE	METALF	PLOTEL	RBSMS
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

Remaining cards are optional.†

Card 2	1	2	3	4	5	6	7	8
Variable	NORBIC	GJADSTF	GJADVSC	TJADSTF	TJADVSC	RCVLR2D		
Type	I	F	F	F	F	I		
Default	0	0.0	0.0	0.0	0.0	0		

VARIABLE	DESCRIPTION
LMF	Joint formulation flag for explicit analysis. This flag can be used to switch to an implicit formulation for joints (*CONSTRAINED_JOINT_*OPTION*) which uses Lagrange multipliers to impose prescribed kinematic boundary conditions and joint constraints. There is a slight cost overhead due to the assembly of sparse matrix equations which are solved using standard procedures for nonlinear problems in rigid multi-body dynamics. EQ.0: Penalty formulation for joints (default) EQ.1: Lagrange-multiplier-based formulation for joints
JNTF	Generalized joint stiffness formulation; see Remark 1 below: EQ.0: Incremental update EQ.1: Total formulation (exact)

VARIABLE	DESCRIPTION
	EQ.2: Total formulation intended for implicit analysis
ORTHMD	Orthogonalize modes with respect to each other: EQ.0: True EQ.1: False. The modes are already orthogonalized.
PARTM	Use global mass matrix to determine part mass distribution. This mass matrix may contain mass from other parts that share nodes. See Remark 2 below. EQ.0: True EQ.1: False
SPARSE	Use sparse matrix multiply subroutines for the modal stiffness and damping matrices. See Remark 3. EQ.0: False. Do full matrix multiplies (frequently faster). EQ.1: True
METALF	Use fast update of rigid body nodes. Only applicable to sheet metal forming analysis using 2D and 3D shell elements. If this option is active, the rotational motion of all rigid bodies should be suppressed. EQ.0: Full treatment EQ.1: Fast update for metal forming applications
PLOTEL	Automatic generation of *ELEMENT_PLOTEL for *CONSTRAINED_NODAL_RIGID_BODY: EQ.0: No generation EQ.1: One part is generated for all nodal rigid bodies with the PID set to 1000000. EQ.2: One part is generated for each nodal rigid body in the problem with a part ID of 1000000 + PID, where PID is the nodal rigid body ID.
RBSMS	Flag to apply consistent treatment of rigid bodies in selective and conventional mass scaling, Remark 4. EQ.0: Off EQ.1: On

VARIABLE	DESCRIPTION
NORBIC	Circumvent rigid body inertia check, see Remark 5. EQ.0: Off EQ.1: On
GJADSTF	Rotational stiffness is added to all joints in the model as a mean to model a small resistance, such as joint friction, or to avoid zero energy modes in implicit. This is equivalent to defining a *CONSTRAINED_JOINT_STIFFNESS_GENERALIZED to the free rotational degrees of freedom of all joints, using a slope in LCIDPH, LCIDT, LCIDPS that equal to GJADSTF. For models with many joints this field is advantageous since it only has to be defined once for all joints, whereas the equivalent keyword must be defined for each joint.
GJADVSC	Rotational damping is added to all joints in the model as a mean to model a small resistance, such as joint friction, or to avoid zero energy modes in implicit. This is equivalent to defining a *CONSTRAINED_JOINT_STIFFNESS_GENERALIZED to the free rotational degrees of freedom of all joints, using a slope in DLCIDPH, DLCIDT, DLCIDPS that equal to GJADVSC. Like GJADSTF, for models many joints this field is advantageous since it only has to be defined once for all joints, whereas the equivalent keyword must be defined for each joint.
TJADSTF	Translational stiffness is added to all joints in the model as a mean to model a small resistance, such as joint friction, or to avoid zero energy modes in implicit. This is equivalent to defining a *CONSTRAINED_JOINT_STIFFNESS_TRANSLATIONAL to the free translational degrees of freedom of all joints, using a slope in LCIDX, LCIDY, LCIDZ that equal to TJADSTF. Like GJADSTF, for models many joints this field is advantageous since it only has to be defined once for all joints, whereas the equivalent keyword must be defined for each joint.

VARIABLE	DESCRIPTION
TJADVSC	Translational damping is added to all joints in the model as a mean to model a small resistance, such as joint friction, or to avoid zero energy modes in implicit. This is equivalent to defining a *CONSTRAINED_JOINT_STIFFNESS_TRANSLATIONAL to the free translational degrees of freedom of all joints, using a slope in DLCIDX, DLCIDY, DLCIDZ that equal to TJADVSC. Like GJADSTF, for models many joints this field is advantageous since it only has to be defined once for all joints, whereas the equivalent keyword must be defined for each joint.
RCVLR2D	Recover the lead rigid body of constrained rigid bodies, which was changed due to *DEFORMABLE_TO_RIGID_AUTOMATIC, (see Remark 6): EQ.0: Off EQ.1: On

Remarks:

1. **JNTF.** The default behavior is for the relative angles between the two coordinate systems to be done incrementally. This is an approximation, in contrast to the total formulation where the angular offsets are computed exactly. The disadvantage of the latter approach is that a singularity exists when an offset angle equals 180 degrees. In most applications, the stop angles exclude this possibility and JNTF=1 should not cause a problem. JNTF=2 is implemented with smooth response and especially intended for implicit analysis.

2. **PARTM.** If the determination of the normal modes included the mass from both connected bodies and discrete masses, or if there are no connected bodies, then the default is preferred. When the mass of a given part ID is computed, the resulting mass vector includes the mass of all rigid bodies that are merged to the given part ID, but does not included discrete masses. See the keyword: *CONSTRAINED_RIGID_BODIES. A lumped mass matrix is always assumed.

3. **SPARSE.** Sparse matrix multipliers save a substantial number of operations if the matrix is truly sparse. However, the overhead will slow the multipliers for densely populated matrices.

4. **RBSMS.** In selective mass scaling, rigid bodies connected to deformable elements can result in significant addition of inertia due missing terms in the SMS mass matrix. This problem has been observed in automotive applications where spotwelds are modeled using constrained nodal rigid bodies. By applying consistent rigid body treatment significant improvement in accuracy and robustness

are observed at the expense of increased CPU intensity. This flag also applies to conventional mass scaling as it has been observed that inconsistencies for various reasons may result in unstable solution schemes even for this case.

5. **NORBIC.** During initialization, the determinant of the rigid body inertia tensor is checked. If it falls below a tolerance value of 10^{-30}, LS-DYNA issues an error message and the calculation stops. In some rare cases (for example with an unfavorable system of units), such tiny values would still be valid. In this case, NORBIC should be set to 1 to circumvent the implied inertia check.

6. **RCVLR2D.** When a deformable part PID is switched to rigid and becomes constrained to lead rigid part LRB, the rigid part PIDL sharing common nodes with PID will be constrained to LRB as well. At the same time, the rigid part PIDC having PIDL as the lead rigid body through *CONSTRAINED_RIGID_BODIES will now have LRB as its new lead rigid body (see *DEFORMABLE_TO_RIGID_AUTOMATIC and *CONSTRAINED_RIGID_BODIES). When PID is switched back to deformable, PIDC will be constrained to its old lead PIDL if RCVLR2D = 1. Otherwise, PIDC will stay constrained LRB.

*CONTROL_SEGMENTS_IN_ALE_COUPLING

Purpose: Deactivate segments in the ALE penalty coupling (see CTYPE = 4, 5 and 6 in *CONSTRAINED_LAGRANGE_IN_SOLID) if the segments are face to face with other segments. By default, all the segments (element faces with 4 or 3 nodes in 3D or element sides with 2 nodes in 2D) search for the ALE material interface involved in the coupling. If the interface is close to a segment, penalty coupling forces are applied on both to keep them together. Some segments might not need to be involved in the coupling if they face another segment. For example, let 2 side-by-side cubic structures have element faces in contact. As long as these segments face each other, they do not need to apply coupling forces on the material interface. In this particular example, if inside segments near the corners were to drag the material interfaces to them, leakages could occur; see Figure 12-85.

See also *CONSTRAINED_LAGRANGE_IN_SOLID (CTYPE = 4, 5 and 6), *SET_SEGMENT, and *ALE_MULTI-MATERIAL_GROUP.

Segment Set Card. This card is optional.

Card 1	1	2	3	4	5	6	7	8
Variable	RANKEY	SEGSET	NCYCHK	SYM				
Type	I	I	I	I				
Default	0	0	10	0				

Coupling Card. This card is optional card.

Card 2	1	2	3	4	5	6	7	8
Variable	NINTHK	CONTHK						
Type	I	F						
Default	0	0.0						

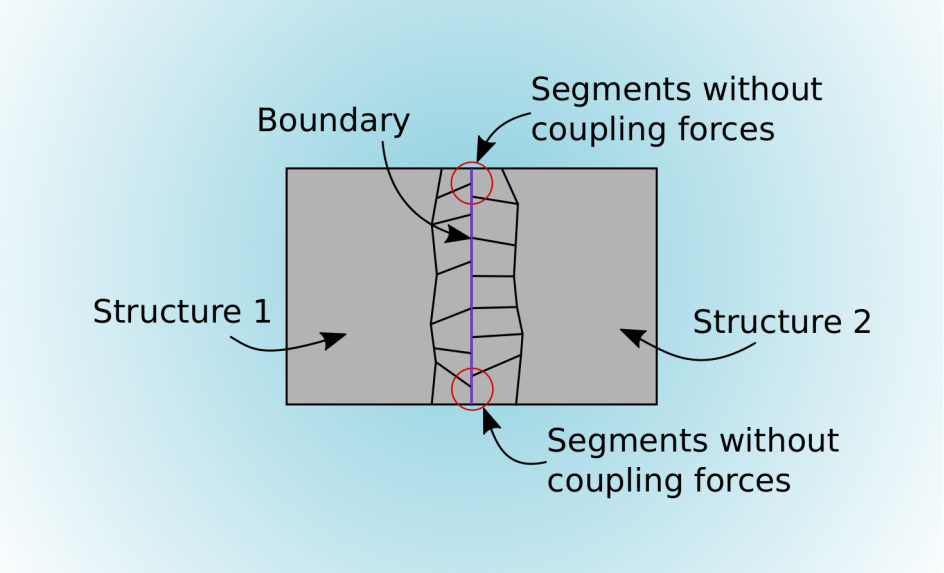

Figure 12-85. An example of when penalty coupling should be deactivated for certain segments.

VARIABLE	DESCRIPTION
RANKEY	Instantiation of *CONSTRAINED_LAGRANGE_IN_SOLID in the input deck controlled by this keyword (see Remarks 1 and 2). For example, if RANKEY = 2, then the second *CONSTRAINED_LAGRANG_IN_SOLID definition is controlled by this keyword.
SEGSET	Set ID of *SET_SEGMENT (see Remark 2)
NCYCHK	Number of cycles between checks to activate/deactivate coupling segments (see Remark 3)
SYM	Flag to deactivate coupling segments with normal boundary constraints. EQ.0: Off EQ.1: On
NINTHK	Minimum number of coupling points in contact to deactivate the segment (see Remark 4).
CONTHK	Contact thickness (see Remark 5)

Remarks:

1. **Keyword without Data Cards.** If *CONTROL_SEGMENTS_IN_ALE_COUPLING is included without any data cards, namely, Cards 1 and 2, all the *CON-

STRAINED_LAGRANGE_IN_SOLID keywords are controlled by *CONTROL_SEGMENTS_IN_ALE_COUPLING.

2. **Segment Sets.** The RANKEYth *CONSTRAINED_LAGRANGE_IN_SOLID keyword definition in the keyword deck determines the segment set controlled by *CONTROL_SEGMENTS_IN_ALE_COUPLING. The parameter LSTRSID with LSTRSTYP = 2 in *CONSTRAINED_LAGRANGE_IN_SOLID refers to a segment set. If LSTRSTYP < 2, LSTRSID refers to a part or part set. However, the segments of these parts are still generated during the initialization. If RANKEY and SEGSET are both nonzero, the segments common to RANKEY and SEGSET will be controlled. If RANKEY and SEGSET do not have segments in common, their segment lists will both be controlled.

3. **Check Frequency.** The parameter NBKT in *CONTROL_ALE controls how often the bucket sorting to search segments in contact is updated.

4. **Coupling Points.** NQUAD in *CONSTRAINED_LAGRANGE_IN_SOLID defines the number of coupling points by segment (NQUAD × NQUAD in 3D and NQUAD in 2D). If NINTHK = 0, all the coupling points of a segment should be in contact to deactivate it.

5. **Contact Thickness.** For this keyword, a segment, SG1, is in contact with another segment, SG2, if at least one coupling point of SG1 is inside a cylinder formed by SG2's area as its base and SG2's normal as its generatrix (see *SET_SEGMENT for the normal definition). The cylinder height is CONTHK. If CONTHK = 0 and the segment is attached to a shell (or beam in 2D), CONTHK by default is half the element thickness. If CONTHK = 0 and the segment is attached to a solid (or shell in 2D), CONTHK by default is a thousandth of the largest segment diagonal.

*CONTROL_SHELL

Purpose: Provide controls for computing shell response.

Card Summary:

Card 1. This card is required.

WRPANG	ESORT	IRNXX	ISTUPD	THEORY	BWC	MITER	PROJ

Card 2. This card and all the following cards are optional.

ROTASCL	INTGRD	LAMSHT	CSTYP6	THSHEL			

Card 3. This card is optional.

PSTUPD	SIDT4TU	CNTCO	ITSFLG	IRQUAD	W-MODE	STRETCH	ICRQ

Card 4. This card is optional.

NFAIL1	NFAIL4	PSNFAIL	KEEPCS	DELFR	DRCPSID	DRCPRM	INTPERR

Card 5. This card is optional.

DRCMTH	LISPSID	NLOCDT					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	WRPANG	ESORT	IRNXX	ISTUPD	THEORY	BWC	MITER	PROJ
Type	F	I	I	I	I	I	I	I
Default	20.	0	-1	0	2	2	1	0

VARIABLE	DESCRIPTION
WRPANG	Shell element warpage angle in degrees. If a warpage greater than this angle is found, a warning message is printed.
ESORT	Sorting of triangular shell elements to automatically switch degenerate quadrilateral shell formulations to more suitable triangular

VARIABLE	DESCRIPTION
	shell formulations. EQ.0: Do not sort (default). EQ.1: Sort (switch to C0 triangular shell formulation 4, or if a quadratic shell, switch to shell formulation 24, or if a shell formulation with thickness stretch, switch to shell formulation 27). EQ.2: Sort (switch to DKT triangular shell formulation 17, or if a quadratic shell, switch to shell formulation 24). The DKT formulation will be unstable for an uncommonly thick, triangular shell.
IRNXX	Shell normal update option. This option applies to the Hughes-Liu formulations (ELFORMs 1, 6, 7, and 11), the BWC formulation (ELFORM 10), and if warping stiffness is turned on, the Belytschko-Tsay formulations (ELFORMs 2 and 25 with BWC = 1 and ELFORMs -16, 16, and 26 with hourglass type 8). EQ.-2: Unique nodal fibers which are incrementally updated based on the nodal rotation at the location of the fiber EQ.-1: Recomputed fiber directions each cycle EQ.0: Default set to -1 EQ.1: Compute on restarts EQ.n: Compute every *n* cycles (Hughes-Liu shells only)
ISTUPD	Shell thickness change option for deformable shells. For crash analysis, neglecting the elastic component of the strains, ISTUPD = 4, may improve energy conservation and stability. The option specified with ISTUPD applies to all shell parts unless the variable PSTUPD, and optionally the variable SIDT4TU, on Card 3 are specified. See the description of those variables below. EQ.0: No thickness change (default) EQ.1: Membrane straining causes thickness change in 3 and 4 node shell elements. This option is important in sheet metal forming or whenever membrane stretching is important. EQ.2: Membrane straining causes thickness change in 8 node thick shell elements, types 1 and 2. We do not recommend this option for implicit or explicit solutions which use the fully integrated type 2 elements. Types 3 and 5 thick shells

VARIABLE	DESCRIPTION
	are continuum based, and thickness changes are always considered. EQ.3: Options 1 and 2 apply EQ.4: Option 1 applies, but the elastic strains are neglected for the thickness update. This option only applies to shells (not thick shells) and the most common elastic-plastic materials for which the elastic response is isotropic. See SIDT4TU for selective application of this option.
THEORY	Default shell formulation. For a complete list of shell formulations, refer to *SECTION_SHELL. For remarks on overriding this default and how THEORY may affect contact behavior, see Remark 2. EQ.1: Hughes-Liu EQ.2: Belytschko-Tsay (default) EQ.3: BCIZ triangular shell (not recommended) EQ.4: C0 triangular shell EQ.5: Belytschko-Tsay membrane EQ.6: S/R Hughes Liu EQ.7: S/R co-rotational Hughes Liu EQ.8: Belytschko-Leviathan shell EQ.9: Fully integrated Belytschko-Tsay membrane EQ.10: Belytschko-Wong-Chiang EQ.11: Fast (co-rotational) Hughes-Liu EQ.12: Plane stress (xy-plane) EQ.13: Plane strain (xy-plane) EQ.14: Axisymmetric solid (y-axis of symmetry) – area weighted. See Remark 6 EQ.15: Axisymmetric solid (y-axis of symmetry) – volume weighted. See Remark 6 EQ.16: Fully integrated shell element (very fast) EQ.17: Discrete Kirchhoff triangular shell (DKT) EQ.18: Discrete Kirchhoff linear shell either quadrilateral or Triangular with 6DOF per node EQ.20: C0 linear shell element with 6 DOF per node

VARIABLE	DESCRIPTION
	EQ.21: C0 linear shell element with 5 DOF per node with the Pian-Sumihara membrane hybrid quadrilateral membrane EQ.25: Belytschko-Tsay shell with thickness stretch EQ.26: Fully integrated shell with thickness stretch EQ.27: C0 triangular shell with thickness stretch
BWC	Warping stiffness for Belytschko-Tsay shells: EQ.1: Belytschko-Wong-Chiang warping stiffness added EQ.2: Belytschko-Tsay (default)
MITER	Plane stress plasticity option (applies to materials 3, 18, 19, and 24): EQ.1: Iterative plasticity with 3 secant iterations (default) EQ.2: Full iterative plasticity EQ.3: Radial return noniterative plasticity. May lead to false results and must be used with great care.
PROJ	Projection method for the warping stiffness in the Belytschko-Tsay shell (BWC above) and the Belytschko-Wong-Chiang elements (see Remark 1 below). This parameter only applies to explicit calculations since the implicit solver always uses the full projection method. EQ.0: Drill projection EQ.1: Full projection

Card 2	1	2	3	4	5	6	7	8
Variable	ROTASCL	INTGRD	LAMSHT	CSTYP6	THSHEL			
Type	F	I	I	I	I			
Default	1.	0	0	1	0			

VARIABLE	DESCRIPTION
ROTASCL	Define a scale factor for the rotary shell mass. This option is not for general use. The rotary inertia for shells is automatically scaled to permit a larger time step size. A scale factor other than the default, that is, unity, is not recommended.
INTGRD	Default through thickness numerical integration rule for shells and thick shells. If more than 10 integration points are requested, a trapezoidal rule is used unless a user defined rule is specified. EQ.0: Gauss integration. If 1 - 10 integration points are specified, the default rule is Gauss integration. EQ.1: Lobatto integration. If 3 - 10 integration points are specified, the default rule is Lobatto. For 2 point integration, the Lobatto rule is very inaccurate, so Gauss integration is used instead. Lobatto integration has an advantage in that the inner and outer integration points are on the shell surfaces.
LAMSHT	Laminated shell theory flag. Except for those using the Green-Lagrange strain tensor, laminated shell theory is available for all thin shell and thick shell materials (this feature is developed and implemented by Professor Ala Tabiei). It is activated when LAMSHT = 3, 4, or 5 and by using *PART_COMPOSITE or *INTEGRATION_SHELL to define the integration rule. See Remark 7. EQ.0: Do not update shear corrections. EQ.1: Activate laminated shell theory. EQ.3: Activate laminated thin shells. EQ.4: Activate laminated shell theory for thick shells. EQ.5: Activate laminated shell theory for thin and thick shells.
CSTYP6	Coordinate system for the type 6 shell element. The default system computes a unique local system at each in plane point. The uniform local system computes just one system used throughout the shell element. This involves fewer calculations and is therefore more efficient. The change of systems has a slight effect on results; therefore, the older, less efficient method is the default. EQ.1: Variable local coordinate system (default) EQ.2: Uniform local system

VARIABLE	DESCRIPTION
THSHEL	Thermal shell option (applies only to thermal and coupled structural thermal analyses). See parameter THERM on DATABASE_EXTENT_BINARY keyword. EQ.0: No temperature gradient is considered through the shell thickness (default). EQ.1: A temperature gradient is calculated through the shell thickness.

Card 3	1	2	3	4	5	6	7	8
Variable	PSTUPD	SIDT4TU	CNTCO	ITSFLG	IRQUAD	W-MODE	STRETCH	ICRQ
Type	I	I	I	I	I	F	F	I
Default	0	0	0	0	0	inactive	inactive	0

VARIABLE	DESCRIPTION
PSTUPD	|PSTUPD| is the optional shell part set ID specifying which part IDs have or do not have their thickness updated according to ISTUPD, subject to further specification as given by SIDT4TU below. The shell thickness update option as specified by ISTUPD by default applies to all shell elements in the mesh. LT.0: Parts in shell part set |PSTUPD| are excluded from the shell thickness update. EQ.0: All deformable shells use the shell thickness update as specified by ISTUPD. GT.0: Only parts in shell part set PSTUPD undergo shell thickness update.
SIDT4TU	Shell part set ID for parts which use the type 4 thickness update where elastic strains are ignored. The shell parts in part set SIDT4TU must also be included in the part set defined by PSTUPD. SIDT4TU has no effect unless ISTUPD is set to 1 or 3. Shell parts in the shell part set PSTUPD but which are not also in the shell part set SIDT4TU use the type 1 thickness update.
CNTCO	Flag affecting location of contact surfaces for shells when NLOC is nonzero in *SECTION_SHELL or in *PART_COMPOSITE, or

VARIABLE	DESCRIPTION
	when OFFSET is specified using *ELEMENT_SHELL_OFFSET. CNTCO is not supported for the tracked side of NODES_TO_SURFACE type contacts, nor does it have any effect on Mortar contacts. For Mortar contacts NLOC or OFFSET completely determines the location of the contact surfaces, as if CNTCO = 1. EQ.0: NLOC and OFFSET have no effect on location of shell contact surfaces. EQ.1: Contact reference plane (see Remark 3) coincides with shell reference surface. EQ.2: Contact reference plane (see Remark 3) is affected by contact thickness. This is typically not physical.
ITSFLG	Flag to activate/deactivate initial transverse shear stresses (local shell stress components σ_{yz} and σ_{zx}) from *INITIAL_STRESS_SHELL: EQ.0: Keep transverse shear stresses EQ.1: Set transverse shear stresses to zero
IRQUAD	In plane integration rule for the 8-node quadratic shell element (shell formulation 23): EQ.2: 2 × 2 Gauss quadrature EQ.3: 3 × 3 Gauss quadrature (default)
W-MODE	W-Mode amplitude for element deletion, specified in degrees. See Figure 12-86 and Remark 5 for the definition of the angle.
STRETCH	Stretch ratio of element diagonals for element deletion. This option is activated if and only if either NFAIL1 or NFAIL4 are nonzero and STRETCH > 0.0.
ICRQ	Continuous treatment across element edges for some specified result quantities. See Remark 8. EQ.0: Not active EQ.1: Thickness and plastic strain EQ.2: Thickness

Card 4	1	2	3	4	5	6	7	8
Variable	NFAIL1	NFAIL4	PSNFAIL	KEEPCS	DELFR	DRCPSID	DRCPRM	INTPERR
Type	I	I	I	I	I	I	F	
Default	inactive	inactive	0	0	0	0	1.0	

VARIABLE **DESCRIPTION**

NFAIL1 Flag to check for highly distorted under-integrated shell elements, print a message, and delete the element or terminate. Generally, this flag is not needed for one point elements that do not use warping stiffness. A distorted element is one where a negative Jacobian exist within the domain of the shell, not just at integration points. The checks are made away from the CPU requirements for one point elements. If nonzero, NFAIL1 can be changed in a restart.

EQ.1: Print message and delete element.

EQ.2: Print message, write d3dump file, and terminate.

GT.2: Print message and delete element. When NFAIL1 elements are deleted, then write d3dump file and terminate. These NFAIL1 failed elements also include all shell elements that failed for other reasons than distortion. Before the d3dump file is written, NFAIL1 is doubled, so the run can immediately be continued if desired.

NFAIL4 Flag to check for highly distorted fully-integrated shell elements, print a message, and delete the element or terminate. Generally, this flag is recommended. A distorted element is one where a negative Jacobian exist within the domain of the shell, not just at integration points. The checks are made away from the integration points to enable the bad elements to be deleted before an instability leading to an error termination occurs. If nonzero, NFAIL4 can be changed in a restart.

EQ.1: Print message and delete element.

EQ.2: Print message, write d3dump file, and terminate.

GT.2: Print message and delete element. When NFAIL4 elements are deleted, then write d3dump file and terminate. These NFAIL4 failed elements also include all shell elements that failed for other reasons than distortion. Before

VARIABLE	DESCRIPTION
	the d3dump file is written, NFAIL4 is doubled, so the run can immediately be continued if desired.
PSNFAIL	Optional shell part set ID specifying which part IDs are checked by the NFAIL1, NFAIL4, and W-MODE options. If zero, all shell part IDs are included.
KEEPCS	Flag to keep the contact segments of failed shell elements in the calculation. The contact segments of the failed shells remain active until a node shared by the segments has no active shells attached. Only then are the segments deleted. EQ.0: Inactive EQ.1: Active
DELFR	Flag to delete shell elements whose neighboring shell elements have failed; consequently, the shell is detached from the structure and moving freely in space. This condition is checked if NFAIL1 or NFAIL4 are nonzero. EQ.0: Inactive EQ.1: Isolated elements are deleted. EQ.2: Elements that are isolated and triangular elements that are connected by only one node are deleted. EQ.3: Elements that are either isolated or connected by only one node are deleted.
DRCPSID	Part set ID for drilling rotation constraint method (see Remark 4 below).
DRCPRM	Drilling rotation constraint parameter (default = 1.0). GT.0: Constant scaling value. LT.0: |DRCPRM| is a *DEFINE_FUNCTION ID (FID), see Remark 4 below.
INTPERR	Flag for behavior in case of unwanted interpolation/extrapolation of initial stresses from *INITIAL_STRESS_SHELL. EQ.0: Only warning is written, calculation continues (default). EQ.1: Error exit, calculation stops.

Card 5	1	2	3	4	5	6	7	8
Variable	DRCMTH	LISPSID	NLOCDT					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
DRCMTH	Drilling rotation constraint method. Options to choose how drilling kinematics are determined. EQ.0: Generalized drilling strain rate at shell element nodes involving drill rotation at the specific node plus the translational velocities of two adjacent nodes. See more details in Erhart and Borrvall [2013]. EQ.1: Direct use of the spin tensor (e.g. see section 21 in the LS-DYNA Theory Manual) with respect to the shell element normal direction, numerically integrated at element level. A similar approach is described in Kanok-Nukulchai [1979].
LISPSID	Part set ID related to *INITIAL_STRESS_SHELL. For all parts in this set, the initial stress components SIGXX, SIGYY, …, SIGZX are defined in the local (element) coordinate system.
NLOCDT	Flag for time step handling for shell elements with offset. If the shell reference surface is offset by NLOC (*SECTION_SHELL) or OFFSET (*ELEMENT_SHELL), the time step size of those shell elements is reduced to fix instabilities. The reduction of the time step size is based on numerical tests which show a dependence on the offset distance and the ratio of shell thickness to edge length (T/L). EQ.0: Reduce time step size up to 10% to avoid instabilities. Care must be taken since a smaller time step will lead to larger masses due to mass scaling. EQ.1: No reduction of time step to restore prior behavior if necessary. Instabilities were most likely observed for aspect ratios of $T/L > 0.5$.

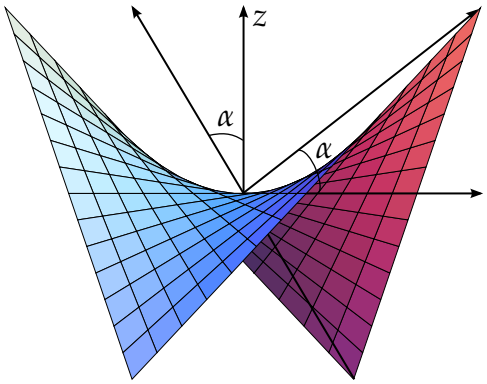

Figure 12-86. Illustration of an element in a *W-Mode*. One pair of opposite corners go up, and the other pair goes down. The plane of the flat element and the vector connecting the center to the corner form the angle, α. See Remark 5.

Remarks:

1. **Drill versus full projections for warping stiffness.** The drill projection is used in the addition of warping stiffness to the Belytschko-Tsay and the Belytschko-Wong-Chiang shell elements. This projection generally works well and is very efficient, but to quote Belytschko and Leviathan:

   > "The shortcoming of the drill projection is that even elements that are invariant to rigid body rotation will strain under rigid body rotation if the drill projection is applied. On one hand, the excessive flexibility rendered by the 1-point quadrature shell element is corrected by the drill projection, but on the other hand, the element becomes too stiff due to loss of the rigid body rotation invariance under the same drill projection."

   They later went on to add in the conclusions:

   > "The projection of only the drill rotations is very efficient and hardly increases the computation time, so it is recommended for most cases. However, it should be noted that the drill projection can result in a loss of invariance to rigid body motion when the elements are highly warped. For moderately warped configurations the drill projection appears quite accurate."

   In crashworthiness and impact analysis, elements that have little or no warpage in the reference configuration can become highly warped in the deformed configuration and may affect rigid body rotations if the drill projection is used, that is, DO NOT USE THE DRILL PROJECTION. Of course, it is difficult to define what is meant by "moderately warped." The full projection circumvents these problems but at a significant cost. The cost increase of the drill projection versus no projection as reported by Belytschko and Leviathan is 12 percent and by

timings in LS-DYNA, 7 percent, but for the full projection they report a 110 percent increase and in LS-DYNA an increase closer to 50 percent is observed.

In Version 940 of LS-DYNA, the drill projection was used exclusively, but in one problem the lack of invariance was observed; consequently, the drill projection was replaced in the Belytschko-Leviathan shell with the full projection and the full projection is now optional for the warping stiffness in the Belytschko-Tsay and Belytschko-Wong-Chiang elements. Starting with version 950 the Belytschko-Leviathan shell, which now uses the full projection, is somewhat slower than in previous versions. In general, in light of these problems, the drill projection cannot be recommended. For implicit calculations, the full projection method is used in the development of the stiffness matrix.

2. **THEORY, ELFORM, and contact with tapered shells.** All shell parts need not share the same element formulation. A nonzero value of ELFORM, given either in *SECTION_SHELL or *PART_COMPOSITE, overrides the element formulation specified by THEORY in *CONTROL_SHELL.

   When using MPP, THEORY = 1 in *CONTROL_SHELL has special meaning when dealing with non-uniform-thickness shells, that is, it serves to set the nodal contact thickness equal to the average of the nodal thicknesses from the shells sharing that node. Thus, when a contact surface is comprised of non-uniform-thickness shells, THEORY = 1 is recommended and the user still has the option of setting the actual shell theory using ELFORM in *SECTION_SHELL. (This remark concerning THEORY does not apply to SOFT = 2 contact wherein each contact segment is considered to be of uniform thickness.)

3. **Contact surfaces.** For automatic contact types, the shell contact surfaces are always, regardless of CNTCO, offset from a contact reference plane by half a contact thickness. Contact thickness is taken as the shell thickness by default but can be overridden, for example, with input on Card 3 of *CONTACT.

   The parameter CNTCO affects how the location of the contact reference plane is determined. When CNTCO = 0, the contact reference plane coincides with the plane of the shell nodes. Whereas when CNTCO = 1, the contact reference plane coincides with the shell reference surface as determined by NLOC or by OFFSET. For CNTCO = 2, the contact reference plane is offset from the plane of the nodes by

$$-\frac{\text{NLOC}}{2} \times \text{contact thickness}$$

   or by

$$\text{OFFSET} \times \left(\frac{\text{contact thickness}}{\text{shell thickness}}\right)$$

   whichever applies.

4. **Drilling rotation constraint method.** The drilling rotation constraint method which is used by default in implicit calculations (see parameter DRCM = 4 on *CONTROL_IMPLICIT_SOLVER) can be used in explicit calculations as well by defining an appropriate part set DRCPSID. This might be helpful in situations where single constraints (such as spotwelds) are connected to flat shell element topologies. The additional drill force can by scaled with DRCPRM (default value is 1.0), where a moderate value should be chosen to avoid excessive stiffening of the structure. A speed penalty of 15% at maximum may be observed with this option.

   As an alternative to a constant drill force scaling parameter (DRCPRM > 0), a general function can be defined (DRCPRM < 0) with *DEFINE_FUNCTION ID |DRCPRM|. The arguments of that function include elastic shear modulus *gmod*, the shear correction factor *shrf* (from *SECTION_SHELL), the mass density *rho*, the shell element area *sarea*, and the element thickness *thk* in the following order:

```
*DEFINE_FUNCTION
<FID>
func(gmod,shrf,rho,sarea,thk)=...
```

   The function should have the units of a force.

5. **W-mode failure criterion.** The w-mode failure criterion depends on the magnitude of the w-mode, w, compared to the approximate side length ℓ. The magnitude, w, is defined as

$$w = \frac{1}{4}[(\mathbf{x}_1 - \mathbf{x}_2) + (\mathbf{x}_3 - \mathbf{x}_4)] \cdot \mathbf{n} \ ,$$

   where $\mathbf{x}_i$ is the position vector for node i, and $\mathbf{n}$ is the element normal vector evaluated at the centroid. The element normal is the unit vector obtained from the cross product of the diagonal vectors $\mathbf{a}$ and $\mathbf{b}$ as,

$$\begin{aligned} \mathbf{a} &= \mathbf{x}_3 - \mathbf{x}_1 \\ \mathbf{b} &= \mathbf{x}_4 - \mathbf{x}_2 \\ \mathbf{n} &= \frac{\mathbf{a} \times \mathbf{b}}{\|\mathbf{a} \times \mathbf{b}\|} \ . \end{aligned}$$

   The failure criterion depends on the ratio of w to ℓ, where ℓ is defined as

$$\ell = \frac{1}{2}\underbrace{\left[\sqrt{2}\underbrace{\sqrt{\frac{1}{2}\|\mathbf{a} \times \mathbf{b}\|}}_{\sim\sqrt{\text{area}}}\right]}_{\sim\text{diagonal length}}$$

   such that the element is deleted when

$$\frac{|w|}{\ell} \geq \tan(\text{WMODE}).$$

The angle, α, in Figure 12-86 may be identified as,

$$\alpha = \arctan\left(\frac{|w|}{\ell}\right) .$$

6. **2D axisymmetric solid elements.** The 2D axisymmetric solid elements come in two types: area weighted (type 14) and volume weighted (type 15).

   a) High explosive applications work best with the area weighted approach and structural applications work best with the volume weighted approach. The volume weighted approach can lead to problems along the axis of symmetry under very large deformations. Often the symmetry condition is not obeyed, and the elements will kink along the axis.

   b) The volume-weighted approach must be used if 2D shell elements are used in the mesh. Type 14 and 15 elements cannot be mixed in the same calculation.

7. **Lamination theory.** Lamination theory should be activated when the assumption that shear strain through the shell is uniform and constant becomes violated. Unless this correction is applied, the stiffness of the shell can be grossly incorrect if there are drastic differences in the elastic constants from ply to ply, especially for sandwich type shells. Generally, without this correction the results are too stiff. For the discrete Kirchhoff shell elements, which do not consider transverse shear, this option is ignored. For thin shells of material types, *MAT_COMPOSITE_DAMAGE, *MAT_ENHANCED_COMPOSITE_DAMAGE, and *MAT_GENERAL_VISCOELASTIC, laminated shell theory may also be applied through stiffness correction by setting LAMSHT = 1.

8. **Continuous result quantities**. A nodal averaging technique is used to achieve continuity for some quantities across element edges. Applying this approach to the thickness field and plastic strains (ICRQ = 1) or only thickness (ICRQ=2) can reduce alternating weak localizations sometimes observed in metal forming applications when shell elements get stretch-bended over small radii. This option currently works with shell element types 2, 4, and 16. A maximum number of 9 through thickness integration points is allowed for this method. A maximum speed penalty of 15% may be observed with this option.

*CONTROL_SOLID

Purpose: Provides controls for solid element response.

Card 1	1	2	3	4	5	6	7	8

Card 3	1	2	3	4	5	6	7	8
Variable	TET13V	RINRT						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
ESORT	Automatic sorting of tetrahedral and pentahedral elements to avoid use of degenerate formulations for these shapes. See *SECTION_SOLID. EQ.0: No sorting (default)

VARIABLE	DESCRIPTION
	EQ.1: Sort tetrahedron to type 10; pentahedron to type 15; cohesive pentahedron types 19 and 20 to types 21 and 22, respectively.
	EQ.2: Sort tetrahedron to type 10; 1-point integrated pentahedron to type 115; fully integrated pentahedron to type 15; cohesive pentahedron types 19 and 20 to types 21 and 22, respectively.
	EQ.3: Same as EQ.1 but also print switched elements in messag file
	EQ.4: Same as EQ.2 but also print switched elements in messag file
FMATRX	Default method used in the calculation of the deformation gradient matrix.
	EQ.1: Update incrementally in time. This is the default for explicit.
	EQ.2: Directly compute **F**. This is the default for implicit and implicit/explicit switching.
NIPTETS	Number of integration points used in the quadratic tetrahedron elements. Either 4 or 5 can be specified. This option applies to the types 4, 16, and 17 tetrahedron elements.
SWLOCL	Output option for stresses in solid elements used as spot welds with material *MAT_SPOTWELD. Affects elout, d3plot, d3part, etc.
	EQ.1: Stresses in global coordinate system (default)
	EQ.2: Stresses in element coordinate system
PSFAIL	Solid element erosion from negative volume is limited *only* to solid elements in the part set indicated by PSFAIL. This is similar to setting ERODE = 1 in *CONTROL_TIMESTEP except that it is not global.
	In other words, when PSFAIL is nonzero, the time-step-based criterion for erosion (TSMIN) applies to all solid elements (except formulations 11 and 12) while the negative volume criterion for erosion applies only to solids in part set PSFAIL.

VARIABLE	DESCRIPTION
T10JTOL	Tolerance for Jacobian in 4-point 10-noded quadratic tetrahedra (type 16). If the quotient between the minimum and maximum Jacobian values falls below this tolerance, a warning message is issued in the messag file. This is useful for tracking (badly shaped) elements that deteriorate convergence during implicit analysis; a value of 1.0 indicates a perfectly shaped element.
ICOH	Flag for cohesive elements to control deletion and time step estimate. Breaking LS-DYNA convention ICOH is interpreted digitwise, namely as, $$\text{ICOH} = [LK] = K + 10 \times L\ .$$ The first digit, in the one's place, which we shall call K is interpreted as follows: K.EQ.0: No cohesive element deletion due to neighbor failure. K.EQ.1: Solid elements having ELFORM = 19 – 22 (or ELFORM = 1, 2, 15 being used with *MAT_169) will be eroded when neighboring shell or solid elements fail. This works for nodewise connected parts and tied contacts. The second digit, in the ten's place is, which we shall call L is interpreted as stated below. Note that if ICOH is less than 10 (having a single digit) then L defaults to zero. See Remark 1. L.EQ.0: Default stable time step estimate, which is computed from the stiffness and the nodal masses of the top and bottom as with discrete elements. L.EQ.1: Most conservative (smallest) stable time step estimate. This method calculates mass by integrating the density. L.EQ.2: Intermediate stable time step estimate. Same as the default except reduced by a factor of $1/\sqrt{2}$ corresponding to halving the masses.
TET13K	Set to 1 to invoke a consistent tangent stiffness matrix for the pressure averaged tetrahedron (type 13). This feature is available only for the implicit integrator *and it is not supported in the MPP/MPI version*. This element type averages the volumetric strain over adjacent elements to alleviate volumetric locking; therefore, the corresponding material tangent stiffness should be treated accordingly. In contrast to a hexahedral mesh where a node usually connects to fewer than 8 elements, tetrahedral meshes offer no such regularity. Consequently, for nonlinear implicit analysis matrix

VARIABLE	DESCRIPTION
	assembly is computationally expensive, so this option is recommended only for linear or eigenvalue analysis to exploit the stiffness characteristics of the type 13 tetrahedron.
PM1 – PM10	Components of a permutation vector for nodes that define the 10-node tetrahedron. The nodal numbering of 10-node tetrahedron elements is somewhat arbitrary. The permutation vector allows other numbering schemes to be used. Unless defined, this permutation vector is not used. PM1 – PM10 are unique numbers between 1 to 10 inclusive that reorders the input node ID's for a 10-node tetrahedron into the order used by LS-DYNA.
TET13V	Choice of type 13 solid implementation: EQ.0: Efficient version (default). With the single precision version of LS-DYNA, a little noise in the solution for elements that are moving long distances with rigid body motion could be observed. EQ.1: More accurate version (smoother results) with an additional cost of about 15%.
RINRT	Option to compute rotational inertia for the nodes of solid elements. This is to ensure consistent results if constraints are applied which assume rotational degrees of freedom, as with tied contacts using the option SHELL_EDGE_TO_SURFACE. EQ.0: By default, an average of the existing rotational inertia from the shell and beam elements in the model is distributed to the nodes of the solid elements. This method is sufficient in most situations but might lead to inconsistencies between different model assemblies in the case of rotational motion. EQ.1: Compute rotational inertia for each solid element based on its dimensions and mass density to ensure consistency.

Remarks:

1. **Computation of cohesive element time step.** As mentioned in the Theory Manual, we can estimate the stable time step of a cohesive element by representing the element as a mass-spring element. The critical time step is then:

$$\Delta t_e = \sqrt{\frac{2m}{k}},$$

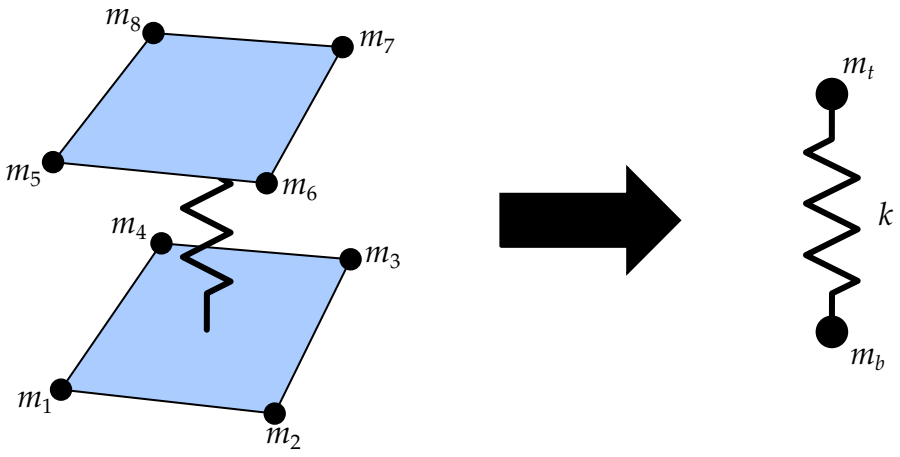

Figure 12-87. Representing a cohesive element as a mass-spring element.

where

$$m = \frac{2m_b m_t}{m_b + m_t}$$

is the harmonic mean of the top and bottom spring masses m_t and m_b. The equivalent spring stiffness (force per length) is

$$k = \sum_{i=1}^{N_\mathrm{IP}} \max[E_n, E_t]\, w_i J_i = \max[E_n, E_t]\, A\ ,$$

where E_n and E_t are the normal/tangential cohesive stiffness (stress per length), w_i are weights, and A is the interface area. Note that the last step assumes a constant stiffness and Jacobian determinant over the element.

The setting of L in the ICOH parameters determines the method for computing the top and bottom masses. For L = 0, LS-DYNA treats the cohesive element like a series of mass-spring elements stacked on each other. Two elements share each mass, resulting in

$$m_t = \frac{1}{2} M_t$$
$$m_b = \frac{1}{2} M_b$$

where M_t and M_b are the sum of the top and bottom masses, respectively. That is,

$$M_t = m_5 + m_6 + m_7 + m_8$$
$$M_b = m_1 + m_2 + m_3 + m_4$$

Note that for a pentahedral element, $m_4 = m_8 = 0$. The resulting time step is

$$\Delta t_e = \sqrt{\frac{2M_b M_t}{k(M_b + M_t)}}\ .$$

For L = 1, the mass contribution is from the cohesive element only. Thus,

$$m = \frac{1}{2} H \rho A$$

or

$$m = \frac{1}{2} \rho A \ ,$$

depending on whether the provided density is mass per volume or mass per area. In the above, H is the thickness. The resulting time step is

$$\Delta t_e = \sqrt{\frac{H\rho}{\max[E_n, E_t]}}$$

or

$$\Delta t_e = \sqrt{\frac{\rho}{\max[E_n, E_t]}} \ .$$

For L = 2, we assume a regular mesh such that four neighboring elements share each corner node. Thus, we have

$$m_t = \frac{1}{4} M_t$$
$$m_b = \frac{1}{4} M_{\mathrm{b}}$$

These masses result in a time-step estimation of

$$\Delta t_e = \sqrt{\frac{M_b M_t}{k(M_b + M_t)}},$$

which is a factor of $\sqrt{2}$ smaller than the default L = 0.

The above description shows that option L = 1 results in the most conservative estimation, followed by L = 2 and lastly, L = 0. However, we want to stress that the masses determined with L = 2 lead to the theoretical time step for two surfaces connected by cohesive interfaces, so we recommend using this option

*CONTROL_SOLUTION

Purpose: To specify the analysis solution procedure if thermal only or combined thermal analysis is performed. Other solutions parameters including the vector length and NaN (not a number) checking can be set.

Card 1	1	2	3	4	5	6	7	8
Variable	SOLN	NLQ	ISNAN	LCINT	LCACC	NCDCF	NOCOPY	
Type	I	I	I	I	I	I	I	
Default	0	0	0	100	0	1	0	

VARIABLE	DESCRIPTION
SOLN	Analysis solution procedure: EQ.0: Structural analysis only EQ.1: Thermal analysis only EQ.2: Combined structural, multiphysics, and thermal analysis
NLQ	Define the vector length used in the solution. This value must not exceed the vector length of the system which varies based on the machine manufacturer. The default vector length is printed at termination in the messag file.
ISNAN	Flag to check for a NaN in the force and moment arrays after the assembly of these arrays is completed. This option can be useful for debugging purposes. A cost overhead of approximately 2% is incurred when this option is active. EQ.0: No checking EQ.1: Checking is active.
LCINT	Number of equally spaced points used in curve (*DEFINE_CURVE) rediscretization. A minimum number of 100 is always used, that is, only larger input values are possible. Curve rediscretization applies only to curves used in material models. Curves defining loads, motion, etc. are not rediscretized.

VARIABLE	DESCRIPTION
LCACC	Flag to truncate curves to 6 significant figures for single precision and 13 significant figures for double precision. The truncation is done after applying the offset and scale factors specified in *DEFINE_CURVE. Truncation is intended to prevent curve values from deviating from the input value, such as 0.7 being stored as 0.69999999. This small deviation was seen to have an adverse effect in a particular analysis using *MAT_083. In general, curve truncation is not necessary and is unlikely to have any effect on results. EQ.0: No truncation NE.0: Truncate
NCDCF	Global option to evaluate *DEFINE_CURVE_FUNCTION every NCDCFth cycle.
NOCOPY	Avoid copying of material history variables to temporary buffers for constitutive evaluations (see Remark 1): EQ.0: Not active EQ.1: Active

Remarks:

1. **NOCOPY.** Setting NOCOPY = 1 reduces overhead during element calculations and could potentially decrease the *Element processing* in *Timing Information* between 5% and 25% depending on the choice of element and material. The most substantial gain is obtained when the material is combined with a modular damage model, such as GISSMO (see *MAT_ADD_DAMAGE_GISSMO) or DIEM (see *MAT_ADD_DAMAGE_DIEM), for which another level of copying is avoided.

   Currently this option is *restricted to MPP* (not hybrid). It also only works for materials 24 and 123 in combination with shell elements 2, 4 or 16, solid elements -1, -2, 1, 2, 10 or 15, and all thick shells and for materials 36 and 133 in combination with shell elements 2, 4, or 16. Other combinations of materials and elements ignore this option and will be supported in an order of priority/importance.

*CONTROL_SPH

Purpose: Provide controls related to SPH (Smooth Particle Hydrodynamics).

Card 1	1	2	3	4	5	6	7	8
Variable	NCBS	BOXID	DT	IDIM	NMNEIGH	FORM	START	MAXV
Type	I	I	F	I	I	I	F	F
Default	1	0	10^{20}	none	150	0	0.0	10^{15}

Remaining cards are optional.†

Card 2	1	2	3	4	5	6	7	8
Variable	CONT	DERIV	INI	ISHOW	IEROD	ICONT	IAVIS	ISYMP
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	100

Card 3	1	2	3	4	5	6	7	8
Variable	ITHK	ISTAB	QL		SPHSORT	ISHIFT		
Type	I	I	F		I	I		
Default	0	0	0.01		0	0		

VARIABLE	DESCRIPTION
NCBS	Number of time steps between particle sorting.
BOXID	SPH approximations are computed inside a specified box (see *DEFINE_BOX). When a particle has gone outside the BOX, it is deactivated. This will save computational time by eliminating particles that no longer interact with the structure.

VARIABLE	DESCRIPTION
DT	Death time. Determines when the SPH calculations are stopped.
IDIM	Space dimension for SPH particles: EQ.3: 3D problems EQ.2: 2D plane strain problems EQ.-2: 2D axisymmetric problems (see Remark 2)
NMNEIGH	Defines the initial number of neighbors per particle (see Remark 1 below).
FORM	Particle approximation theory (Remark 2): EQ.0: Default formulation EQ.1: Renormalization approximation EQ.2: Symmetric formulation EQ.3: Symmetric renormalized approximation EQ.4: Tensor formulation EQ.5: Fluid particle approximation EQ.6: Fluid particle with renormalization approximation EQ.7: Total Lagrangian formulation EQ.8: Total Lagrangian formulation with renormalization EQ.9: Adaptive SPH formulation (ASPH) with anisotropic smoothing tensor (Remark 2g) EQ.10: Renormalization approximation for adaptive SPH formulation (ASPH) with anisotropic smoothing tensor EQ.12: Moving least-squares based formulation (MPP only, see Remark 2e) EQ.13: Incompressible formulation (MPP only, see Remark 2h) EQ.15: Enhanced fluid formulation EQ.16: Enhanced fluid formulation with renormalization
START	Start time for particle approximation. Particle approximations will be computed when time of the analysis has reached the value defined in START.

VARIABLE	DESCRIPTION
MAXV	Maximum magnitude of the velocity for SPH particles. Particles with a velocity magnitude greater than MAXV are deactivated. A value of 0.0 will turn off the velocity checking. If a negative value is used, particles with a velocity magnitude greater than |MAXV| will be reassigned a velocity field with a magnitude equal to |MAXV|.
CONT	Flag for inter-part particle interaction by "particle approximation": EQ.0: Particle approximation is used for computing inter-part particle interaction for all SPH parts (default). EQ.1: Particle approximation is not used for inter-part particle interaction, except as specified by the INTERACTION option of *SECTION_SPH. As an alternative to particle approximation, inter-part particle interaction can be accomplished using *DEFINE_SPH_TO_SPH_COUPLING.
DERIV	Time integration type for the smoothing length: EQ.0: $\frac{d}{dt}[h(t)] = \frac{1}{d}h(t)\nabla \cdot \mathbf{v}$, (default) EQ.1: $\frac{d}{dt}[h(t)] = \frac{1}{d}h(t)(\nabla \cdot \mathbf{v})^{1/3}$
INI	Computation of the smoothing length during the initialization: EQ.0: Bucket sort based algorithm (default, very fast) EQ.1: Global computation on all the particles of the model EQ.2: Based on the mass of the SPH particle
ISHOW	Display option for deactivated SPH particles: EQ.0: No distinction in active SPH particles and deactivated SPH particles when viewing in LS-PrePost EQ.1: Deactivated SPH particles are displayed only as points and active SPH particles are displayed as spheres when Setting → SPH → Style is set to "smooth" in LS-PrePost.
IEROD	Deactivation control for SPH particles: EQ.0: Particles remain active. See Remark 3. EQ.1: SPH particles are partially deactivated and stress states are set to 0 when erosion criteria are satisfied. See Remark 3.

VARIABLE	DESCRIPTION
	EQ.2: SPH particles are totally deactivated and stress states are set to 0 when erosion criteria are satisfied. See Remark 3.
	EQ.3: SPH particles are partially deactivated and stress states are set to 0 when erosion criteria are satisfied. If an EOS is defined, the volumetric response is unaffected. See Remark 3.
ICONT	Controls contact behavior for deactivated SPH particles:
	EQ.0: Any contact defined for SPH remains active for deactivated particles.
	EQ.1: Contact is inactive for deactivated particles.
IAVIS	Defines artificial viscosity formulation for SPH elements (Remark 4):
	EQ.0: Monaghan type artificial viscosity formulation is used.
	EQ.1: Standard type artificial viscosity formulation from solid element is used (this option is not supported in SPH 2D and 2D axisymmetric elements).
ISYMP	Defines the percentage of original SPH particles used for memory allocation of SPH symmetric planes ghost nodes generation process (default is 100%). Recommended for large SPH particles models (value range 10~20) to control the memory allocation for SPH ghost particles with *BOUNDARY_SPH_SYMMETRY_PLANE keyword.
ITHK	Contact thickness option:
	EQ.0: The contact thickness is set to zero (default).
	EQ.1: The contact thickness is automatically calculated based on the volume of each SPH particle.
	This contact thickness calculation is ignored if a nonzero contact thickness for the SURFA surface (SAST) is provided by the contact card.
ISTAB	Stabilization type, only used when IFORM = 12:
	EQ.0: Incremental stabilization (default). Adequate for most materials.
	EQ.1: Total stabilization. Only recommended for hyperelastic materials.

VARIABLE	DESCRIPTION
QL	Quasi-Linear coefficient, only used when IFORM = 12. See Remark 5.
SPHSORT	For the implicit solver, sort and move SPH nodes from *NODE list to the end of the list. EQ.0: No sorting (default) EQ.1: Perform sorting
ISHIFT	Flag for applying the shifting algorithm to SPH particles (available from R13.0). With the shifting algorithm, particles are advanced and then shifted slightly across streamlines. This process reduces particle clustering in the maximum compression and stretching directions. EQ.0: Do not apply shifting algorithm applied (default). EQ.1: Apply shifting algorithm applied.

Remark:

1. **NMNEIGH.** NMNEIGH is used to determine the initial memory allocation for the SPH arrays. Its value can be positive or negative. If NMNEIGH is positive, memory allocation is dynamic such that the number of neighboring particles is initially equal to NMNEIGH but that number is subsequently allowed to exceed NMNEIGH as the solution progresses. If NMNEIGH is negative, memory allocation is static and |NMNEIGH| is the maximum allowed number of neighboring particles for each particle throughout the entire solution. Using this static memory option can avoid memory allocation problems.

2. **FORM.** The user must be careful to pick the right FORM which depends upon the application. Below are some guidelines for selecting the FORM value:

   a) For most solid structure applications, FORM = 1 is recommended for more accurate results around the boundary area.

   b) For fluid or fluid-like material applications, FORM = 15 or 16 is recommended. FORM = 16 usually has better accuracy but requires more CPU time. Also note that formulations 15 and 16 include a smoothing of the pressure field and are, therefore, not recommended for materials with failure or problems with important strain localization.

   c) All SPH formulations with Eulerian kernel, that is, FORM with values 0 to 6, 15 and 16, can be used for large or extremely large deformation

applications but will have tensile instability issues. FORM = 2 or 3 is not recommended for any case.

d) All SPH formulations with Lagrangian kernel (FORM = 7 or 8) can be used to avoid tensile instability issue but they cannot endure very large deformations.

e) For improved accuracy and tensile stability, a formulation based on moving least-squares (FORM = 12) is available. This formulation can be used for extremely large deformation applications but entails a significant computational cost. FORM = 12 is available for MPP simulations only. It is strongly recommended to keep a constant smoothing length for this formulation by setting HMIN = 1.0 and HMAX = 1.0 in *SECTION_SPH.

f) Only formulations 0, 1, 15 and 16 are implemented for 2D axisymmetric problems (IDIM = -2).

g) Formulations 9 and 10 are adaptive smoothed particle hydrodynamics formulations with an anisotropic kernel (Eulerian kernel) whose axes evolve automatically to follow the mean particles spacing as it varies in time, space and direction based on the strain rate tensors. These forms must be used with the *SECTION_SPH_ELLIPSE keyword. They have better accuracy and stability than the standard SPH. These forms can be used for extremely large deformation problems and are available for 3D case only.

h) Formulation 13 is an implicit incompressible fluid formulation based on operator splitting. used mainly for water wading simulations. The fluid should be assigned to a *MAT_SPH_INCOMPRESSIBLE_FLUID material, and any structure interacting with the fluid needs to be sampled with SPH particles (see the *DEFINE_SPH_MESH_SURFACE keyword) assigned to a *MAT_SPH_INCOMPRESSIBLE_STRUCTURE material. The density of the structure particles should be the same as the rest density of the interacting fluid. The time-step is calculated based on a CFL condition on the particles velocity and usually needs to be limited using the LCTM option in *CONTROL_TIMESTEP. The smoothing length of fluid and structure particles should be set to the initial inter-particle distance of the fluid, using SPHINI in *SECTION_SPH. The fluid-structure interaction is calculated entirely based on the SPH interaction of fluid and structure particles, and no *CONTACT keyword is necessary.

3. **Erosion.** The erosion criteria, which triggers particle deactivation when IEROD = 1, 2 or 3, may come from the material model, from *MAT_ADD_EROSION, or from the ERODE field in *CONTROL_TIMESTEP.

a) For IEROD = 0, SPH particles remain active. This option is generally not recommended when materials with erosion are used, as many material

models will still reset the stress field to zero periodically. If an unaltered stress field is desired, simply remove the erosion criteria in the material model parameters.

b) For IEROD = 1, SPH particles are partially deactivated; that is, the stress states of the deactivated SPH particles will be set to zero, but these particles still remain in the domain integration for more stable results.

c) For IEROD = 2, SPH particles are totally deactivated, so the stress states will be set to 0 and the deactivated particles do not remain in the domain integration.

d) For IEROD = 3, SPH particles remain active. The deviatoric stress is set to zero. If an equation of state is used, the volumetric response remains unaltered; otherwise the volumetric stress is set to zero as well.

e) Deactivated particles can be distinguished from active particles by setting ISHOW = 1.

f) To disable contact for deactivated particles, set ICONT = 1.

4. **Artificial Viscosity.** The artificial viscosity for standard solid elements, which is active when AVIS = 1, is given by:

$$\begin{aligned} q &= \rho l\left(Q_1 l\dot{\varepsilon}_{kk}^2 - Q_2 a\dot{\varepsilon}_{kk}\right) \quad \dot{\varepsilon}_{kk} < 0 \\ q &= 0 \qquad\qquad\qquad\qquad\quad \dot{\varepsilon}_{kk} \geq 0 \end{aligned}$$

where Q_1 and Q_2 are dimensionless input constants, which default to 1.5 and .06, respectively (see *CONTROL_BULK_VISCOSITY); l is a characteristic length given as the square root of the area in two dimensions and as the cube root of the volume in three; and a is the local sound speed. This formulation, which is consistent with solid artificial viscosity, has better energy balance for SPH elements.

For general applications, Monaghan type artificial viscosity is recommended since this type of artificial viscosity is specifically designed for SPH particles. The Monaghan type artificial viscosity, which is active when AVIS = 0, is defined as follows:

$$q = \begin{cases} \dfrac{-Q_2\bar{c}_{ij}\phi_{ij} + Q_1\phi_{ij}^2}{\bar{\rho}_{ij}} & v_{ij}x_{ij} < 0 \\ 0 & v_{ij}x_{ij} \geq 0 \end{cases}$$

where

$$\phi_{ij} = \frac{h_{ij}v_{ij}x_{ij}}{|x_{ij}|^2 + \varphi^2}$$

$$\bar{c}_{ij} = 0.5(c_i + c_j)$$
$$\bar{\rho}_{ij} = 0.5(\rho_i + \rho_j)$$
$$h_{ij} = 0.5(h_i + h_j)$$
$$\varphi = 0.1h_{ij}$$

and Q_1 and Q_2 are input constants. When using Monaghan type artificial viscosity, it is recommended that the user set both Q_1 and Q_2 to 1.0 on either the *CONTROL_BULK_VISCOSITY or *HOURGLASS keywords; see for example G. R. Liu.

5. **Quasi-Linear Coefficient.** The moving least-squares based formulation contains a quasi-linear approximation term to combine accuracy with stability in extremely large deformations simulations. The default value QL = 0.01 gives a good compromise between accuracy and stability in most cases. For greater accuracy, its value can be reduced to QL = 0.001 in simulations with small deformations, or increased to QL = 0.1 for extreme deformations, if instabilities are present.

*CONTROL_SPH_INCOMPRESSIBLE

Purpose: Provide controls relating to incompressible SPH (FORM = 13; see *CONTROL_SPH for more information).

Card 1	1	2	3	4	5	6	7	8
Variable	IBNDP	TAVG	TMAX	ROL	IHTC	IMAT		
Type	I	Fs	F	F	I	I		
Default	0	10^{-2}	10^{20}	10^{20}	0	0		

VARIABLE	DESCRIPTION
IBNDP	Pressure treatment of boundary particles: EQ.0: Pressure on boundary particles is extrapolated from fluid particles. EQ.1: Pressure on boundary particles is explicitly calculated.
TAVG	Tolerance criteria for convergence. If the average relative density (ρ/ρ_0) of particles under compression is below TAVG, this condition is satisfied.
TMAX	Tolerance criteria for convergence. If the maximum relative density (ρ/ρ_0) of particles under compression is below TMAX, this condition is satisfied.
ROL	Stuck particle detection criteria. In certain scenarios, some fluid particles can end up stuck between moving structures and as a result accumulate very large pressure values. If a particle's relative density contribution from boundaries is above ROL, it is deactivated. Its displacement is prescribed from the interpolated structure motion until it is sufficiently away from the structure at which point it is activated again.
IHTC	Flag for Heat Transfer Coefficient calculation: EQ.0: HTCs are not calculated. EQ.1: HTCs are calculated based on fluid properties given in *MAT_SPH_INCOMPRESSIBLE_FLUID input.

VARIABLE	DESCRIPTION
IMAT	Flag for *MAT_SPH_INCOMPRESSIBLE_FLUID formulations: EQ.0: Surface tension and surface adhesion forces are calculated based on numerical parameters given in the material cards. EQ.1: Surface tension and surface adhesion forces are calculated based on physical properties given in the material cards.

*CONTROL_SPOTWELD_BEAM

Purpose: Provides factors for scaling the failure force resultants of beam spot welds as a function of their parametric location on the contact segment and the size of the segment. Also, an option is provided to replace beam welds with solid hexahedron element clusters.

Card 1	1	2	3	4	5	6	7	8
Variable	LCT	LCS	T_ORT	PRTFLG	T_ORS	RPBHX	BMSID	ID_OFF
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
LCT	Load curve ID for scaling the response in tension based on the shell element size.
LCS	Load curve ID for scaling the response in shear based on the shell element size.
T_ORT	Table ID for scaling the tension response (and shear response if T_ORS = 0) based on the location of the beam node relative to the centroid of the shell.
PRTFLG	Set this flag to 1 to print for each spot weld attachment: the beam, node, and shell ID's, the parametric coordinates that define the constraint location, the angle used in the table lookup, and the three scale factors obtained from the load curves and table lookup. See Figure 12-88.
T_ORS	Optional table ID for scaling the shear response based on the location of the beam node relative to the centroid of the shell.
RPBHX	Replace each spot weld beam element with a cluster of RPBHX solid elements. The net cross-section of the cluster of elements is dimensioned to have the same area as the replaced beam. RPBHX may be set to 1, 4, or 8. When RPBHX is set to 4 or 8, a table is generated to output the force and moment resultants into the SWFORC file if this file is active. This table is described by the keyword: *DEFINE_HEX_SPOTWELD_ASSEMBLY. The IDs of the beam elements are used as the cluster spot weld IDs so the IDs

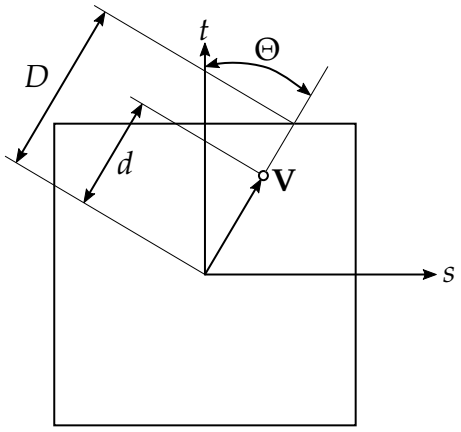

Figure 12-88. Definition of parameters for table definition.

VARIABLE	DESCRIPTION
	in the SWFORC file are unchanged. The beam elements are automatically deleted from the calculation, and the section and material data is automatically changed to be used with solid elements. See Figure 17-53.
BMSID	Optional beam set ID defining the beam element IDs that are to be converted to hex assemblies. If zero, all spot weld beam elements are converted to hex assemblies.
ID_OFF	This optional ID offset applies if and only if BMSID is nonzero. Beams, which share part IDs with beams that are converted to hex assemblies, will be assigned new part IDs by adding to the original part ID the value of ID_OFF. If ID_OFF is zero, the new part ID for such beams will be assigned to be larger than the largest part ID in the model.

Remarks:

The load curves and table provide a means of scaling the response of the beam spot welds to reduce any mesh dependencies for failure model 6 in *MAT_SPOTWELD. Figure 12-89 shows such dependencies that can lead to premature spot weld failure. Separate scale factors are calculated for each of the beam's nodes. The scale factors s_T, s_s, s_{OT}, and s_{OS} are calculated using LCT, LCS, T_ORT, and T_ORS, respectively, and are introduced in the failure criteria,

$$\left[\frac{s_T s_{OT}\sigma_{rr}}{\sigma_{rr}^F(\dot{\varepsilon}_{\text{eff}})}\right]^2 + \left[\frac{s_S s_{OS}\tau}{\tau^F(\dot{\varepsilon}_{\text{eff}})}\right]^2 - 1 = 0 \ .$$

If a curve or table is given an ID of 0, its scale factor is set to 1.0. The load curves LCT and LCS are functions of the characteristic size of the shell element used in the time step calculation at the start of the calculation. The orientation table is a function of the spot weld's

isoparametric coordinate location on the shell element. A vector **V** is defined from the centroid of the shell to the contact point of the beam's node. The arguments for the orientation table are the angle:

$$\Theta = \tan^{-1}\left[\frac{\min(|s|,|t|)}{\max(|s|,|t|)}\right],$$

and the normalized distance $\bar{d} = d/D = \max(|s|,|t|)$. See Figure 12-88. The table is periodic over a range of 0 (**V** aligned with either the s or t axis) to 45 degrees (**V** is along the diagonal of the element). The table is specified by the angle of **V** in degrees, ranging from 0 to 45, and the individual curves give the scale factor as a function of the normalized distance of the beam node, $\bar{d}$, for a constant angle.

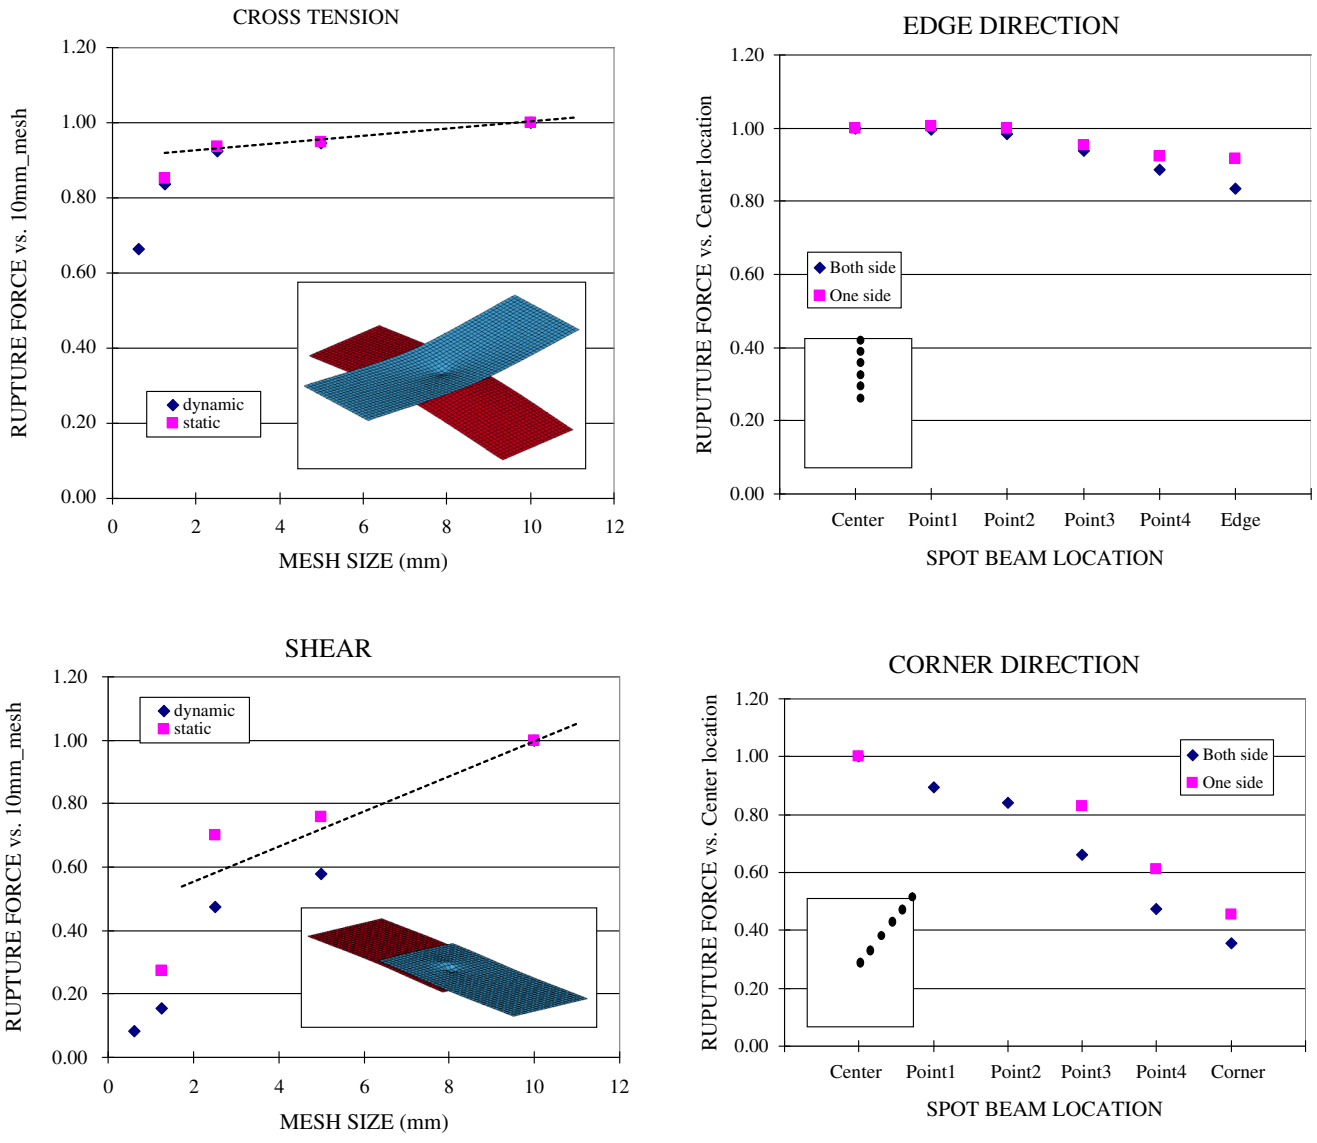

Figure 12-89 The failure force resultants can depend both on mesh size and the location of weld relative to the center of the contact segment

*CONTROL_STAGED_CONSTRUCTION

Purpose: Help break down analyses of construction processes into stages.

Card 1	1	2	3	4	5	6	7	8
Variable	TSTART	STGS	STGE	ACCEL	FACT	blank	DORDEL	NOPDEL
Type	F	I	I	F	F		I	I

This card is optional.

Card 2	1	2	3	4	5	6	7	8
Variable	ITIME	blank	IDYNAIN					
Type	I		I					
Default	0		0					

VARIABLE	DESCRIPTION
TSTART	Time at start of analysis (normally leave blank). See Remark 5.
STGS	Construction stage at start of analysis
STGE	Construction stage at end of analysis
ACCEL	Default acceleration for gravity loading
FACT	Default stiffness and gravity factor for parts before they are added
DORDEL	Dormant part treatment in d3plot file (see Remark 6): EQ.0: Parts not shown when dormant (flagged as "deleted"). EQ.1: Parts shown normally when dormant.

VARIABLE	DESCRIPTION
NOPDEL	Treatment of pressure loads on deleted elements (see Remark 7): EQ.0: Pressure loads automatically deleted. EQ.1: No automatic deletion.
ITIME	Treatment of "Real Time" on *DEFINE_CONSTRUCTION_STAGES (see Remark 8): EQ.0: Real Time is ignored. EQ.1: Time in output files (d3plot, d3thdt, binout…) is converted to Real Time.
IDYNAIN	Flag to control output of dynain file at the end of every stage (see Remark 9): EQ.0: Write dynain file. EQ.1: Do not write dynain file.

Remarks:

1. **Related Keywords.** See also *DEFINE_CONSTRUCTION_STAGES and *DEFINE_STAGED_CONSTRUCTION_PART.

2. **Re-Running Analysis.** The staged construction options offer flexibility to carry out the whole construction simulation in one analysis or to run it stage by stage. Provided that at least one construction stage is defined (*DEFINE_CONSTRUCTION_STAGES), a dynain file will be written at the end of each stage (file names are end_stage001_dynain, etc.). These contain node and element definitions and the stress state; the individual stages can then be re-run without re-running the whole analysis. To do this, make a new input file as follows:

   - Copy the original input file, containing *DEFINE_CONSTRUCTION_STAGES and *DEFINE_STAGED_CONSTRUCTION_PART.
   - Delete node and element definitions as these will be present in the dynain file (*NODE, *ELEMENT_SOLID, *ELEMENT_SHELL, and *ELEMENT_BEAM).
   - Delete any *INITIAL cards; the initial stresses in the new analysis will be taken from the dynain file.
   - On *CONTROL_STAGED_CONSTRUCTION set STGS to start at the desired stage.

- Add an *INCLUDE statement referencing, for example, end_stage002_dynain if starting the new analysis from Stage 3.

- Move or copy the dynain file into the same directory as the new input file.

3. **Starting and Ending Stages.** When STGS is > 1 the analysis starts at a non-zero time (the start of stage STGS). In this case a dynain file must be included to start the analysis from the stress state at the end of the previous stage. The end time for stage STGE overrides the termination time on *CONTROL_TERMINATION. A new dynain file will be written at the end of all stages from STGS to STGE.

   If STGS > 1 and elements have been deleted in a previous stage, these elements will be absent from the new analysis and should not be referred to (for example, *DATABASE_HISTORY_SOLID) in the new input file.

4. **ACCEL and FACT.** ACCEL is the gravity loading applied to parts referenced by *DEFINE_STAGED_CONSTRUCTION_PART. FACT, which should be a very small number such as 10^{-6}, is the factor by which stresses and gravity load are scaled when parts referenced by *DEFINE_STAGED_CONSTRUCTION_PART are inactive.

5. **Start Time.** TSTART can be used to set a non-zero start time (again, assuming a compatible dynain file is included). This option is used only if construction stages have not been defined.

6. **Dormant Parts.** By default, parts for which *DEFINE_STAGED_CONSTRUCTION_PART is defined are flagged as "deleted" in the d3plot file at time-states for which the part is not active (that is, stage STGA has not yet been reached). Parts that are deleted because STGR has been reached are also flagged as "deleted." When animating the results, the parts become visible when they become active, as if they had been added to the model at that time; and they disappear as they are deleted. If DORDEL is non-zero, inactive parts (before STGA) are shown normally. The parts are still shown as deleted after STGR is reached.

7. **Pressure Load Segments.** By default, LS-DYNA automatically deletes pressure load "segments" if they share all four nodes with a deleted solid or shell element. In staged construction, you may want to apply a pressure load to the surface of an element, A, that is initially shared with an element, B, where B is deleted during the calculation. For example, B may be in a layer of soil that is excavated, leaving A as the new top surface. The default scheme would delete the pressure segment when B is removed, despite A still being present. NOPDEL instructs LS-DYNA to skip the automatic deletion of pressure segments, irrespective of whether the elements have been deleted due to staged construction or material failure. You must then ensure that pressure loads are not applied to nodes no longer supported by an active element.

8. **Real Time.** Construction processes that in real life take days, weeks, or months may be modelled in seconds of analysis time using a "time acceleration" method. For example, one second of analysis time might represent ten days of real time. The speed-up factor might differ at different stages of the analysis. You may, however, want to present plots and graphs with real time rather than the analysis time used in LS-DYNA's calculations. To do this, set ITIMES to 1, and set RTS and RTE (see optional fields RTS and RTE on *DEFINE_CONSTRUCTION_STAGES) to the real time at the start and end of each stage. This feature has no effect on the calculations as it changes only the times shown in the d3plot, d3thdt and binout files.

9. **IDYNAIN.** Output of the dynain files can be suppressed by setting IDYNAIN to 1. If dynain files are required for some stages but not others, set IDYNAIN on *DEFINE_CONSTRUCTION_STAGES instead.

*CONTROL_START

Purpose: Define the start time of analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	BEGTIM							
Type	F							

VARIABLE	DESCRIPTION
BEGTIM	Start time of analysis (default = 0.0). *Load curves are not shifted to compensate for the time offset.* Therefore, this keyword will change the results of any calculation involving time-dependent load curves.

*CONTROL_STEADY_STATE_ROLLING

Card 1	1	2	3	4	5	6	7	8
Variable	IMASS	LCDMU	LCDMUR	IVEL	SCL_K			
Type	I	I	I	I	I			
Default	0	0	0	0	↓			

VARIABLE	DESCRIPTION
IMASS	Inertia switching flag: EQ.0: include inertia during an implicit dynamic simulation. EQ.1: treat steady state rolling subsystems as quasi-static during implicit dynamic simulations.
LCDMU	Optional load curve for scaling the friction forces in contact.
LCDMUR	Optional load curve for scaling the friction forces in contact during dynamic relaxation. If LCDMUR isn't specified, LCDMU is used.
IVEL	Velocity switching flag: EQ.0: eliminate the steady state rolling body forces and set the velocities of the nodes after dynamic relaxation. EQ.1: keep the steady state rolling body forces after dynamic relaxation instead of setting the velocities.
SCL_K	Scale factor for the friction stiffness during contact loading and unloading. The default values are 1.0 and 0.01 for explicit and implicit, respectively. Any scaling applied here applies only to contact involving the subsystem of parts defined for steady state rolling.

Remarks:

1. **Quasi-Static.** Treating the steady state rolling subsystems as quasi-static during an implicit simulation may eliminate vibrations in the system that are not of interest and is generally recommended.

2. **Scaling Friction and Convergence.** Ramping up the friction by scaling it with LCDMU and LCDMUR may improve the convergence behavior of implicit calculations. The values of the load curves should be 0.0 at initial contact and ramp up smoothly to a value of 1.0.

3. **Steady State Rolling Body Forces.** After dynamic relaxation, the default behavior is to initialize the nodes with the velocities required to generate the body forces on elements and remove the body forces. This initialization is skipped, and the body forces retained, after dynamic relaxation if IVEL = 1.

4. **Friction Stiffness Scale Factor.** The friction model in contact is similar to plasticity, where there is an elastic region during the loading and unloading of the friction during contact. The elastic stiffness is scaled from the normal contact stiffness. For implicit calculations, the default scale factor is 0.01, which results in long periods of time being required to build the friction force, and, in some cases, oscillations in the contact forces. A value between 10 and 100 produces smoother solutions and a faster build-up and decay of the friction force as the tire velocity or slip angle is varied, allowing a parameter study to be performed in a single run.

***CONTROL_STRUCTURED**_{OPTION}

Available options include:

<BLANK>

TERM

Purpose: Write out an LS-DYNA structured input deck that is largely or wholly equivalent to the keyword input deck. This option may be useful in debugging errors that occur during processing of the input file, particularly if error messages of the type "*** ERROR ##### (STR + ###)" are written. The name of the structured input deck is "dyna.str".

Not all LS-DYNA features are supported in structured input format. Some data such as load curve numbers will be output in an internal numbering system.

If the TERM option is activated, termination will occur after the structured input deck is written.

Adding "outdeck = s" to the LS-DYNA execution line serves the same purpose as including *CONTROL_STRUCTURED in the keyword input deck.

***CONTROL_SUBCYCLE**_{K}_{L} or
***CONTROL_SUBCYCLE**_{OPTION}*

Available options for subcycling first form with K and L

$K, L \in \{$<BLANK>$, 1, 2, 4, 8, 16, 32, 64\}$

Available options for multiscale (*OPTION*) include:

<BLANK>

MASS_SCALED_PART

MASS_SCALED_PART_SET

Purpose: This keyword is used to activate subcycling or mass scaling (multiscale). The common characteristic of both methods is that the time step varies from element to element, thereby eliminating unnecessary stepping on more slowly evolving portions of the model. These techniques are suited for reducing the computational cost for models involving large spatial variation in mesh density and/or material characteristics.

Subcycling is described in the LS-DYNA Theory Manual and in detail in Borrvall et.al. [2014] and may be seen as an alternative to using selective mass scaling, see the keyword *CONTROL_TIMESTEP.

This keyword comes in two variations:

1. **Subcycling.** Plain subcycling is activated by the *CONTROL_SUBCYCLE_{K}_{L} variant of this keyword. This form of the card should *not* be included more than once. It may be used in conjunction with mass scaling to limit the time step characteristics.

   For subcycling, time steps for integration are determined automatically from the characteristic properties of the elements in the model, with the restriction that the ratio between the largest and smallest time step is limited by K. Furthermore, L determines the relative time step at which external forces such as contacts and loads are calculated

   For example, *CONTROL_SUBCYCLE_16_4 limits the largest explicit integration time step to at most 16 times the smallest. Contact forces are evaluated every 4 time steps. The defaults are $K = 16$ and $L = 1$, and L cannot be specified larger than K. This option may be used without mass scaling activated but internally elements may still be slightly mass scaled to maintain computational efficiency.

2. **Mass Scaling/Multiscale.** For a multiscale simulation, mass scaling is mandatory and the time steps are directly specified in the input. The specified parts (see the PID field) or part sets (see the PSID field) run at the time step specified

in the TS field. All other elements evolve with a time step set by |DT2MS|, which is set on *CONTROL_TIMESTEP card.

This feature was motivated by automotive crash simulation, wherein it is common for a small subset of *solid* elements to limit the time step size. With this card the finely meshed parts (consisting of solid elements) can be made to run with a smaller time step through mass scaling so that the rest of the vehicle can run with a time step size of |DT2MS|.

Part Card. Additional card for the MASS_SCALED_PART and MASS_SCALED_-PART_SET keyword options. Provide as many cards as necessary. Input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	TS						
Type	I	F						
Default	none	none						

VARIABLE	DESCRIPTION
PID/PSID	Part ID or part set ID if the SET option is specified.
TS	Time step size at which mass scaling is invoked for the PID or PSID

*CONTROL_TERMINATION

Purpose: Stop the job.

Card 1	1	2	3	4	5	6	7	8
Variable	ENDTIM	ENDCYC	DTMIN	ENDENG	ENDMAS	NOSOL		
Type	F	I	F	F	F	I		
Default	0.0	0	0.0	0.0	10^8	0		
Remarks	1		2					

VARIABLE	DESCRIPTION
ENDTIM	Termination time. Mandatory.
ENDCYC	Termination cycle. The termination cycle is optional and will be used if the specified cycle is reached before the termination time. Cycle number is identical with the time step number.
DTMIN	Reduction (or scale) factor to determine minimum time step, tsmin, where tsmin = dtstart × DTMIN and dtstart is the initial step size determined by LS-DYNA. When the time step drops to tsmin, LS-DYNA terminates with a restart dump. See the exception described in Remark 2. Also note that dtstart is the initial step size regardless of whether the first step is explicit or implicit; this can have implications if an analysis starts as implicit and later switches to explicit, resulting in a large drop in step size.
ENDENG	Percent change in energy ratio for termination of calculation. If undefined, this option is inactive.
ENDMAS	Percent change in the total mass for termination of calculation. This option is relevant if and only if mass scaling is used to limit the minimum time step size; see *CONTROL_TIMESTEP field DT2MS. LT.0.0: |ENDMAS| is the load curve ID defining the percent change in the total mass as a function of the total mass.
NOSOL	Flag for a non-solution run, that is, normal termination directly after initialization.

VARIABLE	DESCRIPTION
	EQ.0: Off (default),
	EQ.1: On.

Remarks:

1. **Displacement Termination.** Termination by displacement may be defined in the *TERMINATION section.

2. **Erosion.** If the erosion flag on *CONTROL_TIMESTEP is set (ERODE = 1), then solid elements and thick shell elements whose time step falls below tsmin will be eroded and the analysis will continue. This time-step-based failure option is not recommended when solid formulations 11 or 12 are included in the model. Furthermore, when PSFAIL in *CONTROL_SOLID is nonzero, regardless of the value of ERODE, then all solid elements excepting those with formulation 11 or 12, whose time step falls below tsmin will be eroded and the analysis will continue. This time-step-based erosion of solids due to a nonzero PSFAIL is not limited to solids in part set PSFAIL. Only the negative-volume-based erosion criterion is limited to solids in part PSFAIL.

*CONTROL_THERMAL_EIGENVALUE

Purpose: Compute eigenvalues of thermal conductance matrix for model evaluation purposes.

Card 1	1	2	3	4	5	6	7	8
Variable	NEIG							
Type	I							
Default	0						.	.

VARIABLE	DESCRIPTION
NEIG	Number of eigenvalues to compute: EQ.0: No eigenvalues are computed. GT.0: Compute NEIG eigenvalues of each thermal conductance matrix.

Remarks:

1. **Feature Description.** This feature causes LS-DYNA to compute NEIG eigenvalues for each thermal conductance matrix. This tool is for model evaluation, so only a small number of thermal time steps, such as 1, should be used with this feature.

*CONTROL_THERMAL_FORMING

Purpose: Simplify keyword input deck by defining key control parameters for hot stamping simulations. A hot stamping simulation is in general a thermo-mechanical-coupled analysis, which requires adding a set of thermal control keywords to fully define the simulation job. However, for certain situations this keyword can simplify input by reducing the number of keywords required.

Card Summary:

Card 1. This card is required.

ITS	PTYPE	TSF	THSHEL	ITHOFF	SOLVER	FWORK	

Card 2.1. The card set, Cards 2.1 and 2.2, is optional. When present Card 2.1 sets the default values for the fields of "THRM 1" on *CONTACT and "THRM 1" becomes optional.

K	FRAD	H0	LMIN	LMAX	FTOSA	BC_FLG	ALGO

Card 2.2. The card set, Cards 2.1 and 2.2, is optional. When present Card 2.2 sets the default values for the fields of "THRM 2" on *CONTACT and "THRM 2" becomes optional.

LCFST	LCFDT	FORMULA	A	B	C	D	LCH

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	ITS	PTYPE	TSF	THSHEL	ITHOFF	SOLVER	FWORK	
Type	F	I	F	I	I	I	F	
Default	none	0	1.	0	0	3	1.0	

VARIABLE	DESCRIPTION
ITS	Initial thermal time step size

VARIABLE	DESCRIPTION
PTYPE	Thermal problem type (see Remark 1 for determining the type of problem): EQ.0: Linear problem EQ.1: Nonlinear problem with material properties evaluated at the temperature of the gauss point EQ.2: Nonlinear problem with material properties evaluated at the average temperature of the element
TSF	Thermal Speedup Factor. This factor multiplies all thermal parameters with units of time in the denominator (such as thermal conductivity and convection heat transfer coefficients). It is used to artificially scale the problem in time. For example, if the velocity of the stamping punch is artificially increased by 1000, then set TSF = 1000 to scale the thermal parameters.
THSHEL	Thermal shell option: EQ.0: No temperature gradient is considered through the shell thickness. EQ.1: A temperature gradient is calculated through the shell thickness.
ITHOFF	Flag for offsetting thermal contact surfaces for thick thermal shells: EQ.0: No offset; if thickness is not included in the contact, the heat will be transferred between the mid-surfaces of the corresponding contact segments (shells). EQ.1: Offsets are applied so that contact heat transfer is always between the outer surfaces of the contact segments (shells).
SOLVER	Thermal analysis solver type (see *CONTROL_THERMAL_SOLVER). For SMP only: EQ.1: Using solver 11 (enter -1 to use the old ACTCOL solver) EQ.2: Nonsymmetric direct solver EQ.3: Diagonal scaled conjugate gradient iterative (default) EQ.4: Incomplete choleski conjugate gradient iterative EQ.5: Nonsymmetric diagonal scaled bi-conjugate gradient

VARIABLE	DESCRIPTION
	For SMP or MPP: EQ.11: Direct solver EQ.12: Diagonal scaling conjugate gradient iterative (default) EQ.13: Symmetric Gauss-Seidel conjugate gradient iterative EQ.14: SSOR conjugate gradient iterative EQ.15: ILDLT0 (incomplete factorization) conjugate gradient iterative EQ.16: Modified ILDLT0 (incomplete factorization) conjugate gradient iterative For Conjugate Heat transfer problems in SMP or MPP: EQ.17: GMRES solver
FWORK	Fraction of mechanical work converted into heat EQ.0.0: Use default value 1.0.

Card 2.1	1	2	3	4	5	6	7	8
Variable	K	FRAD	H0	LMIN	LMAX	FTOSA	BC_FLG	ALGO
Type	F	F	F	F	F	F	I	I
Default	none	none	none	none	none	0.5	0	0

VARIABLE	DESCRIPTION
K	Thermal conductivity of fluid between the contact surfaces. If a gap with a thickness l_{gap} exists between the contact surfaces, then the conductance due to thermal conductivity between the contact surfaces is $$h_{cond} = \frac{K}{l_{gap}}$$ Note that LS- DYNA calculates l_{gap} based on deformation.

VARIABLE	DESCRIPTION
FRAD	Radiation factor between the contact surfaces. $$f_{\text{rad}} = \frac{\sigma}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1},$$ where σ = Stefan-Boltman constant, ε_1 = emissivity of SURFB surface, ε_2 = emissivity of SURFA surface. LS-DYNA calculates a radiant heat transfer conductance $$h_{\text{rad}} = f_{\text{rad}}(T_{\text{SURFA}} + T_{\text{SURFB}})\left(T_{\text{SURFA}}^2 + T_{\text{SURFB}}^2\right)$$
H0	Heat transfer conductance for closed gaps. Use this heat transfer conductance for gaps in the range $$0 \le l_{\text{gap}} \le l_{\text{min}}$$
LMIN	Minimum gap, l_{min}; use the heat transfer conductance defined (H0) for gap thicknesses less than this value. LT.0.0: -LMIN is a load curve ID defining l_{min} as a function of time.
LMAX	No thermal contact if gap is greater than this value (l_{max}).
FTOSA	Fraction, f, of sliding friction energy partitioned to the SURFA surface. Energy partitioned to the SURFB surface is $(1-f)$. EQ.0: Default set to 0.5. The sliding friction energy is partitioned 50% - 50% to the SURFA and SURFB surfaces in contact. $$f = \frac{1}{1 + \frac{\sqrt{(\rho C_p k)_{\text{SURFB side material}}}}{\sqrt{(\rho C_p k)_{\text{SURFA side material}}}}}$$
BC_FLAG	Thermal boundary condition flag: EQ.0: Thermal boundary conditions are on when parts are in contact. EQ.1: Thermal boundary conditions are off when parts are in contact.

VARIABLE	DESCRIPTION
ALGO	Contact algorithm type. EQ.0: Two-way contact; both surfaces change temperature due to contact. EQ.1: One-way contact; SURFB surface does not change temperature due to contact. SURFA surface does change temperature.

Card 2.2	1	2	3	4	5	6	7	8
Variable	LCFST	LCFDT	FORMULA	A	B	C	D	LCH
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
LCFST	Load curve number for static coefficient of friction as a function of temperature. The load curve value multiplies the coefficient value FS.
LCFDT	Load curve number for dynamic coefficient of friction as a function of temperature. The load curve value multiplies the coefficient value FD.
FORMULA	Formula that defines the contact heat conductance as a function of temperature and pressure. EQ.1: $h(P)$ is defined by load curve A, which contains data for contact conductance as a function of pressure. EQ.2: $h(P)$ is given by the following where A, B, C and D although defined by load curves are typically constants for use in this formula. The load curves are given as functions of temperature. $$h(P) = a + bP + cP^2 + dP^3$$

VARIABLE	DESCRIPTION
	EQ.3: $h(P)$ is given by the following formula from [Shvets and Dyban 1964]. $$h(P) = \frac{\pi k_{\text{gas}}}{4\lambda}\left[1. + 85\left(\frac{P}{\sigma}\right)^{0.8}\right] = \frac{a}{b}\left[1. + 85\left(\frac{P}{c}\right)^{0.8}\right] \ ,$$ where *a*: is evaluated from the load curve, A, for the thermal conductivity, k_{gas}, of the gas in the gap as a function of temperature. *b*: is evaluated from the load curve, B, for the parameter grouping $\pi/4\lambda$. Therefore, this load curve should be set to a constant value. λ is the surface roughness. *c*: is evaluated from the load curve, C, which specifies a stress metric for deformation (e.g., yield) as a function of temperature.
	EQ.4: $h(P)$ is given by the following formula from [Li and Sellars 1996]. $$h(P) = a\left[1 - \exp\left(-b\frac{P}{c}\right)\right]^d \ ,$$ where *a*: is evaluated from the load curve, A, which defines a load curve as a function of temperature. *b*: is evaluated from the load curve, B, which defines a load curve as a function of temperature. *c*: is evaluated from the load curve, C, which defines a stress metric for deformation (e.g., yield) as a function of temperature. *d*: is evaluated from the load curve D, which is a function of temperature.
	EQ.5: $h(\text{gap})$ is defined by load curve A, which contains data for contact conductance as a function of interface gap.
	LT.0: This is equivalent to defining the keyword *USER_INTERFACE_CONDUCTIVITY. The user subroutine `usrhcon` will be called for this contact interface to define the contact heat transfer coefficient.
A	Load curve ID for the *a* coefficient used in the formula.
B	Load curve ID for the *b* coefficient used in the formula.
C	Load curve ID for the *c* coefficient used in the formula.
D	Load curve ID for the *d* coefficient used in the formula.

VARIABLE	DESCRIPTION
LCH	Load curve ID for h. This parameter can refer to a curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION). When LCH is a curve ID (and a function ID) it is interpreted as follows: GT.0: The heat transfer coefficient is defined as a function of time, t, by a curve consisting of $(t, h(t))$ data pairs. LT.0: The heat transfer coefficient is defined as a function of temperature, T, by a curve consisting of $(T, h(T))$ data pairs. When the reference is to a function it is prototyped as follows $h = h(t, T_{avg}, T_{slv}, T_{msr}, P, g)$ where: t = solution time T_{avg} = average interface temperature T_{SURFA} = SURFA segment temperature T_{SURFB} = SURFB segment temperature P = interface pressure g = gap distance between SURFA and SURFB segments

Remarks:

1. **Problem Type.** The thermal problem becomes nonlinear when any of the following applies: (1) the material properties are temperature-dependent, (2) the thermal loads are temperature-dependent (for example, the convection coefficient is a function of temperature), (3) radiation exists.

2. **Heat Transfer at the Contact Interface between the Die and Blank.** The heat transfer coefficient h at the contact interface between the die and blank can be summarized as follows:

$$h = \begin{cases} h_0 & 0 \le l_{gap} \le l_{min} \\ h_{cond} + h_{rad} & l_{min} < l_{gap} \le l_{max} \\ 0 & l_{gap} > l_{max} \end{cases}$$

Examples:

The following input defines the thermal control parameters for a hot stamping simulation using *CONTROL_THERMAL_FORMING:

```
*CONTROL_THERMAL_FORMING
$      its     ptype       tsf    THSHEL    ITHOFF    solver     fwork
```

```
    1.0e-5         1       10.                             11
```

This is equivalent to defining the following set of keywords:

```
*CONTROL_SOLUTION
$#    soln       nlq     isnan     lcint     lcacc
         2
*CONTROL_THERMAL_SOLVER
$#   atype     ptype    solver     cgtol       gpt    eqheat     fwork       sbc
         1         1        11                 0  1.000000  1.00e-10  5.67e-11
$#  MSGLVL     MAXITR   ABSTOL    RELTOL     OMEGA                           TSF
                                                                            10.
*CONTROL_THERMAL_TIMESTEP
$#      ts       tip       its      tmin      tmax     dtemp      tscp      lcts
         0  1.000000    1.0e-5
*CONTROL_THERMAL_NONLINEAR
$#  refmax       tol
        10    1.0e-4
```

As shown above, *CONTROL_THERMAL_FORMING simplifies the user input by setting default values to less-frequently-used parameters implicitly. However, the user can always use a thermal control keyword to overwrite the default values of these hidden parameters. For instance, *CONTROL_THERMAL_FORMING sets FWORK (Fraction of mechanical Work converted to heat) to 10^{-10} implicitly. If FWORK needs to be increased to 0.8, add the following to the input deck to override the default value:

```
*CONTROL_THERMAL_SOLVER
$#   atype     ptype    solver     cgtol       gpt    eqheat     fwork       sbc
         1         1        11                 0  1.000000       0.8  5.67e-11
```

The thick shell option from Card 2 of *CONTROL_SHELL can also be turned on with just *CONTROL_THERMAL_FORMING with the THSHEL field as follows:

```
*CONTROL_THERMAL_FORMING
$       its     ptype       tsf    THSHEL    ITHOFF    solver     fwork
    1.0e-5         1       10.         1                   11
```

The ITHOFF field for this keyword changes the offset for thermal contact for shells which normally requires the inclusion of optional Card 5 in *CONTROL_CONTACT.

```
*CONTROL_THERMAL_FORMING
$       its     ptype       tsf     TSHEL    ITHOFF    solver     fwork
    1.0e-5         1       10.         1         1        11
```

A standard stamping simulation usually has multiple blank/die contact pairs with uniform or similar thermal/friction properties at the contact interface. With *CONTROL_-THERMAL_FORMING a default set of thermal/friction parameters can be defined by including the optional Cards 2.1 and 2.2. Input values in Cards 2.1 and 2.2 will be automatically applied to thermal/friction parameters of all contact pairs defined in THRM 1 and THRM 2 of *CONTACT. Therefore, the user does not need to repeat input of these parameters for every contact pair. An example is shown below:

```
*CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE_ID
```

```
$#     cid                                                                  title
         1 Die
$#   surfa     surfb  surfatyp  surfbtyp   saboxid   sbboxid      sapr      sbpr

```

Although Cards 2.1 and 2.2 of *CONTROL_THERMAL_FORMING provide a convenient way to define/update thermal/friction properties at multiple contact interfaces, some contact pairs require different values for the properties. In that case, simply add the THERMAL or THERMAL_FRICTION keyword option to this particular contact pair and input the thermal/friction parameters in the THRM 1 and THRM 2 cards which will override the default values set by *CONTROL_THERMAL_FORMING. The following examples shows how we use *CONTACT_THERMAL_FORMING to set HTC (Heat Transfer Coefficient) = 4.0 for all contact pairs except contact pair 2, which has HTC = 3.0.

*CONTROL_THERMAL_NONLINEAR

Purpose: Set parameters for a nonlinear thermal or coupled structural/thermal analysis. The control card, *CONTROL_SOLUTION, is also required.

Card 1	1	2	3	4	5	6	7	8
Variable	REFMAX	TOL	DCP	LUMPBC	THLSTL	NLTHPR	PHCHPN	
Type	I	F	F	I	F	I	F	
Default	10	10^{-4}	1.0 or 0.5	0	0.	0	100.	

VARIABLE	DESCRIPTION
REFMAX	Maximum number of matrix reformations per time step. EQ.0: Set to 10 reformations.
TOL	Convergence tolerance for temperature. EQ.0.0: Set to 1000 × machine roundoff.
DCP	Divergence control parameter: steady state problems $0.3 \le DCP \le 1.0$ default 1.0 transient problems $0.0 < DCP \le 1.0$ default 0.5
LUMPBC	Lump thermal boundary conditions. LUMPBC = 1 activates a numerical method to damp out anomalous temperature oscillations resulting from very large step function boundary conditions. This option is not generally recommended. EQ.0: Off (default) EQ.1: On
THLSTL	Line search convergence tolerance: EQ.0.0: No line search GT.0.0: Line search convergence tolerance
NLTHPR	Thermal nonlinear print out level: EQ.0: No print out

VARIABLE	DESCRIPTION
	EQ.1: Print convergence parameters during solution of nonlinear system.
PHCHPN	Phase change penalty parameter: EQ.0.0: Set to default value 100. GT.0.0: Penalty to enforce constant phase change temperature

*CONTROL_THERMAL_SOLVER

Purpose: Set options for the thermal solution in a thermal only or coupled structural-thermal analysis. The control card, *CONTROL_SOLUTION, is also required.

Card Summary:

Card 1. This card is required.

ATYPE	PTYPE	SOLVER		GPT	EQHEAT	FWORK	SBC

Card 2a. This card is optional. It is only read when SOLVER ≠ 17.

MSGLVL	MAXITR	ABSTOL	RELTOL	OMEGA			TSF

Card 2b. This card is optional. It is only read when SOLVER = 17.

MSGLVL	NINNER	ABSTOL	RELTOL	NOUTER			

Card 3. This card is optional.

MXDMP	DTVF	VARDEN		NCYCL			

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	ATYPE	PTYPE	SOLVER		GPT	EQHEAT	FWORK	SBC
Type	I	I	I		I	F	F	F
Default	0	0	↓		8	1.	1.	0.
Remark				11				

VARIABLE	DESCRIPTION
ATYPE	Thermal analysis type: EQ.0: Steady state analysis (see Remark 4) EQ.1: Transient analysis (see Remark 3)

VARIABLE	DESCRIPTION
PTYPE	Thermal problem type: (see *CONTROL_THERMAL_NONLINEAR if nonzero) EQ.0: Linear problem, EQ.1: Nonlinear problem with material properties evaluated at gauss point temperature. EQ.2: Nonlinear problem with material properties evaluated at element average temperature.
SOLVER	Thermal analysis solver type (see Remarks 1 and 2): EQ.11: Direct solver EQ.12: Diagonal scaling (default for MPP) conjugate gradient iterative EQ.13: Symmetric Gauss-Seidel conjugate gradient iterative EQ.14: SSOR conjugate gradient iterative EQ.15: ILDLT0 (incomplete factorization) conjugate gradient iterative EQ.16: Modified ILDLT0 (incomplete factorization) conjugate gradient iterative EQ.17: GMRES solver for conjugate heat transfer problems EQ.18: ILDLT(T) (incomplete factorization with threshold pivoting) EQ.19: Preconditioned conjugate gradient with MUMPS (see Remark 2 in *CONTROL_IMPlICIT_SOLVER) EQ.30: Direct nonsymmetric factorization
GPT	Number of Gauss points to be used in the solid elements: EQ.0: Use default value 8, EQ.1: One point quadrature is used.
EQHEAT	Mechanical equivalent of heat (see Remark 10). EQ.0.0: Default value 1.0, LT.0.0: Designates a load curve number for EQHEAT as a function of time.

VARIABLE	DESCRIPTION
FWORK	Fraction of mechanical work converted into heat. EQ.0.0: Use default value 1.0.
SBC	Stefan Boltzmann constant. Value is used with enclosure radiation surfaces; see *BOUNDARY_RADIATION_… LT.0.0: Use a smoothing algorithm when calculating view factors to force the row sum = 1.

Card 2a	1	2	3	4	5	6	7	8
Variable	MSGLVL	MAXITR	ABSTOL	RELTOL	OMEGA			TSF
Type	I	I	F	F	F			F
Default	0	500	10^{-10}	10^{-6}	1.0 or 0.			1.

VARIABLE	DESCRIPTION
MSGLVL	Output message level (For SOLVER > 10) EQ.0: No output (default), EQ.1: Summary information, EQ.2: Detailed information, use only for debugging.
MAXITR	Maximum number of iterations. For SOLVER > 11. EQ.0: Use default value 500,
ABSTOL	Absolute convergence tolerance. For SOLVER > 11. EQ.0.0: Use default value 10^{-10}
RELTOL	Relative convergence tolerance. For SOLVER > 11. EQ.0.0: Use default value 10^{-6}
OMEGA	Relaxation parameter omega for SOLVER 14 and 16. EQ.0.0: Use default value 1.0 for Solver 14, use default value 0.0 for Solver 16.

VARIABLE	DESCRIPTION
TSF	Thermal Speedup Factor. This factor multiplies all thermal parameters with units of time in the denominator (e.g., thermal conductivity, convection heat transfer coefficients). It is used to artificially time scale the problem. EQ.0.0: Default value 1.0, LT.0.0: |TSF| is a load curve ID. Curve defines speedup factor as a function of time. Its main use is in metal stamping. If the velocity of the stamping punch is artificially increased by 1000, then set TSF = 1000 to scale the thermal parameters.

Card 2b	1	2	3	4	5	6	7	8
Variable	MSGLVL	NINNER	ABSTOL	RELTOL	NOUTER			
Type	I	I	F	F	I			
Default	0	100	10^{-10}	10^{-6}	100			

VARIABLE	DESCRIPTION
MSGLVL	Output message level (For SOLVER > 10) EQ.0: No output (default), EQ.1: Summary information, EQ.2: Detailed information, use only for debugging.
NINNER	Number of inner iterations for GMRES solve
ABSTOL	Absolute convergence tolerance. For SOLVER > 11. EQ.0.0: Use default value 10^{-10}
RELTOL	Relative convergence tolerance. For SOLVER > 11. EQ.0.0: Use default value 10^{-6}
NOUTER	Number of outer iterations for GMRES solve

Card 3	1	2	3	4	5	6	7	8
Variable	MXDMP	DTVF	VARDEN		NCYCL			
Type	I	F	I		I			
Default	0	0.	0		1			.

VARIABLE	DESCRIPTION
MXDMP	Matrix Dumping for SOLVER > 11 EQ.0: No Dumping GT.0: Dump using ASCII format every MXDMP time steps. LT.0: Dump using binary format every |MXDMP| time steps.
DTVF	Time interval between view factor updates.
VARDEN	Variable thermal density for solid elements in a coupled thermal-structural analysis. Setting VARDEN to 1 or 2 will adjust the material density in the thermal solver to account for changes in element volume due to, for example, material compaction, thermal expansion, etc. In applications where volume changes are small, the default is recommended. EQ.0: Thermal density remains constant and equal to TRO as given in *MAT_THERMAL_*OPTION* (default). EQ.1: Thermal density varies to account for change in volume. If an equation of state (*EOS) is used, the initial internal energy specified therein is taken into account. EQ.2: Thermal density varies to account for change in volume. The initial internal energy is not considered.
NCYCL	Thermal matrix reassembly frequency. Default is at every thermal cycle.

Remarks:

1. **Recommended Direct Solver.** Solver 11 is the preferred direct solver. Solver type 30 is a nonsymmetric direct solver.

2. **Direct versus Iterative Solver.** Even though using a direct solver is usually less efficient than using an iterative solver (SOLVER = 12, 13, 14, 15, 16, 17, 18 and 19), we recommend it for thermal coupling analysis. If you are running a thermal only analysis, then consider using an iterative solver to decrease execution time (particularly for large models); otherwise we recommend a direct solver.

3. **Transient Problems.** For transient problems, diagonal scaling conjugate gradient (SOLVER = 12) should be adequate.

4. **Steady State Problems.** For steady state problems, convergence may be slow or unacceptable, so consider using direct solver (SOLVER = 11) or a more powerful preconditioner (SOLVER = 13, 14, 15, 16, 18 and 19).

5. **Solvers 13 & 14.** Solver 13 (symmetric Gauss-Seidel) and solver 14 (SSOR) are related. When OMEGA = 1.0, solver 14 is equivalent to solver 13. The optimal omega value for SSOR is problem dependent but lies between 1.0 and 2.0.

6. **Solvers 15 & 16.** Solver 15 (incomplete LDLT0) and solver 16 (modified incomplete LDLT0) are related. Both are no-fill factorizations that require one extra n-vector of storage. The sparsity pattern of the preconditioner is exactly the same as that of the thermal stiffness matrix. Solver 16 uses the relaxation parameter OMEGA. The optimal OMEGA value is problem dependent, but lies between 0.0 and 1.0.

7. **Solver 17.** The GMRES solver has been developed as an alternative to the direct solvers in cases where the structural thermal problem is coupled with the fluid thermal problem in a monolithic approach using the ICFD solver. A significant gain of calculation time can be observed when the problem reaches 1M elements.

8. **Completion Conditions for Solvers 12 – 15.** Solvers 12, 13, 14, 15 and 16 terminate the iterative solution process when (1) the number of iterations exceeds MAXITR or (2) the 2-norm of the residual drops below:

$$\text{ABSTOL} + \text{RELTOL} \times \text{2-norm of the initial residual.}$$

9. **Debug Data.** Solvers 11 and up can dump the thermal conductance matrix and right-hand-side using the same formats as documented under *CONTROL_IMPLICIT_SOLVER. If this option is used, files beginning with T_will be generated.

10. **Unit Conversion Factor.** EQHEAT is a unit conversion factor. EQHEAT converts the mechanical unit for work into the thermal unit for energy according to,

$$\text{EQHEAT} \times [\text{work}] = [\text{thermal energy}]$$

However, it is recommended that a consistent set of units be used with EQHEAT set to 1.0. For example, when using SI,

$$[\text{work}] = 1\text{Nm} = [\text{thermal energy}] = 1\text{J} \Rightarrow \text{EQHEAT} = 1.$$

11. **Obsolete Variable CGTOL.** Starting with LS-DYNA R12, the variable CGTOL is obsolete; use RELTOL for non-default values of the relative convergence tolerance.

*CONTROL_THERMAL_TIMESTEP

Purpose: Set time step controls for the thermal solution in a thermal only or coupled structural/thermal analysis. This card requires that the deck also include *CONTROL_-SOLUTION, and, *CONTROL_THERMAL_SOLVER needed.

Card 1	1	2	3	4	5	6	7	8
Variable	TS	TIP	ITS	TMIN	TMAX	DTEMP	TSCP	LCTS
Type	I	F	F	F	F	F	F	I
Default	0	1.0	none	↓	↓	1.0	0.5	0

VARIABLE	DESCRIPTION
TS	Time step control: EQ.0: Fixed time step, EQ.1: Variable time step (may increase or decrease).
TIP	Time integration parameter. See Remark 1 for details. EQ.0.5: Crank-Nicolson scheme EQ.1.0: fully implicit (default)
ITS	Initial thermal time step
TMIN	Minimum thermal time step: EQ.0.0: Set to structural explicit time step (default). LT.0.0: Curve ID = (-TMIN) gives minimum thermal time step size as function of time. The load curve defines pairs (thermal time breakpoint, new minimum time step). See Remark 2.
TMAX	Maximum thermal time step: EQ.0.0: Set to 100 * structural explicit time step (default). LT.0.0: Curve ID = (-TMAX) gives maximum thermal time step size as function of time. The load curve defines pairs (thermal time breakpoint, new minimum time step).

VARIABLE	DESCRIPTION
	The time step will be adjusted to hit the time breakpoints exactly. See Remark 2.
DTEMP	Maximum temperature change in each time step above which the thermal time step will be decreased: EQ.0.0: Set to a temperature change of 1.0. LT.0.0: Curve ID = (-DTEMP) gives maximum temperature change as a function of time. The load curve defines pairs (thermal time breakpoint, new temperature change). See Remark 2.
TSCP	Time step control parameter (0. < TSCP < 1.0). The thermal time step is decreased by this factor, if the temperature change in the time step exceeds DTEMP or if the nonlinear solver fails to reach convergence within the given maximum number of matrix reformations. If the nonlinear solution algorithm is actually diverging, the thermal time step is decreased by DCP defined in *CONTROL_THERMAL_NONLINEAR. EQ.0.0: Set to a factor of 0.5.
LCTS	Load curve ID which defines data pairs of (thermal time breakpoint, new time step). The time step will be adjusted to hit the time breakpoints exactly. After the time breakpoint, the time step will be set to the 'new time step' ordinate value in the load curve.

Remarks:

1. **Time Integration Parameter.** TIP is relevant only to a transient analysis and is ignored for a steady state analysis. The only two accepted values that make mathematical sense are TIP = 0.5 or TIP = 1. TIP = 0.5 is the classical Crank-Nicolson method. It is mathematically more accurate than TIP = 1 and is unconditionally stable in time. However, a plot of nodal temperature as a function of time can be oscillatory, especially in a nonlinear problem. The oscillations decrease with time. TIP = 1.0 is the classical implicit method. It is also unconditionally stable. For this method, the plot of nodal temperature as a function of time does not have oscillations.

2. **Time Step Size Control.** If automatic time step size control is used with load curve definitions of the limits (dtmin, dtmax, dtemp), the time step is adjusted

to hit the breakpoints in the curves exactly. The time stepping algorithm ensures that the step size of the last time step before the breakpoint is not smaller than 50% of the previous one. If necessary, the sizes of the last two time steps before the breakpoint are averaged.

*CONTROL_TIMESTEP

Purpose: Set structural time step size control using different options.

Card 1	1	2	3	4	5	6	7	8
Variable	DTINIT	TSSFAC	ISDO	TSLIMT	DT2MS	LCTM	ERODE	MS1ST
Type	F	F	I	F	F	I	I	I
Default	↓	↓	0	0.0	0.0	0	0	0

This card is optional.

Card 2	1	2	3	4	5	6	7	8
Variable	DT2MSF	DT2MSLC	IMSCL			RMSCL	EMSCL	IHDO
Type	F	I	I			F	F	I
Default	not used	not used	0			0.0	0.0	0

This card is optional.

Card 3	1	2	3	4	5	6	7	8
Variable		IGADO	DTUSR					
Type		I	F					
Default		0	0.0					

VARIABLE	DESCRIPTION
DTINIT	Initial time step size: EQ.0.0: LS-DYNA determines initial step size.
TSSFAC	Scale factor for computed time step (old name SCFT). See Remark 2 below.

VARIABLE	DESCRIPTION

LT.0.0: |TSSFAC| is the load curve or function ID defining the scale factor as a function of time.

ISDO Basis of time size calculation for 4-node shell elements. 3-node shells use the shortest altitude for options 0,1 and the shortest side for option 2. This option has no relevance to solid elements, which use a length based on the element volume divided by the largest surface area.

EQ.0: Characteristic length is given by

$$\frac{\text{area}}{\min(\text{longest side},\ \text{longest diagonal})}.$$

EQ.1: Characteristic length is given by

$$\frac{\text{area}}{\text{longest diagonal}}.$$

EQ.2: Based on bar wave speed and,

$$\max\left[\text{shortest side}, \frac{\text{area}}{\min(\text{longest side},\ \text{longest diagonal})}\right].$$

WARNING:	Option 2 can give a much larger time step size that can lead to instabilities in some applications, especially when triangular elements are used.

EQ.3: This feature is currently unavailable. Time step size is based on the maximum eigenvalue. This option is okay for structural applications where the material sound speed changes slowly. The cost related to determining the maximum eigenvalue is significant, but the increase in the time step size often allows for significantly shorter run times without using mass scaling.

TSLIMT Shell element minimum time step assignment, TSLIMT. When a shell controls the time step, element material properties (moduli *not* masses) will be modified such that the time step does not fall below the assigned step size. This option is applicable only to shell elements using material models:

*MAT_PLASTIC_KINEMATIC,

*MAT_POWER_LAW_PLASTICITY,

VARIABLE	DESCRIPTION

*MAT_STRAIN_RATE_DEPENDENT_PLASTICITY,

*MAT_PIECE-WISE_LINEAR_PLASTICITY.

> WARNING: This so-called stiffness scaling option is NOT recommended. The DT2MS option below applies to all materials and element classes and is preferred.

If both TSLIMT and DT2MS below are active and if TSLIMT is input as a positive number, then TSLIMT defaults to 10^{-18}, thereby disabling it.

If TSLIMT is negative and less than |DT2MS|, then |TSLIMT| is applied prior to the mass being scaled. If |DT2MS| exceeds the magnitude of TSLIMT, then TSLIMT is set to 10^{-18}.

DT2MS — Time step size for mass scaled solutions. (Default = 0.0)

GT.0.0: Positive values are for quasi-static analyses or time history analyses where the inertial effects are insignificant.

LT.0.0: TSSFAC × |DT2MS| is the minimum time step size permitted and mass scaling is done if and only if it is necessary to meet the Courant time step size criterion. This option can be used in transient analyses if the mass increases remain insignificant. See also the variable MS1ST below and the *CONTROL_TERMINATION variable ENDMAS.

> WARNING: Superelements from, *ELEMENT_DIRECT_MATRIX_INPUT, are not mass scaled; consequently, DT2MS does not affect their time step size. In this case an error termination will occur, and DT2MS will need to be reset to a smaller value.

LCTM — Load curve ID that limits the maximum time step size (optional). This load curve defines the maximum time step size permitted as a function of time. If the solution time exceeds the final time value defined by the curve, the computed step size is used. If the time

VARIABLE	DESCRIPTION
	step size from the load curve is exactly zero, the computed time step size is also used.
ERODE	Erosion flag for elements with small time step. See Remark 6. EQ.0: Calculation will terminate if the solution time step drops to tsmin (see *CONTROL_TERMINATION). EQ.1: Solid elements or thick shell elements that cause the time step to drop to tsmin will erode; similarly, SPH particles that cause the time step to drop will be deactivated. EQ.10: Shell elements with time step below tsmin will erode. EQ.11: Same as ERODE = 1 but shell elements will also erode EQ.100: Beam elements with time step below tsmin will erode. EQ.101: Same as ERODE = 1 but beam elements will also erode EQ.110: Beam and shell elements will erode. EQ.111: Same as ERODE = 1 but beam and shell elements will also erode
MS1ST	Option for mass scaling that applies when DT2MS < 0. EQ.0: Mass scaling is considered throughout the analysis to ensure that the minimum time step cannot drop below TSSFAC × |DT2MS|. Added mass may increase with time, but it will never decrease. (default) EQ.1: Added mass is calculated at the first time step and remains unchanged thereafter. The initial time step will not be less than TSSFAC × |DT2MS|, but the time step may subsequently decrease, depending on how the mesh deforms and the element characteristic lengths change.
DT2MSF	Reduction (or scale) factor for initial time step size to determine the minimum time step size permitted. Mass scaling is done if it is necessary to meet the Courant time step size criterion. If this option is used, DT2MS effectively becomes –DT2MSF multiplied by the initial time step size, Δt, before scaling Δt by TSSFAC. This option is active only if DT2MS = 0 above.
DT2MSLC	Load curve for determining the magnitude of DT2MS as a function of time, $f_{\mathrm{DT2MS}}(t)$, during the explicit solutions phase. Time zero must be in the abscissa range of this curve. At a given simulation

VARIABLE	DESCRIPTION
	time t, $f_{\text{DT2MS}}(t) \times \text{sign}(\text{DT2MS})$ plays the role of DT2MS according to the description for DT2MS above. *All* negative ordinate values may be used in the curve, but the ordinate values *may not* change sign during the simulation. In the negative ordinate values case, $f_{\text{DT2MS}}(t)$ itself (sign and magnitude) determines how mass scaling is performed and DT2MS is neglected. GT.0: The magnitude of the added mass is the maximum of the current value and the value from the load curve. Hence, the amount of added mass will never decrease, although the time step size may be reduced as desired using DT2MSLC. LT.0: Uses load curve |DT2MSLC|. Allows the amount of added mass to decrease with time.
IMSCL	Flag for selective mass scaling if and only if mass scaling active. Selective mass scaling does not scale the rigid body mass and is therefore more accurate. Since it is memory and CPU intensive, it should be applied only to small finely meshed parts. EQ.0: No selective mass scaling EQ.1: All parts undergo selective mass scaling. LT.0: Recommended; |IMSCL| is the part set ID of the parts that undergo selective mass scaling. All other parts are mass scaled the usual way.
RMSCL	Flag for using rotational option in selective mass scaling EQ.0.: Only translational inertia are selectively mass scaled. NE.0.: Both translational and rotational inertia are selectively mass scaled.
EMSCL	Fraction of added mass from mass scaling that contributes to gravity loads, in addition to the physical mass. See also *LOAD_BODY. This number should be between 0 and 1.
IHDO	Method for calculating solid element time steps (see Remark 7): EQ.0: Default method EQ.1: Modified method to improve time step continuity
IGADO	Method for calculating time steps for IGA elements: EQ.0: Default method (conservative)

VARIABLE	DESCRIPTION
	EQ.1: Account for interelement continuity (usually leads to larger time steps)
DTUSR	User-defined time step for explicit analysis. A nonzero value invokes a call to user subroutine `utimestep` in dyn21.F. This feature can be used to synchronize time steps between coupled codes.

Remarks:

1. **Time Step Scale Factor TSSFAC.** During the solution we loop through the elements and determine a new time step size by taking the minimum value over all elements:

$$\Delta t^{n+1} = \text{TSSFAC} \times \min\{\Delta t_1, \Delta t_2, \ldots, \Delta t_N\}$$

where N is the number of elements. The time step size roughly corresponds to the transient time of an acoustic wave through an element using the shortest characteristic distance. For stability reasons the scale factor TSSFAC should be set to a value less than 1.0. The default value of TSSFAC is as follows:

   a) If contacts are present, and SLSFAC is specified in CONTROL_CONTACT, then

$$\text{TSSFAC} = \begin{cases} 0.333 & \text{for} \quad \text{SLSFAC} \geq 9. \\ 0.667 & \text{for} \quad 1. \leq \text{SLSFAC} < 9. \end{cases}$$

   b) TSSFAC = 0.667 if either of the following cards is used:

      *INITIAL_DETONATION

      *BOUNDARY_NON_REFLECTING

   c) TSSFAC = 0.90 otherwise

   Values larger than .90 will often lead to instabilities

2. **Sound Speed and Element Size.** The sound speed in steel and aluminum is approximately 5 mm per microsecond; therefore, if a steel structure is modeled with element sizes of 5 mm, the computed time step size would be 1 microsecond. Elements made from materials with lower sound speeds, such as foams, will give larger time step sizes. Avoid excessively small elements and be aware of the effect of rotational inertia on the time step size in the Belytschko beam element. Sound speeds differ for each material, for example, consider:

Air	331 m/s
Water	1478

Steel	5240
Titanium	5220
Plexiglass	2598

3. **Use Rigid Bodies when Possible.** It is recommended that stiff components be modeled by using rigid bodies. Do not scale the Young's modulus, as that can substantially reduce the time step size.

4. **Triangular Elements.** The altitude of the triangular element should be used to compute the time step size. Using the shortest side is okay only if the calculation is closely examined for possible instabilities. This is controlled by parameter ISDO.

5. **Selective Mass Scaling.** In the explicit time integration context and in contrast to conventional mass scaling, selective mass scaling (SMS) is a well thought out scheme that not only reduces the number of simulation cycles but that also does not significantly affect the dynamic response of the system under consideration. The drawback is that a linear system of equations must be solved in each time step for the accelerations. In this implementation a preconditioned conjugate gradient method (PCG) is used.

   An unfortunate consequence of this choice of solver is that the efficiency will worsen when attempting large time steps since the condition number of the assembled mass matrix increases with the added mass. Therefore, caution should be taken when choosing the desired time step size. For large models it is also recommended to only use SMS on critical parts since it is otherwise likely to slow down execution; the bottleneck being the solution step for the system of linear system of equations.

   While some constraints and boundary conditions available in LS-DYNA are not supported for SMS, they can be implemented upon request from a user.

   A partial list of constraints and boundary conditions supported with SMS:

   - Pointwise nodal constraints in global and local directions
   - Prescribed motion in global and local directions
   - Adaptivity
   - Rigid walls
   - Deformable elements merged with rigid bodies
   - Constraint contacts and spotwelds
   - Beam release constraints

   By default, only the translational dynamic properties are treated. This means that only rigid body translation will be unaffected by the mass scaling imposed. There is an option to also properly treat rigid body rotation in this way, this is invoked by flagging the parameter RMSCL. A penalty in computational expense

is incurred, but the results could be improved if rotations are dominating the simulation.

Selective mass scaling is supported for most element formulations. For beam elements, only types 1 (Hughes-Liu) and 9 (Spotweld) are supported at the moment.

6. **ERODE.** If DTMIN > 0 on CONTROL_TERMINATION, then tsmin is calculated by tsmin = dtstart × DTMIN where dtstart is the initial step size determined by LS-DYNA.

   If tsmin > 0 and ERODE > 0, and if the solution time step drops below tsmin, then those elements that cause the time step to drop will be deleted so that that the solution can continue with a time step that stays at or above tsmin. Valid values for ERODE are 0, 1, 10, 11, 100, 101, 110, and 111. Each digit in ERODE switches on or off checking and deletion for a type of element where a one turns on checking and a zero turns it off. The one's place controls solid and thick shell elements as well as SPH particles. The tens place controls shell elements and the hundreds place controls beam elements. Set ERODE = 111 to check all element types.

   In addition to maintaining a reasonable time step, setting ERODE = 1, 11, or 111 will also prevent error terminations due to negative volume of solid elements. However, the solid elements checked for negative volume can be limited to those contained in a part set by setting part set PSFAIL on *CONTROL_SOLID.

7. **IHDO.** The explicit time step calculation for solid elements is dependent not only on the highest element frequency but also on the volumetric strain rate and linear coefficient of bulk viscosity. The default method for including the viscous effects causes a discontinuity in the equation when the volumetric strain rate changes sign. As a result, some explicit dynamic solutions are observed to have a solution time step that fluctuates between two values that differ by a few percent. An alternative method which eliminates the discontinuity in the viscous effects is invoked by setting IHDO = 1.

*CONTROL_UNITS

Purpose: Specify the user units for the current keyword input deck. This does not provide any mechanism for automatic conversion of units of any entry in the keyword input deck. It is intended to be used for several purposes, but currently only for the situation where an external database in another set of units will be loaded and used in the simulation. In this case, *CONTROL_UNITS provides the information necessary to convert the external data into internal units (see *CHEMISTRY_CONTROL for such external databases).

If the needed unit is not one of the predefined ones listed for use on the first card, then the second optional card is used to define that unit. Any non-zero scales that are entered on optional Card 2 override what is specified on the first card. These scales are given in terms of the default units on Card 1. For instance, if 3600.0 is given in the second 20 character field on the optional second card (TIME_SCALE), then 'hour' is the time unit (3600 seconds).

Card 1	1	2	3	4	5	6	7	8
Variable	LENGTH	TIME	MASS	TEMP				
Type	A	A	A	A				
Default	m	sec	kg	K				

User Defined Units Card. Optional card only used when a new unit needs to be defined.

Card 2	1	2	3	4	5	6	7	8
Variable	LENGTH_SCALE		TIME_SCALE		MASS_SCALE			
Type	F		F		F			
Default	1.0		1.0		1.0			

VARIABLE	DESCRIPTION
LENGTH	Length units: EQ.m: meter (default) EQ.mm: millimeter EQ.cm: centimeter EQ.in: inch EQ.ft: foot
TIME	Time units: EQ.sec: second (default) EQ.ms: millisecond EQ.micro_s: microsecond
MASS	Mass units: EQ.kg: kilogram (default) EQ.g: gram EQ.mg: milligram EQ.lb: pound EQ.slug: pound × second^2 / foot EQ.slinch: pound × second^2 / inch EQ.mtrc_ton: metric ton
TEMP	Temperature units: EQ.K: Kelvin (default) EQ.C: Celsius EQ.F: Fahrenheit EQ.R: Rankine
LENGTH_SCALE	Number of meters in the length unit for the input deck
TIME_SCALE	Number of seconds in the time unit for the input deck
MASS_SCALE	Number of kilograms in the mass unit for the input deck

*CONTROL_2D_REMESHING_REGION

Purpose: Specify a region of a 2D mesh to remesh. The keyword should be used with *CONTROL_ADAPTIVE and ADPTYP = 8.

Note that each definition of *CONTROL_2D_REMESHING_REGION specifies one region. To include more than one region, you need to include multiple *CONTROL_2D_-REMESHING_REGION keywords in the input deck.

Include as many cards as necessary. This input ends at the next keyword ("*") card. Each line for LTYP = 1, 2, or 3 defines a region to remesh. If there are several of these lines, the intersection of these regions is remeshed.

Card 1	1	2	3	4	5	6	7	8
Variable	LTYP	PAR1	PAR2	PAR3	PAR4	PAR5	PAR6	PAR7
Type	I	F	F	F	F	F	F	F
Default	none	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
LTYP	Type of regions defined by the parameters PAR*i*: EQ.1: Box. PAR1 is the ID of *DEFINE_BOX that defines the region to remesh. The other parameters are not used. EQ.2: Part set. PAR1 is the ID of *SET_PART that selects the parts to remesh. The other parameters are not used. EQ.3: Region around elements in contact from a specified contact. To specify the desired contact, set PAR1 to its order of appearance in the input deck. For instance, PAR1 = 5 if the desired contact is the 5th contact keyword to appear in the input deck. A box is created around each element in contact for the remeshing. PAR2 through PAR4 add padding around the box to increase the remeshing region. PAR2 > 0 is the length subtracted from the x-coordinate of the box's lower corner. PAR3 > 0 is the length added to the x-coordinate of the box's upper corner. PAR4 > 0 is the length subtracted from the y-coordinate of the box's lower corner. PAR5 > 0 is the length added to the y-coordinate of the box's upper corner. The last 2 parameters are not used.

VARIABLE	DESCRIPTION
	EQ.4: PAR1 is the ID of *DEFINE_BOX that selects mesh boundaries (edges) of remeshing regions along which nodes added after remeshing (hanging nodes between edge ends) keep their initial parametric positions between the boundary corner nodes (edge-end constraining nodes). The other parameters are not used. By default, when nodes are added to the edges of elements in the region and the edges are not on the mesh boundary, the positions and velocities of the hanging nodes are interpolated from the positions and velocities of the original constraining nodes along these edges (constraining nodes are nodes that existed before remeshing). If the edge of a remeshed element is on the mesh boundaries, the positions and velocities of the hanging nodes on the edge are, by default, not interpolated because they are likely to be subject to boundary conditions. With LTYP = 4, the hanging nodes on the boundary of the mesh are interpolated.
	EQ.5: PAR1 is the ID of *SET_NODE that selects nodes along shell edges. After remeshing, the node set is recreated with nodes along the same shell edges. PAR2 > 0 is a thickness for the shell edges to select the new nodes after remeshing. The other parameters are not used.
	EQ.6: PAR1 is the ID of *SET_PART that selects the parts for which the total displacements are output to d3plot after remeshings.
	EQ.7: PAR1 is the ID of *SET_SHELL that selects the shells to remesh. The other parameters are not used.
PAR*i*	Parameters defined by LTYP

*CONTROLLER

Purpose: The keyword *CONTROLLER provides capability related to the control application, such as controller design, model order reduction, etc.

*CONTROLLER_PLANT

*CONTROLLER_PLANT

Purpose: Perform model order reduction for linear systems and export the reduced matrices into the state space format $\dot{X} = AX + Bu, Y = CX + Du$. Matrices A, B, C, D can be written in specified file format, such as SCILAB and MATLAB.

This feature currently works for the SMP, double precision versions. We implemented two methods for model order reduction: modal truncation and Krylov subspace method. The modal truncation method is based on the truncated modes, meaning eigenvectors, which carry more physical meaning. The Krylov subspace method matches moments of transfer functions to ensure the reduced system has a similar response to the original one. For both methods, the input deck requires necessary *CONTROL_IMPLICIT cards.

ID card. Define plant ID, specify input/output channel numbers and method.

Card 1	1	2	3	4	5	6	7	8
Variable	PLNTID	NIN	NOUT	NMODE	MTXQ	MTXR	MOPT	
Type	I	I	I	I	I	I	I	
Default	none	none	none	0	0	0	0	

File card. Specify file names in SCILAB and MATLAB format.

Card 2	1	2	3	4	5	6	7	8
Variable	FSCILAB				FMATLAB			
Type	A				A			

Input DOFs card. Specify the input node/set and its DOFs. Repeat this card if necessary.

Card 3	1	2	3	4	5	6	7	8
Variable	NODI1	DOFI1	NODI2	DOFI2	NODI3	DOFI3	NODI4	DOFI4
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

Output DOFs card. Specify the output node/set and its DOFs. Repeat this card if necessary.

Card 4	1	2	3	4	5	6	7	8
Variable	NODO1	DOFO1	NODO2	DOFO2	NODO3	DOFO3	NODO4	DOFO4
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

Settings card. Set frequency number and tolerance for the Krylov subspace method.

Card 5	1	2	3	4	5	6	7	8
Variable	NFEQ	DEFTOL						
Type	I	F						
Default	1	10^{-9}						

Mode/Frequency card. Specify the mode and frequency index. Repeat this card if necessary.

Card 6	1	2	3	4	5	6	7	8
Variable	MOD1	MOD2	MOD3	MOD4	MOD5	MOD6	MOD7	MOD8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
PLNTID	Plant ID
NIN	Number of input DOFs, such as nodal force or voltage. If all nodes within a set share a single input variable, together they account for one DOF. For example, all nodes within a set share a single input voltage for a piezo actuator.
NOUT	Number of output DOFs, such as nodal displacement or voltage. Note that the same node velocity will be automatically exported as well.
NMODE	Number of modes for the modal truncation, or number of base vectors for the Krylov method. If zero, all active DOFs will be used (not recommended). The reduced system will have a dimension of 2NMODE for the modal truncation method, and NMODE for the Krylov method.
MTXQ	*Q* matrix for linear-quadratic-regular (LQR) method (unused currently)
MTXR	*R* matrix for linear-quadratic-regular (LQR) method (unused currently)
MOPT	Modal order reduction method (see Remark 1): EQ.0: Modal truncation method EQ.1: Krylov subspace method
FSCILAB	File name in SCILAB format .sci. If specified, the reduced matrices will be written accordingly. If left blank, no such file will be generated.

VARIABLE	DESCRIPTION
FMATLAB	File name in MATLAB format .m. If specified, the reduced matrices will be written accordingly. If left blank, no such file will be generated.
NODI*x*	Node or node set index for the input channel. GT.0: Node index LT.0: Node set index within which all nodes share the same input variable, such as force, voltage.
DOFI*x*	Degree-of-freedom for input: EQ.1: Nodal force in the x-direction, f_x EQ.2: Nodal force in the y-direction, f_y EQ.3: Nodal force in the z-direction, f_z EQ.7: Voltage if piezoelectric materials are defined. See Remark 2.
NODO*x*	Node index for output
DOFO*x*	Degree-of-freedom for output: EQ.1: Displacement along the x-direction EQ.2: Displacement along the y-direction EQ.3: Displacement along the z-direction EQ.7: Voltage output if piezoelectric materials are defined.
NFEQ	Number of shifted frequencies to generate the Krylov base vectors. In most cases, a single frequency at zero rad/s works. For the modal truncation method, just leave as it is.
DEFTOL	Deflation tolerance for the Krylov method. The default value of 10^{-9} works in most cases. For the modal truncation method, just leave as it is.
MOD*x*	List all NMODE mode indexes for the modal truncation method, or NFEQ shifting frequencies (unit: rad/s) for the Krylov method. The default setting of a single frequency at 0 rad/s works in most Krylov cases. For the modal truncation method, a negative MOD*x* triggers mode generation between MOD_{x-1} and $-MOD_x$, meaning all modes between MOD_{x-1} and $-MOD_x$ will be considered.

Remarks:

1. **MOPT.** If MOPT = 0, the modal truncation method is selected to perform the model order reduction based on the NMODE eigenvectors. Users need to define *CONTROL_IMPLICIT_GENERAL and *CONTROL_IMPLICIT_EIGENVALUE to generate the required eigenvectors, and the eigenvalue number *neig* should not be less than NMODE. If MOPT = 1, the Krylov subspace method will be selected. No eigenvalues are calculated, but *CONTROL_IMPLICIT_GENERAL is still needed to acquire the system matrices. The default setting of NFEQ = 1, DEFTOL = 10^{-9}, and 0 frequency works in most cases for the Krylov method.

2. **Voltage Input.** DOFI*x* = 7 indicates a voltage input. The material of that respective index should be piezoelectric, that is, *MAT_ADD_PZELECTRIC should be used.

*COSIM

Purpose: The keyword *COSIM allows LS-DYNA to co-simulate with other software. Currently, co-simulation only works through the functional mock-up interface (FMI).

*COSIM_FMI_CONTROL

*COSIM_FMI_INTERFACE

*COSIM_FMI_CONTROL

Purpose: Define the functional mock-up interface (FMI) co-simulation settings. With this keyword, you will define the co-simulation role of LS-DYNA, such as primary or secondary. You can also specify additional settings, such as IP address/port, functional mock-up unit (FMU) location, and co-simulation time step.

This keyword should be included in the input deck along with *COSIM_FMI_INTERFACE. You also need to download a free plugin called "FMU Manager" to enable this feature. The latest zip file that includes this plugin is located at https://ftp.lstc.com/anonymous/outgoing/isheng/deliver. The zip file also contains detailed documentation and illustrative sample decks.

Card 1	1	2	3	4	5	6	7	8
Variable	APPID		OPT	MODE	FMI			
Type	A20		A10	A10	I			
Default	none		none	none	0			

Settings card. Define additional settings. Repeat this card if necessary. The next keyword ("*") card terminates this input.

Card 2	1	2	3	4	5	6	7	8
Variable	SETTING							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
APPID	FMU identification. Each FMU must have a unique APPID.
OPT	LS-DYNA's role (see Remark 1): EQ.G: Generation mode. LS-DYNA will generate a new FMU. EQ.C: Co-simulation mode. LS-DYNA will co-simulate with an existing FMU.

VARIABLE	DESCRIPTION
MODE	LS-DYNA's mode (see Remark 1): EQ.P: LS-DYNA is primary, and another software is secondary. EQ.S: LS-DYNA is secondary, and another software is primary.
FMI	Flag to select FMI standard: EQ.1: The generated or co-simulated FMU is based on FMI1.0 standard. EQ.0.OR.2: The generated or co-simulated FMU is based on FMI2.0 standard. This is the default.
SETTINGS	Settings for the generating or using the FMU. Up to 80 characters per line. Multiple lines are allowed for each setting and multiple settings can be defined for each FMU. See Remark 2.

Remarks:

1. **How Co-Simulation Works.** The secondary software generates an FMU, which is imported into the primary software for co-simulation. The primary controls the co-simulation time step, Δt_1, which is different from the explicit time step, Δt_2, in LS-DYNA. Generally, the former should be greater than the latter by several magnitudes, depending on your application ($\Delta t_1 \leq \Delta t_2$ is also allowed). If LS-DYNA is secondary, Δt_1 is set in the primary software. If LS-DYNA is the primary, Δt_1 is set in LS-DYNA by "<time> fmudt=*xxx*" through Card 2 of this keyword as discussed in Remark 2.

   The process of setting up the FMU and running the co-simulation depends on whether LS-DYNA is the primary or secondary:

   a) *LS-DYNA is the secondary.* In prior versions of LS-DYNA this would correspond to LS-DYNA being the *slave*. If you want to run LS-DYNA as the secondary during a co-simulation, usually you need to set OPT = G and run LS-DYNA to generate an FMU. After importing the FMU into another primary software, switch OPT from G to C to run LS-DYNA in the co-simulation mode to co-simulate with the 3rd party software. In this case, you run LS-DYNA twice.

   b) *LS-DYNA is the primary.* In prior versions of LS-DYNA this would correspond to LS-DYNA being the *master*. If you want to run LS-DYNA as the primary during a co-simulation, you usually need to generate an FMU with another software and import the FMU into LS-DYNA for co-simulation. In

this case, set OPT = C and run LS-DYNA only once to connect to the other software for co-simulation.

2. **SETTINGS.** This field is used to setup general settings for the FMU, such as the FMU directory or the co-simulation time. Each setting must start on a new line and begins with <*setting name here*> followed by parameters for the setting. A setting can span multiple lines with each line having a maximum of 80 characters.

   See the table below for a full list of settings in alphabetical order. A description of each setting is below in the Overview of Settings section which is followed by some examples.

Setting Name	Description	OPT	MODE
<fmudir>	Specify FMU directory	C, G	P, S
<fmu_input>	Generate FMU with additional input variables	G	P
<fmu_output>	Generate FMU with additional output variables	G	P
<home>	Specify the direction of the FMU manager	C, G	P, S
<hopsan>	Generate FMU / co-simulate with Hopsan	C, G	S
<name>	Match variables in LS-DYNA and FMU	C, G	P, S
<message>	Specify how often to print out the co-sim messages		
<parameter>	Generate FMU with additional parameter variables	G	P
<socket>	Generate FMU with specified socket properties	G	S
<tcp>	Generate FMU with specified IP and bind LS-DYNA with specified port	C, G	S
<time>	Specify time step and duration of co-simulation	C	P, S

Overview of Settings:

The settings are described in greater detail below. Parameters in italics are for illustration only and indicate the parameters that you will replace for your co-simulation.

<fmudir> ***path***

The setting specifies either where the FMU is located during co-simulation mode or where the FMU is generated in the generation mode. If not included, the directory is assumed to be the folder of the input keyword file. Note the difference of \ and / in Windows or Linux. If the directory is relative to the input file, you should start with ..\ or .\ for Windows, ../ or ./ for Linux. Please avoid any space characters in or after the directory.

<fmu_input> name = ***current*****, type =** ***real*****, value =** ***0***

With this setting, you can define additional FMU input variables during generation mode. Currently only variables of **type=*real*** are supported. The initial value is set with **value**. LS-DYNA must be in the primary mode for this setting to work, meaning MODE = P and OPT = G.

<fmu_output> name=*voltage***, type=***real***, value=***0***

With this setting, you can define additional FMU output variables during generation mode. Currently only variables of **type=*real*** are supported. The initial value is set with **value**. LS-DYNA must be in the primary mode for this setting to work, meaning MODE = P and OPT = G.

<home> ***path***

This setting specifies the directory of the FMU manager kit. If not included, the directory is assumed to be the parent folder of the keyword input file, meaning ..\. You can also specify a directory relative to the input file, starting with ..\ or .\ for Windows and ../ or ./ for Linux. Please avoid any space character in or after the directory.

<hopsan> name = ***port1*****, type =** ***hydraulic_Q*****, segment =** ***1*****, node =** ***1867*****, dir = +***z*

You specify this setting when you want to co-simulate with piston models in Hopsan. Here, **name** is the port number, **type** is the piston type, **segment** is the piston segment set ID to which the hydraulic force is applied, and **node** can be any node on the piston where piston velocity is picked up. The parameter **dir** gives the direction of the piston motion. The positive direction is the extension while the negative direction is the retraction.

<message> step = ***100***

This setting specifies how often co-simulation messages are output to fmu_msg. They are output every ***step*** co-simulation time steps. If not specified, LS-DYNA will print out the following message every 100 co-simulation time steps:

FMU time: 0.000000e+00 cosim-dt: 6.644e-05 cosim-step: 1

FMU time: 6.471417e-03 cosim-dt: 6.258e-05 cosim-step: 101

<name> *DX500* = *In1*

This setting is used to match variables in LS-DYNA and the FMU during the generation or co-simulation mode. The above example tells LS-DYNA that *In1* in FMU is equivalent to the *X* displacement of node 500 (additional cases are documented in the co-simulation examples manual). During co-simulation, LS-DYNA will match the variables on both sides of "=" to send out or receive data from the FMU. The variable on the right side can be found inside the modelDescription.xml of the FMU. The variable on the left side corresponds to the LS-DYNA local variables with its name being the combination of the value of FIELD with the node number; see *COSIM_FMI_INTERFACE.

<parameter> name=*PCOEF1*, type=*real*, value=*1*

This setting is used to define parameter variables for an FMU to be generated. Currently, only variables of **type=*real*** are supported. The parameter **value** defines the initial value for the parameter. LS-DYNA must be in the primary mode for this setting to work, that is, MODE = P and OPT = G. Usually, you need to modify function `getReal()` in template/fmi_udf.c for such application to generate the needed FMU.

<socket> nconnect=*20*, tdelay=*1000*, recvtimeout=*0*

This setting is used to define the socket properties of an FMU to be generated. LS-DYNA must be in the secondary mode for this item to work, meaning MODE = S and OPT= G. At the beginning of the co-simulation, the other software will try **nconnect** times at most to reach the LS-DYNA computer for connection. If the socket communication to the IP designated with **<tcp>** is not successful, the co-simulation fails. **tdelay** is the time delay in milliseconds for the other software to reconnect to LS-DYNA if the previous connection fails. **recvtimeout** is the max time in milliseconds that FMU waits for data from LS-DYNA, and beyond this time limit, the co-simulation fails due to lost data. If **recvtimeout=0**, the FMU will wait infinitely for LS-DYNA.

<tcp> ip=*127.0.0.1*, port=*39400*

This setting is used to define the FMU properties to be generated. LS-DYNA must be in secondary mode (MODE = S) for this setting to work. The parameter **ip** is the IP address of the LS-DYNA computer in the co-simulation. If the co-simulation is local, you can always set **ip** to be 127.0.0.1. You can also specify a .txt file that includes the IP address in the first line instead of the IP address with **ip=*ip_addr.txt***. If this setting is not included, the default IP address is 127.0.0.1 with port 39400.

<time> tstart = *0*, tend = *1.2*, option = *0*, fmudt = *0.0005*, *tscale = 10*

This setting defines the LS-DYNA properties during co-simulation. When tstart < t < tend, the co-simulation is occurring. The parameter **option** controls the value of exported/imported variables in LS-DYNA when t > tend. When option = 0, the exported/imported variables are set to 0 when t > tend; when option = 1, the exported/imported variables for t > tend are held constant with the value from t = tend. When t < tstart, the imported variables are set to 0 and the exported variables are set to their initial values, which are specified by VINIT in *COSIM_FMI_INTERFACE.

The parameter **fmudt** defines the co-simulation time step between LS-DYNA and the FMU, and it only applies when LS-DYNA is the primary during the co-simulation. The co-simulation time step is different from the explicit time step of LS-DYNA. Generally, the former is usually greater by several magnitudes, however, values of smaller or comparable magnitude are also allowed. Between co-simulation time steps, the FMU variables are held constant. If this setting is not defined, tstart = 0, tend = 10^6, option = 0, fmudt = 100 × tstep, where tstep is the LS-DYNA explicit time step.

For cases when the FMU and LS-DYNA have different time scales, use **tscale** to specify the scale factor between the time scales for FMU and LS-DYNA. The default value is 1 without specification. For instance, if the MATLAB side is based on seconds and LS-DYNA is based on milliseconds, set **tscale** = 1000. In this case, when MATLAB proceeds by 1 s in co-simulation, LS-DYNA will proceed by 1000 ms. Note that the values of tstart, tend and fmudt are based on the LS-DYNA time unit.

Examples:

The following examples only serve as an illustration of syntax.

Example 1

In this example, LS-DYNA is the secondary and generates the FMU. The FMU is then imported into another primary software. You can switch G to C and run LS-DYNA to connect to the primary software.

```
*COSIMULATION_FMI_CONTROL
               MOTOR         G         S
<home> C:\DYNA_bin\FMU_Manager_v4_deliver
<fmudir> C:\DYNA_bin\FMU_Manager_v4_deliver\dyna_key
<tcp> ip=127.0.0.1,port=39400
<socket> nconnect=20,tdelay=1000,recvtimeout=0
<name> DX500=input1
<time> tstart=0, tend=0.2, option=1
```

Example 2

Here LS-DYNA is the primary during co-simulation. You generate an FMU with another secondary software and import it into LS-DYNA for co-simulation. In the settings, you set the co-simulation time step and match variables in LS-DYNA and FMU.

```
*COSIMULATION_FMI_CONTROL
                PID1         C         P
<home> ..\
<fmudir> .\
<time> fmudt=0.005
<name> DX500=disp_in1, VX500=veloc_in2
<name> FX500=force_out1
```

*COSIM_FMI_INTERFACE

Purpose: Define the interface variables during co-simulation. For instance, you may need LS-DYNA to export certain node displacements to another software and to import certain nodal forces.

This keyword should be included in an input deck with *COSIM_FMI_CONTROL. *You also need to download a free plugin called "FMU Manager" to enable this feature.*

This feature is available as of R12.

ID card. Specify the FMU, where the interface variables are imported or exported.

Card 1	1	2	3	4	5	6	7	8
Variable	APPID							
Type	A20							
Default	none							

Variable card. Specify the interface variables to be imported and exported. Repeat this card if necessary. This input terminates with the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	IMPEXP	REGTYP	REGID	FIELD	VINIT	RATIO	CID	REF
Type	A	A	I	A	F	F	I	I
Default	none	none	none	none	0	1.0	0	0

VARIABLE	DESCRIPTION
APPID	FMU (functional mock-up unit) identification. Each FMU must have a unique APPID.
IMPEXP	Import/export flag: EQ.IMP: Variables are to be imported into LS-DYNA. EQ.EXP: Variables are to be exported from LS-DYNA.

VARIABLE	DESCRIPTION
REGTYP	Type of interface region: EQ.NODE: Single node EQ.NSET: Node set EQ.SSET: Segment set EQ.PART: Rigid part EQ.FUNC: User defined curve function to be exported only. See Remark 1 and Example 2. EQ.CURV: User defined curve to be imported only. See Remark 2 and Example 3. EQ.SESW: Sense switch to be imported only. REGID is neglected with the sense switch specified in FIELD. See Remark 3 and Example 4. EQ.BAG: Control-volume airbag.
REGID	ID of the corresponding region type in LS-DYNA. If region ID is negative for a node set and FIELD = FX, FY or FZ, all nodes within this set share the same imported force value from the FMU. Otherwise, a distinct force value will be imported for each node.
FIELD	Field data to be imported or exported, depending on the region type. See Remark 4 for a full list of fields.
VINIT	Initial value. For variables to be exported, VINIT is the initial value for the FMU. Therefore, its units must be the same as the FMU's units.
RATIO	Scale factor applied during co-simulation (not FMU generation). When LS-DYNA exports variables, the actual value to be sent is RATIO × LS-DYNA value. When LS-DYNA imports data from FMU, the actual value received is the FMU value / RATIO.
CID	Coordinate system ID (see *DEFINE_COORDINATE). EQ.0: Global (default)
REF	Control how the coordinate system is used for the variable output when CID > 0 (see Remark 5): EQ.0: Variable output is in the local system fixed from the beginning. Note that you should set FLAG = 0 in *DEFINE_COORDINATE_NODES.

VARIABLE	DESCRIPTION
	EQ.1: Variable output is projected onto the moving local system.
	EQ.2: Variable output is the projection of the nodal translation motion relative to node N1 of the local coordinate system, COOR. Double precision LS-DYNA is recommended with REF = 2.

Remarks:

1. **REGTYP = "FUNC".** You can export variables from *DEFINE_CURVE_FUNCTION with the corresponding curve function ID. Note that it is for export only. For example, if you want to export the value of SENSOR(*n*) through the FMU, you must do the following three steps (see Example 2):

   a) Set up sensors through *SENSOR.

   b) Include the sensor in *DEFINE_CURVE_FUNCTION.

   c) Add the curve function to *COSIM_FMI_INTERFACE.

2. **REGTYP = "CURV".** You can import general variables through *DEFINE_CURVE. During co-simulation, the curve value in LS-DYNA will be dynamically updated. Note that it is for import only. For instance, if you want to import velocity from the controller in MATLAB and impose it onto a node in LS-DYNA, you must do the following three steps (see Example 3):

   a) Define a curve with initial values of all zero and the time range greater than the termination time of the co-simulation

   b) Set up *BOUNDARY with the defined curve.

   c) Add the curve to *COSIM_FMI_INTERFACE.

3. **REGTYP = "SESW".** If you want to import a sense switch (see Sense Switch Controls in Getting Started) ranging from "SW1~SW4" and "SWA~SWD" to control the status of LS-DYNA, you must specify the switch name in FIELD. All other fields, namely, REGID, VINIT, RATIO, CID, and REF, are neglected. The rising edge of the imported signal (the transition from a low to high value) will trigger the corresponding sense switch in LS-DYNA. If multiple switches are defined, they cannot be triggered at the same time. See Example 4.

4. **FIELD.** See the table below for a detailed list of possible values for FIELD. Not that PART must be for a rigid part.

FIELD	Description	REGTYP	Export	Import	REF
CX, CY, CZ	Position	NODE, NSET, PART	✓		0, 1
DX, DY, DZ	Translational displacement in *X*, *Y*, and *Z*, respectively	NODE, NSET, PART	✓		0, 1, 2
VX, VY, VZ	Translational velocity in *X*, *Y*, and *Z*, respectively	NODE, NSET, PART	✓		0, 1, 2
ACCX, ACCY, ACCZ	Translational acceleration in *X*, *Y*, and *Z*, respectively	NODE, NSET, PART	✓		0, 1, 2
AX, AY, AZ	Angular displacement in *X*, *Y*, and *Z*, respectively	PART	✓		0, 1
WX, WY, WZ	Angular velocity in *X*, *Y*, and *Z*, respectively	PART	✓		0, 1
WDTX, WDTY, WDTZ	Angular acceleration in *X*, *Y*, and *Z*, respectively	PART	✓		0, 1
BAGP, BAGV, BAGT	Airbag pressure, volume and temperature	BAG	✓		N/A
FX, FY, FZ	Force in *X*, *Y*, and *Z*, respectively	NODE, NSET, PART		✓	0, 1
P	Pressure	SSET		✓	N/A
TX, TY, TZ	Torque	PART		✓	0, 1
Variable name in FMU	Defined curve function	FUNC	✓		N/A
Variable name in FMU	Defined curve	CURV		✓	N/A
SW1-SW4, SWA-SWD	Sense switch	SESW		✓	N/A

5. **REF.** The following are general comments about REF:

   a) REF = 1 and 2 differ in that variables with REF = 2 are measured relative to the changing local system.

   b) You cannot set REF to a different value for the same coordinate. For instance, you cannot export DX for node 1 based on CID = 1 with REF = 1, and then export DY for node 2 based on CID = 1 with REF = 2. To avoid this, you can define a new coordinate with a different REF.

   c) If you also define *DATABASE_HISTORY_NODE_LOCAL, please make sure the REF of the corresponding coordinate system is consistent, meaning you cannot set REF = 1 for CID = 1 in *COSIM_FMI_INTERFACE and REF = 2 for the same CID in *DATABASE_HISTORY_NODE_LOCAL.

Examples:

The following examples only serve as an illustration of syntax.

Example 1

This example illustrates exporting the velocity in the *X*-direction for node 100, exporting the displacements in the *Y*-direction for all nodes within set 3, importing the forces along the *X*-direction for all nodes in set 3, importing the same force along the *Y*-direction for all nodes in set 4, and importing the pressure in segment set 1.

```

```

*DAMPING

The keyword options in this section in alphabetical order are:

*DAMPING_FREQUENCY_RANGE

*DAMPING_GLOBAL

*DAMPING_PART_MASS

*DAMPING_PART_STIFFNESS

*DAMPING_RELATIVE

*DAMPING_STRUCTURAL

DAMPING_FREQUENCY_RANGE_*{OPTION}

Purpose: This feature provides approximately constant damping (that is, frequency-independent) over a range of frequencies. It applies to explicit analysis and to time-integrated implicit dynamic analysis (IMASS = 1 on *CONTROL_IMPLICIT_DYN-AMICS) but not to any of the implicit analysis types that use modal superposition or those that work in the frequency domain.

Available OPTIONS are:

<BLANK> Applies damping to global motion

DEFORM Applies damping to element deformation

Card 1	1	2	3	4	5	6	7	8
Variable	CDAMP	FLOW	FHIGH	PSID		PIDREL	IFLG	
Type	F	F	F	I		I	I	
Default	0.0	0.0	0.0	0		0	0	

VARIABLE	DESCRIPTION
CDAMP	Damping in fraction of critical. Accurate application of this damping depends on the time step being small compared to the period of interest.
FLOW	Lowest frequency in range of interest (cycles per unit time, such as Hz if time unit is seconds)
FHIGH	Highest frequency in range of interest (cycles per unit time, such as Hz if time unit is seconds)
PSID	Part set ID. The requested damping is applied only to the parts in the set. If PSID = 0, the damping is applied to all parts except those referred to by other *DAMPING_FREQUENCY_RANGE cards.
PIDREL	Optional part ID of rigid body. Damping is then applied to the motion relative to the rigid body motion. This input does not apply to the DEFORM option.

VARIABLE	DESCRIPTION
IFLG	Method used for internal calculation of damping constants: EQ.0: Iterative (more accurate). See Iterative Method. EQ.1: Approximate (same as R9 and previous versions)

Remarks:

This feature provides approximately constant damping (frequency-independent) over a range of frequencies. $F_{low} < F < F_{high}$. It is intended for small damping ratios (< 0.05) and frequency ranges such that F_{high}/F_{low} is in the range 10 to 300. The drawback to this method of damping without the DEFORM keyword option is that it reduces the dynamic stiffness of the model, especially at low frequencies.

Where the model contains, for example, a rigid foundation or base, the effects of this stiffness reduction can be ameliorated by using PIDREL. In this case, the damping forces resist motion relative to the base and are reacted onto the rigid part PIDREL. "Relative motion" here means the difference between the velocity of the node being damped, and the velocity of a point rigidly connected to PIDREL at the same coordinates as the node being damped.

This undesirable effect of *DAMPING_FREQUENCY_RANGE on dynamic stiffness is somewhat predictable. As an example, when the DEFORM keyword option is not used, the natural frequencies of modes close to F_{low} are reduced by 3% for a damping ratio of 0.01 and F_{high}/F_{low} in the range 10-30. Near F_{high} the error is between zero and one third of the error at F_{low}. Estimated frequency errors are shown in the following table. The tabulated values indicate the percent reduction in frequency at FLOW. The error at FHIGH is much less.

Damping Ratio	% error in frequency for F_{high}/F_{low} =		
	3 to 30	30 to 300	300 to 3000
0.01	3%	4.5%	6%
0.02	6%	9%	12%
0.04	12%	18%	24%

We recommend that the elastic stiffnesses in the model be increased slightly to account for this effect; for example, for 1% damping across a frequency range of 30 to 600 Hz, the average error across the frequency range is about 2%. It would therefore be appropriate to increase the stiffness by $(1.02)^2$, that is, by 4%.

Keyword Option DEFORM:

The DEFORM option applies damping to the element responses (unlike the standard *DAMPING_FREQUENCY_RANGE which damps the global motion of the nodes). Therefore, rigid body motion is not damped when the DEFORM keyword option is used. For this reason, DEFORM is recommended over the standard option. The damping is adjusted based on current tangent stiffness; this is believed to be more appropriate for a nonlinear analysis, which could be over-damped if a strain-rate-proportional or viscous damping scheme were used.

The DEFORM keyword option works with the following element formulations:

- Solids – types -1, -2, 1, 2, 3, 4, 9, 10, 13, 15, 16, 17, 99
- Beams – types 1, 2, 3, 4, 5, 9 (note: not type 6)
- Shells – types 1-5, 7-17, 20, 21, 23-27, 99
- Thick Shells – all types
- Discrete elements

The DEFORM option differs from the standard option in several ways:

Standard Damping vs. Deformation Damping

Characteristic Property	Keyword Option	
	<BLANK>	DEFORM
Damping on	Node velocities	Element responses
Rigid body motion	Can be damped	Never damped
Natural frequencies	Reduced (by percentages shown in the above table)	Increased (percentages shown in the above table)
Recommended compensation	Increase elastic stiffness	Reduce elastic stiffness
Effect on time step	None	Small reduction applied automatically, same percentage as in the frequency change
Element types damped	All	See list above
Damping energy output	Included in "system damping energy"	Included in Internal Energy only if RYLEN = 2 on *CONTROL_ENERGY

The effect of the DEFORM option on frequency is to increase the frequency, which is opposite the effect when the DEFORM option is not used. Furthermore, when the DEFORM option is invoked, the percent error in frequency shown in first table above occurs at FHIGH and the error at FLOW is much less.

Iterative Method:

Starting with version R10, the internal calculation of the damping constants uses an interative method by default (see input variable IFLG). This iterative method is available both with and without the DEFORM keyword option. The iterative method results in the actual damping matching the user-input damping ratio CDAMP more closely across the frequency range FLOW to FHIGH. As an example, for CDAMP = 0.01, FLOW = 1 Hz and FHIGH = 30 Hz, the actual damping achieved by the previous approximate method varied between 0.008 and 0.012 (different values at different frequencies), that is, there were errors of up to 20% of the target CDAMP. With the iterative algorithm, the errors are reduced to 1% of the target CDAMP.

*DAMPING_GLOBAL

Purpose: Define mass weighted nodal damping that applies globally to the nodes of deformable bodies and to the mass center of the rigid bodies. For specification of mass damping by part ID or part set ID, use *DAMPING_PART_MASS.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	VALDMP	STX	STY	STZ	SRX	SRY	SRZ
Type	I	F	F	F	F	F	F	F
Default	0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Remarks	1		2	2	2	2	2	2

VARIABLE	DESCRIPTION
LCID	Load curve ID (see *DEFINE_CURVE) which specifies the system damping constant vs. time: EQ.0: a constant damping factor as defined by VALDMP is used, GT.0: system damping is given by load curve LCID (which must be an integer). The damping force applied to each node is $f = -d(t)mv$, where $d(t)$ is defined by load curve LCID.
VALDMP	System damping constant, D_s (this option is bypassed if the load curve number defined above is non zero).
STX	Scale factor on global x translational damping forces.
STY	Scale factor on global y translational damping forces.
STZ	Scale factor on global z translational damping forces.
SRX	Scale factor on global x rotational damping moments.
SRY	Scale factor on global y rotational damping moments.
SRZ	Scale factor on global z rotational damping moments.

Remarks:

1. **Restart.** This keyword is also used for the restart, see *RESTART.

2. **Defaults for Scale Factors.** If STX = STY = STZ = SRX = SRY = SRZ = 0.0 in the input above, all six values are defaulted to unity.

3. **Damping Exceptions.** Mass damping will not be applied to deformable nodes with prescribed motion or to nodes tied with CONSTRAINED_NODE_SET.

4. **Formulation.** With mass proportional system damping the acceleration is computed as:

$$\mathbf{a}^n = \mathbf{M}^{-1}\left(\mathbf{P}^n - \mathbf{F}^n - \mathbf{F}^n_{\text{damp}}\right)$$

where, $\mathbf{M}$ is the diagonal mass matrix, $\mathbf{P^n}$ is the external load vector, $\mathbf{F}^n$ is the internal load vector, and $\mathbf{F}^n_{\text{damp}}$ is the force vector due to system damping. This latter vector is defined as:

$$\mathbf{F}^n_{\text{damp}} = D_s m \mathbf{v}$$

The best damping constant for the system is usually some value approaching the critical damping factor for the lowest frequency mode of interest.

$$(D_s)_{\text{critical}} = 2\omega_{\text{min}}$$

The natural frequency ω_{min} (given in radians per unit time) is generally taken as the fundamental frequency of the structure. This frequency can be determined from an eigenvalue analysis or from an undamped transient analysis. Note that this damping applies to both translational and rotational degrees of freedom. Also note that mass proportional damping will damp rigid body motion as well as vibration.

Energy dissipated by through mass weighted damping is reported as system damping energy in the ASCII file glstat. This energy is computed whenever system damping is active.

5. **Filtering.** When global damping is used, IACCOP = 1 is automatically set in *CONTROL_OUTPUT, causing nodal accelerations to be averaged in the nodout and d3thdt files.

***DAMPING_PART_MASS**_*{OPTION}*

OPTION specifies that a part set ID is given with the single option:

<BLANK>

SET

If not used a part ID is assumed.

Purpose: Define mass weighted damping by part ID. Parts may be either rigid or deformable. In rigid bodies the damping forces and moments act at the center of mass. This command may appear multiple times in an input deck but cannot be combined with *DAMPING_GLOBAL.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	LCID	SF	FLAG				
Type	I	I	F	I				
Default	0	0	1.0	0				

Scale Factor Card. Additional Card for FLAG = 1.

Card 2	1	2	3	4	5	6	7	8
Variable	STX	STY	STZ	SRX	SRY	SRZ		
Type	F	F	F	F	F	F		
Default	0.0	0.0	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
PID/PSID	Part ID, see *PART or part set ID, see *SET_PART.
LCID	Load curve ID (see *DEFINE_CURVE) which specifies the damping constant vs. time, applied to the part(s) specified in PID/PSID.
SF	Scale factor for load curve. This allows a simple modification of the load curve values.

VARIABLE	DESCRIPTION
FLAG	Set this flag to unity if the global components of the damping forces require separate scale factors.
STX	Scale factor on global x translational damping forces.
STY	Scale factor on global y translational damping forces.
STZ	Scale factor on global z translational damping forces.
SRX	Scale factor on global x rotational damping moments.
SRY	Scale factor on global y rotational damping moments.
SRZ	Scale factor on global z rotational damping moments.

Remarks:

Mass weighted damping damps all motions including rigid body motions. For high frequency oscillatory motion stiffness weighted damping may be preferred. With mass proportional system damping the acceleration is computed as:

$$\boldsymbol{\alpha}^n = \mathbf{M}^{-1}(\mathbf{P}^n - \mathbf{F}^n - \mathbf{F}^n_{\text{damp}})$$

where, $\mathbf{M}$ is the diagonal mass matrix, $\mathbf{P}^n$ is the external load vector, $\mathbf{F}^n$ is the internal load vector, and $\mathbf{F}^n_{\text{damp}}$ is the force vector due to system damping. This latter vector is defined as:

$$\mathbf{F}^n_{\text{damp}} = D_s m \boldsymbol{\nu}$$

The critical damping constant for the lowest frequency mode of interest is

$$D_s = 2\omega_{\text{min}}$$

where ω_{min} is that lowest frequency in units of radians per unit time. The damping constant specified as the ordinate of curve LCID is typically less than the critical damping constant. The damping is applied to both translational and rotational degrees of freedom. The component scale factors can be used to limit which global components see damping forces.

Energy dissipated by through mass weighted damping is reported as system damping energy in the ASCII file glstat. This energy is computed whenever system damping is active.

Mass damping will not be applied to deformable nodes with prescribed motion or to nodes tied with CONSTRAINED_NODE_SET.

*DAMPING_PART_STIFFNESS_{OPTION}

OPTION specifies that a part set ID is given with the single option:

<BLANK>

SET

If the SET option is not used, a part ID goes in the first field of Card 1.

Purpose: Assign stiffness damping coefficient by part ID or part set ID. This damping command does not apply to parts comprised of discrete elements (*ELEMENT_DISCRETE) or discrete beams (*ELEMENT_BEAM with ELFORM = 6).

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	COEF						
Type	I	F						
Default	none	0.0						

VARIABLE	DESCRIPTION
PID/PSID	Part ID (see *PART) or part set ID (see *SET_PART).
COEF	Rayleigh damping coefficient. Two methods are now available: LT.0.0: Rayleigh damping coefficient in units of time, set based on a given frequency and applied uniformly to each element in the specified part or part set. This method is typically used for implicit dynamic analysis. See remarks below. EQ.0.0: Inactive. GT.0.0: Unitless damping coefficient for stiffness weighted damping. This non-classical method is typically used for explicit analyses as it does not require assembly of a stiffness matrix. Values between 0.01 and 0.25 are recommended. Higher values are strongly discouraged, and values less than 0.01 may have little effect. The damping coefficient is uniquely calculated internally for each element of the part ID.

Remarks:

The damping matrix in classical Rayleigh damping is defined as:

$$\mathbf{C} = \alpha\mathbf{M} + \beta\mathbf{K}$$

where **C**, **M**, and **K** are the damping, mass, and stiffness matrices, respectively. The constants α and β are the mass and stiffness proportional damping constants. The mass proportional damping can be treated by system damping (see keywords *DAMPING_GLOBAL and *DAMPING_PART_MASS). Transforming **C** with the i^{th} eigenvector $\boldsymbol{\phi}_i$ gives:

$$\boldsymbol{\phi}_i^{\mathrm{T}}\mathbf{C}\boldsymbol{\phi}_i = \boldsymbol{\phi}_i^{\mathrm{T}}(\alpha\mathbf{M} + \beta\mathbf{K})\boldsymbol{\phi}_i = \alpha + \beta\omega_i^2 = 2\omega_i\xi_i\delta_{ij}$$

where ω_i is the i^{th} frequency (radians/unit time) and ξ_i is the corresponding modal damping parameter.

Generally, the stiffness proportional damping is effective for high frequencies and is orthogonal to rigid body motion. Mass proportional damping is more effective for low frequencies and will damp rigid body motion.

The critical stiffness damping coefficient for mode i is equal to 2 divided by ω_i. For example, 10% of critical damping in the i^{th} mode corresponds to

$$\beta = \frac{0.20}{\omega_i}$$

If COEF < 0.0 is input, then COEF is $-\beta$. For implicit dynamic analysis, classical Rayleigh stiffness damping is performed. For an explicit analysis, a negative COEF is generally impractical because solution stability requires that β be significantly smaller than the explicit time step.

If COEF > 0.0 is input, COEF represents, in only a very approximate sense, a fraction of critical damping in the high frequency domain. This approach is *not* classical Rayleigh damping and is only recommended for explicit analysis.

Energy dissipated by Rayleigh damping is computed only if the RYLEN on *CONTROL_ENERGY is set to 2. This energy is accumulated as element internal energy and is included in the energy balance. In the glstat file this energy will be lumped in with the internal energy.

NOTE: Type 2 beam elements are a special case in which COEF is internally scaled by 0.1. Thus, there is a factor of 10 less damping than stated above. This scaling applies to both negative and positive values of COEF.

*DAMPING_RELATIVE

Purpose: Apply damping relative to the motion of a rigid body. For example, it could damp the deformation of a rotating tire relative to the wheel without damping the rotating motion.

Card 1	1	2	3	4	5	6	7	8
Variable	CDAMP	FREQ	PIDRB	PSID	DV2	LCID		
Type	F	F	F	I	F	I		
Default	0	0	0	0	0.0	0		

VARIABLE	DESCRIPTION
CDAMP	Fraction of critical damping.
FREQ	Frequency at which CDAMP is to apply (cycles per unit time; for example, Hz if time unit is seconds).
PIDRB	Part ID of rigid body; see *PART. Motion relative to this rigid body will be damped.
PSID	Part set ID. The requested damping is applied only to the parts in the set.
DV2	Optional constant for velocity-squared term. See Remark 3.
LCID	ID of curve that defines fraction of critical damping as a function of time. CDAMP will be ignored if LCID is non-zero.

Remarks:

1. **Model Description.** This feature provides damping of vibrations for objects that are moving through space. The vibrations are damped, but not the rigid body motion. This is achieved by calculating the velocity of each node relative to that of a rigid body, and applying a damping force proportional to that velocity. The forces are reacted onto the rigid body such that overall momentum is conserved. It is intended that the rigid body is embedded within the moving object.

2. **Damping.** Vibrations at frequencies below FREQ are damped by more than CDAMP, while those at frequencies above FREQ are damped by less than CDAMP. It is recommended that FREQ be set to the frequency of the lowest mode of vibration.

3. **Damping Force.** The damping force of each node is calculated as follows:

$$F = -(Dmv) - \left(\text{DV2} \times mv^2\right),$$

where $D = 4\pi \times \text{CDAMP} \times \text{FREQ}$, m is the mass of the node, and v is the velocity of the node relative to the velocity of a point on the rigid body at the same coordinates as the node.

*DAMPING_STRUCTURAL

Purpose: Define structural damping coefficients to be used in frequency domain analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	G	LCID	LCTYP					
Type	F	I	I					
Default	0.0	0	0					

VARIABLE	DESCRIPTION
G	Constant structural damping coefficient.
LCID	Curve ID to define frequency dependent structural damping coefficients.
LCTYP	Type of load curve defining structural damping coefficients: EQ.0: abscissa value defines frequency. EQ.1: abscissa value defines mode number.

Remarks:

1. **Damping Force.** The structural damping force F is calculated as follows:

$$F = iGKu$$

where i is imaginary unit, G is structural damping coefficient, K is global stiffness matrix, and u is nodal displacements. The damping force F and the nodal displacements u are both complex variables.

*DATABASE

The database definitions are optional, but they are necessary to obtain output files containing results information. The ordering of the database definition cards in the input file is completely arbitrary. In this section the database keywords are defined in alphabetical order:

DATABASE_*OPTION1_{OPTION2}

*DATABASE_ACEOUT

***DATABASE**_*OPTION1_{OPTION2}*

OPTION1 specifies the type of database. LS-DYNA will *not* create an ASCII database unless the corresponding *DATABASE_*OPTION1* card is included in the input deck. *OPTION1* may be any of the items in the following list:

ABSTAT Airbag statistics. See *AIRBAG_*OPTION*.

ATDOUT Automatic tiebreak damage statistics for *CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK with OPTION set to 7, 9, 10, or 11 (only SMP at the moment).

AVSFLT AVS database. See *DATABASE_EXTENT_*OPTION*.

BEARING *ELEMENT_BEARING force output.

BNDOUT Boundary condition forces and energy.

CURVOUT Output from *DEFINE_CURVE_FUNCTION.

DEFGEO Deformed geometry file (Note that to output this file in Chrysler format insert the following line in your .cshrc file: "setenv LSTC_DEFGEO chrysler"). The nasbdf file (NASTRAN Bulk Data) is created whenever the DEFGEO file is requested.

DCFAIL Failure function data for *MAT_SPOTWELD_DAIMLERCHRYSLER

DEFORC Discrete spring and discrete damper (*ELEMENT_DISCRETE) data. If the user wishes to be selective about which discrete elements are output in deforc, use *DATABASE_HISTORY_DISCRETE_*OPTION* to select elements for output (but only if BEAM = 0 in *DATABASE_BINARY_D3PLOT) or set PF = 1 in *ELEMENT_DISCRETE to turn off output for particular elements; otherwise all discrete elements are output.

DEMASSFLOW Mass flow rate across a plane as specified by *DEFINE_DE_MASSFLOW_PLANE.

DESTAT Frequency distribution and mean value of stress energies ratio for DES, including translational normal, translational shear, translational rolling, rotational normal, rotational shear, and rotational rolling energy. The stress energies of both DES-DES contact and DES-Structure contact (if *DEFINE_DE_TO_SURFACE_COUPLING is used) are included. The distribution is based on translational normal stress energy.

DISBOUT Discrete beam element, type 6, relative displacements, rotations, and force resultants, all in the local coordinate system, which is also output. Use with *DATABASE_HISTORY_BEAM.

ELOUT Element data. See *DATABASE_HISTORY_*OPTION*. Also, see the fields INTOUT and NODOUT on Card 3 of the *DATABASE_EX-

TENT_BINARY keyword. This latter option will output all integration point data or extrapolated data to the connectivity nodes in a file call eloutdet.

GCEOUT Geometric contact entity forces. See *CONTACT_ENTITY.

GLSTAT Global statistics and energies (recommended). See *CONTROL_ENERGY.

H3OUT Joint forces and moments for Hybrid III rigid body dummies. See *COMPONENT_HYBRIDIII.

ICVOUT Incompressible control volume output file. See *DEFINE_CONTROL_VOLUME.

JNTFORC Joint forces. See *CONSTRAINED_JOINT_*OPTION*.

MATSUM Part energies. See Remarks 1 and 2 below.

MOVIE See MOVIE option of *DATABASE_EXTENT_*OPTION*.

MPGS See MPGS option of *DATABASE_EXTENT_*OPTION*.

NCFORC Nodal contact forces. See *CONTACT, Card 1 (SAPR and SBPR).

NODFOR Nodal force groups. See *DATABASE_NODAL_FORCE_GROUP.

NODOUT Nodal translational motion and, where applicable, nodal rotational motion. See *DATABASE_HISTORY_NODE_*OPTION*.

PBSTAT Particle blast data. This data is written only to the binout binary database, under the branch name abstat_pbm. See *DEFINE_PARTICLE_BLAST.

PLLYOUT Pulley element data for *ELEMENT_BEAM_PULLEY.

PRTUBE Pressure tube data for *DEFINE_PRESSURE_TUBE.

PYRO Pyro actuator data for *LOAD_PYRO_ACTUATOR.

RBDOUT Motion of rigid bodies in global and local coordinate systems. See Remark 2.

RCFORC Resultant contact interface forces. To output in a local coordinate system, see *CONTACT, Optional Card C.

RWFORC Rigidwall forces. See *RIGIDWALL_*OPTION*.

SBTOUT Seatbelt output file. See *ELEMENT_SEATBELT_*OPTION*.

SECFORC Cross section forces. See *DATABASE_CROSS_SECTION_*OPTION*.

SLEOUT Contact interface energies. See *CONTACT_*OPTION*.

SPCFORC SPC reaction forces. See *BOUNDARY_SPC_*OPTION*.

SPHOUT SPH data. See *DATABASE_HISTORY_*OPTION*.

SPHMASSFLOW Mass flow rate across a plane as specified by *DEFINE_SPH_MASS-FLOW_PLANE.

SPHVICINITY SPH vicinity sensor. See *DEFINE_SPH_VICINITY_SENSOR.

SSSTAT Subsystem data. See *DATABASE_EXTENT_SSSTAT.

SWFORC Spot weld forces (spot welds and rivets).

TPRINT Thermal output from a coupled structural/thermal or thermal only analysis. Includes all nodes unless *DATABASE_HISTORY_-NODE_*OPTION* is also provided in the keyword input.

TRHIST Tracer particle history information. See *DATABASE_TRACER.

OPTION2, if set, must be set to FILTER. FILTER can only be used when OPTION1 is NCFORC or SECFORC. With the FILTER option, this keyword requires an additional data card; see Card 2 below.

To include global and subsystem mass and inertial properties in the glstat and ssstat files add the keyword option MASS_PROPERTIES as show below. If this option is active the current mass and inertia properties are output including the principle inertias and their axes. Mass of deleted nodes and rigid bodies are not included in the calculated properties.

GLSTAT_MASS_PROPERTIES This is an option for the glstat file to include mass and inertial properties.

SSSTAT_MASS_PROPERTIES This is an option for the ssstat file to include mass and inertial properties for the subsystems.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	BINARY	LCUR	IOOPT	OPTION1	OPTION2	OPTION3	OPTION4
Type	F	I	I	I	F/I	I	I	I
Default	0.	1 or 2	none	0.	0	0	0	0

VARIABLE	DESCRIPTION
DT	Time interval between outputs. If DT is zero, no output is printed. If DT < 0.0, the result will be output every -DT time steps.
BINARY	Flag for binary output. See remarks under "Output Files and Post-Processing" in Appendix O, "LS-DYNA MPP User Guide."

VARIABLE	DESCRIPTION
	EQ.1: ASCII file is written. This is the default for shared memory parallel (SMP) LS-DYNA executables. EQ.2: Data written to a binary database binout, which contains data that would otherwise be output to the ASCII file. The ASCII file in this case is not created. This is the default for MPP LS-DYNA executables. EQ.3: ASCII file is written, and the data is also written to the binary database (NOTE: MPP LS-DYNA executables will only produce the binary database).
LCUR	Optional curve ID specifying time interval between outputs. Use *DEFINE_CURVE to define the curve; abscissa is time and ordinate is time interval between dumps.
IOOPT	Flag to govern behavior of the output frequency load curve defined by LCUR: EQ.1: When output is generated at time t_n, the next output time t_{n+1} is computed as $t_{n+1} = t_n + \mathrm{LCUR}(t_n)$. This is the default behavior. EQ.2: When output is generated at time t_n, the next output time t_{n+1} is computed as $t_{n+1} = t_n + \mathrm{LCUR}(t_{n+1})$. EQ.3: Output is generated for each abscissa point in the load curve definition. The actual value of the load curve is ignored.
OPTION1	OPTION1 applies to the bndout, nodout, and elout files. For the nodout file OPTION1 is a *real* variable that defines the time interval between outputs for the high frequency file, nodouthf. If OPTION1 is zero, no output is printed. Nodal points that are to be output at a higher frequency are flagged using HFO in the input for *DATABASE_HISTORY_NODE_LOCAL. For the elout file OPTION1 is an *integer* variable that gives the number of additional history variables written into the elout file for each integration point in the solid elements. See Remark 7 below for the elout file. See Remark 9 for the bndout file.

VARIABLE	DESCRIPTION
OPTION2	OPTION2 applies to the bndout, nodouthf and elout files. For the nodouthf OPTION2 defines the binary file flag for the high frequency nodouthf file. See the field BINARY above. For the elout file OPTION2 is an *integer* variable that gives the number of additional history variables written into the elout file for each integration point in the shell elements. See Remark 7 below for the elout file. See Remark 9 for the bndout file.
OPTION3	OPTION3 applies to the bndout and elout files only. For the elout file OPTION3 is an *integer* variable that gives the number of additional history variables written into the elout file for each integration point in the thick shell elements. See Remark 7 below for the elout file and Remark 9 for the bndout file.
OPTION4	OPTION4 applies to the bndout and elout files only. For the elout file OPTION4 is an *integer* variable that gives the number of additional history variables written into the elout file for each integration point in the beam elements. See Remark 7 below for the elout file and Remark 9 for the bndout file.

The following Card 2 applies only to *DATABASE_NCFORC_FILTER and *DATABASE_SECFORC_FILTER.

Card 2	1	2	3	4	5	6	7	8
Variable	RATE	CUTOFF	WINDOW	TYPE				
Type	F	F	F	I				
Default	none	none	none	0	0	0	0	0

VARIABLE	DESCRIPTION
RATE	Time interval *T* between filter sampling.
CUTOFF	Frequency cut-off *C* in Hz.
WINDOW	The width of the window *W* in units of time for storing the single, forward filtering required for the TYPE = 2 filter option. Increasing the width of the window will increase the memory required for the

VARIABLE	DESCRIPTION
	analysis. A window that is too narrow will reduce the amplitude of the filtered result significantly, and values below 15 are not recommended for that reason. In general, the results for the TYPE = 2 option are sensitive to the width of the window and experimentation is required.
TYPE	Flag for filtering options: EQ.0: No filtering (default) EQ.1: Single pass, forward Butterworth filtering EQ.2: Two pass filtering over the specified time window. Backward Butterworth filtering is applied to the forward Butterworth results that have been stored. This option improves the phase accuracy significantly at the expense of memory.

axial force
shear force
torsional moment
bending moment

DEFORC
x, y, z force / moment
relative rotation / dis-placement

ELOUT		
Beams	**(t)Shells**	**Solids**
axial force resultant	xx, yy, zz stress	xx, yy, zz stress
s shear resultant	xy, yz, zx stress	xy, yz, zx stress
t shear resultant	plastic strain	effective stress
s moment resultant	xx, yy, zz strain†	yield function††
t moment resultant	xy, yz, zx strain†	xx, yy, zz strain†
torsional resultant		xy, yz, zx strain†
for ELFORM = 1,7,8,9,11,14		
sig11, sig12, sig31		
plastic strain		

† Strains written for solids and for lower and upper integration points of shells and tshells if STRFLG = 1 in *DATABASE_EXTENT_BINARY.

†† "yield function" is whatever is written as the 7th history variable. For example, this would be effective plastic strain for *MAT_024.

GCEOUT	
x, y, z force	x, y, z moment

GLSTAT	
time step	total energy
kinetic energy	external work
internal energy	total and initial energy
sprint and damper energy	energy ratio without eroded energy
hourglass energy	element & part ID controlling time step
system damping energy	global x, y, z velocity
sliding interface energy	time per zone cycle
eroded kinetic energy	joint internal energy
eroded internal energy	stonewall energy
eroded hourglass energy	rigid body stopper energy
added mass	percentage [mass] increase
drilling energy	dissipation energy†

† For implicit, integration errors due to large time steps will result in inaccurate estimates of kinetic and internal energies, regardless of how tight the convergence tolerances are. The "lost" energy arising from this discretization error is accumulated in the dissipated kinetic and internal energies, respectively, to render energy balance in the sense described in the introduction. Energy balance

in implicit is an implication of having solved the implicit problem to sufficient degree of accuracy, and even though the opposite may not be true it can still be used as an indicator; energy balance *likely* implies a good solution while poor energy balance *definitely* implies a less accurate one.

JNTFORC	
x, y, z force	x, y, z moment

MATSUM	
kinetic energy	x, y, z rigid body velocity
internal energy	eroded internal energy
hourglass energy	eroded kinetic energy
x, y, z momentum	added mass

NCFORC

xx, yy, zz strain rate
xy, yz, zx strain rate
SPH to SPH coupling forces

Remarks:

1. **Discrepancies between "matsum" and "glstat" Output.** The kinetic energy quantities in the matsum and glstat files may differ slightly in values for several reasons. First, the energy associated with added mass (from mass-scaling) is included in the glstat calculation but is not included in matsum. Secondly, the energies are computed element by element in matsum for the deformable

materials and, consequently, nodes which are merged with rigid bodies will also have their kinetic energy included in the rigid body total. Furthermore, kinetic energy is computed from nodal velocities in glstat and from element midpoint velocities in matsum.

2. **PRINT Keyword Option on *PART.** The PRINT option in the part definition allows some control over the extent of the data that is written into the matsum and rbdout files. If the print option is used, the variable PRBF can be defined such that the following numbers take on the meanings:

   EQ.0: default is taken from the keyword *CONTROL_OUTPUT.

   EQ.1: write data into rbdout file only.

   EQ.2: write data into matsum file only.

   EQ.3: do not write data into rbdout and matsum.

   Also see CONTROL_OUTPUT and PART_PRINT.

3. **The Restart Feature.** This keyword is also used in the restart phase, see *RESTART. Thus, the output interval can be changed when restarting.

4. **LS-PrePost.** All information in the files except in AVSFLT, MOVIE, and MPGS can also be plotted using LS-PrePost. Arbitrary cross plotting of results between ASCII files is easily handled.

5. **The "rcforc" File.** Resultant contact forces reported in rcforc are averaged over the preceding output interval.

6. **Spring and Damper Energy.** "Spring and damper energy" reported in glstat is a subset of "internal energy". The "spring and damper energy" includes internal energy of discrete elements, seatbelt elements, and that associated with joint stiffness (see *CONSTRAINED_JOINT_STIFFNESS_…).

7. **OPTION*n* Field for "elout."** OPTION1, OPTION2, OPTION3, and OPTION4 give the number of additional history variables output for the integrated solids, shells, thick shells, and beams, respectively. Within this special option, each integration point is printed with its corresponding history data. No integration points are averaged. This is different than the default output where the stress data within a shell ply of a fully integrated shell, for example, are averaged and then written as output. The primary purpose of this database extension is to allow the actual integration point stress data and history variable data to be checked. There are no transformations applied to either the output stresses or history data; for example, EOCS in *CONTROL_OUTPUT and CMPFLG in *DATABASE_EXTENT_BINARY do not apply to elout when OPTION2 is nonzero.

8. **The Failure Function.** The failure function reported to the DCFAIL database is set to zero when the weld fails. If damage is active, then it is set to the negative of the damage scale factor which goes from 1 to 0 as damage grows.

9. **OPTION*n* Field for "bndout."** For the bndout file, OPTION1 controls the nodal force group output, OPTION2 controls the concentrated force output, OPTION3 controls the pressure boundary condition output, and OPTION4 controls the velocity/displacement/acceleration nodal boundary conditions. If the value is 0 or left blank, the category is included (the default), and if it is 1, the category is not included in the bndout file.

10. **Contents of "glstat."** The glstat table above includes all items that *may* appear in the glstat data. The items that are actually written depend on the contents of the input deck. For example, hourglass energy appears only if HGEN = 2 in *CONTROL_ENERGY and added mass only appears if DT2MS < 0 in *CONTROL_TIMESTEP.

11. **Element ID Controlling the Time Step.** The element ID controlling the time step is included in the glstat data but is not read by LS-PrePost. If the element ID is of interest to the user, the ASCII version of the glstat file can be opened with a text editor.

12. **The FILTER Option.** The FILTER option uses a Butterworth filter for the forward, single pass filtering and the backward, double pass filtering options. The forward filtered output $Y(n)$ at sampling interval n is obtained from the solution value $X(n)$ using the formula

$$Y(n) = a_0X(n) + a_1X(n-1) + a_2X(n-2) + b_1Y(n-1) + b_2Y(n-2)\ ,$$

where the coefficients are

$$\begin{aligned}
\omega_d &= 2\pi\left(\frac{C}{0.6}\right)1.25\\
\omega_a &= \tan(\omega_a T/2)\\
a_0 &= \omega_a^2/(1+\sqrt{2}\omega_a+\omega_a^2)\\
a_1 &= 2a_0\\
a_2 &= a_0\\
b_1 &= 2\left(1-\omega_a^2\right)/\left(1+\sqrt{2}\omega_a+\omega_a^2\right)\\
b_2 &= \left(-1+\sqrt{2}\omega_a-\omega_a^2\right)/\left(1+\sqrt{2}\omega_a+\omega_a^2\right)
\end{aligned}$$

The two previous solution values and filtered values at $n-1$ and $n-2$ are stored.

Backward filtering improves the phase response of the filtered output. It is performed according to the formula

$$Z(n) = a_0Y(n) + a_1Y(n+1) + a_2Y(n+2) + b_1Z(n+1) + b_2Z(n+2)\ ,$$

where $Z(n)$ is the backward filtered value at sample time n. This implies that all the forward filtered values $Y(n)$ are stored during the analysis which requires a prohibitive amount of memory. To limit the amount of memory required, the forward filtered values are stored for the time interval W, where the number of stored states is W/T, and the backward filtering is applied starting at the last saved value of the forward filtered values. As the window width increases, the filtered values approach the values that would be obtained from storing all of the forward filtered values.

The results of the backward filtering are sensitive to the window width, and experimentation with the width is necessary to obtain good results with the minimum window width. A window width of at least 10 to 15 times the sample rate T should be used as a starting point. Some applications may require a window width that is much larger. The required window width decreases as the cut-off frequency increases. Or, to put it another way, the window width must be increased to make the filtered output smoother.

As an example, a random series of numbers between 0 and 1 was generated and filtered at intervals of 0.1 milliseconds with cut-off frequencies from 60 Hz to 420 Hz. The reverse filtering was applied with various window widths to determine how many forward filtered states must be saved to achieve fixed levels of accuracy compared to complete reverse filtering from the last state to the first state. The results are shown in the table below. Note that the error is calculated *only* for the first state and the numbers being filtered are random. *This example should only be used as a very rough guide that indicates the overall trends and not as a recommendation for specific problems*.

Cut-off Frequency	No. of States 50% Error	No. of States 25% Error	No. of States 10% Error	No. of States 5% Error	No. of States 1% Error
60 Hz	26	33	55	68	87
120 Hz	13	16	30	37	44
180 Hz	8	10	22	26	30
240 Hz	6	8	17	19	23
300 Hz	5	6	12	15	18
360 Hz	5	6	10	12	16
420 Hz	4	5	9	10	15

*DATABASE_ACEOUT

Purpose: Time interval for nodal output of acoustic solution results of SSD and spectral analyses invoked with *CONTROL_IMPLICIT_SSD_DIRECT and *CONTROL_ACOUSTIC_SPECTRAL.

Card 1	1	2	3	4	5	6	7	8
Variable	DT							
Type	F							
Default	none							

VARIABLE	DESCRIPTION
DTOUT	Time interval between the outputs

*DATABASE_ALE

Purpose: For each ALE group (or material), this card controls the output for element time-history variables (in a tabular format that can be plotted in LS-PrePost by using the XYPlot button). It can also control d3plot output for ALE elements (see Remark 3).

Card 1	1	2	3	4	5	6	7	8
Variable	DTOUT	SETID						
Type	F	I						
Default	none	none						

Variable Cards. Optional cards that can be used to add more variables with the volume fractions in the database (the volume fractions are always output). Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	VAR1	VAR2	VAR3	VAR4	VAR5	VAR6	VAR7	VAR8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
DTOUT	Time interval between the outputs (see Remark 3)
SETID	ALE element set ID (see Remark 3). If the model is 1D (*SECTION_ALE1D), the set should be *SET_-BEAM. If the model is 2D (*SECTION_ALE2D), the set should be *SET_-SHELL. If the model is 3D (*SECTION_SOLID), the set should be *SET_-SOLID.
VAR*i*	Variable rank in the following list: LT.0: |VAR*i*| is the rank of the auxiliary variable to be replaced in d3plot (see Remark 3)

VARIABLE	DESCRIPTION
	EQ.1: *xx*-stress
	EQ.2: *yy*-stress
	EQ.3: *zz*-stress
	EQ.4: *xy*-stress
	EQ.5: *yz*-stress
	EQ.6: *zx*-stress
	EQ.7: plastic strain
	EQ.8: internal energy
	EQ.9: bulk viscosity
	EQ.10: previous volume
	EQ.11: pressure
	EQ.12: mass
	EQ.13: volume
	EQ.14: density
	EQ.15: kinetic energy
	EQ.16: internal energy density
	EQ.17: impulse (pressure integrated over time)
	If there is a blank column between 2 VAR*i* values, the list between these 2 values is selected. For example, if the card is input as follows:
	`1, ,6`
	then the 6 stresses are added to the database.

Remarks:

1. **Creating .xy Files.** The .xy files are created when the termination time is reached or if one of the following switches (after pressing the keys Ctrl - C) stops the job: sw1, stop, quit. During the run, they can be created with the switch sw2.

2. **Curve Output.** The .xy files are created by element. There is a curve for each ALE group (or material). A curve can be added for volume averaged variables.

3. **Modification of Auxiliary Variables in d3plot.** If VAR1 and VAR2 are input with VAR1 > 0 and VAR2 < 0, |VAR2| is a location in the auxiliary array (array listing for each element and ALE group: 6 stresses, plastic strain, internal energy,

bulk viscosity, previous volume, history variable #1, history variable #2,…). Before outputting data to d3plot, the variable at location |VAR2| is replaced by the variable at location VAR1 in the variable list. For instance, if VAR1 = 10 and VAR2 = -1, then the previous volume will be output in the *xx*-stress spot in d3plot. More than one variable can be output using this method by setting additional VAR*i*. This is a way to control output to d3plot. If this method is used, the .xy file is not output. Therefore, DTOUT is not used (see *DATABASE_BINARY_D3PLOT). If SETID is not provided, all the ALE elements are considered.

*DATABASE_ALE_MAT

Purpose: For each ALE group (or material), this card activates extra output for:

1. material volume: alematvol.xy,
2. material mass: alematmas.xy,
3. internal energy: alematEint.xy,
4. kinetic energy: alematEkin.xy,
5. and kinetic energy loss during the advection: alematEkinlos.xy.

These files are written in the ".xy" format, which LS-PrePost can plot with its "XYPlot" button.

Card	1	2	3	4	5	6	7	8
Variable	DTOUT	BOXLOW	BOXUP	DTXY				
Type	F	I	I	F				
Default	none	0	0	0				

VARIABLE	DESCRIPTION
DTOUT	Time interval between the outputs
BOXLOW, BOXUP	Range of *DEFINE_BOX ids. BOXLOW is the lower bound for the range while BOXUP is the upper bound. The series of volumes covered by the specified range of *DEFINE_BOX determines the mesh regions for which ALE material data are to be output.
DTXY	Time interval between the extractions of ".xy" files from datalemat.tmp.

Remarks:

The ".xy" files are created at termination or if one of the following switches (Ctrl-C) is encountered: sw2, sw1, stop, quit.

*DATABASE_ALE_OPERATION

Purpose: Output values from a function defined by *DEFINE_FUNCTION to certain databases, namely d3plot and .xy history files. The function arguments are defined by the variable cards in this keyword as well as predefined variables (see Remark 1). The value computed by the function for each ALE element can replace a history variable in d3plot at a frequency defined in *DATABASE_BINARY_D3PLOT. Also, the function can output values for a set of elements to .xy history files (in a tabular format that can be plotted in LS-PrePost by using the XYPlot button) at a frequency defined by a time interval set in the input for this keyword. This keyword is only supported for ALE and ALE 2D.

Card Summary:

Card 1. This card is required.

FCT	HISVN	WRT					

Card 2. This card is included if WRT ≥ 10.

DT	SETID						

Card 3. This card is optional. Include as many of this card as needed. The next keyword ("*") card terminates this input.

VAR	VAR	VAR	VAR	VAR	VAR	VAR	VAR

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	FCT	HISVN	WRT					
Type	I	I	I					
Default	none	none	1					

VARIABLE	DESCRIPTION
FCT	*DEFINE_FUNCTION ID; see Remark 1.
HISVN	Number of the history variable replaced in d3plot (see Remark 2.)

VARIABLE	DESCRIPTION
WRT	File output flag. WRT must be a two digit number: $$WRT = L + M \times 10$$ The 1's digit controls the replacement of the history variable number HISVN in d3plot: L.EQ.1: For each ALE element in the mesh, replace the values of the history variable with values computed by the function FCT. (See Remark 2.) L.EQ.0: Do not modify d3plot. The 10's digit controls the history output of values computed by the function FCT: M.EQ.1: For each ALE element in the set SETID, write .xy file that stores values computed by FCT at a frequency DT. (See Remarks 3 and 4.) M.EQ.0: Do not output this history file.

History Card. This card is included if WRT $\geq$ 10.

Card 2	1	2	3	4	5	6	7	8
Variable	DT	SETID						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
DT	Time interval between computed function values included in the .xy file. (See Remarks 3 and 4.)
SETID	ALE element set ID. See Remarks 3 and 4. If the model is 2D (*SECTION_ALE2D), the set should be a shell set (see *SET_SHELL). If the model is 3D (*SECTION_SOLID), the set should be a solid set (see *SET_SOLID).

Function Argument Cards. Optional cards used to add more arguments to the user-defined function (time, time step, cycle number and volume fractions are always included as the first arguments to the function). Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	VAR	VAR	VAR	VAR	VAR	VAR	VAR	VAR
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
VAR	Arguments that can be included in function FCT (see Remark 1): EQ.1: *xx*-stress EQ.2: *yy*-stress EQ.3: *zz*-stress EQ.4: *xy*-stress EQ.5: *yz*-stress EQ.6: *zx*-stress EQ.7: Plastic strain EQ.8: Internal energy EQ.9: Bulk viscosity EQ.10: Previous volume EQ.11: Mass EQ.12: Volume EQ.13: Nodal *x*-positions EQ.14: Nodal *y*-positions EQ.15: Nodal *z*-positions EQ.16: Nodal *x*-velocities EQ.17: Nodal *y*-velocities EQ.18: Nodal *z*-velocities EQ.19: Nodal *x*-accelerations

VARIABLE	DESCRIPTION
	EQ.20: Nodal y-accelerations
	EQ.21: Nodal z-accelerations

Remarks:

1. **Function Argument Specification.** The argument values are presented to the function FCT as floating point data (see the example below). The time, time step, cycle number and volume fractions are the first arguments of the function by default. Then the order of the following arguments appearing in *DEFINE_-FUNCTION should match the order of the input in Card 3. For example, if the model has 2 ALE groups (so 2 volume fractions) and Card 3 has input "7, 8, 11", the arguments should be as follows:

   - Time,
   - Time step,
   - Cycle number,
   - Volume fraction of the 1st group,
   - Volume fraction of the 2nd group,
   - Plastic strain of the 1st group,
   - Plastic strain of the 2nd group,
   - Internal energy of the 1st group,
   - Internal energy of the 2nd group,
   - Mass of the 1st group,
   - Mass of the 2nd group.

   If there is a blank column between 2 inputs, all the variables between the two values are also included. For example, if the card contains "1, ,6", then the 6 stresses (1 through 6) are selected as arguments.

   For the nodal variables (VAR $\geq$ 13), the number of arguments in the function depends on the element type and its number of nodes. For a solid, 8 nodal variables are expected as arguments each time VAR is greater than or equal to 13., one for each node. For a shell, 4 nodal variables are expected as arguments. For example, VAR = 17 in a 3D ALE model would mean 8 y-velocities are arguments of the function FCT.

2. **Modification of History Variables in d3plot.** The history variables appear in d3plot after the first 7 volume averaged auxiliary variables: 6 stresses and plastic strain. The number of additional history variables output to d3plot is controlled by NEIPH (for solids) or NEIPS (for shells) in *DATABASE_EXTENT_BINARY. The history variables are listed in the MISC menu of LSPREPOST as history variable #1, history variable #2, … (the exact number in the code depends on *MAT

and *EOS). Before outputting data in d3plot, the history variable at history variable number HISVN is replaced by the value computed using FCT.

3. **Creating .xy Files.** The .xy files are created when the termination time is reached or if one of the following switches (after pressing the keys Ctrl - C) stops the job: sw1, stop, quit. During the run, they can be created with switch sw2. The file names start with "dataleop" followed by the Element ID and end with the extension .xy

4. **Curve Output.** Values computed by the function FCT are included in the .xy file for each element listed in the shell (2D) or solid (3D) set SETID at a frequency defined by the time interval DT.

Example:

In the example below, LS-DYNA computes the volume averaged pressure:

- for each ALE element so that the pressure can be fringed in d3plot in the place of history variable #2
- for each ALE element included in SETID so that the pressure history for these elements can be output to a .xy file

```

}
```

DATABASE_BINARY_*OPTION1_{OPTION2}

Purpose: Request binary output. See also *DATABASE_EXTENT_BINARY.

Choices for *OPTION1* are:

BLSTFOR Blast pressure database. See also *LOAD_BLAST_ENHANCED and Remark 3.

CPMFOR Corpuscular Particle Method interface force database. See Remark 2.

D3CRACK Option to control output interval for ASCII aea_crack file for the Winfrith concrete model (*MAT_084/085). Oddly, this command does not control the output of the binary crack database for the Winfrith concrete model. The binary crack database is written when "q = " appears on the execution line, and its output interval is taken from *DATABASE_BINARY_D3PLOT. LS-PrePost displays cracks in deformed Winfrith concrete materials with the combination of this file and d3plot.

D3DRLF Dynamic relaxation database.

D3DUMP Database for restarts. Define output frequency in cycles.

D3PART Database for subset of parts. See also *DATABASE_EXTENT_BINARY and *DATABASE_EXTENT_D3PART.

D3PLOT Database for entire model. See also *DATABASE_EXTENT_BINARY.

D3PROP Database containing property data. See *DATABASE_BINARY_D3PROP.

D3THDT Database containing time histories for subsets of elements and nodes. See *DATABASE_HISTORY. This database does not include geometry.

DEMFOR DEM interface force database. See Remark 5.

FSIFOR ALE interface force database. The fsifor database does *not* have a default filename, so it *must* be given a filename using "h=" on the execution line. See Remark 1.

FSILNK ALE interface linking database. See Remark 4.

RUNRSF Database for restarts. Define output frequency in cycles.

INTFOR Contact interface database. The intfor database does *not* have a default filename, so it *must* either be given a filename using the FILE option or using "S=" on the execution line. Also see *CONTACT fields SPR and MPR.

ISPHFOR Incompressible SPH interface force database. See Remark 8.

PBMFOR Particle Blast Method interface force database. See Remark 6.

The only choice for *OPTION2* is FILE. When *OPTION2* is set to FILE, LS-DYNA requires one extra data card indicating the filename for the database selected in *OPTION1*. *Presently, this is only implemented for *DATABASE_BINARY_INTFOR.*

The D3DUMP and the RUNRSF options create complete databases which are necessary for restarts. See *RESTART. When RUNRSF is specified, the same file is overwritten after each interval, unless the field NR is set which causes a series of restart files to be overwritten in a cyclic order. When D3DUMP is specified, a new d3dump file is created after each interval. After the first interval, LS-DYNA will write d3dump01, after the second d3dump02, and so on. The default file names are runrsf and d3dump unless other names are specified on the execution line, see EXECUTION SYNTAX in the GETTING STARTED section. Since all data held in memory is written to the restart files, these files can be quite large. Care should be taken with the d3dump files not to create too many.

If *DATABASE_BINARY_D3PLOT is not specified in the keyword deck, then the output interval for d3plot is automatically set to one-twentieth of the termination time.

The d3plot, d3part, d3drlf, and intfor databases contain histories of geometry and of state variables. With LS-PrePost these databases can be used to, for example, animate deformed geometry and plot time histories of element stresses and nodal displacements. The d3thdt database contains time history data for element subsets and global information, but it does not include information about the geometry. See *DATABASE_HISTORY. This data can be plotted with LS-PrePost. For the contents of the d3plot, d3part, and d3thdt databases, see the *DATABASE_EXTENT_BINARY keyword. The size of the databases can be reduced by restricting the information that is dumped. The contents of the d3thdt database are also specified with the *DATABASE_HISTORY definition. Note that in particular the databases can be considerably reduced for models with rigid bodies containing many elements.

The fsifor database, like the intfor database, does not have a default filename. For this database a unique filename must be specified on the execution line with h=filename; see EXECUTION SYNTAX in the GETTING STARTED section. The file structure is such that each file contains the full geometry at the beginning, followed by the analysis-generated output data at the specified time intervals.

Card Summary:

Card 0. Additional card for the FILE keyword option (*OPTION2*). Presently, this is only implemented for *DATABASE_BINARY_INTFOR.

FNAME

Card 1. This card is required.

DT/CYCL	LCDT/NR	BEAM	NPLTC	PSETID	CID		

Card 2a. This card is read when *OPTION1* is D3PLOT. It is optional.

IOOPT	RATE	CUTOFF	WINDOW	TYPE	PSET		

Card 2b. This card is read when *OPTION1* is D3PART. It is optional.

HSETID	BSETID	SSETID	TSETID				

Card 2c. This card is read when *OPTION1* is INTFOR or D3DUMP. It is optional.

IOOPT							

Data Card Definitions:

FILE Card. When *OPTION2* is set to FILE, this card is included. *Presently, this is only implemented for *DATABASE_BINARY_INTFOR.*

Card 0	1	2	3	4	5	6	7	8
Variable	FNAME							
Type	A80							

VARIABLE	DESCRIPTION
FNAME	Name of the database for the INTFOR data. S=filename on the execution line will override FNAME.

Card 1	1	2	3	4	5	6	7	8
Variable	DT/CYCL	LCDT/NR	BEAM	NPLTC	PSETID	CID		
Type	F/I	I	I	I	I	I		

VARIABLE	DESCRIPTION
DT	This field defines the time interval between output states, DT, for all options except D3DUMP, RUNRSF, and D3DRLF.

VARIABLE	DESCRIPTION
CYCL	For D3DUMP and RUNRSF options this field is the number of time steps between output states. For the D3DLF option, the value, n, inputted in this field causes an output state to be written every n^{th} convergence check during the explicit dynamic relaxation phase.
NR	Number of RUNning ReStart Files, runrsf, written in a cyclical fashion. The default is 1, that is, only one runrsf file is created and the data therein is overwritten each time data is output.
LCDT	Optional load curve ID specifying the output time interval as a function of time. This variable is only available for options D3DUMP, D3PART, D3PLOT, D3THDT, INTFOR and BLSTFOR.
BEAM	Discrete element option flag (*DATABASE_BINARY_D3PLOT only): EQ.0: Discrete spring and damper elements are added to the d3plot database where they are displayed as beam elements. The discrete elements' global x, global y, global z and resultant forces (moments) and change in length (rotation) are written to the database where LS-PrePost (incorrectly) labels them as though they were beam quantities, such as axial force, S-shear resultant, T-shear resultant, etc. EQ.1: No discrete spring, damper and seatbelt elements are added to the d3plot database. This option is useful when translating old LS-DYNA input decks to KEYWORD input. In older input decks there is no requirement that beam and spring elements have unique IDs, and beam elements may be created for the spring and dampers with identical IDs to existing beam elements causing a fatal error. However, this option comes with some limitations and, therefore, should be used with caution. 1. Contact interfaces which are based on part IDs of seatbelt elements will not be properly generated if this option is used. 2. DEFORMABLE_TO_RIGID will not work if PID refers to discrete, damper, or seatbelt elements. EQ.2: Discrete spring and damper elements are added to the d3plot database where they are displayed as beam elements (similar to option 0). In this option the element resultant force is written to its first database position

VARIABLE	DESCRIPTION
	allowing beam axial forces and spring resultant forces to be plotted at the same time. This can be useful during some post-processing applications.
	This flag, set in *DATABASE_BINARY_D3PLOT, also affects the display of discrete elements in several other databases, such as d3drlf and d3part.
NPLTC	DT = ENDTIM/NPLTC. Applies to D3PLOT, D3PART, D3-DUMP, DEMFOR, and INTFOR options only. This overrides the DT specified in the first field. ENDTIM is specified in *CONTROL_TERMINATION.
PSETID	Part set ID for D3PART and D3PLOT options only. See *SET_-PART. Parts in PSETID will excluded in the d3plot database. Only parts in PSETID are included in the d3part database.
CID	Coordinate system ID for FSIFOR and FSILNK. See *DEFINE_COORDINATE_SYSTEM.

D3PLOT Card. Additional card for the D3PLOT option. It is optional.

Card 2a	1	2	3	4	5	6	7	8
Variable	IOOPT	RATE	CUTOFF	WINDOW	TYPE	PSET		
Type	I	F	F	F	I	I		
Default	0	none	none	none	0	0		

VARIABLE	DESCRIPTION
IOOPT	This input field governs how the plot state frequency is determined from curve LCDT:
	EQ.1: When a plot is generated at time t_n, the next plot time t_{n+1} is computed as $$t_{n+1} = t_n + \text{LCDT}(t_n) \ .$$ This is the default behavior.
	EQ.2: When a plot is generated at time t_n, the next plot time t_{n+1} is computed as

VARIABLE	DESCRIPTION
	$t_{n+1} = t_n + \mathrm{LCDT}(t_{n+1})$.
	EQ.3: A plot is generated for each abscissa point in the load curve definition. The actual value of the load curve is ignored.
RATE	Time interval T between filter sampling. See Remark 7.
CUTOFF	Frequency cut-off C in Hz. See Remark 7.
WINDOW	The width of the window W in units of time for storing the single, forward filtering required for the TYPE = 2 filter option. Increasing the width of the window will increase the memory required for the analysis. A window that is too narrow will reduce the amplitude of the filtered result significantly, and values below 15 are not recommended for that reason. In general, the results for the TYPE = 2 option are sensitive to the width of the window and experimentation is required. See Remark 7.
TYPE	Flag for filtering options. See Remark 7. EQ.0: No filtering (default). EQ.1: Single pass, forward Butterworth filtering. EQ.2: Two pass filtering over the specified time window. Backward Butterworth filtering is applied to the forward Butterworth results that have been stored. This option improves the phase accuracy significantly at the expense of memory.
PSET	Part set ID for filtering. If no set is specified, all parts are included. For each element integration point in the d3plot file, 24 words of memory are required in LS-DYNA for the single pass filtering, and more for the two-pass filtering. Specifying PSET is recommended to minimize the memory requirements. See Remark 7.

Optional D3PART Card. This card is read for the D3PART option. It is meant to specify element sets for which data is to be output and works in addition to PSETID. It is optional.

Card 2b	1	2	3	4	5	6	7	8
Variable	HSETID	BSETID	SSETID	TSETID				
Type	I	I	I	I				
Default	0	0	0	0				

VARIABLE	DESCRIPTION
HSETID	Set ID of a *SET_SOLID for which data will be output to d3part
BSETID	Set ID of a *SET_BEAM for which data will be output to d3part
SSETID	Set ID of *SET_SHELL for which data will be output to d3part
TSETID	Set ID of *SET_TSHELL for which data will be output to d3part

INTFOR Card. Additional card for the INTFOR and D3DUMP options. This card is optional.

Card 2c	1	2	3	4	5	6	7	8
Variable	IOOPT							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
IOOPT	This input field governs how the plot state frequency is determined from curve LCDT: EQ.1: When a plot is generated at time t_n, then next plot time t_{n+1} is computed as $$t_{n+1} = t_n + \mathrm{LCDT}(t_n)\ .$$ This is the default behavior.

VARIABLE	DESCRIPTION

EQ.2: When a plot is generated at time t_n, then next plot time t_{n+1} is computed as

$$t_{n+1} = t_n + \mathrm{LCDT}(t_{n+1}) \, .$$

EQ.3: A plot is generated for each abscissa point in the load curve definition. The actual value of the load curve is ignored.

Remarks:

1. **FSIFOR.** *DATABASE_BINARY_FSIFOR only applies to models having penalty-based coupling between Lagrangian and ALE materials CTYPE = 4 or 5 in the coupling card, *CONSTRAINED_LAGRANGE_IN_SOLID, or in case of S-ALE, *ALE_STRUCTURED_FSI. When *DATABASE_FSI is defined, a few pieces of coupling information of some Lagrangian surface entities interacting with the ALE materials may be output as history parameters into a file called "dbfsi". Coupling pressure is one of the output variables. However, this coupling pressure is averaged over the whole surface entity being monitored. To obtain coupling pressure contour plot as a function of time over the coupled surface, a user can define the *DATABASE_BINARY_FSIFOR keyword. To use it, three things must be done:

   a) The INTFORC parameter (*CONSTRAINED_LAGRANGE_IN_SOLID, 4th row, 3rd column) must be turned ON (INTFORC = 1). This is not required for *ALE_STRUCTURED_FSI. In that case, it is always ON.

   b) A *DATABASE_BINARY_FSIFOR card is defined controlling the output interval. The time interval between output is defined by the parameter DT in this card.

   c) Executing LS-DYNA as follows activates writing this interface force file:

      lsdyna i=**inputfilename.k** ... h=**interfaceforcefilename**

      LS-DYNA will then write out the segment coupling pressure and forces to a binary interface force file for contour plotting over the whole simulation interval.

      To plot the binary data in this file, type: lsprepost interfaceforcefilename.

      For example, when all 3 of the above actions are taken, and assuming "h" is set to "fsifor", then a series of "fsifor##" binary files are output for

contour plotting. To plot this, type "lsprepost fsifor" (without the double quotes).

d) Forces from a 2D axisymmetric simulation are reported per radian, regardless of the element formulation used. Multiply the 2D force by 2π to get the 3D force.

2. **CPMFOR.** *DATABASE_BINARY_CPMFOR applies to models using *AIRBAG_PARTICLE feature which controls the output interval of the CPM interface force file. This file does not have a default name. Thus, activating the writing of this file requires the cpm command line option (cpm=):

lsdyna i=**inputfilename.k** … cpm=**interfaceforce_filename**

The CPM interface force file stores each segment's coupling pressure and forces. The coupling pressure is averaged over each segment without considering the effect of ambient pressure, P_{atm}.

3. **BLSTFOR.** The BLSTFOR database is available for two-dimensional axisymmetric analysis. While line plotting is possible, fringing is not, at this time.

4. **FSILNK.** The *DATABASE_BINARY_FSILNK variant writes the selected *CONSTRAINED_LAGRANGE_IN_SOLID interface's segment pressure to the fsilink file for the next analysis without ALE meshes. This file does not have a default name. Thus, activating the writing of this file requires the fsilnk command line option (fsilnk=):

lsdyna i=**inputfilename.k** … fsilnk=**filename**

5. **DEMFOR.** *DATABASE_BINARY_DEMFOR applies to models using DEM coupling option *DEFINE_DE_TO_SURFACE_COUPLING. This keyword controls the output interval of DEM interface force file. This file does not have a default name. Thus, activating the writing of this file requires the dem command line option (dem=):

lsdyna i=**inputfilename.k** … dem=**interfaceforce_filename**

The DEM interface force file stores the coupling pressure and forces at each segment.

6. **PBMFOR.** *DATABASE_BINARY_PBMFOR applies to models using *DEFINE_PARTICLE_BLAST. It controls the output interval of PBM interface force file. This file does not have a default name. Thus, activating the writing of this file requires the pbm command line option (pbm=):

lsdyna i=**inputfilename.k** … pbm=**interfaceforce_filename**

The PBM interface force file stores the pressure and forces applied to the segments of the structure.

7. **D3PLOT Filtering.** The filtering fields cause the stress data in the d3plot file to be replaced with the filtered stress data.

8. **ISPHFOR.** *DATABASE_BINARY_ISPHFOR applies to models using incompressible SPH (FORM = 13 in *CONROL_SPH) with *DEFINE_SPH_MESH_SURFACE. This keyword controls the output interval of the ISPH interface force file. This file does not have a default name. Thus, activating the writing of this file requires the isph command line option (isph=):

lsdyna i=**inputfilename.k** … isph=**interfaceforce_filename**

The incompressible SPH interface force file stores the pressures and forces applied to the segments of the mesh surface by the SPH fluid. It also reports output whether a given segment is wet or not (instantaneous wetness flag) at each outputted time step as well as how long a segment has been wet (time-accumulated wetness).

*DATABASE_BINARY_D3PROP

Purpose: This card causes LS-DYNA to add the part, material, equation of state, section, and hourglass data to the first d3plot file or else write the data to a separate database d3prop. Rigidwall data can also be included.

Card 1	1	2	3	4	5	6	7	8
Variable	IFILE	IMATL	IWALL					
Type	I	I	I					
Default	1	0	0					

VARIABLE	DESCRIPTION
IFILE	Specify file for d3prop output (This can also be defined on the command line by adding d3prop = 1 or d3prop = 2 which also sets IMATL = IWALL = 1): EQ.1: Output data at the end of the first d3plot file. EQ.2: Output data to the file d3prop.
IMATL	Output *EOS, *HOURGLASS, *MAT, *PART and *SECTION data: EQ.0: No EQ.1: Yes
IWALL	Output *RIGIDWALL data: EQ.0: No EQ.1: Yes

*DATABASE_CPM_SENSOR

Purpose: This card activates an ASCII file cpm_sensor. Its input defines the sensors' locations based on the positions of some Lagrangian segments. The output gives the history of the velocity, temperature, density and pressure averaged on the number of particles contained in the sensors. This card is activated only when the *AIRBAG_PARTICLE card is used.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	BINARY						
Type	F	I						

Sensor Definition Cards. Each card defines one sensor. This card may be repeated to define multiple sensors. Input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	SEGID	OFFSET	LX	LY	LZ			
Type	I	F	F	F	F			

VARIABLE	DESCRIPTION
DT	Output interval
BINARY	Flag for the binary file EQ.1: ASCII file is written, EQ.2: Data is written to the binary file binout, EQ.3: ASCII file is written and the data is written to the binary file binout.
SEGID	Segment set ID. See *SET_SEGMENT.
OFFSET	Offset distance, d, between sensor and the segment center. See Remark 2.
LX	Radius(sphere and cylinder)/length in local x-direction(rectangular) of the sensor. See Remarks 1 and 2.

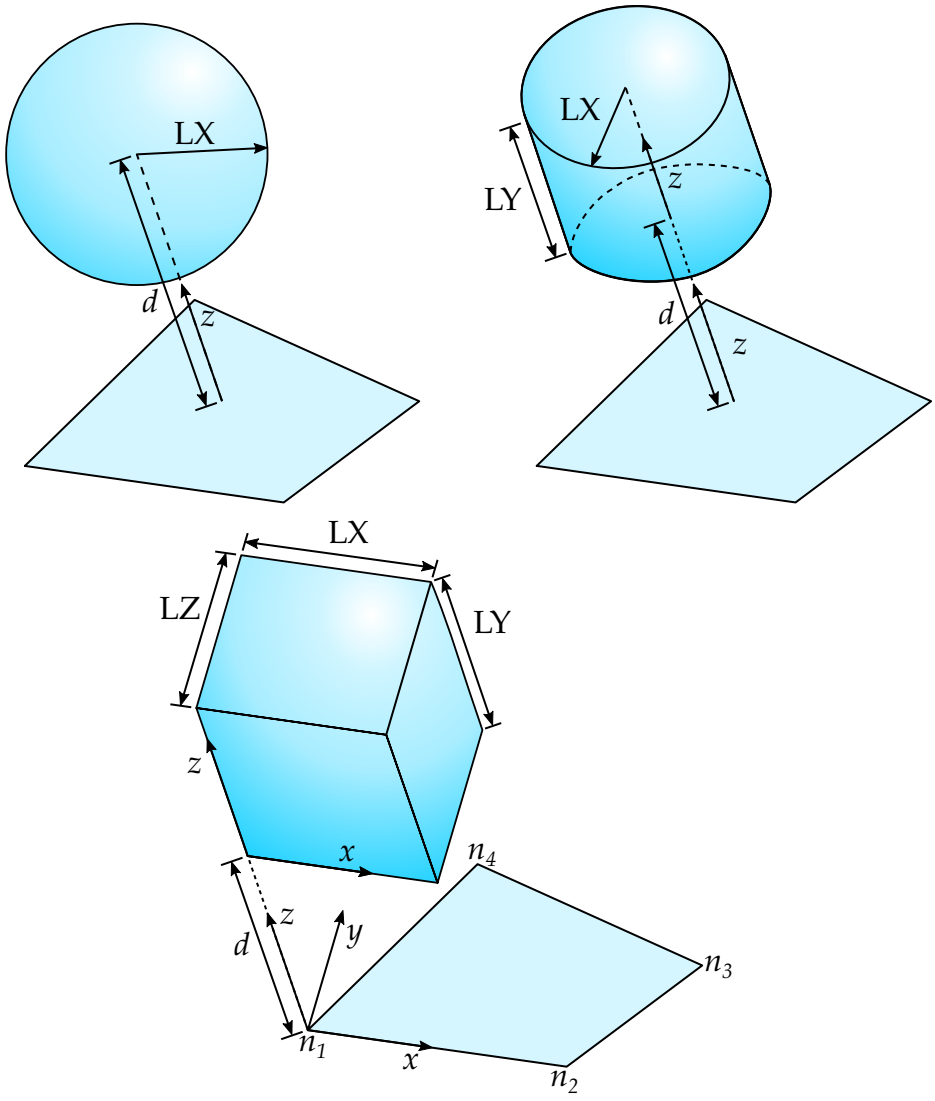

Figure 16-1. Sensor shapes

VARIABLE	DESCRIPTION
LY	Length(cylinder)/length in local *y*-direction(rectangular) of the sensor. See Remarks 1 and 2.
LZ	Length in local *z*-direction(rectangular) of the sensor. See Remarks 1 and 2.

Remarks:

1. **Sensor Shape.** The sensor can be three different shapes, a sphere, cylinder, or rectangle, depending on the length fields defined (LX, LY, and LZ). See Figure 16-1.

   a) If only LX is defined, then the sensor is sphere with radius LX.

b) If LX and LY are defined, then the sensor is a cylinder with radius LX and length LY.

c) If LX, LY, and LZ are defined, then the sensor is a rectangular prism with side lengths LX, LY, and LZ.

2. **OFFSET.** Each segment has a sensor. The distance between the segment and the sensor is defined by OFFSET (d in Figure 16-1) in the normal direction of the segment. This distance is constant, that is, the sensor moves along with the segment.

a) For a spherical sensor, OFFSET is the distance between the sphere center and the segment center. OFFSET should be larger than the radius of the sensor to prevent the segment from cutting the sphere.

b) For a cylindrical sensor, OFFSET is the distance from the segment center to the center of the base of the cylinder. The cylinder is extruded in the normal direction of the segment from the base.

c) For a rectangular sensor, OFFSET is the distance from the segment to the sensor. The sensor is defined using the segment's coordinates system. The base point for the coordinate system is n_1 from the segment definition (see *SET_SEGMENT). The local x-direction is along the vector $n_2 - n_1$. The local z-direction is the segment normal direction, and the local y-direction is constructed by the cross product of the local z- and x-directions.

3. **Output.** The output parameters in the cpm_sensor file are:

velx	=	x-velocity
vely	=	y-velocity
velz	=	z-velocity
velr	=	velocity
temp	=	temperature
dens	=	density
pres	=	pressure

These values are averaged on the number of particles in the sensor. The sensor should be large enough to contain a reasonable number of particles for the averages.

Example:

```
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|.
$ INPUT:
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|.
*DATABASE_CPM_SENSOR
      0.01
```

```
$   SEGSID    OFFSET        LX        LY
       123       5.0       5.0
       124      -0.2       0.1
       125       0.7       0.6       1.0
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|..
$ The segment set id: 123 has 1 segment.
$ The segment set id: 124 has 1 segment.
$ The segment set id: 125 has 11 segments.

$ Each segment has an ID defined in D3HSP
$ The D3HSP file looks like the following:
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|..
Segments for sensor          1
  Sensor id        n1        n2        n3        n4
         1      3842      3843      3848      3847
 Segments for sensor          2
  Sensor id        n1        n2        n3        n4
         2      3947      3948      3953      3952

 Segments for sensor          3
  Sensor id        n1        n2        n3        n4
         3      3867      3868      2146      2145
         4      3862      3863      3868      3867

        13      1125      1126      3823      3822
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|..
```

DATABASE_CROSS_SECTION_*OPTION1_{OPTION2}

OPTION1 includes:

PLANE

SET

To define an ID and heading for the database cross section, set *OPTION2* to:

ID

Purpose: Define a cross section for resultant forces written to ASCII file secforc.

1. For the PLANE option, a set of two cards defines a cutting plane, see Figure 16-2. Based on this cutting plane, a node set and element set(s) which comprise the cross section are internally generated. Using the variable ICRFILE in *CONTROL_OUTPUT, those sets may be output for the purpose of displaying the nodes and elements of the cross section using LS-PrePost.

2. If the SET option is used, just one card is needed which identifies a node set and at least one element set. In this case the node set(s) defines the cross section, and the forces from the elements belonging to the element set(s) are summed up to calculate the section forces. Thus, the element set(s) should include elements on only one side (not both sides) of the cross section.

The cross-section should cut through deformable elements only, not rigid bodies. Cutting through reference segments for deformable solid element spot welds can lead to incorrect section forces since the constraint forces are not accounted for in the force and moment summations. Beam element modeling of welds do *not* require any special precautions.

Card Summary:

Card ID. This card is included if the ID keyword option is used.

CSID	HEADING

Card 1a.1. This card is included if the PLANE keyword option is used.

PSID	XCT	YCT	ZCT	XCH	YCH	ZCH	RADIUS

Card 1a.2. This card is included if the PLANE keyword option is used.

XHEV	YHEV	ZHEV	LENL	LENM	ID	ITYPE	

Card 1b. This card is included if the SET keyword option is used.

NSID	HSID	BSID	SSID	TSID	DSID	ID	ITYPE

Data Card Definitions:

ID Card. Additional card for ID keyword option. The heading is picked up by some of the peripheral LS-DYNA codes to aid in post-processing.

Card ID	1	2	3	4	5	6	7	8
Variable	CSID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
CSID	Cross section ID. This must be a unique number.
HEADING	Cross section descriptor. It is suggested that unique descriptions be used.

Plane Card 1. First additional card for PLANE keyword option.

Card 1a.1	1	2	3	4	5	6	7	8
Variable	PSID	XCT	YCT	ZCT	XCH	YCH	ZCH	RADIUS
Type	I	F	F	F	F	F	F	F
Default	0	0.	0.	0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
PSID	Part set ID. If zero, all parts are included.
XCT	x-coordinate of tail of any outward drawn normal vector, **N**, originating on wall (tail) and terminating in space (head), see Figure 16-2.
YCT	y-coordinate of tail of normal vector, **N**.

VARIABLE	DESCRIPTION
ZCT	z-coordinate of tail of normal vector, **N**.
XCH	x-coordinate of head of normal vector, **N**.
YCH	y-coordinate of head of normal vector, **N**.
ZCH	z-coordinate of head of normal vector, **N**.
RADIUS	Optional radius: EQ.0.0: Not used. GT.0.0: A circular cut plane will be created that is centered at (XCT,YCT,ZCT) with radius = RADIUS and has a normal vector originating at (XCT,YCT,ZCT) and pointing towards (XCH,YCH,ZCH). LT.0.0: The radius will be the absolute value of RADIUS and XCT and XCH will be nodes IDs. The node with ID XCT is the center of the circular cut plane. The normal vector of the plane is the vector pointing from the node with ID XCT to the node with ID XCH. YCT, ZCT, YCH, and ZCH are ignored. If RADIUS ≠ 0.0, the variables XHEV, YHEV, ZHEV, LENL, and LENM, which are specified on Card 1a.2, will be ignored.

Plane Card 2. Second additional card for PLANE keyword option.

Card 1a.2	1	2	3	4	5	6	7	8
Variable	XHEV	YHEV	ZHEV	LENL	LENM	ID	ITYPE	
Type	F	F	F	F	F	I	I	
Default	0.	0.	0.	infinity	infinity	global	0	

VARIABLE	DESCRIPTION
XHEV	x-coordinate of head of edge vector, **L**.
YHEV	y-coordinate of head of edge vector, **L**.
ZHEV	z-coordinate of head of edge vector, **L**.

VARIABLE	DESCRIPTION
LENL	Length of edge *a*, in **L** direction.
LENM	Length of edge *b*, in **M** direction.
ID	Rigid body (see *MAT_RIGID, type 20), accelerometer ID (see *ELEMENT_SEATBELT_ACCELEROMETER), or coordinate ID (see *DEFINE_COORDINATE_NODES). The force resultants are output in the *updated* local system of the rigid body or accelerometer. For ITYPE = 2, the force resultants are output in the updated local coordinate system if FLAG = 1 in *DEFINE_COORDINATE_NODES or if NID is nonzero in *DEFINE_COORDINATE_VECTOR.
ITYPE	Flag that specifies whether ID above pertains to a rigid body, an accelerometer, or a coordinate system. EQ.0: rigid body, EQ.1: accelerometer, EQ.2: coordinate system.

Set Card. Additional Card for the SET keyword option. The set option requires that the equivalent of the automatically generated input by the cutting plane capability be identified manually and defined in sets. All nodes in the cross-section and their related elements that contribute to the cross-sectional force resultants must be defined.

Card 1b	1	2	3	4	5	6	7	8
Variable	NSID	HSID	BSID	SSID	TSID	DSID	ID	ITYPE
Type	I	I	I	I	I	I	I	I
Default	required	0	0	0	0	0	global	0

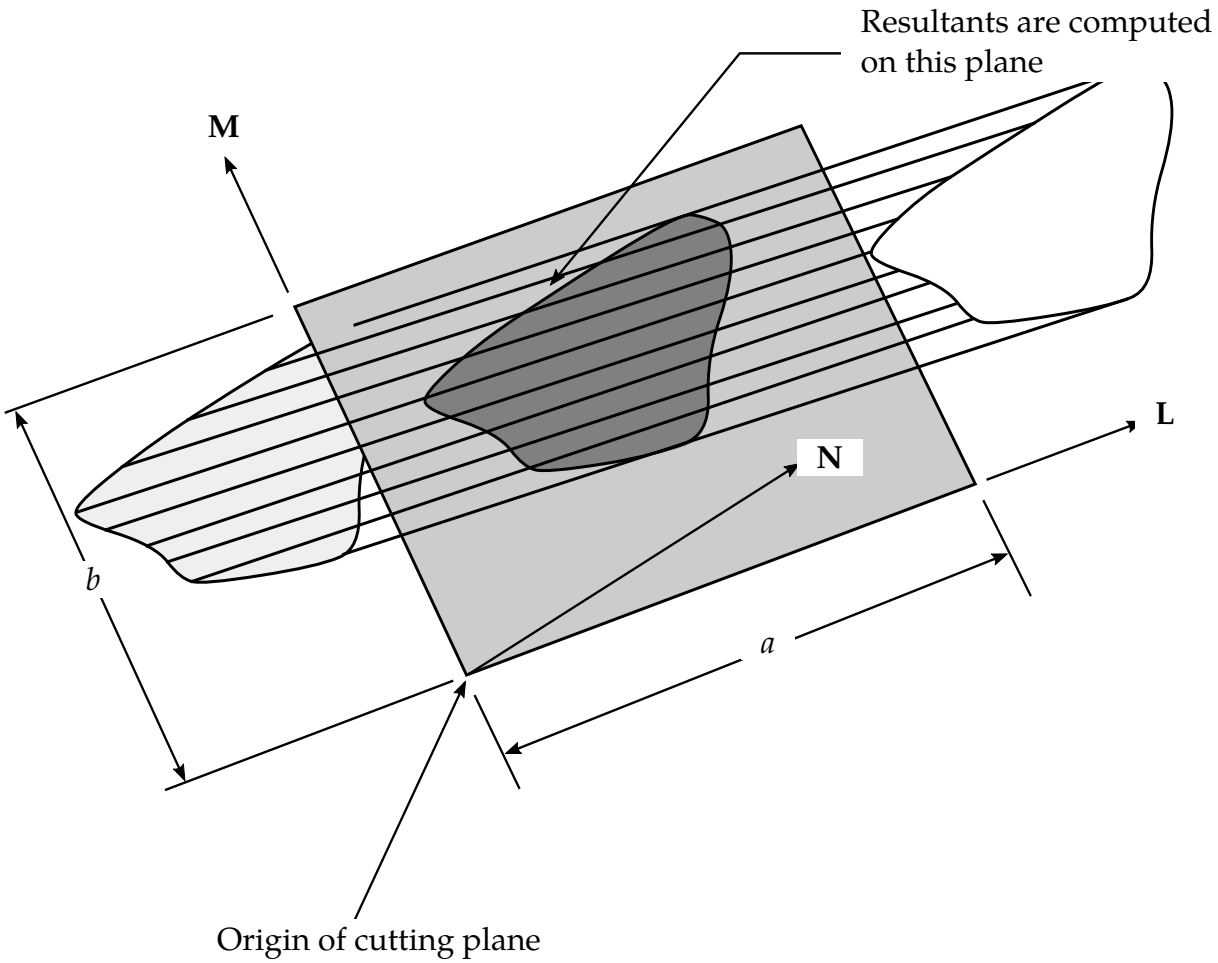

Figure 16-2. Definition of cutting plane for automatic definition of interface for cross-sectional forces. The automatic definition does not check for springs and dampers in the section. For best results the cutting plane should cleanly pass through the middle of the elements, distributing them equally on either side. Elements that intersect the edges of the cutting plane are deleted from the cross-section.

VARIABLE	DESCRIPTION
NSID	Nodal set ID, see *SET_NODE_*OPTION*.
HSID	Solid element set ID, see *SET_SOLID.
BSID	Beam element set ID, see *SET_BEAM.
SSID	Shell element set ID, see *SET_SHELL_*OPTION*.
TSID	Thick shell element set ID, see *SET_TSHELL.

VARIABLE	DESCRIPTION
DSID	Discrete element set ID, see *SET_DISCRETE.
ID	Rigid body (see *MAT_RIGID, type 20), accelerometer ID (see *ELEMENT_SEATBELT_ACCELEROMETER), or coordinate ID (see *DEFINE_COORDINATE_NODES). The force resultants are output in the *updated* local system of the rigid body or accelerometer. For ITYPE = 2, the force resultants are output in the updated local coordinate system if FLAG = 1 in *DEFINE_COORDINATE_NODES or if NID is nonzero in *DEFINE_COORDINATE_VECTOR.
ITYPE	Flag that specifies whether ID above pertains to a rigid body, an accelerometer, or a coordinate system. EQ.0: rigid body, EQ.1: accelerometer, EQ.2: coordinate system.

*DATABASE_D3FTG

Purpose: This card activates writing binary plot database d3ftg, which saves fatigue analysis results.

Card 1	1	2	3	4	5	6	7	8
Variable	BINARY	DT						
Type	I	F						
Default	1	0.0						

VARIABLE	DESCRIPTION
BINARY	Flag for writing the binary plot file: EQ.0: off EQ.1: write the binary plot file d3ftg.
DT	Time interval between output states in time domain fatigue analysis (see *FATIGUE_*{OPTION}*) EQ.0.0: only fatigue results at the end of the analysis are output.

Remarks:

1. **Frequency Domain Fatigue.** To activate writing the d3ftg database for frequency domain fatigue analysis, including random vibration fatigue (*FREQUENCY_DOMAIN_RANDOM_VIBRATOIN_FATIGUE) and steady state vibration fatigue (*FREQUENCY_DOMAIN_SSD_FATIGUE), either this keyword or *DATABASE_FREQUENCY_BINARY_D3FTG can be used. More details about the d3ftg database can be found in *DATABASE_FREQUENCY_BINARY_*OPTION.*

2. **Time Domain Fatigue.** For time domain fatigue (keyword *FATIGUE_*OPTION*), if DT is blank or is defined as 0, only the fatigue results at the end of the analysis are saved to d3ftg, so d3ftg includes only one state. If DT is defined as a nonzero value, the fatigue results at every DT are saved in d3ftg, so d3ftg includes multiple states. With this option, the user can observe the evolution of the fatigue results (e.g. the cumulative damage ratio) in the model over time.

*DATABASE_D3MAX

Purpose: This card activates writing binary plot database d3max (accessible with LS-PrePost) d3max contains the maximum or minimum (depending on OUTPUT in Card 1) values of stresses or strains for each element or certain elements during a transient analysis. The maximum (or minimum) stresses/strains can be dumped to d3part database if needed. You can restrict which elements have their maximum (or minimum) values extracted with *DATABASE_MAX_*OPTION*. Note that when this keyword is enabled, stresses are always output. The output of the strains, however, is controlled by STRFLG on *DATABASE_EXTENT_BINARY.

Card 1	1	2	3	4	5	6	7	8
Variable	DTCHECK	ME	PSTRS	PSTRN	IFILT	OUTPUT	FCUTOUT	
Type	F	I	I	I	I	I	F	
Default	none	1	0	0	0	0	0.	

VARIABLE	DESCRIPTION
DTCHECK	Time step for checking and updating maximum (or minimum) values. For instance, if DTCHECK = 10^{-6}, LS-DYNA will check and update the maximum values every 10^{-6} seconds (assuming for this example the time units are seconds). It will compare the current values (stress or strain) with the maximum values up to now. If the current values are larger, the maximum values will be replaced by the current values. Otherwise, the maximum values will remain unchanged. If OUTPUT = 3, minimum values are output instead of maximum. The same algorithm applies to the minimum values, except the minimum values are replaced if the current values are smaller.
ME	Method for extracting stresses / strains: EQ.1: Extract maximum (or minimum) stress / strain during transient analysis. EQ.2: Extract maximum (or minimum) stress / strain after transient analysis (not used).
PSTRS	Output maximum or minimum principal stress in place of maximum or minimum normal stresses in the global coordinate system (see Remark 2):

VARIABLE	DESCRIPTION
	EQ.0: No EQ.1: Yes
PSTRN	Output maximum or minimum principal strain in place of the maximum or minimum normal strains in the global coordinate system (see Remark 2): EQ.0: No EQ.1: Yes
IFILT	Use filter: EQ.0: No EQ.1: Use low pass 2nd order Butterworth filter
OUTPUT	Output format and flag to determine whether minimum or maximum values are output: EQ.0: Write maximum stress / strain to d3max EQ.1: Append the maximum stress / strain results to d3part EQ.2: Write the maximum stress / strain results to d3part instead of the normal data that goes into d3part (negative time stamps are used in d3part to distinguish when this is done from the normal d3part output, which saves time history results for selected parts) EQ.3: Write minimum stress / strain to d3max
FCUTOUT	Cutout frequency for Butterworth filter

Remarks:

1. **D3MAX.** This keyword activates saving the maximum stress and/or strain values of elements in a structure during a transient simulation to the d3max or d3part database. The time step, DTCHECK, determines how often the maximum values are updated. The following keywords can be used to restrict which elements are included in the d3max database:

   DATABASE_MAX_SOLID_*{OPTION}

   DATABASE_MAX_BEAM_*{OPTION}

   DATABASE_MAX_SHELL_*{OPTION}

DATABASE_MAX_TSHELL_*{OPTION}

2. **Principal stress and strain.** By default, the maximum or minimum stress / strain components in the global coordinate system are output. When PSTRS = 1, the maximum or the minimum of the principal stress components are stored at the location of the normal stresses in the global coordinate system in the output file. Similarly, when PSTRN = 1, the maximum or the minimum of the principal strain components are stored at the location of normal strain components in the global coordinate system. The maximum or minimum shear stress / strain components in the global coordinate system are output regardless of the setting of PSTRS / PSTRN.

3. **Save d3max data to d3part.** With OUTPUT = 2, the maximum stress / strain data for each state is output to the d3part database. The normal data in d3part is not output in this case. The time stamps of the output data to d3part are changed to negative values. Only the elements in the parts specified with PSETID on *DATABASE_BINARY_D3PART will be saved to d3part. If you specify elements with *DATABASE_MAX_*OPTION* that are not in parts in PSETID, those elements will not be in the output. However, if you include *DATABASE_MAX_*OPTION* and do not include some elements that are in the parts of PSETID, then the elements that are in the parts but not in *DATABASE_MAX_*OPTION* will have values of zero in the output to d3part.

4. **OUTPUT.** You can choose to output the maximum or the minimum stress / strain to d3max. Maximum (OUTPUT = 0, 1, our 2) should be used if the stress values are mostly positive (tension), and minimum (OUTPUT = 3) should be used if the stress values are mostly negative (compression).

*DATABASE_EXTENT

This family of keywords control to some extent the content of specific output databases. They are listed below in alphabetical order:

*DATABASE_EXTENT_AVS

*DATABASE_EXTENT_BINARY

*DATABASE_EXTENT_D3PART

*DATABASE_EXTENT_INTFOR

*DATABASE_EXTENT_MOVIE

*DATABASE_EXTENT_MPGS

*DATABASE_EXTENT_SSSTAT

The BINARY option of *DATABASE_EXTENT applies to the binary databases d3plot, d3thdt, and d3part. In the case of the d3part database, variables set using the D3PART option will override the corresponding variables of the BINARY option. See also *DATABASE_BINARY_*OPTION*.

The AVS, MOVIE, and MPGS databases will be familiar to users that have a use for those databases.

*DATABASE_EXTENT_AVS

Purpose: Control the content written to the avsflt database. See AVSFLT option to *DATABASE card.

Variable Cards. Define as many cards as needed. Input ends at next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	VTYPE	COMP						
Type	I	I						

VARIABLE	DESCRIPTION
VTYPE	Variable type: EQ.0: node, EQ.1: brick, EQ.2: beam, EQ.3: shell, EQ.4: thick shell.
COMP	Component ID. For the corresponding VTYPE, integer components from the following tables can be chosen: VTYPE.EQ.0: Table 16-3, VTYPE.EQ.1: Table 16-4, VTYPE.EQ.2: not supported, VTYPE.EQ.3: Table 16-5, VTYPE.EQ.4: not supported.

Remarks:

The AVS database consists of a title card, then a control card defining the number of nodes, brick-like elements, beam elements, shell elements, and the number of nodal vectors, NV, written for each output interval. The next NV lines consist of character strings that describe the nodal vectors. Nodal coordinates and element connectivity follow. For each state, the solution time is written, followed by the data requested below. The last word in the file is the number of states. We recommend creating this file and examining its contents, since the organization is relatively transparent.

*DATABASE_EXTENT_BINARY_{OPTION}

Purpose: Control to some extent the content of binary output databases d3plot, d3thdt, and d3part. See also *DATABASE_BINARY_*OPTION* and *DATBASE_EXTENT_D3-PART. The content of the binary output database intfor may be modified using *DATA-BASE_EXTENT_INTFOR.

Available options include:

<BLANK>

COMP

The *DATABASE_EXTENT_BINARY_COMP reduces the content of binary output data-bases d3plot and d3eigv to a maximum of only seven categories (see the seven variables of Card 1a) and therefore overrides most of the settings in *DATABASE_EXTENT_BINA-RY. Furthermore, a maximum of three through-thickness shell or tshell integration points are output to all binary databases (d3plot, d3eigv, d3part, d3drlf, etc.) when *DATA-BASE_EXTENT_BINARY_COMP is used, that is, if MAXINT in *DATABASE_EXTENT_-BINARY is set greater than 3, that variable is automatically reset to 3.

Card Summary:

Card 1a. This card is included if the COMP keyword option is used

IGLB	IXYZ	IVEL	IACC	ISTRS	ISTRA	ISED	

Card 1b. This card is included if no keyword option is used.

NEIPH	NEIPS	MAXINT	STRFLG	SIGFLG	EPSFLG	RLTFLG	ENGFLG

Card 2. This card is included if no keyword option is used.

CMPFLG	IEVERP	BEAMIP	DCOMP	SHGE	STSSZ	N3THDT	IALEMAT

Card 3. This card may be included if no keyword option is used. This card is optional.

NINTSLD	PKP_SEN	SCLP	HYDRO	MSSCL	THERM	INTOUT	NODOUT

Card 4. This card may be included if no keyword option is used. This card is optional.

DTDT	RESPLT	NEIPB	QUADSLD	CUBSLD	DELERES		

Data Card Definitions:

COMP Card. For COMP option, use this card (no Cards 2-4).

Card 1a	1	2	3	4	5	6	7	8
Variable	IGLB	IXYZ	IVEL	IACC	ISTRS	ISTRA	ISED	
Type	I	I	I	I	I	I	I	
Default	0	0	0	0	0	0	0	

VARIABLE	DESCRIPTION
IGLB	Output flag for global and part history variables such as internal energy, kinetic energy, rigid body velocity, etc., that is, the sort of data that can also be output to glstat and matsum. EQ.0: No EQ.1: Yes
IXYZ	Output flag for nodal coordinates: EQ.0: No EQ.1: Yes
IVEL	Output flag for nodal velocities: EQ.0: No EQ.1: Yes
IACC	Output flag for nodal accelerations: EQ.0: No EQ.1: Yes
ISTRS	Output flag for stress tensor and “plastic strain”: EQ.0: No EQ.1: Yes

VARIABLE	DESCRIPTION
ISTRA	Output flag for strain tensor: EQ.0: No EQ.1: Yes
ISED	Output flag for strain energy density: EQ.0: No EQ.1: Yes

Variable	NEIPH	NEIPS	MAXINT	STRFLG	SIGFLG	EPSFLG	RLTFLG	ENGFLG
Type	I	I	I	I	I	I	I	I
Default	0	0	3	0	1	1	1	1
Remarks			1	10				

VARIABLE	DESCRIPTION
NEIPH	Number of additional integration point history variables written to the binary databases (d3plot, d3part, d3drlf) for solid elements and SPH particles. The integration point data is written in the same order that it is stored in memory; each material model has its own history variables that are stored. For user defined materials the history data that is needed for plotting should be stored before the data which is not of interest. See also *DEFINE_MATERIAL_HISTORIES. For output of additional integration point history variables for solid elements to the elout database, see the field OPTION1 for *DATABASE_ELOUT.
NEIPS	Number of additional integration point history variables written to the binary databases (d3plot, d3part, d3drlf) for both shell and thick shell elements for each integration point; see NEIPH above and *DEFINE_MATERIAL_HISTORIES. For output of additional integration point history variables for shell and thick shell elements to the elout database, see the fields OPTION2 and OPTION3, respectively, in *DATABASE_ELOUT.

VARIABLE	DESCRIPTION

MAXINT

Number of shell and thick shell through-thickness integration points for which output is written to d3plot. This does not apply to the strain tensor output flagged by STRFLG.

MAXINT (def = 3)	Number of Integration Points	Description
3	> 3 (even & odd)	results are output for the outermost (top) and innermost (bottom) integration points together with results for the neutral axis.
3	1	All three results are identical.
> 3	≤ MAXINT	Results for the first MAXINT integration points in the element will be output.
≠ 3	Even	See above. This will *exclude* mid-surface results, whereas when MAXINT = 3 mid-surface results are calculated and reported.
< 0	Any	MAXINT integration points are output for each in plane integration point location and no averaging is used. This can greatly increase the size of the binary databases d3plot, d3thdt, and d3part.

See Remark 1 for more information.

STRFLG

Flag for output of strain tensors. STRFLG is interpreted digit-wise STRFLG = [*NML*],

$$\text{STRFLG} = L + M \times 10 + N \times 100$$

L.EQ.1: Write strain tensor data to d3plot, elout, and dynain. For shell and thick shell elements two tensors are written, one at the innermost and one at the outermost integration point. For solid elements a single strain tensor is written.

M.EQ.1: Write plastic strain data to d3plot.

N.EQ.1: Write thermal strain data to d3plot.

VARIABLE	DESCRIPTION
	Examples. For STRFLG = 11 (011) LS-DYNA will write both strain and plastic strain tensors, but no thermal strain tensors. Whereas for STRFLG = 110, LS-DYNA will write plastic and thermal strain tensors but no strain tensors. For more information and supported elements and materials, see Remark 10.
SIGFLG	Flag for including the stress tensor for shells and solids. EQ.1: Include (default), EQ.2: Exclude for shells, include for solids. EQ.3: Exclude for shells and solids.
EPSFLG	Flag for including the effective plastic strains for shells and solids: EQ.1: Include (default), EQ.2: Exclude for shells, include for solids. EQ.3: Exclude for shells and solids.
RLTFLG	Flag for including stress resultants in the shell LS-DYNA database: EQ.1: Include (default), EQ.2: Exclude.
ENGFLG	Flag for including shell and tshell internal energy density and shell thickness: EQ.1: Include (default), EQ.2: Exclude.

Card 2	1	2	3	4	5	6	7	8
Variable	CMPFLG	IEVERP	BEAMIP	DCOMP	SHGE	STSSZ	N3THDT	IALEMAT
Type	I	I	I	I	I	I	I	I
Default	0	0	0	1	1	1	2	1

VARIABLE	DESCRIPTION
CMPFLG	Flag to indicate the coordinate system for output of stress and strain of solids, shells and thick shells comprised of orthotropic or anisotropic materials. CMPFLG affects d3plot, d3part, eloutdet, and elout, with exceptions as noted below. EQ.-1: Same as 1, but for *MAT_FABRIC (FORM = 14 or -14) and *MAT_FABRIC_MAP the stress and strain is in engineering quantities instead of Green-Lagrange strain and 2nd Piola-Kirchhoff stress. EQ.0: Global coordinate system with exception of elout for shells (see EOCS in *CONTROL_OUTPUT). EQ.1: Local material coordinate system (as defined by AOPT and associated parameters in the *MAT input, and if applicable, by angles B1, B2, etc. in *SECTION_SHELL, *SECTION_TSHELL, or *PART_COMPOSITE, and by optional input in the *ELEMENT data). The effect of CMPFLG = 1 on shell output in elout is overridden by EOCS = 1 or 2 in *CONTROL_OUTPUT or by OPTION2 > 0 in *DATABASE_ELOUT. These overriding conditions do not apply to eloutdet.
IEVERP	Every output state for the d3plot database is written to a separate file. EQ.0: More than one state can be on each plot file, EQ.1: One state only on each plot file.
BEAMIP	Number of beam integration points for output. This option does not apply to beams that use a resultant formulation. See Remark 2.
DCOMP	Data compression to eliminate rigid body data: EQ.1: Off (default), no rigid body data compression, EQ.2: On, rigid body data compression active, EQ.3: Off, no rigid body data compression, but all nodal velocities and accelerations are eliminated from the database. EQ.4: On, rigid body data compression active and all nodal velocities and accelerations are eliminated from the database. EQ.5: On, rigid body data compression active and rigid nodal data are eliminated from the database. Only 6 DOF rigid body motion is written.

VARIABLE	DESCRIPTION
	EQ.6: On, rigid body data compression active, rigid nodal data, and all nodal velocities and accelerations are eliminated from the database. Only 6 DOF rigid body motion is written.
SHGE	Flag for including shell hourglass energy density: EQ.1: Off (default), no hourglass energy written, EQ.2: On.
STSSZ	Flag for including shell element time step, mass, or added mass: EQ.1: Off (default), EQ.2: Output time step size, EQ.3: Output mass, added mass, or time step size. See Remark 3 below.
N3THDT	Flag for including material energy in d3thdt database: EQ.1: Off, energy is *not* written to d3thdt database, EQ.2: On (default), energy is written to d3thdt database.
IALEMAT	Output solid part ID list containing ALE materials. EQ.1: On (default)

Card 3	1	2	3	4	5	6	7	8
Variable	NINTSLD	PKP_SEN	SCLP	HYDRO	MSSCL	THERM	INTOUT	NODOUT
Type	I	I	F	I	I	I	A	A
Default	1	0	1.0	0	0	0	none	none

VARIABLE	DESCRIPTION
NINTSLD	Number of solid element integration points written to the LS-DYNA database. When NINTSLD is set to 1 (default) or to any value other than 8, integration point values are averaged and only those averages are written output. To obtain values for individual integration points, set NINTSLD to 8, even if the multi-integration point solid has fewer than 8 integration points.
PKP_SEN	Flag to output the peak pressure and surface energy (energy per unit area) computed by each contact interface into the interface force database. To obtain the surface energy, FRCENG, must be sent to 1 on the control contact card. When PKP_SEN = 1, it is possible to identify the energies generated on the upper and lower shell surfaces, which is important in metal forming applications. This data is mapped after each h-adaptive remeshing. EQ.0: No data is written. EQ.1: Output the peak pressures and surface energy by contact interface.
SCLP	A scaling parameter used in the computation of the peak pressure. This parameter is generally set to unity (the default), but it must be greater than 0.
HYDRO	Either 3, 5 or 7 additional history variables useful to shock physics are output as the last history variables to d3plot (does not apply to elout). For HYDRO = 1, the internal energy per reference volume, the reference volume, and the pressure from bulk viscosity are added to the database; for HYDRO = 2, the relative volume and current density are also added; and for HYDRO = 4, volumetric strain (defined as relative volume – 1.0) and hourglass energy per unit initial volume are additionally added. These history variables are not valid for ALE elements.
MSSCL	Output nodal and part information related to mass scaling into the d3plot database. This option can be activated only if DT2MS < 0.0. See Remark 3. Also, see control keyword *CONTROL_TIMESTEP. MSSCL is interpreted digit-wise, MSSCL = [*ML*], $\text{MSSCL} = L + M \times 10$ *L* sets the nodal mass output: L.EQ.0: No incremental nodal mass data is written.

VARIABLE	DESCRIPTION
	L.EQ.1: Output incremental nodal mass. L.EQ.2: Output percentage increase in nodal mass. *M* determines what mass is output for each part into d3plot: M.EQ.0: Output original mass for each part. M.EQ.1: Output effective mass for each part. Effective mass is the original mass plus the incremental mass.
THERM	Output of thermal data to d3plot. The use of this option (THERM > 0) may make the database incompatible with other 3rd party software. EQ.0: Output temperature (default). EQ.1: Output temperature. EQ.2: Output temperature and flux. EQ.3: Output temperature, flux, and shell bottom and top surface temperature.
INTOUT	Output stress/strain at all integration points for detailed element output in the ASCII file eloutdet. DT and BINARY of *DATABASE_ELOUT apply to eloutdet. See Remark 4. EQ.STRESS: When stress output is required EQ.STRAIN: When strain output is required EQ.ALL: When both stress and strain output are required
NODOUT	Output extrapolated stress/strain at connectivity nodes for detailed element output in the ASCII file eloutdet. DT and BINARY of *DATABASE_ELOUT apply to eloutdet. See Remark 4. EQ.STRESS: When stress output is required EQ.STRAIN: When strain output is required EQ.ALL: When both stress and strain output are required EQ.STRESS_GL: When nodal averaged stress output along the global coordinate system is required EQ.STRAIN_GL: When nodal averaged strain output along the global coordinate system is required EQ.ALL_GL: For global nodal averaged stress and strain output

Card 4	1	2	3	4	5	6	7	8
Variable	DTDT	RESPLT	NEIPB	QUADSLD	CUBSLD	DELERES		
Type	I	I	I	I	I	I		
Default	0	0	0	0	0	0		

VARIABLE	DESCRIPTION
DTDT	Output of node point Δtemperature/Δtime data to d3plot. EQ.0: No output (default) EQ.1: Output $\Delta T/\Delta t$
RESPLT	Output of translational and rotational residual forces to d3plot and d3iter. EQ.0: No output EQ.1: Output residual
NEIPB	Number of additional element or integration point history variables written to the binary databases (d3plot, d3part, d3drlf) for beam elements; see NEIPH above, BEAMIP and *DEFINE_MATERIAL_HISTORIES. See also Remark 12. For output of additional integration point history variables for beam elements to the elout database, see the variable OPTION4 in *DATABASE_ELOUT.
QUADSLD	(Under development) Output flag for quadratic solid types 24, 25, and 26: EQ.0: Average stress and strain and rendered with 8 nodes EQ.1: Average stress and strain and rendered with all edge and face nodes EQ.2: All integration points written and rendered with all edge and face nodes
CUBSLD	(Under development) Output flag for cubic solids types 27, 28, and 29: EQ.0: Average stress and strain and rendered with 8 nodes

VARIABLE	DESCRIPTION
	EQ.1: Average stress and strain and rendered with all edge and face nodes
	EQ.2: All integration points written and rendered with all edge and face nodes
DELERES	Output flag for results of deleted elements:
	EQ.0: No results output (all zero)
	EQ.1: Last available results, such as stresses and history variables, are written to d3plot and d3part.

Remarks:

1. **MAXINT Field.** If MAXINT is set to 3, then mid-surface, inner-surface and outer-surface stresses are output at the center of the element. For an even number of integration points, the points closest to the center are averaged to obtain the midsurface values. If multiple integration points are used in the shell plane, the stresses at the center of the element are found by computing the average of these points. For MAXINT equal to 3, LS-DYNA assumes that the data for the user defined integration rules are ordered from bottom to top even if this is not the case. If MAXINT is not equal to 3, then the stresses at the center of the element are output in the order that they are stored for the selected integration rule. If multiple points are used in plane, the stresses are first averaged.

2. **BEAMIP Field.** Beam stresses are output if and only if BEAMIP is greater than zero. In this latter case the data that is output is written in the same order that the integration points are defined. The data at each integration point consists of the following five values for elastic-plastic Hughes-Liu beams: the normal stress, σ_{rr}; the transverse shear stresses, σ_{rs} and σ_{tr}; the effective plastic strain; and the axial strain which is logarithmic. For beams that are not elastic-plastic, the first history variable, if any, is output instead of the plastic strain. For the beam elements of Belytschko and his co-workers, the transverse shear stress components are not used in the formulation. No data is output for the Belytschko-Schwer resultant beam.

3. **Mass Scaling.** If mass scaling is active, the output of the time step size reveals little information about the calculation. If global mass scaling is used for a constant time step, the total element mass is output; however, if the mass is increased so that a minimum time step size is maintained (DT2MS is negative), the added mass is output. Also, see the control card *CONTROL_TIMESTEP.

4. **Estimated Stress and Strain Output to eloutdet for Nodes.**

   a) When NODOUT is set to STRESS, STRAIN , or ALL. Each node of the element nodal connectivity will be output. See Example 1.

   b) When NODOUT is set to STRESS_GL, STRAIN_GL, or ALL_GL. Averaged nodal results are calculated by summing up all contributions from elements sharing the common node, and then dividing the total by the number of contributing elements. Averaged nodal values are always output in the global coordinate system. See Example 2.

5. **Contents of eloutdet.** Available stress/strain components in eloutdet stress components includes 6 stress components (sig-*xx*, sig-*yy*, sig-*zz*, sig-*xy*, sig-*yz*, sig-*zx*), yielding status, and effective plastic strain. Strain components includes 6 strain components.

6. **Shell Element Output at Integration Points.** Stresses at all integration points can be output. The strain at the top and bottom integration layer can be output. At a connective node the extrapolated stress and strain at the top and bottom layer can be output.

7. **Thick Shells.** Thick shell element output includes the six stress components at each integration point. Strain at the top and bottom layer can be output. At the element node, values at the bottom layer are extrapolated to yield the values of nodes 1 - 4, and values at the top layer are extrapolated to yield values of nodes 5 - 8.

8. **Integration Point Locations.** Stresses and strain at all integration points can be output. The integration point order is as follows:

   a) point #1 is the point closest to node #1 in the connectivity array

   b) point #2 is the closest point to node #2, etc

   c) For tetrahedral types 4, 16 and 17 with 5 integration points, point #5 is the midpoint.

   d) For the nodal points, values at the integration points are extrapolated.

9. **Reporting Residual Forces and Moments.** The output of residual forces and moments is supported for implicit and double precision only. With this option, the forces and moments appear under the *Ndv* button in the fringe menu in LS-PrePost. The residual for rigid bodies is distributed to the constrained nodes for the body without scaling for the purpose of capturing the complete residual vector.

10. **Calculation of Strains (STRFLG).** The strain tensors ε that are output to the d3plot database are calculated using proper time integration of the rate-of-deformation tensor $\mathbf{D}$. More specifically, to assert objectivity of the resulting strain, it is for solids using a Jaumann rate of strain whereas for shells it uses the co-rotational strain rate. In mathematical terms the integration is using the following strain rates

$$\dot{\varepsilon} = \mathbf{D} - \varepsilon\mathbf{W} + \mathbf{W}\varepsilon \quad \text{(solids)}$$

$$\dot{\varepsilon} = \mathbf{D} - \varepsilon\boldsymbol{\Omega} + \boldsymbol{\Omega}\varepsilon \quad \text{(shells)}$$

where $\mathbf{W}$ is the spin tensor and $\boldsymbol{\Omega} = \dot{\mathbf{Q}}\mathbf{Q}^{\mathrm{T}}$ is the rotational velocity of the co-rotational system $\mathbf{Q}$ used for the shell element in question, taking into account invariant node numbering and such. This is to say that the resulting strains would be equal to the Cauchy stress for a hypo-elastic material (MAT_ELASTIC) with a Young's modulus of 1 and a Poisson's ratio of 0. This should be kept in mind when interpreting the results since they are not invariant to changes in element formulations and possibly nodal connectivities.

11. **Plastic and Thermal Strain (STRFLG).** The algorithm for writing plastic and thermal strains, which is also activated using STRFLG, is a modification of the algorithm used for mechanical strains (see Remark 10).

    a) For solids the element average strain in the global system having 6 components is written (local system if CMPFLG is set).

    b) For shells both plastic and thermal strains have 6 components. The thermal strain is written as a single tensor as in the solid case. The plastic strain output consists of 3 plane-averaged tensors: one for the bottom, one for the middle, and one for the top. For an even number of through thickness integration points, the middle is taken to be the average of the two integration points closest to the mid surface. Currently, only the following element/materials combinations are supported but others *will* be added upon request.

Thermal strain tensors			*Plastic strain tensors*		
Shells	Solids	Materials	Shells	Solids	Materials
2, 16, 23	1, 2	Add thermal expansion, 255	2, 16, 23	1, 2	24, 255

12. **History Variables for Beams (NEIPB).** In general, NEIPB follows the same conventions as NEIPH and NEIPS do for solid and shell elements and is supported in LS-PrePost v4.3 or later. Average, min and max values for each element are output, including data for resultant elements. If BEAMIP is nonzero, then

element data is complemented with BEAMIP integration point values that can be examined individually. Beam history data is post-processed similarly to that of solid and shell element history data.

Example 1:

Excerpt from eloutdet file for a shell element with two through-thickness integration points and four in-plane integration points, with INTOUT = STRESS and NODOUT = STRESS:

```
element  materl
     ipt  stress  sig-xx   sig-yy   sig-zz   sig-xy   sig0yz   sig-zx   yield         location
       1-      1
   1- 10 elastic  4.41E-2  2.51E-1  0.00E+0  7.76E-8  0.00E+0  0.00E+0  0.00E+0  int.  point  1

*DATABASE_EXTENT_D3PART

The following cards control content to the d3part binary database (Card 3 is optional). The parameters given here will supercede the corresponding parameters in *DATABASE_EXTENT_BINARY when writing the d3part binary database. See also *DATABASE_BINARY_D3PART which defines the output interval for d3part and the set of parts included in d3part.

Card 1	1	2	3	4	5	6	7	8
Variable	NEIPH	NEIPS	MAXINT	STRFLG	SIGFLG	EPSFLG	RLTFLG	ENGFLG
Type	I	I	I	I	I	I	I	I
Default	0	0	3	0	1	1	1	1

Card 2	1	2	3	4	5	6	7	8
Variable		IEVERP			SHGE	STSSZ		
Type		I			I	I		
Default		0			0	0		

Card 3	1	2	3	4	5	6	7	8
Variable	NINTSLD							
Type	I							
Default	1							

VARIABLE	DESCRIPTION
NEIPH	Number of additional integration point history variables written to the binary database for solid elements. The integration point data is written in the same order that it is stored in memory; each material model has its own history variables that are stored. For user defined materials the history data that is important for plotting should be stored before the data that is not of interest.
NEIPS	Number of additional integration point history variables written to the binary database for both shell and thick shell elements for each integration point; see NEIPH above.
MAXINT	Number of shell integration points written to the binary database; see also *INTEGRATION_SHELL. See Remark 1.
STRFLG	Set to 1 to dump strain tensors for solid, shell and thick shell elements for plotting by LS-PrePost and ASCII file elout. For shell and thick shell elements two tensors are written, one at the innermost and one at the outermost integration point. For solid elements a single strain tensor is written.
SIGFLG	Flag for including the stress tensor for shells: EQ.1: include (default), EQ.2: exclude.
EPSFLG	Flag for including the effective plastic strains for shells: EQ.1: include (default), EQ.2: exclude.
RLTFLG	Flag for including stress resultants for shells: EQ.1: include (default), EQ.2: exclude.
ENGFLG	Flag for including shell internal energy density and shell thickness: EQ.1: include (default), EQ.2: exclude.

VARIABLE	DESCRIPTION
IEVERP	Every plot state for the d3part database is written to a separate file. This option will limit the database to 1000 states: EQ.0: more than one state can be on each plot file, EQ.1: one state only on each plot file.
SHGE	Flag for including shell hourglass energy density: EQ.1: off (default), no hourglass energy written, EQ.2: on.
STSSZ	Flag for including shell element time step, mass, or added mass: EQ.1: off (default), EQ.2: output time step size, EQ.3: output mass, added mass, or time step size. See Remark 2 below.
NINTSLD	Number of solid element integration points written. The default value is 1. For solids with multiple integration points NINTSLD may be set to 8. Currently, no other values for NINTSLD are allowed. For solids with multiple integration points, an average value is output if NINTSLD is set to 1.

Remarks:

1. **MAXINT.** If the default value of 3 is used, then results are output for the outermost (top) and innermost (bottom) integration points together with results for the neutral axis. If MAXINT is set to 3 and the element has 1 integration point, then all three results will be the same. If a value other than 3 is used, then results for the first MAXINT integration points in the element will be output. Note that if the element has an even number of integration points and MAXINT is not set to 3, then you will not get mid-surface results. If MAXINT is set to a negative number, MAXINT integration points are output for each in-plane integration point location and no averaging is used. This can greatly increase the size of the binary d3part database.

2. **Mass Scaling.** If mass scaling is active, the output of the time step size reveals little information about the calculation. If global mass scaling is used for a constant time step, the total element mass is output; however, if the mass is increased so that a minimum time step size is maintained (DT2MS is negative), the added mass is output. Also, see the control card *CONTROL_TIMESTEP.

*DATABASE_EXTENT_INTFOR

Purpose: The following card controls to some extent the content of the optional intfor binary database. See also *DATABASE_BINARY_INTFOR. The intfor database contains geometry and time history data pertaining to those contact surfaces which are flagged in *CONTACT with the variables SAPR and/or SBPR. The name of the intfor database may be given either on the execution line using "s=**filename**", or using the option FILE on *DATABASE_BINARY_INTFOR.

Card 1	1	2	3	4	5	6	7	8
Variable	NGLBV	NVELO	NPRESU	NSHEAR	NFORC	NGAPC	NFAIL	IEVERF
Type	I	I	I	I	I	I	I	I
Default	1	1	1	1	1	1	0	0

Optional Card.

Card 2	1	2	3	4	5	6	7	8
Variable	NWEAR	NWUSR	NHUF	NTIED	NENG	NPEN		
Type	I	I	I	I	I	I		
Default	0	0	0	0	0	0		

VARIABLE	DESCRIPTION
NGLBV	Output global variables: EQ.-1: No, EQ.1: Yes (default).
NVELO	Output nodal velocity: EQ.-1: No, EQ.1: Yes (default).
NPRESU	Output pressures: EQ.-1: No,

VARIABLE	DESCRIPTION
	EQ.1: Normal interface pressure (default), EQ.2: Normal interface pressure and peak pressure, EQ.3: Normal interface pressure, peak pressure and time to peak.
NSHEAR	Output shear stresses: EQ.-1: No, EQ.1: Shear stress in *r*-direction and *s*-direction (default).
NFORC	Output forces: EQ.-1: No, EQ.1: *x*-, *y*-, *z*-force at all nodes (default).
NGAPC	Output contact gaps at all nodes and surface energy density. For Mortar contact, see Remark 1. EQ.-1: No, EQ.1: Yes (default).
NFAIL	Flag for display of deleted contact segments: EQ.0: All segments are displayed (default). EQ.1: Remove deleted contact segments from display.
IEVERF	Every interface force state for the intfor database is written to a separate file: EQ.0: More than one interface force state can be on each intfor file (default). EQ.1: One interface force output state only on each intfor file.
NWEAR	Output contact wear data; see *CONTACT_ADD_WEAR. EQ.0: No output (default). GE.1: Output wear depth. GE.2: Output sliding distance.
NWUSR	Number of user wear history variables to output from user defined wear routines; see *CONTACT_ADD_WEAR. See Remark 2.

VARIABLE	DESCRIPTION
NHUF	Number of user friction history variables to output from user defined friction routines; see *USER_INTERFACE_FRICTION (MPP only). See Remark 2.
NTIED	Output tied segments for Mortar contact. See Remark 3. EQ.0: No output EQ.1: Output
NENG	Output contact energy density for Mortar contact and SOFT = 2 contact (see also ENGOUT on *CONTROL_OUTPUT): EQ.0: No output EQ.1: Output
NPEN	Output penetration information for Mortar contact. A nodal field gives the penetration for each node (magnitude and direction) in the sliding interface; see also PENOUT on *CONTROL_OUTPUT. EQ.0: No output EQ.1: Output absolute penetration EQ.2: Output absolute and relative penetrations. Relative penetration is output as a percentage of the penetration at which the contact is released.

Remarks:

1. **Gaps in Mortar Contact.** Gaps in Mortar contact are measured with respect to the *nominal* contact surfaces of the two interacting segments. For instance, if IGNORE = 2 on *CONTACT_...MORTAR, then an initial penetration d will dislocate the tracked contact surface in the negative direction of the tracked surface normal $\mathbf{n}$. If NGAPC = 1, the gap g reported to the intfor file is still measured between the tracked and reference surface, neglecting this dislocation; thus, only *physical* gaps are reported.

2. **Wear Outputs.** Wear outputs are governed by NWEAR and NWUSR and require the use of a wear model associated with the contact interface. For NWEAR the "wear depth" (NWEAR ≥ 1) and "sliding distance" (NWEAR ≥ 2) are listed under the Nodal fringe menu in LS-PrePost. Following this, NWUSR user-defined history variables are listed, corresponding to user wear history variables in a user wear routine. These are listed in the order that they are stored in the wear routine; see WTYPE ≤ 0 on *CONTACT_ADD_WEAR.

3. **Mortar Tied Contacts.** For all Mortar tied contacts, that is,

   *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR_TIED,

   *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR_TIED_WELD, and

   *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK_MORTAR.

   NTIED will activate the output of an indicator stating whether a tracked segment is tied (= 1) or not (= 0); nothing is shown on the reference side. When opening the intfor file in LS-PrePost, the fringe menu will have two entries titled "tied at top" and "tied at bottom," corresponding to the top and bottom of a shell segment, respectively. The top and bottom labels are with respect to the shell normal. For obvious reasons, solid segments will only have nonzero values for the "tied at top" field. For tiebreak contact, these variables represent the relative adhesive strength in the contact, that is, $1 - D$, where D is the damage, so fully damaged segments will show 0 and undamaged segments will show 1. For the tied weld contact the entries will give the segments that have been welded to the corresponding reference side of the contact and can thus have only 0 (not welded) or 1 (welded).

*DATABASE_EXTENT_MOVIE

Purpose: Control the content written to the MOVIE databases. See movie option on *DATABASE manual entry.

Variable Cards. Define as many cards as needed. Input ends at next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	VTYPE	COMP						
Type	I	I						

VARIABLE	DESCRIPTION
VTYPE	Variable type: EQ.0: node, EQ.1: brick, EQ.2: beam, EQ.3: shell, EQ.4: thick shell.
COMP	Component ID. For the corresponding VTYPE, integer components from the following tables can be chosen: VTYPE.EQ.0: Table 16-3 (see DATABASE_EXTENT_AVS), VTYPE.EQ.1: Table 16-4 (see DATABASE_EXTENT_AVS), VTYPE.EQ.2: not supported, VTYPE.EQ.3: Table 16-5 (see DATABASE_EXTENT_AVS), VTYPE.EQ.4: not supported.

*DATABASE_EXTENT_MPGS

Purpose: Control the content written to the MPGS databases. The created MPGS databases consist of a geometry file and one file for each output database. See MPGS option to *DATABASE keyword.

Variable Cards. Define as many cards as needed. Input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	VTYPE	COMP						
Type	I	I						

VARIABLE	DESCRIPTION
VTYPE	Variable type: EQ.0: node, EQ.1: brick, EQ.2: beam, EQ.3: shell, EQ.4: thick shell.
COMP	Component ID. For the corresponding VTYPE, integer components from the following tables can be chosen: VTYPE.EQ.0: Table 16-3 (see DATABASE_EXTENT_AVS), VTYPE.EQ.1: Table 16-4 (see DATABASE_EXTENT_AVS), VTYPE.EQ.2: not supported, VTYPE.EQ.3: Table 16-5 (see DATABASE_EXTENT_AVS), VTYPE.EQ.4: not supported.

DATABASE_EXTENT_SSSTAT_*OPTION

The only *OPTION* is:

ID

The ID option allows the definition of a heading which will be written at the beginning of the ASCII file ssstat.

Purpose: This command defines one or more subsystems. A subsystem is simply a set of parts, grouped for convenience. The ASCII output file ssstat provides histories of energy (kinetic, internal, hourglass) and momentum (x, y, and z) for each subsystem. The ssstat file is thus similar to glstat and matsum. But whereas glstat provides data for the whole model and matsum provides data for each individual part, ssstat provides data for each subsystem. The output interval for the ssstat file is given using *DATABASE_SSSTAT. To also include histories of subsystem mass properties in the ssstat file, use *DATABASE_SSSTAT_MASS_PROPERTIES.

For *DATABASE_EXTENT_SSSTAT without the ID option, the following card(s) applies. Define as many cards as necessary. Define one part set ID per subsystem, up to 8 subsystems per card.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID1	PSID2	PSID3	PSID4	PSID5	PSID6	PSID7	PSID8
Type	I	I	I	I	I	I	I	I

For *DATABASE_EXTENT_SSSTAT_ID, the following card(s) applies. Define as many cards as necessary. Define one part set ID per subsystem, 1 subsystem per card.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID1	HEADING1						
Type	I	A70						

VARIABLE	DESCRIPTION
PSID*n*	Part set ID for subsystem *n*; see *SET_PART.
HEADING*n*	Heading for subsystem *n*.

*DATABASE_FATXML

Purpose: Process FATXML data. FATXML is an open, standardized data format based on the Extensible Markup Language (XML). It is developed by the German Research Association of Automotive Technology (Forschungsvereinigung Automobiltechnik - FAT). FATXML is designed for consistent data management in the overall CAE process chain. Schulte-Frankenfeld and Deiters [2016] give a comprehensive explanation of the FATXML data format specification.

LS-DYNA reads all lines between this keyword and the next keyword recognized by the star (*) sign, processes the data with respect to the include file structure and writes everything together in one output file called d3plot.xml.

Remarks:

We intend for a corresponding FE model to consist of one primary file with several associated include files. Each include file should contain a description with *DATABASE_FATXML data, usually at the end of the file. The primary file loads the include files via *INCLUDE_TRANSFORM with potential offset values for nodes, elements, parts, etc. (IDNOFF, IDEOFF, IDPOFF, …). All data from different include files with different offsets are collected and then summarized in d3plot.xml. Since the resulting data format is public domain, post-processors can read that data and correlate it with the associated CAE model.

Example:

```
...
*DATABASE_FATXML
<?xml version="1.0"?>
<CAE_META_DATA>
  < PART_ID NAME="TestCase">
    <PDM_DATA>
      ...
      <PDD_THICKNESS>
        < THICKNESS ID="123">1.0</THICKNESS >
        < THICKNESS ID="124">1.1</THICKNESS >
        ...
      </PDD_THICKNESS >
      ...
    </PDM_DATA >
  </PART_ID >
</CAE_META_DATA >
*END
```

*DATABASE_FORMAT

Purpose: Define the output format for binary files.

Card 1	1	2	3	4	5	6	7	8
Variable	IFORM	IBINARY						
Type	I	I						
Default	0	0						
Remarks	1	2						

VARIABLE	DESCRIPTION
IFORM	Output format for d3plot and d3thdt files: EQ.0: LS-DYNA database format (default), EQ.1: Ansys database format (generally disabled since R12; see Remark 1), EQ.2: Both LS-DYNA and Ansys database formats (generally disabled since R12; see Remark 1).
IBINARY	Flag to control the word size in the binary output files, such as d3plot and d3drlf. This variable applies only to double precision LS-DYNA executables. EQ.0: 64 bit format for binary output (default for double precision), EQ.1: 32 bit IEEE format for binary output. This reduces the volume of binary output from double precision executables by a factor of two.

Remarks:

1. **Availability restrictions.** The Ansys output option is not available in MPP and is not universally available in SMP. The LS-DYNA banner in d3hsp includes "ANSYS database format" under the list of "Features enabled" if the option is available. By default, our most recent executables do not have this feature enabled.

2. **32 bit IEEE format.** As an alternative to setting IBINARY = 1, the user may set the system environment variable LSTC_BINARY to 32ieee.

DATABASE_FREQUENCY_ASCII_*OPTION1_{OPTION2}

OPTION1 specifies one of the following frequency domain ASCII databases:

NODOUT_SSD ASCII database for nodal results for SSD (displacement, velocity and acceleration). See also *FREQUENCY_DOMAIN_SSD.

ELOUT_SSD ASCII database for element results for SSD (stress and strain components). See also *FREQUENCY_DOMAIN_SSD.

NODFOR_SSD ASCII database for nodal force group for SSD (nodal forces for each node and reaction forces for the group). See also *FREQUENCY_DOMAIN_SSD.

NODOUT_PSD ASCII database for nodal PSD results (displacement, velocity and acceleration). See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.

ELOUT_PSD ASCII database for element PSD results (stress and strain components). See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.

OPTION2:

MODAL_CONTRIBUTION (see Remark 6)

SUBCASE (see Remark 7)

<BLANK>

Purpose: Define output frequencies for the specified ASCII databases above. The frequencies can be different from the output frequencies for the binary databases D3SSD and D3PSD which are defined by the keywords *DATABASE_FREQUENCY_BINARY_D3SSD and *DATABASE_FREQUENCY_BINARY_D3PSD, respectively.

Card 1	1	2	3	4	5	6	7	8
Variable	FMIN	FMAX	NFREQ	FSPACE	LCFREQ			
Type	F	F	I	I	I			
Default	0.0	0.0	0	0	0			

VARIABLE	DESCRIPTION
FMIN	Minimum frequency for output (cycles/time)
FMAX	Maximum frequency for output (cycles/time)

VARIABLE	DESCRIPTION
NFREQ	Number of frequencies for output
FSPACE	Frequency spacing option for output: EQ.0: Linear EQ.1: Logarithmic EQ.2: Biased EQ.3: Eigenfrequencies only
LCFREQ	Load curve ID defining the frequencies for output

Remarks:

1. **Output Files.** The ASCII databases NODOUT_SSD, ELOUT_SSD, NODFOR_-SSD, NODOUT_PSD, and ELOUT_PSD are saved in binout files. LS-PrePost can read the binout files directly. The files can be converted to the ASCII format by feeding them to the l2a program like this:

   l2a binout*

2. **Nodal Data.** The nodes to be output to NODOUT_SSD and NODOUT_PSD databases are specified by card *DATABASE_HISTORY_NODE.

3. **Element Data.** The solid, beam, shell and thick shell elements to be output to ELOUT_SSD and ELOUT_PSD are specified by the following cards:

   DATABASE_HISTORY_SOLID_*{OPTION}

   DATABASE_HISTORY_BEAM_*{OPTION}

   DATABASE_HISTORY_SHELL_*{OPTION}

   DATABASE_HISTORY_TSHELL_*{OPTION}

4. **Nodal Set Data.** The nodal sets to be output to NODFOR_SSD are specified by card *DATABASE_NODAL_FORCE_GROUP.

5. **Output Frequencies.** There are two methods to define the output frequencies.

   a) The first method is to define FMIN, FMAX, NFREQ and FSPACE. FMIN and FMAX specify the frequency range of interest and NFREQ specifies the number of frequencies at which results are required. FSPACE specifies the type of frequency spacing (linear, logarithmic, biased or eigenfrequencies only) to be used. These frequency points for which results are required can

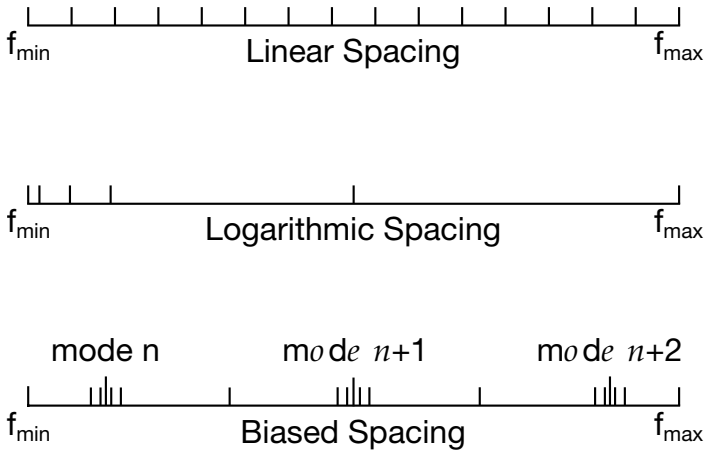

Figure 16-7. Spacing options of the frequency points.

be spaced equally along the frequency axis (on a linear or logarithmic scale); or the can be biased toward the eigenfrequencies (the frequency points are placed closer together at eigenfrequencies in the frequency range) so that the detailed definition of the response close to resonance frequencies can be obtained; or they can be just the eigenfrequencies in the frequency range defined by FMIN and FMAX.

b) The second method is to use a load curve (LCFREQ) to define the frequencies of interest.

6. **MODAL_CONTRIBUTION.** When the keyword option MODAL_CONTRIBUTION is present, LS-DYNA also computes the modal contribution fraction for each of the involved vibration modes. The modal contribution fraction shows the percentage of the response contributed by one particular mode over the total response. The modal contribution fraction values are saved in binout and can be processed using LS-PrePost. This keyword option is only valid for the SSD computation, that is, OPTION1 is NODOUT_SSD or ELOUT_SSD.

7. **SUBCASE.** The option SUBCASE only works when the keyword *FREQUENCY_DOMAIN_SSD_SUBCASE is present. It can only be used with *OPTION1* set to NODOUT_SSD, ELOUT_SSD or NODFOR_SSD. With SUBCASE, Card 1 can be repeated to define individual output frequencies for each of the loading cases defined in *FREQUENCY_DOMAIN_SSD_SUBCASE.

DATABASE_FREQUENCY_BINARY_*OPTION1_{OPTION2}

Purpose: Options for frequency domain binary output files.

OPTION1 specifies one of the following output file names:

D3ACC Binary output file for BEM acoustics (element acoustic pressure contribution and contribution percentage). See also *FREQUENCY_DOMAIN_ACOUSTIC_BEM.

D3ACS Binary output file for FEM acoustics (acoustic pressure and sound pressure level in the acoustic volume) and BEM (collocation BEM) acoustics (acoustic pressure, sound pressure level, and normal velocity on the surface of the acoustic volume). See also *FREQUENCY_DOMAIN_ACOUSTIC_FEM and *FREQUENCY_DOMAIN_ACOUSTIC_BEM.

D3ATV Binary output file for acoustic transfer vectors given by BEM acoustic analysis. See also *FREQUENCY_DOMAIN_ACOUSTIC_BEM_ATV.

D3ERP Binary output file for ERP (Equivalent Radiated Power) density and some other data (e.g. real and imaginary parts of normal velocity at surface nodes). See also *FREQUENCY_DOMAIN_SSD_ERP.

D3FTG Binary output file for random vibration fatigue analysis. See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION_FATIGUE.

D3PSD Binary Power Spectral Density output file for random vibration analysis. See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.

D3RMS Binary Root Mean Square output file for random vibration analysis. See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.

D3SPCM Binary output file for response spectrum analysis. See also *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM.

D3SSD Binary output file for steady state dynamics. See also *FREQUENCY_DOMAIN_SSD.

D3ZCF Binary Zero-Crossing Frequency output file for random vibration analysis. See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.

OPTION2 takes one of the following options:

<BLANK>

SUMMATION

SUBCASE

SUMMATION only works with *OPTION1* set to either D3PSD or D3RMS. With SUMMATION, the existing PSD and RMS databases from multiple random vibration analyses will be summed up to provide the total response of the same model subjected to multiple loading sources.

SUBCASE only works with D3SSD. With SUBCASE, an individual set of output frequencies is specified for each of the loading cases included in *FREQUENCY_DOMAIN_SSD_SUBCASE.

The D3ACC, D3ACS, D3ATV, D3ERP, D3FTG, D3PSD, D3RMS, D3SPCM, D3SSD and D3ZCF files contain plotting information to plot data over the three-dimensional geometry of the model. These databases can be plotted with LS-PrePost.

- The D3ACC file contains the acoustic pressure contribution (and contribution percentage) from each of the boundary elements for a range of frequencies, which are defined in the keyword *FREQUENCY_DOMAIN_ACOUSTIC_BEM.
- The D3ACS file contains acoustic results, including acoustic pressure and sound pressure level, for a range of frequencies, which are defined in the keyword *FREQUENCY_DOMAIN_ACOUSTIC_FEM. Alternatively, it can be used to plot acoustic pressure, sound pressure level and normal velocity on the surface of an acoustic volume for a range of frequencies which are defined in the keyword *FREQUENCY_DOMAIN_ACOUSTIC_BEM. Please note that only collocation BEM (METHOD = 3 or 4 in *FREQUENCY_DOMAIN_ACOUSTIC_BEM) can output the acoustic pressure, sound pressure level and normal velocity on the surface of the acoustic volume to D3ACS.
- The D3ATV file contains NFIELD × NFREQ states, where NFIELD is the number of acoustic field points and NFREQ is the number of output frequencies.
- The D3ERP file contains state data for a range of frequencies. These frequencies are the same as those used in D3SSD output.
- The D3FTG, D3RMS and D3ZCF files contain only one state each as they are the data for cumulative fatigue damage ratio, root mean square of response for random vibration, peak response for response spectrum analysis, and zero-crossing frequency of response for random vibration separately.
- The D3PSD file contains PSD state data for a range of frequencies.
- When BINARY = 1, the D3SPCM file contains only one state which is peak response for response spectrum analysis. When BINARY = 2, D3SPCM contains multiple states. The first state is peak response like for BINARY = 1. The other states are the individual mode response sequentially for the normal modes involved in the mode combination.
- The D3SSD file contains state data for a range of frequencies. The data can be real or complex, depending on the variable BINARY defined below.

Card Summary:

Card 1a. This card is included if *OPTION2* is not used or *OPTION2* is SUBCASE.

BINARY							

Card 1b. This card is included if *OPTION2* is SUMMATION. This card can be repeated if multiple binary databases exist.

FILENAME

Card 2a. This card is included if *OPTION1* is set to D3ACC. Include as many of this card as needed. Up to 10 NIDs are allowed.

NID1	NID2	NID3	NID4	NID5	NID6	NID7	NID8

Card 2b. This card is included if *OPTION1* is set to D3PSD or D3SSD. For D3SSD, when *OPTION2* is set to SUBCASE, this card can be repeated to define the output frequencies for each of the loading cases included in *FREQUENCY_DOMAIN_SSD_SUBCASE (in the same order).

FMIN	FMAX	NFREQ	FSPACE	LCFREQ			

Card 2c. This card is included if *OPTION1* is set to D3SPCM and BINARY = 3.

ISTATE	FILENAME

Data Card Definitions:

Include this card if *OPTION2* is unset or *OPTION2* is set to SUBCASE.

Card 1a	1	2	3	4	5	6	7	8
Variable	BINARY							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
BINARY	Flag for writing the binary plot file. See Remark 1. EQ.0: Off

VARIABLE	DESCRIPTION
	EQ.1: Write the binary plot file.
	EQ.2: Write the complex variable binary plot file D3SSD (*OPTION1* = D3SSD) or include the individual mode response in the binary plot file D3SPCM (*OPTION1* = D3SPCM).
	EQ.3: Write the binary plot file which combines response spectrum analysis results and other structural analysis results provided by the file specified with Card 2c (*OPTION1* = D3SPCM).
	EQ.90: Write only real part of frequency response (D3SSD only).
	EQ.91: Write only imaginary part of frequency response (D3SSD only).

Summation Card. Card 1 when *OPTION1* = D3PSD or D3RMS and *OPTION2* = SUMMATION. This card can be repeated if multiple binary databases exist.

Card 1b	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

VARIABLE	DESCRIPTION
FILENAME	Path and file name of precomputed PSD or RMS binary databases (see Remark 3)

D3ACC Card. Additional card for D3ACC keyword option. Include as many of this card as needed. Up to 10 NIDs are allowed.

Card 2a	1	2	3	4	5	6	7	8
Variable	NID1	NID2	NID3	NID4	NID5	NID6	NID7	NID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
NID*i*	Field point node ID for writing D3ACC file

D3PSD and D3SSD Card. Additional card for D3PSD and D3SSD keyword options.

Card 2b	1	2	3	4	5	6	7	8
Variable	FMIN	FMAX	NFREQ	FSPACE	LCFREQ			
Type	F	F	I	I	I			
Default	0.0	0.0	0	0	0			

VARIABLE	DESCRIPTION
FMIN	Minimum frequency for output (cycles/time). See Remark 2.
FMAX	Maximum frequency for output (cycles/time). See Remark 2.
NFREQ	Number of frequencies for output. See Remark 2.
FSPACE	Frequency spacing option for output (See Remark 2): EQ.0: Linear EQ.1: Logarithmic EQ.2: Biased EQ.3: Eigenfrequencies only
LCFREQ	Load curve ID defining the frequencies for output. See Remark 2.

D3SPCM Card. Additional card for BINARY = 3 option.

Card 2c	1	2	3	4	5	6	7	8
Variable	ISTATE	FILENAME						
Type	I	C						

VARIABLE	DESCRIPTION
ISTATE	State number in a binary plot file with name FILENAME. The structural analysis results at this state will be combined with the results from the current run.

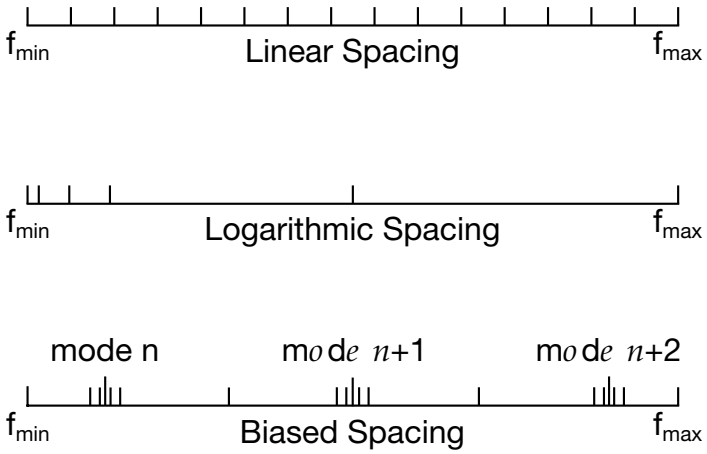

Figure 16-8. Spacing options of the frequency points.

VARIABLE	DESCRIPTION
FILENAME	Path and file name of precomputed structural response binary plot file from which the structural response at a specific state will be combined with the current run's spectrum results (see Remark 4)

Remarks:

1. **Binary Data Written for D3SSD.** For *OPTION1* = D3SSD, if BINARY = 1, only the magnitude of the displacement, velocity, acceleration and stress response is written into the binary database d3ssd which can be accessed by LS-PrePost 3.0 or older versions. For customers using LS-PrePost 3.0 or older versions, it is suggested to set BINARY = 1. If BINARY = 2, both the magnitude and the phase angle of the response are written into d3ssd so that LS-PrePost (3.1 or higher versions) can run modal expansion (to show the cyclic time history fringe plot) on each output frequency. If BINARY = 90 or 91, only real or imaginary part of the response is written into d3ssd.

2. **Output Frequencies.** There are two methods to define the output frequencies.

   a) The first method is to define FMIN, FMAX, NFREQ and FSPACE. FMIN and FMAX specify the frequency range of interest and NFREQ specifies the number of frequencies at which results are required. FSPACE specifies the type of frequency spacing (linear, logarithmic, biased or eigenfrequencies only) to be used. These frequency points for which results are required can be spaced equally along the frequency axis (on a linear or logarithmic scale). Or they can be biased toward the eigenfrequencies (the frequency points are placed closer together at eigenfrequencies in the frequency range) so that the detailed definition of the response close to resonance frequencies can be obtained. Or they can be just the eigenfrequencies in the frequency range defined by FMIN and FMAX. See Figure 16-7.

b) The second method is to use a load curve (LCFREQ) to define the frequencies of interest.

3. **Summation for D3PSD and D3RMS.** For *OPTION1* = D3PSD and D3RMS, if *OPTION2* = SUMMATION, all the precomputed PSD and RMS results saved in existing binary databases defined in Card 1 (by default, d3psd and d3rms under different path or prefix) will be summed up and dumped to a new binary plot database d3psd and d3rms. For d3psd, the new psd results are simply summation of the psd results from each d3psd database (please note that the output frequencies of the existing d3psd databases must be same, and the new d3psd provides psd results at the same set of frequencies). For d3rms, the new rms results are computed as square root of summation of squares of the rms values from each d3rms database. This provides total PSD and RMS response of the same model, subjected to multiple loading resources. This operation is activated by RESTRT = 2 in keyword *FREQUENCY_DOMAIN_RANDOM_VIBRATION.

4. **Combined Results for Response Spectrum Analysis and Other Structural Analysis.** For *OPTION1* = D3SPCM, if BINARY = 3 in Card 1a, LS-DYNA combines the response spectrum analysis results with other structural analysis results. These other results come from a file specified in Card 2c and correspond to a specific state in that file. This feature allows you to obtain the maximum value of total response from multiple loadings.

*DATABASE_FSI

Purpose: When a Lagrangian mesh overlaps with an Eulerian or ALE mesh, the fluid-structure (or ALE-Lagrangian) interaction is often modeled using the *CONSTRAINED_-LAGRANGE_IN_SOLID or *ALE_STRUCTURED_FSI card. This keyword (*DATA-BASE_FSI) causes certain coupling information related to the flux through and load on selected Lagrangian surfaces defined in corresponding *CONSTRAINED_LA-GRANGE_IN_SOLID or *ALE_STRUCTURED_FSI card to be written to the ASCII-based dbfsi file or in the case of MPP-DYNA the binout file.

NOTE: If used with *CONSTRAINED_LAGRANGE_IN_-SOLID, penalty method coupling must be used (CTYPE = 4 or 5). This card is *not* compatible with constraint-based coupling.

Card 1	1	2	3	4	5	6	7	8
Variable	DTOUT	BINARY						
Type	F	I						

Surface Card. Add one card per surface. This input terminates at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	DBFSI_ID	SID	SIDTYPE	SWID	CONVID	NDSETID	CID	
Type	I	I	I	I	I	I	I	

VARIABLE	DESCRIPTION
DTOUT	Output interval time step
BINARY	Flag for binary output. See remarks under "Output Files and Post-Processing" in Appendix O, "LS-DYNA MPP User Guide." EQ.1: ASCII file is written. This is the default for shared memory parallel (SMP) LS-DYNA executables.

VARIABLE	DESCRIPTION
	EQ.2: Data written to binary database binout, which contains data that would otherwise be output to the ASCII file. The ASCII file in this case is not created. This is the default for MPP LS-DYNA executables. EQ.3: ASCII file is written, and the data is also written to the binary database (NOTE: MPP LS-DYNA executables will only produce the binary database).
DBFSI_ID	Surface ID (for reference purposes only) or a DATABASE_FSI entity ID. It consists of a geometric entity defined by the SID below.
SID	Set ID defining the geometrical surface(s) through which or upon which some data is to be tracked and output to a file called "dbfsi". This set ID can be a (1) PID or (2) PSID or (3) SGSID. This Lagrangian SID must be contained in a Lagrangian structure SID defined in a corresponding coupling card, *CONSTRAINED_LAGRANGE_IN_SOLID.
SIDTYPE	Set type: EQ.0: Part set EQ.1: Part EQ.2: Segment set
SWID	This is an ID from a corresponding *ALE_FSI_SWITCH_MMG_ID card. This card allows for the AMMG ID of an ALE material to be switched as it passes across a monitoring surface. If defined, the accumulative mass of the "switched" ALE multi-material group (AMMG) is written out under the "mout" parameter in the "dbfsi" file.
CONVID	This is used mostly for airbag application only: CONVID is an ID from a corresponding *LOAD_ALE_CONVECTION_ID card which computes the heat transfer between inflator gas (ALE material) and the inflator canister (Lagrangian part). If defined, the temperature of the Lagrangian part having heat transfer with the gas, and its change in temperature as function of time are output in the "dbfsi" file.
NDSETID	Set ID consisting of the nodes on which the moments of the forces applied on SID are computed. See Remark 3.
CID	Coordinate system ID, see *DEFINE_COORDINATE_SYSTEM.

Remarks:

1. **Overview of dbfsi File.** The dbfsi parameters output are enumerated below.

   pres = Averaged estimated coupling pressure over each surface entity being monitored. For example, if using SI base units for mass-length-time-temperature, this pressure would then be in Pascal.

   fx, fy, fz = Averaged total estimated coupling force components (N in metric units) along the global coordinate directions, over each surface entity defined, and acting at the centroid of each surface.

   mout = Accumulated mass (Kg in metric units) passing through each DBFS_ID surface entity. See Remark 2 below. (This parameter used to be called "pleak").

   obsolete = (This parameter used to be called "mflux").

   gx, gy, gz = Average estimated leakage-control force component over the surface entity. This data is useful for debugging. Leakage control forces are too large (relative to the main coupling forces, fx, fy and fz) may indicate that alternate coupling approach should be considered since the main coupling force is putting out too little resistance to leakage. (These parameters used to be called fx-lc, fy-lc and fz-lc).

   Ptmp = Lagrangian part Temperature (Activated only when the *LOAD_ALE_CONVECTION card is used).

   PDt = Lagrangian part Temperature change (Activated only when the *LOAD_ALE_CONVECTION card is used).

2. **MOUT.** "mout" parameter in the "dbfsi" output from this keyword contains the accumulated mass passing through each DBFS_ID surface entity. For 4 different cases:

   a) When LCIDPOR is defined in the coupling card (CLIS), porous accumulated mass transport across a Lagrangian shell surface may be monitored and output in "mout".

   b) Porous flow across Lagrangian shell may also be defined via a load curve in the *MAT_FABRIC card, and similar result will be tracked and output. This is an alternate form of (a).

   c) When NVENT in the CLIS card is defined (isentropic venting), the venting mass transport across the isentropic vent hole surface may be output in "mout".

d) When an *ALE_FSI_SWITCH_MMG_ID card is defined, and the SWID parameter specifies this ID to be tracked, then the amount of accumulated mass that has been switched when passing across a monitoring surface is output.

3. **Calculation of Moments for NDSETID.** A geometrical surface SID has a centroid where the coupling forces are averaged. The distances between this centroid and the nodes defined by the set NDSETID are the lever arms. The moments are the cross-products of these distances with the averaged coupling forces. For each node in the set NDSETID, a new line in the "dbfsi" file is inserted after each output for the corresponding coupling forces (see Remark 1). These additional lines have the format following the template established by the example in Remark 1 where the forces are replaced by the moments and the node ID replaces the DBFSI_ID values.

4. **2D axisymmetric models.** The forces from a 2D axisymmetric simulation are reported per radian, regardless of the element formulation used. Multiply the 2D force by 2π to get the 3D force.

Example:

Consider a model with a Lagrangian mesh overlaps with an Eulerian or ALE mesh. On the Lagrangian mesh, there are 3 Lagrangian surface sets over which some data is to be written out.

*DATABASE_FSI_SENSOR

Purpose: Activate the output of an ASCII file called dbsensor. This keyword's input defines the pressure sensors' locations which follow the positions of some Lagrangian segments during the simulation. The ASCII output file, dbsensor, contains the spatial position of the sensor and its recorded pressure from the ALE elements containing the sensors. This card is activated when a *CONSTRAINED_LAGRANGE_IN_SOLID or *ALE_STRUCTURED_FSI card is used and the Lagrangian shell elements defining the locations of the sensors must be included in the structure coupling set.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	BINARY						
Type	F	I						

Surface Card. Add one card per surface. This input terminates at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	DBFSI_ID	NID	SEGMID	OFFSET	ND1	ND2	ND3	
Type	I	I	I	F	I	I	I	

VARIABLE	DESCRIPTION
DT	Output interval
BINARY	Flag for binary output. See "Output Files and Post-Processing" in Appendix O, "LS-DYNA MPP User Guide."

EQ.1: ASCII file is written. This is the default for shared memory parallel (SMP) LS-DYNA executables.

EQ.2: Data written to binary database binout, which contains data that would otherwise be output to the ASCII file. The ASCII file in this case is not created. This is the default for MPP LS-DYNA executables.

EQ.3: ASCII file is written, and the data is also written to the binary database (NOTE: MPP LS-DYNA executables will only produce the binary database).

VARIABLE	DESCRIPTION
DBFSI_ID	Pressure-Sensor ID
NID	An optional Lagrangian node ID defining an approximate pressure sensor location with respect to a Lagrangian shell element. This is not a required input.
SEGMID	A required Lagrangian element ID for locating the pressure sensor. If NID = 0 or is blank, the sensor will be automatically placed in the center of this SEGMID, accounting for the offset distance. If the model is three-dimensional, the Lagrangian element can be a shell or solid (for the solid element, ND1 and ND2 are required to define the face). If the model is two-dimensional, the Lagrangian element can be a beam or shell (for the shell element, ND1 and ND2 are required to define the side).
OFFSET	Offset distance between the pressure sensor and the Lagrangian segment surface. If it is positive, it is on the side pointed to by the segment normal vector; otherwise, vice versa.
ND1, ND2, ND3	Nodes defining the solid face for the solid element in the three-dimensional model or shell side for the shell element in the two-dimensional model, from which the sensor is located. In three dimensions, if the solid face has 4 nodes, only the diagonal opposites ND1 and ND2 are required. If the solid face is triangular, a third node ND3 should be provided. In two dimensions, only ND1 and ND2 are required to define the shell side.

Remarks:

1. The output parameters in the dbsensor ASCII file are:

   ID = Sensor ID.

   x, y, z = Sensor spatial location.

   P = Sensor recorded pressure (Pa) from the ALE fluid element containing the sensor.

   To plot the sensor pressure in LS-PrePost, select:

   ASCII → dbsensor → LOAD → (select sensor ID) → Pressure → PLOT

Example 1:

```
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8

Card Summary:

Card 1a. This card is included if the keyword option is BEAM, BEAM_SET, DISCRETE, DISCRETE_SET, NODE, NODE_SET, SEATBELT, SHELL, SHELL_SET, SOLID, SOLID_SET, SPH, SPH_SET, TSHELL, or TSHELL_SET. Include as many as needed. Input terminates at the next keyword ("*") card.

ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8

Card 1b. This card is included if the keyword option is BEAM_ID, NODE_ID, SEATBELT_ID, SHELL_ID, SOLID_ID, and TSHELL_ID. Include as many as needed. Input terminates at the next keyword ("*") card.

ID	HEADING

Card 1c. This card is included if the keyword option is NODE_LOCAL, NODE_LOCAL_ID, and NODE_SET_LOCAL. If the keyword option is NODE_LOCAL_ID, see Card 1c.1 as well. Include as many cards as needed to specify all the nodes. This input terminates at the next keyword ("*") card.

ID	CID	REF	HFO				

Card 1c.1. This card is only used for the NODE_LOCAL_ID keyword option. When activated, each node is specified by a pair of cards consisting of Card 1c, and, secondly, this card. Include as many pairs as needed to specify all the nodes. This input terminates at the next keyword ("*") card.

HEADING	

Data Card Definitions:

Node/Element Cards for Case I (no "ID", and no "LOCAL"). Cards for keyword options BEAM, BEAM_SET, DISCRETE, DISCRETE_SET, NODE, NODE_SET, SEATBELT, SHELL, SHELL_SET, SOLID, SOLID_SET, SPH, SPH_SET, TSHELL, and TSHELL_SET. Include as many as needed. Input terminates at the next keyword ("*") card.

Card 1a	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
ID*n*	NODE/NODE_SET or element/element set ID *n*. Elements may be BEAM/BEAM_SET, DISCRETE/DISCRETE_SET, SEATBELT, SHELL/SHELL_SET, SOLID/SOLID_SET, SPH/SPH_SET or TSHELL/TSHELL_SET. ID*n* for NODE_SET and for SPH_SET refers to node set ID *n* defined using the *SET_NODE_*{OPTION}*. The contents of the files are given in Table 16-3 for nodes, Table 16-4 for solid elements, Table 16-5 for shells and thick shells, and Table 16-6 for beam elements. In the binary file, d3thdt, the contents may be extended or reduced with the *DATABASE_EXTENT_BINARY definition.

Node/Element Cards for Case II ("ID" option, but no "LOCAL"). Cards for keyword options BEAM_ID, NODE_ID, SEATBELT_ID, SHELL_ID, SOLID_ID, and TSHELL_ID. Include as many as needed. Input terminates at the next keyword ("*") card.

Card 1b	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
ID	Node or element ID

VARIABLE	DESCRIPTION
HEADING	A description of the node or element. It is suggested that unique descriptions be used. This description is written into the d3hsp file and into the ASCII databases nodout and elout.

Node Cards for Case III ("LOCAL" option). Card 1 for keyword options NODE_LOCAL, NODE_LOCAL_ID, and NODE_SET_LOCAL. Include as many cards as needed to specify all the nodes. This input terminates at the next keyword ("*") card.

Card 1c	1	2	3	4	5	6	7	8
Variable	ID	CID	REF	HFO				
Type	I	I	I	I				

ID Card for Case III. Additional card for ID option. This card is only used for the NODE_LOCAL_ID keyword option. When activated, each node is specified by a pair of cards consisting of Card 1c, and, secondly, this card. Include as many pairs as needed to specify all the nodes. This input terminates at the next keyword ("*") card.

Card 1c.1	1	2	3	4	5	6	7	8
Variable	HEADING							
Type	A70							

VARIABLE	DESCRIPTION
ID	NODE/NODE_SET set ID. The contents of the files are given in Table 16-3 for nodes. See Remark 1 concerning accelerometer nodes.
CID	Coordinate system ID for nodal output. See DEFINE_COORDINATE options.
REF	Output coordinate system for displacements, velocities, and accelerations. (Nodal coordinates are always in the global coordinate system.)

VARIABLE	DESCRIPTION
	EQ.0: Output is in the local system fixed for all time from the beginning of the calculation. If CID is nonzero, FLAG in the corresponding *DEFINE_COORDINATE_NODES command must be set to 0. FLAG has no bearing on results when REF is set to 1 or 2.
	EQ.1: Translational output is the projection of the node's absolute translational motion onto the local system. The local system is defined by the *DEFINE_COORDINATE_NODES command and can change orientation according to the movement of the three defining nodes. The defining nodes can belong to either deformable or rigid parts.
	EQ.2: Translational output is the motion of the node, expressed in the local system attached to node N1 of CID. The local system is defined as described in REF = 1 above. For displacements, the fixed reference location is defined to contain the initial coordinates of the history node in the local coordinate system. During the analysis, the coordinates of the history node are first expressed in the translating and rotating local coordinate system and then the local displacement vector is determined by subtracting the reference location from these coordinates. If dynamic relaxation is used, the reference location is reset when convergence is achieved. Rotational output is truly relative to the updated location coordinate system only if REF = 2.
HFO	Flag for high frequency output into nodouthf: EQ.0: Nodal data written to nodout file only. EQ.1: Nodal data also written nodouthf at the higher frequency.
HEADING	A description of the nodal point. It is suggested that unique description be used. This description is written into the d3hsp file and into the ASCII database nodout.

Remarks:

1. **Accelerometer.** If a node belongs to an accelerometer, see *ELEMENT_SEATBELT_ACCELEROMETER, and if it also appears as an active node in the NODE_LOCAL or NODE_SET_LOCAL keyword, the coordinate system, CID, transformations will be skipped and the LOCAL option will have no effect.

2. **Seatbelt.** The SEATBELT keyword option is only for 1D (bar-type) seatbelts, not 2D (shell-type).

*DATABASE_HISTORY_ACOUSTIC

Purpose: Identify acoustic nodes for time history output.

Card 1	1	2	3	4	5	6	7	8
Variable	NID1	NID2	NID3	NID4	NID5	NID6	NID7	NID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
NID*n*	Node ID of the acoustic node.

Remarks:

1. **Results File Name.** In explicit, transient solutions, the histories are written to file ACEOUT. In implicit, direct SSD solutions, the histories are written to ACEOUT_SSD.

*DATABASE_ISPHHTC

Purpose: Create Heat Transfer Coefficient output for Incompressible SPH simulations. HTC values are time-averaged over the defined output time interval.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	BINARY	LCDT	IOOPT	PSET			
Type	F	I	I	I	I			

VARIABLE	DESCRIPTION
DT	Time interval between output states. If DT is zero, the output will be skipped even if LCDT is defined.
BINARY	Currently unused. The output format is currently a profile file that can be directly imported inside Ansys Fluent or Ansys Mechanical.
LCDT	Optional load curve ID specifying the output time interval as a function of time.
IOOPT	This input field governs how the plot state frequency is determined from curve LCDT: EQ.1: When a plot is generated at time t_n, the next plot time t_{n+1} is computed as $t_{n+1} = t_n + \mathrm{LCDT}(t_n)$. This is the default behavior. EQ.2: When a plot is generated at time t_n, the next plot time t_{n+1} is computed as $t_{n+1} = t_n + \mathrm{LCDT}(t_{n+1})$. EQ.3: A plot is generated for each abscissa point in the load curve definition. The actual value of the load curve is ignored.
PSET	Optional part set. If defined, only parts contained in this part set will be included in the HTC output file.

*DATABASE_MASSOUT

Purpose: Output nodal masses into ASCII file MASSOUT.

Card 1	1	2	3	4	5	6	7	8
Variable	SETID	NDFLG	RBFLG					
Type	I	I	I					
Default	0	1	0					

VARIABLE	DESCRIPTION
SETID	Optional set ID. EQ.0: mass output for all nodes, LT.0: no output, GT.0: set ID identifying nodes whose mass will be output.
NDFLG	Database extent: EQ.1: output translational mass for deformable nodes identified by SETID (default), EQ.2: output translational mass and rotary inertias for the deformable nodes identified by the SETID. EQ.3: output translational mass for deformable and rigid nodes identified by SETID (default), EQ.4: output translational mass and rotary inertias for the deformable and rigid nodes identified by the SETID.
RBFLG	Rigid body data: EQ.0: no output for rigid bodies, EQ.1: output rigid body mass and inertia.

Remarks:

1. **Massless Nodes and Rigid Bodies.** Nodes and rigid bodies with no mass are not output. By inference, when the set ID is zero and no output shows up for a node, then the mass of that node is zero.

***DATABASE_MAX**_OPTION

Available options include:

BEAM

BEAM_ID

BEAM_SET

SHELL

SHELL_ID

SHELL_SET

SOLID

SOLID_ID

SOLID_SET

TSHELL

TSHELL_ID

TSHELL_SET

Purpose: Control which elements have data output to the binary history file d3max. See also *DATABASE_D3MAX.

Card Summary:

Card 1a. This card is included if the keyword option is BEAM, BEAM_SET, SHELL, SHELL_SET, SOLID, SOLID_SET, TSHELL, or TSHELL_SET. Include as many as needed. Input terminates at the next keyword ("*") card.

ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8

Card 1b. This card is included if the keyword option is BEAM_ID, SHELL_ID, SOLID_-ID, and TSHELL_ID. Include as many as needed. Input terminates at the next keyword ("*") card.

ID	HEADING

Data Card Definitions:

Element Cards for Case I (no "ID"). Cards for keyword options BEAM, BEAM_SET, SHELL, SHELL_SET, SOLID, SOLID_SET, TSHELL, and TSHELL_SET. Include as many as needed. Input terminates at the next keyword ("*") card.

Card 1a	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
ID*n*	Element/element set ID *n*. The elements may be beams, shells, solids, or tshells depending on the keyword option.

Element Cards for Case II ("ID" option"). Cards for keyword options BEAM_ID, SHELL_ID, SOLID_ID, and TSHELL_ID. Include as many as needed. Input terminates at the next keyword ("*") card.

Card 1b	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
ID	Element ID
HEADING	A description of the element. We suggest using unique descriptions.

*DATABASE_NODAL_FORCE_GROUP

Purpose: Define a nodal force group for output into the ASCII file nodfor. The output interval must be specified using *DATABASE_NODFOR (see *DATABASE_*OPTION*).

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	CID						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
NSID	Nodal set ID, see *SET_NODE
CID	Coordinate system ID for output of data in local system

Remarks:

1. The reaction forces in the global x, y, and z directions (and local x, y, and z directions if CID is defined above) for the nodal force group are written to the nodfor file (see *DATABASE_NODFOR) along with the external work done by these reaction forces. The reaction forces in the global x, y, and z directions for each node in the nodal force group are also written to nodfor. These forces can be a result of applied boundary forces such as nodal point forces and pressure boundary conditions, body forces, and contact interface forces. In the absence of body forces, interior nodes would always yield a null force resultant vector. In general this option would be used for surface nodes.

*DATABASE_PAP_OUTPUT

Purpose: Set contents of output files for pore air pressure calculations.

Card 1	1	2	3	4	5	6	7	8
Variable	IVEL	IACCX	IACCY	IACCZ	NCYOUT			
Type	I	I	I	I	I			
Default	0	0	0	0	100			

VARIABLE	DESCRIPTION
IVEL	Meaning of "Velocity" in d3plot and d3thdt output files EQ.0: Nodal velocity vector EQ.1: Seepage velocity vector
IACCX, Y, Z	Meaning of "X/Y/Z-Acceleration" in d3plot and d3thdt output files EQ.0: Not written EQ.21: Nodal air density EQ.22: Nodal pore air pressure EQ.24: Nodal air mass EQ.25: Nodal air mass flow rate
NCYOUT	Number of cycles between outputs of calculation status to d3hsp and log files

*DATABASE_PBLAST_SENSOR

Purpose: This keyword causes LS-DYNA to output a directory called pblast_sensor to the file, binout. The input for this keyword defines the sensors' locations based on the positions of some Lagrangian shell elements. With this keyword, LS-DYNA outputs the history of the position, temperature, density, and pressure averaged over the number of particles contained in the sensors to binout. This keyword is activated only when the *DEFINE_PARTICLE_BLAST card is used.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	BINARY						
Type	F	I						
Default	none	3						

Sensor Definition Cards. Each card defines one sensor. This card may be repeated to define multiple sensors. Input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	ID	ITYPE	OFFSET	RADIUS				
Type	I	I	F	F	F			

VARIABLE	DESCRIPTION
DT	Output interval
BINARY	Flag for the binary file: EQ.3: Data is written to the binary file binout.
ID	Set ID
ITYPE	Type for ID: EQ.0: *SET_SHELL ID EQ.1: Shell ID

VARIABLE	DESCRIPTION
OFFSET	Offset distance, d, between the sensor and the segment center. Here $d > 0$ is along the shell normal and $d < 0$ is against the shell normal.
RADIUS	Radius of the spherical sensor. Please see *DATABASE_CPM_SENSOR for more details about spherical sensors.

Remarks:

1. **Output.** The output parameters to the pblast_sensor directory are:

x	=	x-coordinate
y	=	y-coordinate
z	=	z-coordinate
temp	=	temperature
dens	=	density
pres	=	pressure
counts	=	number of particles in the sensor

These values are averaged over the number of particles in the sensor. The sensor should be large enough to contain a reasonable number of particles for the averages.

*DATABASE_PROFILE

Purpose: Plot the distribution or profile of a data along x, y, or z-direction.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	ID	TYPE	DATA	DIR	UPDLOC	MMG	
Type	I	I	I	I	I	I	I	
Default	none	none	none	none	none	0	0	

VARIABLE	DESCRIPTION
DT	Interval time.
ID	Set ID.
TYPE	Set type: EQ.1: node set EQ.2: solid set EQ.3: shell set EQ.4: segment set EQ.5: beam set EQ.6: tshell set
DATA	Data type: EQ.1: x-velocity, EQ.2: y-velocity, EQ.3: z-velocity, EQ.4: velocity magnitude, EQ.5: x-acceleration, EQ.6: y-acceleration, EQ.7: z-acceleration, EQ.8: acceleration magnitude, EQ.9: pressure,

VARIABLE	DESCRIPTION
	EQ.10: *xx*-stress, EQ.11: *yy*-stress, EQ.12: *zz*-stress, EQ.13: *xy*-stress, EQ.14: *yz*-stress, EQ.15: *zx*-stress, EQ.16: temperature, EQ.17: volume fraction, EQ.18: kinetic energy, EQ.19: internal energy, EQ.20: density, EQ.21: *xx*-strain, EQ.22: *yy*-strain, EQ.23: *zz*-strain, EQ.24: *xy*-strain, EQ.25: *yz*-strain, EQ.26: *zx*-strain. EQ.27: effective plastic strain
DIR	Direction: EQ.1: *x*-direction EQ.2: *y*-direction EQ.3: *z*-direction EQ.4: curvilinear (relative distances between elements of set ID are added up in the order defined by the set)
UPDLOC	Flag to update the set location: EQ.0: only the initial position of set ID is considered. EQ.1: the positions of the elements composing the set are updated each DT.
MMG	Multi-Material ALE group ID. See Remark 2. GT.0: Multi-Material ALE group ID

VARIABLE	DESCRIPTION
LT.0:	|MMG| is the ID of a *SET_MULTI-MATERIAL_GROUP_-LIST that can list several Multi-Material ALE group IDs.

Remarks:

1. **File Description.** At a given time T the profile is written in a file named profile_DATA_DIR_time$T$.xy (DATA and DIR are replaced by the data and direction names respectively). The file has a xyplot format that LS-PrePost can read and plot. For example, DATA = 9, DIR = 2, and DT = 0.1 sec will save a pressure profile at $t = 0.0$ sec in profile_pressure_y_time0.0.xy, at $t = 0.1$ sec in profile_pressure_y_time0.1.xy, at $t = 0.2$ sec in profile_pressure_y_time0.2.xy. The stresses are output for each integration point. The shell strains are output for the innermost and outermost integration points if STRFLG = 1 in *DATABASE_-EXTENT_BINARY. For stresses and shell strains, the integration point rank is appended to the data names in the filename.

2. **Multi-Material ALE Model.** For the case of a multi-material ALE model (elform = 11 in *SECTION_SOLID or *SECTION_ALE2D or *SECTION_-ALE1D), an element can contain several materials with each material being associated with its own pressures and stresses. By default element data is volume averaged before being written out; however, when the multi-material group field, MMG, is set, then element data are output only for the specified materials.

*DATABASE_PWP_FLOW

Purpose: Request output containing net inflow of fluid at a set of nodes.

Node Sets. Include as many cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NSET							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
NSET	Node set ID

Remarks:

1. **Inflow.** Net inflow or outflow occurs when maintaining an applied PWP boundary condition causes the addition or removal of water.

2. **Output File.** Output is written to a file named database_pwp_flow.csv, a comma-separated ASCII file. Each line consists of (time, flow1, flow2, …) where flow1 is the total inflow at the node set for the first DATABASE_PWP_FLOW request, flow2 is for the second, etc.

*DATABASE_PWP_OUTPUT

Purpose: Set contents of output files for pore pressure calculations.

Card 1	1	2	3	4	5	6	7	8
Variable	IVEL	IACCX	IACCY	IACCZ	NCYOUT			
Type	I	I	I	I	I			
Default	0	0	0	0	100			

VARIABLE	DESCRIPTION
IVEL	Meaning of nodal "Velocity" in d3plot: EQ.0: Nodal velocity vector EQ.1: Seepage velocity vector
IACCX, Y, Z	Meaning of nodal "X/Y/Z-Acceleration" in d3plot, d3thdt, and nodout: EQ.0: Not written EQ.1: Total pwp head EQ.2: Excess pwp head (this is also written as temperature) EQ.3: Target rate of volume change EQ.4: Actual rate of volume change EQ.7: Hydraulic pwp head EQ.8: Error in rate of volume change (calculated from seepage minus actual) EQ.9: Volume at node EQ.10: Rate of volume change calculated from seepage EQ.14: Void volume (generated at suction limit) EQ.17: NFIXCON (e.g: +4/-4 for nodes on suction limit)
NCYOUT	Number of cycles between outputs of calculation status to d3hsp, log, and tdc_control_output.csv files (time-dependent and steady-state analysis types).

*DATABASE_RCFORC_MOMENT

Purpose: Define contact ID and nodes for moment calculations. Moments are written to rcforc according to output interval given in *DATABASE_RCFORC. If *DATABASE_RCFORC_MOMENT is not used, the moments reported to rcforc are about the origin (0,0,0).

Card 1	1	2	3	4	5	6	7	8
Variable	CID	NODESA	NODESB					
Type	I	I	I					

VARIABLE	DESCRIPTION
CID	Contact ID
NODESA	Node about which moments are calculated due to contact forces on SURFA surface
NODESB	Node about which moments are calculated due to contact forces on SURFB surface

*DATABASE_RECOVER_NODE

Purpose: Recovers the stresses at nodal points of solid or thin shell elements by using either Zienkiewicz-Zhu's Superconvergent Patch Recovery (SPR) method or an elemental extrapolation method.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID	IAX	IAY	IAZ	METHOD	IVX	IVY	IVZ
Type	I	A	A	A	I	A	A	A
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
PSID	Part set ID of solid or thin shell elements whose nodal stress will be recovered
IAX, IAY, IAZ, IVX, IVY, IVZ	Meaning of "$x/y/z$-Acceleration" or "$x/y/z$-Velocity" in d3plot and d3thdt output files

EQ.SMNPD: the minimum principal deviator stress

EQ.SMNPR: the minimum principal stress

EQ.SMXPD: the maximum principal deviator stress

EQ.SMXPR: the maximum principal stress

EQ.SMXSH: the maximum shear stress

EQ.SPR: nodal pressure

EQ.SVM: nodal von Mises stress

EQ.SXX: nodal normal stress along x direction

EQ.SYY: nodal normal stress along y direction

EQ.SZZ: nodal normal stress along z direction

EQ.SXY: nodal shear stress along x-y direction

EQ.SYZ: nodal shear stress along y-z direction

EQ.SZX: nodal shear stress along z-x direction

For shell elements append either "B" or "T" to the input string to recover nodal stresses at the bottom or top layer of shell elements. For example, SPRT recovers the nodal pressure at the top layer.

VARIABLE	DESCRIPTION
METHOD	Method used to recover the nodal stress: EQ.0: Zienkiewicz-Zhu's Superconvergent Patch Recovery method EQ.1: elemental extrapolation method

Remarks:

1. **Coordinate System.** Recovered stresses are in global coordinate system.
2. **SPR Method.** The SPR method is based on the extrapolation of an element patch, a group of elements surrounding a node. Therefore, it should be more accurate than the elemental extrapolation method which is based on the extrapolation of a single element. This is especially true for under-integrated elements where the integration points are the super convergent points. However, since SPR requires an element patch, it cannot recover the nodal stresses correctly when a mesh is too course to form a patch (for example, through the thickness direction of a beam, only a single layer of elements is used). Also, when used for shell elements, it can only provide a good solution in two-dimensional analysis or in small strain analysis where most elements remain on the same plane.
3. **Elemental Extrapolation Method.** The elemental extrapolation method is also used for detailed element out, eloutdet. It is more robust and provides acceptable solutions for elements of multiple integration points.

*DATABASE_RVE

Purpose: Output of the RVE homogenization results to the rveout file. Double precision SMP/MPP LS-DYNA version R13 and newer versions support this RVE analysis function.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	BINARY						
Type	F	I						
Default	0	0						

VARIABLE	DESCRIPTION
DT	Time interval for the output of RVE homogenization results to the rveout file.
BINARY	Type of the output file: EQ.0: ASCII database file named rveout

Remarks:

At each output time t, LS-DYNA records the macroscopic material responses to the rveout file. The responses include the macroscopic deformation gradient $\tilde{\mathbf{F}}^t$, Green strain $\tilde{\mathbf{E}}^t$, Cauchy stress $\tilde{\boldsymbol{\tau}}^t$, and the 1st-Piola-Kirchhoff (PK1) stress $\tilde{\mathbf{P}}^t$. These results are obtained through nonlinear computational homogenization of RVE (*Representative Volume Element*) for composite materials. Please refer to the keyword *RVE_ANALYSIS_FEM for more details.

*DATABASE_SPRING_FORWARD

Purpose: Create spring forward nodal force file. This option is to output resultant nodal force components of sheet metal at the end of the forming simulation into an ASCII file, SPRING-FORWARD, for spring forward and die corrective simulations.

Card 1	1	2	3	4	5	6	7	8
Variable	IFLAG							
Type	I							

VARIABLE	DESCRIPTION
IFLAG	Output type: EQ.0: off, EQ.1: output element nodal force vector for deformable nodes.

*DATABASE_SUPERPLASTIC_FORMING

Purpose: Specify the output intervals to the superplastic forming output files. The option *LOAD_SUPERPLASTIC_FORMING must be active.

Card 1	1	2	3	4	5	6	7	8
Variable	DTOUT							
Type	F							

VARIABLE	DESCRIPTION
DTOUT	Output time interval for output to "pressure," "curve1" and "curve2" files. The "pressure" file contains general information from the analysis and the files "curve1" and "curve2" contain pressure as a function of time from phases 1 and 2 of the analysis. The data in the pressure and curve files may be plotted using *ASCII* → *superpl* in LS-PrePost.

*DATABASE_TRACER_{OPTION}

Purpose: Tracer particles will save a history of either a material point or a spatial point into an ASCII file: trhist. This history includes positions, velocities, and stress components. The option *DATABASE_TRHIST must be active. This option applies to ALE, SPH and DEM (Discrete Element Method) problems.

Available options are:

<BLANK>

DE

The DE option defines a tracer corresponding to discrete elements (*ELEMENT_DISCRETE_SPHERE). See Remarks 2 and 4.

Card	1	2	3	4	5	6	7	8
Variable	TIME	TRACK	X	Y	Z	AMMGID	NID	RADIUS
Type	F	I	F	F	F	I	I	F
Default	0.0	0	0.0	0.0	0.0	0	0	0.0

VARIABLE	DESCRIPTION
TIME	Start time for tracer particle
TRACK	Tracking option: EQ.0: particle follows material (see Remark 5). EQ.1: particle is fixed in space. EQ.2: particle follows the mesh
X	Initial *x*-coordinate
Y	Initial *y*-coordinate
Z	Initial *z*-coordinate
AMMGID	The AMMG ID (ALE multi-material group) of the material being tracked in a multi-material ALE element. See Remark 1.

VARIABLE	DESCRIPTION
NID	An optional node ID defining the initial position of a tracer particle. If defined, its coordinates will overwrite the x, y, z coordinates above. This feature is for TRACK = 0 only and can be applied to ALE tracers and DE tracers. See Remark 2.
RADIUS	Radius is used only for the DE option to indicate whether the tracer follows and monitors a single discrete element or multiple discrete elements. GT.0.0: the tracer takes the average results of all discrete elements located inside a sphere with radius = RADIUS. That sphere stays centered on the DE tracer. LT.0.0: the discrete element closest to the tracer is used. The magnitude of RADIUS in this case is unimportant.

Remarks:

1. **Multi-Material Groups.** ALE elements can contain multi-materials. Each material is referred to as an ALE multi-material group or AMMG. Each AMMG has its list of history variables that can be output. For example, if a tracer is in a mixed element consisting of 2 AMMGs, and the history variables of AMMG 1 are to be output or tracked, the AMMGID should be defined as AMMGID = 1. If AMMGID = 0, a volume-fraction-weighted-averaged pressure will be reported instead.

2. **NID Description.** For ALE, NID is a massless dummy node. Its location will be updated according to the motion of the ALE material.

   For the DE option, NID is a discrete element node that defines the initial location of the tracer. The DE tracer continues to follow that node if RADIUS < 0. On the other hand, the DE tracer's location is updated according to the average motion of the group of DE nodes inside the sphere defined by RADIUS when RADIUS > 0.

3. **Tracer Particles in Ambient ALE Elements.** Since the auxiliary variables (6 stresses, plastic strain, internal energy, …) for ambient elements are reset to their initial values before and after advection and tracer data are stored in trhist during the advection cycle, tracers in ambient elements show the initial stresses, not the current ones.

4. **Discrete Elements.** If the DE keyword option is used, tracer particles will save a history of either a material point or a spatial point into an ASCII file: demtrh. This history includes positions, velocities components, stress components,

porosity, void ratio, and coordination number. The option *DATABASE_-TRHIST must be active.

5. **Mapping.** Lagrange (TRACK = 0) tracers with mapping (map =) produce a keyword file tracers_final_positions.k, containing the final positions of the tracer particles. This file should be included in the mapped simulation to correctly locate the Lagrange tracers.

*DATABASE_TRACER_ALE

Purpose: Save a history of either a material point or a spatial point using tracer particles into an ASCII file: traleh. This history includes positions, velocities, and stress and other user-specified element history variables. The option *DATABASE_TRHIST must be active. This keyword is only to be used with ALE problems.

Card	1	2	3	4	5	6	7	8
Variable	NID	TRACK	AMMGID	HVBEG	HVEND	TIME		
Type	I	I	I	I	I	I		
Default	0	0	0	0	0	0.0		

VARIABLE	DESCRIPTION
NID	Node ID defining the initial position of a tracer particle. See Remark 1.
TRACK	Tracking option: EQ.0: particle follows material EQ.1: particle is fixed in space
AMMGID	The AMMG ID (ALE multi-material group) of the material being tracked in a multi-material ALE element. See Remark 2.
HVBEG	The beginning index of element history variables to be output. See Remark 3.
HVEND	The ending index of element history variables to be output. The number of extra history variables must be no more than 15, meaning HVEND -HVBEG = 15.
TIME	Start time for tracer particle activation

Remarks:

1. **NID Description.** NID is a massless dummy node. Its location will be updated according to the motion of the ALE material.

2. **Multi-Material Groups.** ALE elements can contain multi-materials. Each material is referred to as an ALE multi-material group or AMMG. Each AMMG has its list of history variables that can be output. For example, if a tracer is in a mixed element consisting of 2 AMMGs, and the history variables of AMMG 1 are to be output or tracked, the AMMGID should be defined as AMMGID = 1. If AMMGID = 0, a volume-fraction-weighted-averaged pressure will be reported instead.

3. **History Variables.** This keyword provides a way to output specific element history variables. By default, there are 9 element properties output for each particle. They are: 6 stresses, plastic strain, volume fraction, and density. For example, if you want to know the air temperature of AMMG 2 which is material *MAT_148, you set AMMGID to 2 and HVBEG = HVEND = 16 since history variable 16 of *MAT_148 is temperature. At most, data for 15 history variables can be output this way.

4. **Tracer Particles in Ambient ALE Elements.** Since the auxiliary variables (6 stresses, plastic strain, internal energy, …) for ambient elements are reset to their initial values before and after advection, and tracer data are stored in trhist during the advection cycle, tracers in ambient elements show the initial stresses, not the current ones.

Example File:

Below is an example traleh file. 7 and 30 in the second line tells the reader that there are 7 tracers and each tracer has 30 output variables. The next six lines list the output variables as they are output in the file. These output variables are described in Table 16-1.

```
ALE Tracer particle file

```

Variable	Description
elemID	ID of ALE element in which the tracer is currently located
x, y, z	Position
vx, vy, vz	Velocity
sx, sy, sz, sxy, syz, szx	Stress
efp	Effective plastic strain
rho	Density
rvol	Volume fraction
hisvar*i*	History variable *i*

Table 16-1: Output variables to traleh

*DATABASE_TRACER_GENERAL

Purpose: Output histories for any solids, beams, shells, or thick shells in which the tracer, which is a node, is located. The histories are saved into a binary file: trcrgal_binout. These histories include positions, velocities, and stress components. The data structure is identical to the one output by *DATABASE_TRACER_ALE into traleh file. Except for the positions and element ID specifying where the tracer is, the output can be controlled with the VARLOC and VAREPL fields.

Card 1	1	2	3	4	5	6	7	8
Variable	NODE	ELEM	TYPM	MOVE	SET	TYPS		
Type	I	I	I	I	I	I		
Default	0	0	0	0	0	0		

Optional Variable Cards. Cards defining the times to output data in trcrgal_binout.

Card 2	1	2	3	4	5	6	7	8
Variable	DT	TBEG	TEND	FID				
Type	F	F	F	I				
Default	0.0	0.0	10^{20}	0				

Optional Variable Cards. Cards defining new variables to be output to trcrgal_binout instead of the default ones. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	VARLOC	VAREPL						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
NODE	Node ID that locates the tracer (see Remark 1)
ELEM	Element ID that controls the tracer motion (see Remarks 1 and 2) GT.0: data are output for ELEM if tracer is located inside ELEM LT.0: data are not output for ELEM if tracer is located inside ELEM
TYPM	ELEM type: EQ.1: solid EQ.2: beam EQ.3: shell EQ.4: tshell
MOVE	Flag to define how the tracer moves (see Remark 1): EQ.0: the tracer does not move with ELEM EQ.1: the tracer velocity is interpolated from ELEM nodal velocities EQ.2: the tracer position is interpolated from ELEM nodal positions
SET	Element set for which the data are output by the tracer (see Remark 2)
TYPS	SET type: EQ.0: part EQ.1: solid EQ.2: beam EQ.3: shell EQ.4: tshell
DT	Time interval between outputs (see Remark 3)
TBEG	Time to start the output
TEND	Time to stop the output

VARIABLE	DESCRIPTION
FID	ID to be appended to trcrgal_binout (see Remark 3)
VARLOC	Variable location in trcrgal_binout to be replaced with the variable specified in the VAREPL field: EQ.4: *x*-velocity EQ.5: *y*-velocity EQ.6: *z*-velocity EQ.7: *xx*-stress EQ.8: *yy*-stress EQ.9: *zz*-stress EQ.10: *xy*-stress EQ.11: *yz*-stress EQ.12: *zx*-stress EQ.13: plastic strain EQ.14: nodal mass EQ.15: undefined GE.16 and LE.30: other auxiliary variables
VAREPL	Data to be output to the trcrgal_binout file instead of the variable located at VARLOC. The interpretation of VAREPL is enumerated in the following list: EQ.1: *x*-acceleration EQ.2: *y*- acceleration EQ.3: *z*- acceleration EQ.4: nodal temperature EQ.5: density EQ.6: compression ratio EQ.7: pressure

Remarks:

1. **NODE, ELEM and MOVE.** A node represents the tracer. The initial location of the tracer is given by the nodal coordinates of the node defined in *NODE like for any node. If NODE = 0 and ELEM is defined, a node is added at the center

of the element ELEM. If NODE is defined and ELEM = 0, the closest element to the tracer found during the initialization is used for ELEM. NODE and ELEM cannot both be zero. At least one of them should be provided to position the tracer. If MOVE > 0, the tracer will move with ELEM, even if NODE is not in ELEM.

2. **ELEM and SET.** If SET > 0, data will be output for the element in which the tracer is located if the element belongs to the set (if TYPS = 0, it will be the elements in the parts in SET). If SET = 0 and ELEM > 0, the elements of the same type (TYPM) as ELEM will be the output focus. If SET = 0 and ELEM ≤ 0, data will be output for any solid, beam, shell and thick shell.

3. **DT and FID.** DT is the time interval between data outputs to the file trcrgal_binout. If DT = 0.0 and *DATABASE_TRHIST is defined, the time step in this keyword will be used for DT. If DT = 0.0, data will be output every computational cycle. If there are several *DATABASE_TRACER_GENERAL keywords with different DT values, outputs from tracers with identical time steps will be grouped in the same file with a unique ID added to the end of trcrgen_binout. This ID can be provided by the user with FID. Two keywords with different DT but identical FID will terminate the job with an error.

4. **Post-Processing.** The output of *DATABASE_TRACER_GENERATE is written to a file named trcrgal_binout. To access the output in LS-PrePost: *Post* (or *TAB 2*) → *Binout* → *trcrgal_binout* → *traleh* → *"Traleh Branch"* window contains a list of variables output for each tracer.

5. **Binary to ASCII File Conversion.** The variables in traleh and trcrgal_binout are arranged in an identical order. Therefore, the traleh can be obtained from the trcrgal_binout file by using the l2a program located at http://ftp.lstc.com/-user/lsda.

*DATABASE_TRACER_GENERATE

Purpose: Generate tracer particles along an isosurface for a variable defined in the VALTYPE list. The tracer particles follow the motion of this surface and save data histories into a binary file called trcrgen_binout (see Remarks 4 and 5). These histories are identical to the ones output by *DATABASE_TRACER into the trhist file; they include positions, velocities, and stress components. Except for the positions and element ID specifying where the tracer is, the output can be controlled with the VARLOC and VALTYPE2 fields. This option applies to ALE problems.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	VALOW	VALUP	VALTYPE1	SET	SETYPE	MMGSET	UPDT
Type	F	F	F	I	I	I	I	F
Default	none	0.0	0.0	none	0	0	none	DT

Optional Variable Cards. Cards defining new variables to be output to trcrgen_binout instead of the default ones. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	VARLOC	VALTYPE2	MMGSET					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
DT	Interval time between each tracer generation and position update (See Remark 1).
VALOW, VALUP	Range of values between which the isosurface is defined. VALOW is the lower bound while VALUP is the upper bound. See Remark 2. The value at the isosurface is 0.5(VALOW + VALUP). The variable with this value is defined by VALTYPE.

VARIABLE	DESCRIPTION
VALTYPE1	The variable that will be used to generate the isosurfaces. See VALTYPE2 for enumeration of values.
VALTYPE2	Data to be output to the trcrgen_binout file. The interpretation of VALTYPE1 and VALTYPE2 is enumerated in the following list:

EQ.1:	*xx*-stress
EQ.2:	*yy*-stress
EQ.3:	*zz*-stress
EQ.4:	*xy*-stress
EQ.5:	*yz*-stress
EQ.6:	*zx*-stress
EQ.7:	plastic strain
EQ.8:	internal energy
EQ.9:	bulk viscosity
EQ.10:	relative volume
GE.11 and LE.19:	other auxiliary variables
EQ.20:	pressure
EQ.21:	density
EQ.22:	material volume
EQ.23:	compression ratio
EQ.24:	element volume fraction
EQ.25:	nodal volume fraction
EQ.26:	*x*-position
EQ.27:	*y*-position
EQ.28:	*z*-position
EQ.29:	*x*-velocity
EQ.30:	*y*-velocity
EQ.31:	*z*-velocity
EQ.31:	velocity
EQ.33:	*x*-acceleration
EQ.34:	*y*- acceleration

VARIABLE	DESCRIPTION
	EQ.35: *z*- acceleration
	EQ.36: acceleration
	EQ.37: nodal mass
	EQ.38: nodal temperature
SET	Set ID (See Remark 2)
SETYPE	Type of set (See Remark 2):
	EQ.0: solid set
	EQ.1: segment set
	EQ.2: node set
MMGSET	Multi-material group set (See Remark 3).
UPDT	Time interval between tracer position update (See Remark 1).
VARLOC	Variable location in trcrgen_binout to be replaced with the variable specified in the VALTYPE2 field:
	EQ.4: *x*-velocity
	EQ.5: *y*-velocity
	EQ.6: *z*-velocity
	EQ.7: *xx*-stress
	EQ.8: *yy*-stress
	EQ.9: *zz*-stress
	EQ.10: *xy*-stress
	EQ.11: *yz*-stress
	EQ.12: *zx*-stress
	EQ.13: plastic strain
	EQ.14: density
	EQ.15: relative volume

Remarks:

1. **DT.** The frequency to create tracers is defined by DT. The default value of UPDT, which is the time interval between updates to the tracer position, is also set

to DT. The default behavior, then, is to update tracer positions when a new tracer is created; however, by setting UPDT to a value less than DT tracer positions can be updated more frequently without creating new tracers.

2. **Tracing Algorithm.** When LS-DYNA adds new tracer particles (see DT), tracers are created at element centers, segment centers, or nodes depending on the set type (SETYPE). A new tracer particle is created when the value at the element center, segment center, or node center is in the bounding interval [VALOW, VALUP], provided that there is *not* already a nearby tracer particle. The tracer particles follow the isosurface defined by the midpoint of the bounding interval (VALOW + VALUP)/2.

3. **Multi-Material Groups.** ALE elements can contain several materials. Each material is referred to as an ALE multi-material group. The volume fractions define how much of the element volume is occupied by the groups. Each group has their own variables for 0 < VALTYPE < 26. If VALTYPE < 21 or VALTYPE = 23, the variable is volume averaged over the groups defined by MMGSET.

4. **Post-Procesing.** The output of *DATABASE_TRACER_GENERATE is written to a file named trcrgen_binout. To access the output in LS-PrePost: *TAB 2* → *LOAD* → *trcrgen_binout* → *trhist* → *"Trhist Data"* window contains a list of variables output for each tracer.

5. **Binary to ASCII File Conversion.** The variables in trhist and trcrgen_binout are arranged in an identical order. Therefore, the trhist can be obtained from the trcgen_binout file by using the l2a program located at http://ftp.lstc.com/-user/lsda.

.

*DEFINE

The keyword *DEFINE provides a way of defining boxes, coordinate systems, load curves, functions, tables, transformations, and orientation vectors. Some of the *DEFINE keywords also assist with particle methods, airbags, failure, metal forming, welds, generalized elements, and contact. The keyword cards in this section are defined in alphabetical order:

Unless noted otherwise, an additional keyword option TITLE may be appended to the *DEFINE keywords. If this option is used, then an addition line is read for each section in 80a format which can be used to describe the defined curve, table, etc. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

Examples for the *DEFINE keyword can be found at the end of this section.

*DEFINE_ADAPTIVE_SOLID_TO_DES_{OPTION}

Purpose: Adaptively transform a Lagrangian solid part or part set to DES (Discrete Element Sphere) particles (elements) when the Lagrangian solid elements comprising those parts fail. One or more DES particles will be generated for each failed element as debris. The DES particles replacing the failed element inherit the properties of the failed solid element, including mass and kinematical state.

The available options include:

<BLANK>

ID

ID Card. Additional card for the ID keyword option.

Optional	1	2	3	4	5	6	7	8
Variable	DID	HEADING						
Type	I	A70						
Default	none	none						

Card 1	1	2	3	4	5	6	7	8
Variable	IPID	ITYPE	NQ	IPDES	ISDES	RSF	OUTDES	IBOND
Type	I	I	I	I	I	F	I	I
Default	none	none	none	none	none	1.0	0	0

Bonds Card. This card is only included when IBOND = 1.

Card 2	1	2	3	4	5	6	7	8
Variable	PBN	PBS	PBN_S	PBS_S	SFA	ALPHA		
Type	F	F	F	F	F	F		
Default	none	none	none	none	1.0	0.0		

VARIABLE	DESCRIPTION
DID	Definition ID. This must be a unique number.
HEADING	Definition descriptor. It is suggested that unique descriptions be used.
IPID	ID of the solid part or part set to transform.
ITYPE	IPID type: EQ.0: Part ID NE.1: Part set ID
NQ	Adaptive option for hexahedral elements. For tetrahedral and pentahedral elements, see Remark 1. EQ.1: Adapt one solid element to one discrete element EQ.2: Adapt one solid element to 8 discrete elements EQ.3: Adapt one solid element to 27 discrete elements
IPDES	Part ID for newly generated discrete elements. See Remark 2.
ISDES	Section ID for discrete elements. See Remark 2.
RSF	DES radius scale down factor, which is the ratio of the radius of the generated DES to the calculated radius based on volume consistency.
OUTDES	Allow user output generated discrete element nodes and DES properties to a keyword file. EQ.0: No output (default). EQ.1: Write data under filename desvfill.inc.

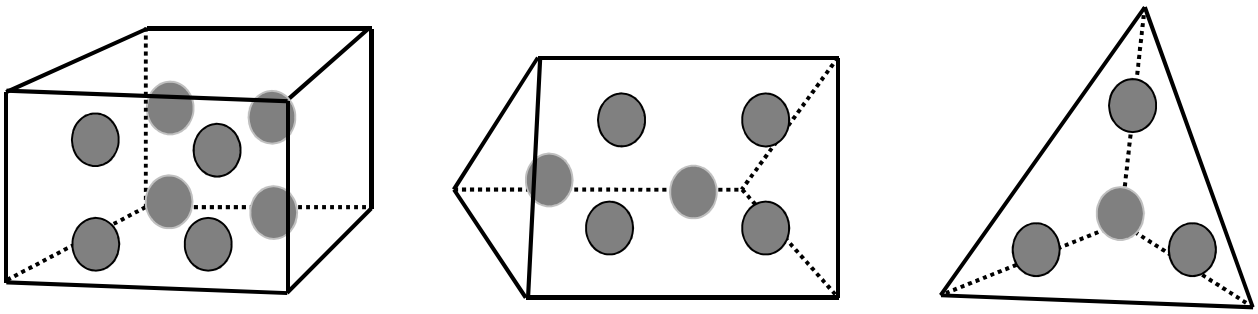

Figure 17-1. Left to right, illustration of conversion from solid to DES for NQ = 2 of hexahedron, pentahedron, and tetrahedron elements.

VARIABLE	DESCRIPTION
IBOND	Allow user define bonds between DES generated from the same solid element. EQ.0: No bonds (default). EQ.1: Bonds generated, need to define Card 2.
PBN	Parallel-bond modulus [Pa]. See Remark 3.
PBS	Parallel-bond stiffness ratio. Shear stiffness/normal stiffness. See Remark 3.
PBN_S	Parallel-bond maximum normal stress. A zero value defines an infinite maximum normal stress.
PBS_S	Parallel-bond maximum shear stress. A zero value defines an infinite maximum shear stress.
SFA	Bond radius multiplier. Default is 1.0.
ALPHA	Numerical damping

Remarks:

1. **DES Element to Solid Element Ratio.** The DES particles are evenly distributed within the solid element. For hexahedral elements the number of the generated DES particles is NQ × NQ × NQ. For pentahedral elements, the number of generated DES particles is 1, 6, and 18 for NQ = 1, 2, and 3, respectively. For tetrahedral elements, the number of generated DES particles is 1, 4, and 10 for NQ = 1, 2, and 3, respectively. See Figure 17-1.

2. **Part ID.** The part ID for newly generated DES particles can be either a new part ID or the ID of an existing DES part.

3. **Bond Forces.** The normal force between two bonded discrete elements with radii r_1 and r_2 is calculated as

$$\Delta f_{\mathrm{n}} = \frac{\mathrm{PBN}}{(r_1 + r_2)} \times \mathrm{A} \times \Delta u_n \ ,$$

where

$$A = \pi r_{\mathrm{eff}}^2$$
$$r_{\mathrm{eff}} = \min(r_1, r_2) \times \mathrm{SFA}$$

The shear force is calculated as

$$\Delta f_{\mathrm{s}} = \mathrm{PBS} \times \frac{\mathrm{PBN}}{(r_1 + r_2)} \times \mathrm{A} \times \Delta u_s \ .$$

*DEFINE_ADAPTIVE_SOLID_TO_SPH_{OPTION}

Purpose: Create SPH particles to either replace or supplement solid Lagrangian elements.

Applications of this feature include adaptively transforming a Lagrangian solid Part or Part Set to SPH particles, when the Lagrangian solid elements comprising those parts fail. One or more SPH particles (elements) will be generated for each failed element. The SPH particles replacing the failed solid Lagrangian elements inherit all the Lagrange nodal quantities and all the Lagrange integration point quantities of these failed solid elements. Those properties are assigned to the newly activated SPH particles. The constitutive properties assigned to the new SPH part will correspond to the MID and EOSID referenced by the SPH *PART definition. This keyword with options of ICPL = 0, 1 has been extended to 2D cases too.

The available options include:

<BLANK>

ID

ID Card. Additional card for the ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	DID	HEADING						
Type	I	A70

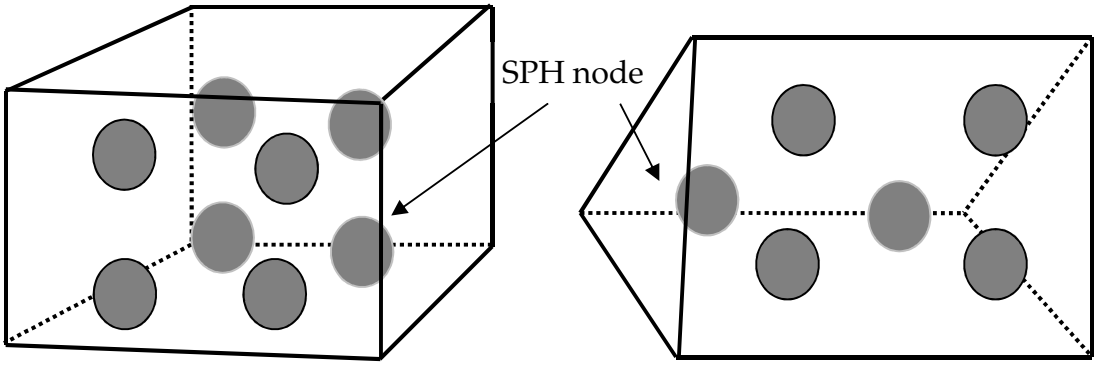
Default	none	none	none	none	none	none	none	average

VARIABLE	DESCRIPTION
DID	Definition ID. This must be a unique number.

VARIABLE	DESCRIPTION
HEADING	Definition descriptor. We suggest using unique descriptions.
IPID	ID of the solid part or part set to transform
ITYPE	IPID type: EQ.0: Part ID NE.0: Part set ID
NQ	Adaptive option for hexahedral elements. For tetrahedral and pentahedral elements, see Remark 1: EQ.n: Adapt one 8-node solid element to $(n \times n \times n)$ SPH elements. The range of n is from 1 to 6.
IPSPH	Part ID for newly generated SPH elements. See Remark 2.
ISSPH	Section ID for SPH elements. See Remark 2.
ICPL	Coupling of newly generated SPH elements to the adjacent solid elements: EQ.0: Failure without coupling (debris simulation), EQ.1: Coupled to solid element, EQ.3: Provide only thermal coupling between SPH part and solid part (must be combined with IOPT = 0 option; see Remark 4).
IOPT	Coupling method: EQ.0: Coupling from beginning (used as constraint between SPH elements and solid elements), EQ.1: Coupling begins when Lagrangian solid element fails. See Remark 3.
CPCD	Thermal coupling conductivity between SPH part and solid part for ICPL = 3 option. The default value is set as the average value of the conductivity from SPH part and the conductivity from solid part.

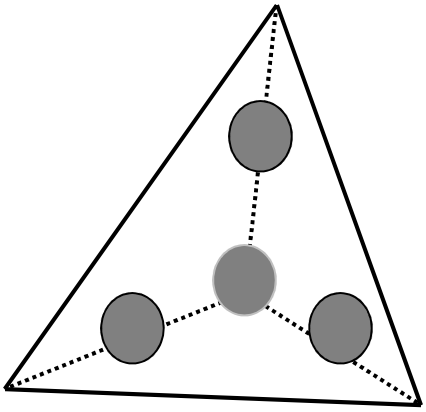
Remarks:

1. **Number of SPH Particles per Element.** The SPH particles are evenly distributed within the solid element. For hexahedral elements the number of the generated SPH particles is NQ × NQ × NQ. For pentahedral elements, the number



Example of SPH nodes for hexahedral element with NQ = 2

Example of SPH nodes for pentahedral element with NQ = 2



Example of SPH nodes for tetrahedral element with NQ = 2

Figure 17-2. Examples of distributions of SPH particles converted from solid Lagrangian elements.

of generated SPH particles is 1, 6, and 18 for NQ equal to 1, 2, and 3, respectively. For tetrahedral elements, the number of generated SPH particles is 1, 4, and 10 for NQ equal to 1, 2, and 3, respectively. See Figure 17-2.

2. **SPH Part ID**. The Part ID for newly generated SPH particles can be either a new Part ID or the ID of an existing SPH Part. For constraint coupling, such as when ICPL = 1 and IOPT = 0, the newly generated SPH part ID should be different from the existing one.

3. **Mechanical Failure Coupling.** ICPL = 0 is used for debris simulation, so no coupling happens between newly generated SPH particles and solid elements; the user, therefore, needs to define node to surface contact for the interaction

between those two parts. When ICPL = 1 and IOPT = 1, the newly generated SPH particles are bonded with solid elements as one part through the coupling, and the new material ID with different failure criteria can be applied to the newly generated SPH particles.

4. **Thermal Coupling.** ICPL = 3, which must be combined with IOPT = 0, is used to thermally couple an SPH part and solid part(s). There is no structural coupling provided. A thermal conductivity value may be defined using the variable CPCD.

*DEFINE_BEAM_SOLID_COUPLING

Purpose: To define a coupling interface between embedded structure and a block defined by solid(s) without sharing nodes.

Card 1	1	2	3	4	5	6	7	8
Variable	LSTRID	SOLID	LSTRTYPE	SOLTYPE	FORM	PSF		
Type	I	I	I	I	I	F		
Default	none	none	0	0	0	1.		

VARIABLE	DESCRIPTION
LSTRID	Part set ID or part ID of the Lagrangian structure. LSTRTYPE below indicates the ID type specified by LSTRTYPE.
SOLID	Part set ID or part ID of the solid block. SOLTYPE below indicates the ID type specified by SOLID.
LSTRTYPE	Type of Lagrangian structure set: EQ.0: Part set EQ.1: Part
TYPE	Type of solid set: EQ.0: Part set EQ.1: Part
Form	Coupling type: EQ.0: Constrained acceleration and velocity EQ.1: Penalty tied in all directions
PSF	Scale factor for penalty stiffness

***DEFINE_BOX**_{OPTION}

Available options include:

<BLANK>

LOCAL

Purpose: Define a box-shaped volume. Two diagonally opposite corner points of a box are specified in global or local coordinates if the LOCAL option is active. The box volume is then used for various specifications for a variety of input options, such as velocities, contact, etc.

If the option, LOCAL, is active, a local coordinate system with two vectors (see Figure 17-10) is defined. The vector cross product, $\mathbf{z} = \mathbf{x} \times \mathbf{v}_{xy}$ where $\mathbf{v}_{xy}$ is a vector in the xy-plane, determines the local z-axis. The local y-axis is then given by $\mathbf{y} = \mathbf{z} \times \mathbf{x}$.

A point, P, in the global coordinate system is considered to lie within the volume of the box if the coordinate $P - C$, where C is the global coordinate offset vector defined on Card 3, lies within the box after transformation into the local system, $P_{\text{local}} = T \times (P - C)$. The local coordinate, P_{local}, is checked against the minimum and maximum coordinates defined on Card 1 in the local system.

For the *INCLUDE_TRANSFORM options that include translations, rotations and mirrors, all box options are automatically converted from *DEFINE_BOX_*xxxx* to *DEFINE_BOX_*xxxx*_LOCAL in the DYNA.INC file. Here, *xxxx* represents the box options: ADAPTIVE, COARSEN, and SPH, which are defined below. If the transformation matrix of *INCLUDE_TRANSFORM involves using negative values for SCALE, see *DEFINE_TRANSFORMATION, to mirror/reflect an object, the box might not be correctly transformed. Instead of SCALE, it is advised to use the MIRROR option with A7 = 1 for the purpose of mirroring/reflecting.

ZV	*Z*-coordinate of local *xy*-vector. Define if the LOCAL option is active.
CX	*X*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.
CY	*Y*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.
CZ	*Z*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.

*DEFINE_BOX_ADAPTIVE_{OPTION}

Available options include:

<BLANK>

LOCAL

Purpose: Define a box-shaped volume enclosing (1) the shells where the *h*-adaptive level is to be specified, or (2) the solids where the tetrahedral *r*-adaptive mesh size is to be specified. If the midpoint of the element falls within the box, the *h*-adaptive level is reset. The box can translate. It is also possible to define a fission box followed by a fusion box, in which case the mesh can refine when deformed and coarsen when flattened. Shells falling outside of this volume use the value, MAXLVL, on the *CONTROL_ADAPTIVE control cards. A related keyword is *DEFINE_CURVE_BOX_ADAPTIVITY. An alternative command in the case of shell *h*-adaptivity is *DEFINE_BOX_NODES_ADAPTIVE.

Card 4	1	2	3	4	5	6	7	8
Variable	CX	CY	CZ					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
BOXID	Box ID. Define unique numbers.
XMN	Minimum x-coordinate. Define in the local coordinate system if the option LOCAL is active.
XMX	Maximum x-coordinate. Define in the local coordinate system if the option LOCAL is active.
YMN	Minimum y-coordinate. Define in the local coordinate system if the option LOCAL is active.
YMX	Maximum y-coordinate. Define in the local coordinate system if the option LOCAL is active.
ZMN	Minimum z-coordinate. Define in the local coordinate system if the option LOCAL is active.
ZMX	Maximum z-coordinate. Define in the local coordinate system if the option LOCAL is active.

VARIABLE	DESCRIPTION
PID	Deformable part ID. EQ.0: all active elements within box are considered.
LEVEL	Maximum number of refinement levels for elements that are contained in the box. Values of 1, 2, 3, 4, ... allow for a maximum of 1, 4, 16, 64, ... elements, respectively, to be created for each original element.
LIDX/NDID	Load curve ID / Node ID (see Remark 1). GT.0: load curve ID. Define adaptive box movement (displacement as a function of time) in global X-axis. LT.0: absolute value is a node ID, whose translation will be followed by the moving adaptive box. The node ID can be on a moving rigid body. EQ.0: no movement
LIDY	Load curve ID (see Remark 1). GT.0: load curve ID. Define adaptive box movement (displacement as a function of time) in global Y-axis. EQ.0: no movement
LIDZ	Load curve ID (see Remark 1). GT.0: load curve ID. Define adaptive box movement (displacement as a function of time) in global Z-axis. EQ.0: no movement
BRMIN	Minimum mesh size in 3D tetrahedron adaptivity
BRMAX	Maximum mesh size in 3D tetrahedron adaptivity
XX	X-coordinate on local x-axis. Origin lies at $(0,0,0)$. Define if the LOCAL option is active.
YX	Y-coordinate on local x-axis. Define if the LOCAL option is active.
ZX	Z-coordinate on local x-axis. Define if the LOCAL option is active.
XV	X-coordinate of local xy-plane vector. Define if the LOCAL option is active.

VARIABLE	DESCRIPTION
YV	*Y*-coordinate of local *xy*-plane vector. Define if the LOCAL option is active.
ZV	*Z*-coordinate of local *xy* -plane vector. Define if the LOCAL option is active.
CX	*X*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.
CY	*Y*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.
CZ	*Z*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.

Remarks:

1. **Moving Box.** The moving adaptive box is very useful and efficient in situations where deformations happens locally, such as roller hemming and incremental forming simulations. With the moving box feature, elements entering one box can be refined and fused together when they enter another box. Mesh fission outside of the moving box envelope is controlled by MAXLVL and other parameters under *CONTROL_ADAPTIVE. The fusion controls (NCFREQ, IADPCL) can be defined using *CONTROL_ADAPTIVE. Currently, only IADPCL = 1 is supported.

   Only when one of the LCIDX/NDID, LICDY, or LCIDZ is defined, the adaptive box will be moving; otherwise it will be stationary.

2. **3D *r*-Adaptivity.** For 3D tetrahedron *r*-adaptivity, the current implementation does not support the LOCAL option. In Card 2, LEVEL is not supported in 3D *r*-adaptivity.

Example:

Referring to a partial input deck below, and Figure 17-3, a strip of sheet metal is being roller hemmed. The process consists of pre- and final hemming. Each pre- and final roller is defined with a moving adaptive box with IDs 2 and 3, respectively. Figure 17-3 shows the box shapes. The first box, a fission box, has a LEVEL = 3 refinement, while the second box, a fusion box, was set at LEVEL = 1 refinement. Elements outside of the volume envelope made by the moving boxes undergo no fission and fusion (MAXLVL = 1). These settings cause mesh fission when the elements enter moving box 2 (LEVEL = 3) and mesh fusion only when the elements enter moving box 3 (LEVEL = 1). No fission/fusion

(MAXLVL = 1) occurs outside of the volume envelope created by the moving boxes. In the example, the boxes 2 and 3 move in the global *X*-direction for a distance of 398 mm as defined by load curve 11 and 450 mm as defined by load curve 12, respectively.

A moving box can also follow the movement of a node, which can be on a moving rigid body. In this case, NDIDs for the motion of the boxes are defined instead of load curves. For example, in Figure 17-3 and a partial keyword example below, box 2 follows a node (ID: 33865) on the pre-roller, and box 3 follows another node (ID: 38265) on the final roller.

Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
BOXID	Box ID. Define unique numbers.
XMN	Minimum x-coordinate. Define in the local coordinate system if the option LOCAL is active.
XMX	Maximum x-coordinate. Define in the local coordinate system if the option LOCAL is active.
YMN	Minimum y-coordinate. Define in the local coordinate system if the option LOCAL is active.
YMX	Maximum y-coordinate. Define in the local coordinate system if the option LOCAL is active.
ZMN	Minimum z-coordinate. Define in the local coordinate system if the option LOCAL is active.
ZMX	Maximum z-coordinate. Define in the local coordinate system if the option LOCAL is active.
IFLAG	Flag for protecting elements inside or outside of box: EQ.0: elements inside the box cannot be coarsened EQ.1: elements outside the box cannot be coarsened
XX	X-coordinate on local x-axis. Origin lies at (0,0,0). Define if the LOCAL option is active.
YX	Y-coordinate on local x-axis. Define if the LOCAL option is active.
ZX	Z-coordinate on local x-axis. Define if the LOCAL option is active.
XV	X-coordinate of local xy-vector. Define if the LOCAL option is active.
YV	Y-coordinate of local xy-vector. Define if the LOCAL option is active.
ZV	Z-coordinate of local xy-vector. Define if the LOCAL option is active.
CX	X-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.

VARIABLE	DESCRIPTION
CY	*Y*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.
CZ	*Z*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.

Remarks:

1. **Multiple Boxes.** Many boxes may be defined. If an element is protected by any box then it may not be coarsened.

*DEFINE_BOX_DRAWBEAD

Purpose: Define a specific box or tube shaped volume around a draw bead. This option is useful for the draw bead contact. If box shaped, the volume will contain the draw bead nodes and elements between the bead and the outer edge of the blank. If tubular, the tube is centered around the draw bead. All elements within the tubular volume are included in the contact definition.

Card	1	2	3	4	5	6	7	8
Variable	BOXID	PID	SID	IDIR	STYPE	RADIUS	CID	
Type	I	F	F	F	I	F	I	
Default	0	0.0	0.0	0.0	4	0.0	0	

VARIABLE	DESCRIPTION
BOXID	Box ID. Define unique numbers.
PID	Part ID of blank.
SID	Set ID that defines the nodal points that lie along the draw bead. If a node set is defined, the nodes in the set must be consecutive along the draw bead. If a part or part set is defined, the set must consist of beam or truss elements. Within the part set, no ordering of the elements is assumed, but the number of nodes must equal the number of beam elements plus 1.
IDIR	Direction of tooling movement. The movement is in the global coordinate direction unless the tubular box option is active and CID is nonzero. In this latter case, the movement is in the local coordinate direction. EQ.1: tooling moves in x-direction, EQ.2: tooling moves in y-direction, EQ.3: tooling moves in z-direction.
STYPE	Set type: EQ.2: part set ID, EQ.3: part ID,

VARIABLE	DESCRIPTION
	EQ.4: node set ID.
RADIUS	The radius of the tube, which is centered around the draw bead. Elements of part ID, PID, that lie within the tube will be included in the contact. If the radius is not defined, a rectangular box is used instead. This option is recommended for curved draw beads and for draw beads that are not aligned with the global axes.
CID	Optional coordinate system ID. This option is only available for the tubular drawbead.

*DEFINE_BOX_NODES_ADAPTIVE

Purpose: Define mesh fission and fusion at the beginning of an adaptive step according to the path of a moving tool and a set of parameters. This method applies only to shell h-adaptivity and is sometimes referred to as "tube" adaptivity for its adaptive boundary shape. (This tube is more accurately described as a torus.) It can help reduce the computational time for incremental forming or roller hemming simulations while maintaining accuracy in the area of interest. This method is a major improvement over the keyword *DEFINE_BOX_ADAPTIVE (see Remarks and Figure 17-4). Related keywords include *DEFINE_CURVE_BOX_ADAPTIVITY and *CONTROL_ADAPTIVE_CURVE.

Card 1	1	2	3	4	5	6	7	8
Variable	BOXID	NODE	LCX	LCY	LCZ	ITYPE	RADIUS	NPIECE
Type	I	F	F	F	F	F	F	
Default	none	none	none	none	none	none	0.0	0

Card 2	1	2	3	4	5	6	7	8
Variable	PID	LEVEL						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
BOXID	Box ID. Define unique numbers.
NODE	A reference node ID from which the tube will form in front of it, following the tool path described by LCX, LCY and LCZ.
LCX, LCY, LCZ	Load curve IDs (see *DEFINE_CURVE) that define the path of the tool in the global X, Y, and Z directions, respectively.

VARIABLE	DESCRIPTION
ITYPE	Type of curves LCX, LCY and LCZ. Currently only time as a function of displacement load curves are supported. EQ.2: LCX, LCY and LCZ are defined as time as a function of displacement.
RADIUS	The radius of the tube that defines the fission/fusion boundary.
NPIECE	Number of segments used to approximate the tool path in one adaptive step. Note that the tool's path is divided into several linear segments for approximation.
PID	The deformable part or part set ID on which the tube adaptivity is to be applied (see *PART). GT.0: Part ID LT.0: |PID| is a part set ID. A part set ID can be useful for simulating the forming of tailor welded blanks.
LEVEL	Desired mesh refinement level. Level set to a value of 1, 2, 3, … allows a maximum of 1, 4, 16, … elements to be created for each original element in the "tube region".

Remarks:

Metal forming simulations for applications similar to incremental forming and roller hemming are computationally intensive, mostly because of long tool paths and localized deformation. Several methods have been developed to increase the efficiency of these applications.

The keyword *DEFINE_BOX_ADAPTIVE was one of those methods. While it offered significant CPU time reduction, the adaptive fission box does not stay in front of the tool when the tool path turns around 180 degrees (see Figure 17-4). Also, the fusion box, which is supposed to stay behind the tool to coarsen the mesh, does not always stay behind the tool. This drawback is addressed by this keyword.

This keyword creates a tube with a user defined radius (RADIUS) that encloses the tool path ahead and moves along with a reference node (NODE) located on the tool. The mesh is refined in the area in front of the tube (look-forward adaptivity). The tube moves with the tool. Formed mesh behind the tube is fused according to user set criterion, thus saving CPU time (see Figure 17-5).

From a parameter study of this keyword [Zhu et. al.]. the following was determined:

- In comparison to a convergence study without this keyword, the simulation time was reduced by 46%.
- The optimum tube radius is 10 times the final element size.
- The optimum ADPFREQ (see *CONTROL_ADAPTIVITY) should be about 1.6% of the total simulation time. Note the ADPFREQ indirectly controls how far the tube with extend in front of the tool.

Example:

To activate this feature, in addition to using this keyword, *CONTROL_ADAPTIVE also needs to be included in the input deck. See Figure 17-5 and the partial input below.

```

***DEFINE_BOX_SPH**_{OPTION}_

Available options include:

<BLANK>

LOCAL

Purpose: Define a box-shaped volume for activating and deactivating SPH particles. To define the box, you specify two diagonally opposite corner points. The corner points are assumed to be in the global coordinate system unless the LOCAL keyword option is active. See *DEFINE_BOX for more details about the LOCAL option. When particles are in the box, the SPH particles are active and LS-DYNA computes the SPH approximation (see FORM in *CONTROL_SPH) for the particles. SPH particles are deactivated as they leave the box but reactivate if they re-enter the box. Unlike a box specified with *DEFINE_BOX, the box may move either with a node or in the direction defined by a vector with a motion determined by a load curve.

> **WARNING:** The box specified for deactivating/activating particles by *CONTROL_SPH (see BOXID) must be a *DEFINE_BOX, not a *DEFINE_BOX_SPH. If BOXID references a *DEFINE_BOX_SPH, LS-DYNA will give an error message.

Card 1	1	2	3	4	5	6	7	8

Type	I	I	I	I	I	I	I	
Default	0	0	0	0	0	0	0	

Local Card 1. First additional card for the LOCAL keyword option. See *DEFINE_BOX for a description of the LOCAL option.

Card 3	1	2	3	4	5	6	7	8
Variable	XX	YX	ZX	XV	YV	ZV		
Type	F	F	F	F	F	F		
Default	0.0	0.0	0.0	0.0	0.0	0.0		

Local Card 2. Second additional card for the LOCAL keyword option.

Card 4	1	2	3	4	5	6	7	8
Variable	CX	CY	CZ					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
BOXID	Box ID. Define unique numbers.
XMN	Minimum x-coordinate. Define in the local coordinate system if the option LOCAL is active.
XMX	Maximum x-coordinate. Define in the local coordinate system if the option LOCAL is active.
YMN	Minimum y-coordinate. Define in the local coordinate system if the option LOCAL is active.
YMX	Maximum y-coordinate. Define in the local coordinate system if the option LOCAL is active.
ZMN	Minimum z-coordinate. Define in the local coordinate system if the option LOCAL is active.
ZMX	Maximum z-coordinate. Define in the local coordinate system if the option LOCAL is active.

VARIABLE	DESCRIPTION
VID	Vector ID to describe direction of box motion when VD = 0 or 1; see *DEFINE_VECTOR.
LCID	Load curve ID to describe value of box motion as a function of time; see *DEFINE_CURVE
VD	Velocity/Displacement flag: EQ.0: Velocity, EQ.1: Displacement, EQ.2: Referential node
NID	Referential nodal ID for VD = 2 (SPH box will move with this node).
IREACT	Reactivation flag: EQ.0: Particles outside of the box are permanently deactivated. EQ.1: Deactivated particles get reactivated when they enter the box.
IBUFF	Buffer zone flag: EQ.0: Particles on the edge of the box do not get any special treatment. EQ.1: Particles on the edge of the box are frozen in space and act as neighbors for active particles inside the box. This option is mainly used for fluid simulations to prevent the fluid from spilling out of the activation box.
ISHOW	Create dummy part for visualizing the position of the activation box during post-processing: EQ.0: No part is created. EQ.1: A dummy part is added for visualization.
PID	Part ID used for visualization if ISHOW = 1: EQ.0: A unique part ID is automatically created. GT.0: PID is the part ID for the created part. This should be a unique part ID.
XX	*X*-coordinate on local *x*-axis. Origin lies at (0,0,0). Define if the LOCAL option is active.

VARIABLE	DESCRIPTION
YX	*Y*-coordinate on local *x*-axis. Define if the LOCAL option is active.
ZX	*Z*-coordinate on local *x*-axis. Define if the LOCAL option is active.
XV	*X*-coordinate of local *xy*-vector. Define if the LOCAL option is active.
YV	*Y*-coordinate of local *xy*-vector. Define if the LOCAL option is active.
ZV	*Z*-coordinate of local *xy*-vector. Define if the LOCAL option is active.
CX	*X*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.
CY	*Y*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.
CZ	*Z*-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active.

DEFINE_CONNECTION_PROPERTIES_*{OPTION}

Available options include:

<BLANK>

ADD

Purpose: Define failure related parameters for solid element spot weld failure by *MAT_-SPOTWELD_DAIMLERCHRYSLER. For each connection identifier, CON_ID, a separate *DEFINE_CONNECTION_PROPERTIES section must be included. The ADD keyword option allows material specific properties to be added to an existing connection ID. See Remark 2.

Card Summary:

Card 1. This card is required.

CON_ID	PRUL	AREAEQ		DGTYP	MOARFL		

Card 2. This card is omitted if the ADD keyword option is used. See Remark 2.

	DSIGY	DETAN	DDGPR	DRANK	DSN	DSB	DSS

Card 3. This card is omitted if the ADD keyword option is used. See Remark 2.

DEXSN	DEXSB	DEXSS	DLCSN	DLCSB	DLCSS	DGFAD	DSCLMRR

Card 4. This card is included if he ADD keyword option is used. For each shell material with material specific data, define for this CON_ID Cards 4 and 5. Add as many pairs of these cards as necessary. This input is terminated by the next keyword ("*") card. See Remark 2.

MID	SGIY	ETAN	DGPR	RANK	SN	SB	SS

Card 5. This card is included if the ADD keyword option is used. For each shell material with material specific data, define for this CON_ID Cards 4 and 5. Add as many pairs of these cards as necessary. This input is terminated by the next keyword ("*") card. See Remark 2.

EXSN	EXSB	EXSS	LCSN	LCSB	LCSS	GFAD	SCLMRR

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	CON_ID	PRUL	AREAEQ		DGTYP	MOARFL		
Type	F	I	I		I	I		
Default	0	0	0		0	0		

VARIABLE	DESCRIPTION
CON_ID	Connection ID, referenced on *MAT_SPOTWELD_DAIMLER-CHRYSLER. Multiple sets of connection data may be used by assigning different connection IDs.
PRUL	The failure rule number for this connection: EQ.1: Use data of weld partner with lower RANK (default). GE.2: Use *DEFINE_FUNCTION expressions to determine weld data depending on several values of both weld partners. Variables DSIGY, DETAN, DDGPR, DSN, DSB, DSS, DEXSN, DEXSB, DEXSS, and DGFAD must be defined as function IDs, see Remark 5.
AREAEQ	Area equation number for the connection area calculation: EQ.0: (default) $Area_{true} = Area_{modelled}$ EQ.1: Millimeter form; see Remark 4 EQ.-1: Meter form; see Remark 4
DGTYP	Damage type: EQ.0: No damage function is used. EQ.1: Strain based damage EQ.2: Failure function based damage EQ.3 or 4: Fading energy based damage (see Remark 4) EQ.5: Improved version of DGTYP = 4 (see Remark 4)
MOARFL	Modeled area flag: EQ.0: $Area_{modelled}$ goes down with shear (default).

VARIABLE	DESCRIPTION
	EQ.1: $Area_{modelled}$ stays constant.

Card 2	1	2	3	4	5	6	7	8
Variable		DSIGY	DETAN	DDGPR	DRANK	DSN	DSB	DSS
Type		F	F	F	F	F	F	F
Default		none	none	10^{10}	none	none	none	none

VARIABLE	DESCRIPTION
DSIGY	Default yield stress for the spot weld element: GT.0: Constant value LT.0: |DSIGY| references a yield curve or table; see Remark 6.
DETAN	Default tangent modulus for the spot weld element
DDGPR	Default damage parameter for hyperbolic based damage function
DRANK	Default rank value
DSN	Default normal strength
DSB	Default bending strength
DSS	Default shear strength

Card 3	1	2	3	4	5	6	7	8
Variable	DEXSN	DEXSB	DEXSS	DLCSN	DLCSB	DLCSS	DGFAD	DSCLMRR
Type	F	F	F	I	I	I	F	F
Default	1.0	1.0	1.0	0	0	0	none	1.0

VARIABLE	DESCRIPTION
DEXSN	Default exponent on normal stress term
DEXSB	Default exponent on bending stress term
DEXSS	Default exponent on shear stress term
DLCSN	Default curve ID for normal strength scale factor as a function of strain rate. If the first strain rate value in the curve is negative, it is assumed that all strain rate values are given as a natural logarithm of the strain rate.
DLCSB	Default curve ID for bending strength scale factor as a function of strain rate. If the first strain rate value in the curve is negative, it is assumed that all strain rate values are given as a natural logarithm of the strain rate.
DLCSS	Default curve ID for shear strength scale factor as a function of strain rate. If the first strain rate value in the curve is negative, it is assumed that all strain rate values are given as a natural logarithm of the strain rate.
DGFAD	Default fading energy for damage type 3 and type 4
DSCLMRR	Default scaling factor for torsional moment in failure function

Material Data Card 1.

Card 4	1	2	3	4	5	6	7	8
Variable	MID	SGIY	ETAN	DGPR	RANK	SN	SB	SS
Type	F	F	F	F	F	F	F	F
Default	none	none	none	10^{10}	none	none	none	none

VARIABLE	DESCRIPTION
MID	Material ID of the shell material for which properties are defined
SIGY	Yield stress to be used in the spot weld element calculation: GT.0: Constant value LT.0: |SIGY| references a yield curve or table; see Remark 6.

VARIABLE	DESCRIPTION
ETAN	Tangent modulus to be used in the spot weld element calculation
DGPR	Damage parameter for hyperbolic based damage function
RANK	Rank value. See Remark 4.
SN	Normal strength
SB	Bending strength
SS	Shear strength

Material Data Card 2.

Card 5	1	2	3	4	5	6	7	8
Variable	EXSN	EXSB	EXSS	LCSN	LCSB	LCSS	GFAD	SCLMRR
Type	F	F	F	I	I	I	F	F
Default	none	none	none	none	none	none	none	1.0

VARIABLE	DESCRIPTION
EXSN	Exponent on normal stress term
EXSB	Exponent on bending stress term
EXSS	Exponent on shear stress term
LCSN	Curve ID for normal strength scale factor as a function of strain rate. If the first strain rate value in the curve is negative, it is assumed that all strain rate values are given as a natural logarithm of the strain rate.
LCSB	Curve ID for bending strength scale factor as a function of strain rate. If the first strain rate value in the curve is negative, it is assumed that all strain rate values are given as a natural logarithm of the strain rate.

VARIABLE	DESCRIPTION
LCSS	Curve ID for shear strength scale factor as a function of strain rate. If the first strain rate value in the curve is negative, it is assumed that all strain rate values are given as a natural logarithm of the strain rate.
GFAD	Fading energy for damage type 3 and 4
SCLMRR	Scaling factor for torsional moment in failure function

Remarks:

1. **Restriction to *MAT_SPOTWELD_DAIMLERCHHRYSLER.** This keyword is used only with *MAT_SPOTWELD_DAIMLERCHRYSLER. The data input is used in a 3 parameter failure model. Each solid spot weld element connects shell elements that may have the same or different materials. The failure model assumes that failure of the spot weld depends on the properties of the welded materials, so this keyword allows shell material specific data to be input for the connection. The default data will be used for any spot weld connected to a shell material that does not have material specific data defined, so it is not necessary to define material specific data for all welded shell materials.

2. **ADD Option.** To simplify data input, the ADD keyword option allows material specific data to be added to an existing *DEFINE_CONNECTION_PROPERTIES table. To use the ADD option, omit Cards 2 and 3, and input only CON_ID on Card 1. Then use Cards 4 and 5 to input material specific data. For each unique CON_ID, control parameters and default values must be input in one set of *DEFINE_CONNECTION_PROPERTIES data. The same CON_ID may be used for any number of sets of material specific data input with the ADD option.

3. **The Three Parameter Failure Function.** The three parameter failure function is

$$f = \left(\frac{\sigma_n}{\sigma_n^F}\right)^{m_n} + \left(\frac{\sigma_b}{\sigma_b^F}\right)^{m_b} + \left(\frac{\tau}{\tau^F}\right)^{m_\tau} - 1 \ ,$$

where the three strength terms are SN, SB, and SS, and the three exponents are EXSN, EXSB, and EXSS. The strengths may be a function of strain rate by using the load curves, LCSN, LCSB, and LCSS. The peak stresses in the numerators are calculated from force resultants and simple beam theory.

$$\sigma_n = \frac{N_{rr}}{A}, \qquad \sigma_b = \frac{\sqrt{M_{rs}^2 + M_{rt}^2}}{Z}, \qquad \tau = \text{SCLMRR} \times \frac{M_{rr}}{2Z} + \frac{\sqrt{N_{rs}^2 + N_{rt}^2}}{A} \ ,$$

where the area is the cross section area of the weld element and Z is given by:

$$Z = \pi \frac{d^3}{32} ,$$

where d is the equivalent diameter of the solid spot weld element assuming a circular cross section.

4. **Control Parameters PRUL, AREAQ. And DGTYP.** There are three control parameters that define how the table data will be used for the connection, PRUL, AREAEQ, and DGTYP.

   a) *PRUL.* PRUL determines how the parameters will be used. Because each weld connects two shell surfaces, one weld can have two sets of failure data as well as two values for ETAN and SIGY. For PRUL = 1 (default), a simple rule is implemented and the data with the lower RANK will be used. For PRUL = 2 or 3, function expressions can be used to determine the data based on several input values from both weld partners (see Remark 5 for details).

   b) *AREAEQ.* The second control parameter is AREAEQ which specifies a rule for calculating a true weld cross section area, A_{true} to be used in the failure function in place of the modeled solid element area, A. For AREAEQ = 1, A_{true} is calculated by

$$A_{\text{true}} = \frac{\pi}{4}\left(5\sqrt{t_{\text{min shell}}}\right)^2 ,$$

   where $t_{\text{min shell}}$ is the thickness of the welded shell surface that has the smaller thickness. For AREAEQ = −1, A_{true} is calculated by

$$A_{\text{true}} = \frac{\pi}{4}\left(\frac{5}{1000}\sqrt{1000 \times t_{\text{min shell}}}\right)^2 ,$$

   The equation for AREAEQ = 1 is valid only for a length unit of millimeters, and AREAEQ = −1 is valid only for a length unit of meters.

   c) *DGTYP.* The third control parameter, DGTYP, chooses from two available damage types. For DGTYP = 0, damage is turned off and the weld fails immediately when $f \geq 0$. For DGTYP > 0, damage is initiated when $f \geq 0$ and complete failure occurs when $\omega \geq 1$. For DGTYP = 1, damage growth is a function of plastic strain:

$$\omega = \frac{\varepsilon^p_{\text{eff}} - \varepsilon^p_{\text{failure}}}{\varepsilon^p_{\text{rupture}} - \varepsilon^p_{\text{failure}}}, \qquad \varepsilon^p_{\text{failure}} \leq \varepsilon^p_{\text{eff}} \leq \varepsilon^p_{\text{rupture}} ,$$

   where $\varepsilon^p_{\text{eff}}$ is the effective plastic strain in the weld material. When the value of the failure function first exceeds zero, the plastic strain at failure, $\varepsilon^p_{\text{failure}}$, is set to the current plastic strain, and the rupture strain is offset from the plastic strain at failure by

$$\varepsilon^p_{\text{rupture}} = \varepsilon^p_{\text{failure}} + \text{RS} - \text{EFAIL} \ ,$$

where RS and EFAIL are the rupture strain and plastic strain at failure which are input on the *MAT_SPOTWELD_DAIMLERCHRYSLER card. If failure occurs when the plastic strain is zero, the weld material yield stress is reduced to the current effective stress such that damage can progress.

For DGTYP = 2, damage is a function of the failure function, f:

$$f \geq 0 \Rightarrow \omega = \frac{f}{f_{\text{rupture}}} \ ,$$

where f_{rupture} is the value of the failure function at rupture which is defined by

$$f_{\text{rupture}} = \text{RS} - \text{EFAIL} \ ,$$

and RS and EFAIL are input on the *MAT_SPOTWELD_DAIMLERCHRYSLER card.

Because the DGTYP = 1 damage function is scaled by plastic strain, it will monotonically increase in time. The DGTYP = 2 damage function is forced to be a monotonically increasing function in time by using the maximum of the current value and the maximum previous value. For both DGTYP = 1 and DGTYP = 2, the stress scale factor is then calculated by

$$\hat{\sigma} = \frac{\text{DGPR} \times (1 - \omega)}{\omega \left(\frac{1}{2} + \sqrt{\frac{1}{4} + \text{DGPR}} \right) + \text{DGPR}} \sigma \ ,$$

This equation becomes nearly linear at the default value of DGPR which is 10^{10}.

For DGTYP = 3, damage is a function of total strain:

$$\omega = \frac{\Delta\varepsilon_n}{\Delta\varepsilon_{\text{fading}}} \ .$$

$\Delta\varepsilon_n$ is the accumulated total strain increment between moment of damage initiation (failure) and current time step t_n

$$\Delta\varepsilon_n = \Delta\varepsilon_{n-1} + \Delta t_n \sqrt{\frac{2}{3} \ \text{tr}(\dot{\boldsymbol{\varepsilon}}_n \dot{\boldsymbol{\varepsilon}}_n^T)} \ , \qquad \Delta\varepsilon|_{t_{\text{failure}}} = 0 \ ,$$

and $\Delta\varepsilon_{\text{fading}}$ is the total strain increment for fading (reduction of stresses to zero)

$$\Delta\varepsilon_{\text{fading}} = \frac{2 \times \text{GFAD}}{\sigma_{\text{failure}}} \ ,$$

where GFAD is the fading energy from input and σ_{failure} is the effective stress at failure. The stress scale factor is then calculated by a linear equation

$$\hat{\sigma} = (1 - \omega)\sigma \ ,$$

where σ is the Cauchy stress tensor at failure and ω is the actual damage value. Problems can occur, if the loading direction changes after the onset of failure, since during the damage process, the components of the stress tensor are kept constant and hence represent the stress state at failure.

DGTYP = 4 should be used when describing the damage behavior of the spotweld in a more realistic way. For DGTYP = 4, damage is a function of the internal work done by the spotweld after failure,

$$\hat{\sigma} = (1 - \omega)\sigma^{\text{ep}}, \quad \omega = \frac{G_{\text{used}}}{2 \times \text{GFAD}}, \quad G_{\text{used}} = G_{\text{used}}^{n-1} + \det\left(F_{ij}\sigma_{ij}^{\text{ep}}\Delta\varepsilon_{ij}\right) \ .$$

In the above, F_{ij} is the deformation gradient. σ^{ep} is a scaled Cauchy stress tensor based on the undamaged Cauchy stress tensor σ^{wd} and scaled in such a way that the same internal work is done in the current time step as in the time step before (equipotential):

$$\sigma^{\text{ep}} = \alpha\sigma^{\text{wd}}, \quad \alpha = \frac{\sigma_{ij}^{n-1,\text{ep}}\Delta\varepsilon_{ij}}{\sigma_{ij}^{\text{wd}}\Delta\varepsilon_{ij}} \ .$$

DGTYP = 4 has two serious disadvantages that may result in unstable behavior after failure:

i) If the spot weld is unloaded during damage, the undamaged Cauchy stress tensor tends to zero and therefore α to infinity.

ii) The factor α is a very instable variable because it depends directly on the total strain increment.

DGTYP = 5 was developed to overcome these disadvantages. In contrast to DGTYP = 4, the undamaged Cauchy stress tensor is only calculated with an elastoplastic material model (not scaled by α). This limitation of the stress tensor makes it more stable during damage. At failure the yield stress is set to the current von Mises stress, and the plastic modulus is set to zero. Calculating the current damage value is the same as for DGTYP = 4. Note that, to achieve realistic behavior for the axial loading situation, you should use the UNIAXIAL keyword option of *MAT_SPOTWELD_DAIMLER. Additionally, with this material model, the spotweld can be deleted based on the current plastic strain with the input field RS.

5. **Failure Rule from *DEFINE_FUNCTION.** The failure rule number PRUL = 2 or 3, is available starting with Release R7. To use this new option, 11 fields must be defined as function IDs: DSIGY, DETAN, DDGPR, DSN, DSB, DSS, DEXSN, DEXSB, DEXSS, DGFAD, and DSCLMRR.

   These functions depend on:

   (t1, t2) = thicknesses of both weld partners
   (sy1, sy2) = initial yield stresses at plastic strain
   (sm1, sm2) = maximum engineering yield stresses
   r = strain rate
   a = spot weld area
   fn = normal term in failure function
   fb = bending term in failure function
   fs = shear term in failure function

   For DSIGY = 100, such a function could look like:

```
*DEFINE_FUNCTION
             100
func(t1,t2,sy1,sy2,sm1,sm2,r,a,fn,fb,fs)=0.5*(sy1+sy2)
```

   All the listed arguments in their correct order must be included in the argument list. For PRUL = 2, the thinner part is the first weld partner. For PRUL = 3, the bottom part (nodes 1-2-3-4) is the first weld partner. Since material parameters must be identified from both weld partners during initialization, this feature is only available for a subset of material models at the moment, namely material types 24, 36, 120, 123, 124, 251, and 258. This new option eliminates the need for the ADD option.

6. **Yield Curve or Table for SIGY.** When using this option, a simplified plasticity algorithm is used, assuming a linear behavior within one time increment. Thus, no iterative return mapping has to be performed.

*DEFINE_CONSTRUCTION_STAGES

Purpose: Define times and durations of construction stages.

Card	1	2	3	4	5	6	7	8
Variable	ISTAGE	ATS	ATE	ATR	RTS	RTE	blank	IDYNAIN
Type	I	F	F	F	F	F		I
Default	none	0.0	0.0	none	ATS	ATE		0

VARIABLE	DESCRIPTION
ISTAGE	Stage ID
ATS	Analysis time at start of stage
ATE	Analysis time at end of stage
ATR	Analysis time duration of ramp
RTS	Real time at start of stage
RTE	Real time at end of stage
IDYNAIN	Flag to control output of dynain file at the end of the stage (see Remark 5): EQ.0: default to setting of IDYNAIN on *CONTROL_STAGED_CONSTRUCTION EQ.1: do not write dynain file.

Remarks:

1. **Related Keywords.** See also *CONTROL_STAGED_CONSTRUCTION and *DEFINE_STAGED_CONSTRUCTION_PART.

2. **Stage Start and End Times.** The first stage should start at time zero. There must be no gaps between stages, that is, ATS for each stage must be the same as ATE for the previous stage.

3. **Ramp Time.** The ramp time allows gravity loading and part removal to be applied gradually during the first time period ATR of the construction stage.

4. **Analysis and Real Time.** The analysis always runs in "analysis time" – typically measured in seconds. The "real time" is used only as a number to appear on output plots and graphs and is completely arbitrary. See ITIME on *CONTROL_STAGED_CONSTRUCTION.

5. **IDYNAIN.** If IDYNAIN is zero or blank, it will default to the same setting as IDYNAIN on *CONTROL_STAGED_CONSTRUCTION. The default of *CONTROL_STAGED_CONSTRUCTION is to write a dynain file at the end of each stage. This can be suppressed for individual stages by setting IDYNAIN to 1 on this keyword.

*DEFINE_CONTACT_EXCLUSION

Purpose: Exclude tied nodes from being treated in specific contact interfaces. This keyword is currently only available in the MPP version.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	TITLE						
Type	I	A70						

ID Card 1. This card sets the contact interface IDs of up to 7 tied interfaces.

Card 2	1	2	3	4	5	6	7	8
Variable	TARGET	C1	C2	C3	C4	C5	C6	C7
Type	I	I	I	I	I	I	I	I

Optional ID Cards. More tied interfaces. Include as many cards as necessary. This input ends at the next keyword (*) card.

Card 3	1	2	3	4	5	6	7	8
Variable	C8	C9	C10	C11	C12	C13	C14	C15
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
EID	Exclusion ID
TITLE	Exclusion Title
TARGET	Contact interface from which tied nodes are to be excluded. This must be the ID of a SINGLE_SURFACE, NODE_TO_SURFACE, or SURFACE_TO_SURFACE contact with SOFT ≠ 2.
C*i*	The IDs of TIED contacts: 7 on the first card and 8 per additional card for as many cards as necessary. Any node which is a tracked node in one of these interfaces, and is in fact tied, will not be processed (as a tracked node) in the TARGET interface.

Remarks:

1. **Contact Forces on Excluded Nodes.** If a node is excluded from the Target by this mechanism, contact forces may still be applied to the node due to any tracked or reference nodes impacting the contact segments of which it is a part (no contact SEGMENTS are deleted, only contact NODES).

2. **SURFACE_TO_SURFACE and SINGLE_SURFACE Targets.** If you intend to exclude tied tracked nodes completely from other contacts in the model, this keyword can be used to do so for NODES_TO_SURFACE and ONE_WAY_SURFACE_TO_SURFACE contacts only. For (TWO_WAY) SURFACE_TO_SURFACE and SINGLE_SURFACE contacts, such nodes should be excluded from the contact definitions if so desired.

*DEFINE_CONTACT_VOLUME

Purpose: Define a rectangular, a cylindrical, or a spherical volume in a local coordinate system. The volume can be referenced by *SET_NODE_GENERAL for the purpose of defining a node set consisting of nodes inside the volume, or by *CONTACT_... for the purpose of defining nodes or segments on the SURFA side or the SURFB side of the contact (see SABOXID and SBBOXID on Card 1 of *CONTACT_...).

Card Summary:

Card 1. This card is required.

CVID	CID	TYPE	XC	YC	ZC		

Card 2a. This card is included if and only TYPE = 0.

XMN	XMX	YMN	YMX	ZMN	ZMX		

Card 2b. This card is included if and only if TYPE = 1.

LENGTH	RINNER	ROUTER	D_ANGC				

Card 2c. This card is included if and only if TYPE = 2.

RINNER	ROUTER	D_ANGS					

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	CVID	CID	TYPE	XC	YC	ZC		
Type	I	I	I	F	F	F		
Default	0	0	0	0.	0.	0.		

VARIABLE	DESCRIPTION
CVID	Contact volume ID
CID	Coordinate system ID. Required for rectangular and cylindrical volumes.

VARIABLE	DESCRIPTION
TYPE	Volume type: EQ.0: Rectangle EQ.1: Cylinder EQ.2: Sphere
XC	x-coordinate which defines the origin of coordinate system or the center of the sphere (TYPE= 3) in the global coordinate system.
YC	y-coordinate which defines the origin of coordinate system or the center of the sphere (TYPE = 3) in the global coordinate system.
ZC	z-coordinate which defines the origin of coordinate system or the center of the sphere (TYPE = 3) in the global coordinate system.

Rectangular Prism. Use when TYPE = 0.

Card 2a	1	2	3	4	5	6	7	8
Variable	XMN	XMX	YMN	YMX	ZMN	ZMX		
Type	F	F	F	F	F	F		
Default	0.0	0.0	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
XMN	Minimum x-coordinate in local coordinate system
XMX	Maximum x-coordinate in local coordinate system
YMN	Minimum y-coordinate in local coordinate system
YMX	Maximum y-coordinate in local coordinate system
ZMN	Minimum z-coordinate in local coordinate system
ZMX	Maximum z-coordinate in local coordinate system

Cylinder. Use when TYPE = 1.

Card 2b	1	2	3	4	5	6	7	8
Variable	LENGTH	RINNER	ROUTER	D_ANGC				
Type	F	F	F	F				
Default	0.0	0.0	0.0	0.0				

VARIABLE	DESCRIPTION
LENGTH	Length of cylinder originating at (XC,YC,ZC) and revolving around the local *x*-axis.
RINNER	Inner radius of cylinder
ROUTER	Outer radius of cylinder
D_ANGC	If the included angle between the axis of the cylinder and the normal vector to the contact segment is *less* than this angle, the segment is deleted.

Sphere. Use when TYPE = 2.

Card 2c	1	2	3	4	5	6	7	8
Variable	RINNER	ROUTER	D_ANGS					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
RINNER	Inner radius of sphere
ROUTER	Outer radius of sphere
D_ANGS	If the included angle between a line draw from the center of the sphere to the centroid of the segment and the normal vector to the contact segment is *greater* than this angle, the segment is deleted.

*DEFINE_CONTROL_VOLUME

Purpose: Specify an incompressible control volume. This control volume only works with the implicit solver.

Card 1	1	2	3	4	5	6	7	8
Variable	CVID	SSID						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
CVID	Control volume ID
SSID	Segment set ID giving the control volume geometry

Remarks:

1. **Volume.** The normal vectors of the segments need to point toward the interior of the control volume for the volume of the control volume to be calculated correctly.

2. **Initial Pressure.** The initial pressure of the control volume is zero.

3. **Output.** Fluid cavity data, such as time history of the volume and pressure, is output to the LSDA binout file.

*DEFINE_CONTROL_VOLUME_FLOW_AREA

Purpose: Specify the flow area between two interacting control volumes (see *DEFINE_-CONTROL_VOLUME).

Card 1	1	2	3	4	5	6	7	8
Variable	FAID	FASID	FASTYP	FCIID				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
FAID	Flow area ID
FASID	Set ID giving the flow area
FASTYP	Type of set specifying flow area (see Remark 2): EQ.1: Node set giving the perimeter of the area. The flow area will be automatically meshed. EQ.2: Segment set covering the flow area
FCIID	Fluid cavity interaction ID referencing the *DEFINE_CONTROL_-VOLUME_INTERACTION for which this area is used

Remarks:

1. **Volume Calculation of the Control Volumes.** The flow area segments are added to both control volumes automatically to close them for the volume calculation.

2. **Specifying Flow Area.** The flow area can be defined with either a segment set or a node set. For the segment set, the nodes forming the segments must be on the boundary of the flow area. Nodes placed inside the flow area will not move as the control volume deforms which may lead to poor accuracy in the flow area calculation. See Remark 4.

   When defining the area with a node set, you must order the nodes giving the perimeter such that the normal of the area points inward toward the first control volume listed in the interaction and, thus, outward from the second. The

numbering, therefore, proceeds clockwise around a hole in the first control volume when viewed from the outside.

3. **Forces in Flow Area.** No force is exerted by the segments or the null shells defining the flow areas on the control volumes.

4. **Calculation of the Flow Area.** The flow area is calculated as the surface area of the segments defining it, and not as a projected area in the direction of some mean normal direction. For example, if the flow area is meshed about a node in the center for the flow area and the perimeter nodes translate relative to the motionless center node, the resulting mesh will define a cone. The flow area will be the surface area of the cone and not the circular cross section area.

*DEFINE_CONTROL_VOLUME_INTERACTION

Purpose: Specify the interaction between two control volumes (see *DEFINE_CONTROL_VOLUME).

Card 1	1	2	3	4	5	6	7	8
Variable	FCIID	CVID1	CVID2	LCID	AREA			
Type	I	I	I	I	F			
Default	none	none	none	none	optional			

VARIABLE	DESCRIPTION
FCIID	Fluid cavity interaction ID
CVID1	First control volume ID (see *DEFINE_CONTROL_VOLUME)
CVID2	Second control volume ID (see *DEFINE_CONTROL_VOLUME)
LCID	Load curve ID for a *DEFINE_CURVE_FUNCTION or user subroutine specifying the pressure gradient driven interaction between the connected cavities (see Remarks 1 and 2): GT.0: ID for *DEFINE_CURVE_FUNCTION. The input arguments for the function are time, pressure difference, the area between the control volumes, the current time step size, and a flag for the start of a new time step. Currently, LS-DYNA will pass the current time and cavity pressures as input arguments. LT.0: User subroutine `usr_icvflow` in dyn21umat.F determines the pressure gradient.
AREA	Constant area for the case when a flow area is not specified with *DEFINE_CONTROL_VOLUME_FLOW_AREA

Remarks:

1. **Function / User Subroutine.** Specifying the load curve as a function with *DEFINE_CURVE_FUNCTION or as a user subroutine provides you with the freedom to define various (nonlinear/time-dependent) lumped parameter models, that is, boundary conditions between the cavities.

2. **Area of Valve Opening.** We assume that the area/size of the valve opening plays no role in the defined interaction for the curve.

*DEFINE_COORDINATE_NODES

Purpose: Define a local coordinate system with three node numbers. The local cartesian coordinate system is defined in the following steps. If the primary direction is along the x-axis, then the z-axis is computed from the cross product of x and $\bar{y}$, $z = x \times \bar{y}$ (see Figure 17-6); the y-axis is, then, computed as $y = z \times x$. A similar procedure applies if the local axis is along the y or z axes.

Card	1	2	3	4	5	6	7	8
Variable	CID	N1	N2	N3	FLAG	DIR		
Type	I	I	I	I	I	A		
Default	none	none	none	none	0	X		

VARIABLE	DESCRIPTION
CID	Coordinate system ID. A unique number has to be defined.
N1	ID of node located at local origin.
N2	ID of node located along local x-axis if DIR = X, the y-axis if DIR = Y, and along the z-axis if DIR = Z.
N3	ID of node located in local x-y plane if DIR = X, the local y-z plane if DIR = Y, and the local z-x plane if DIR = Z.
FLAG	Set to unity, 1, if the local system is to be updated each time step. Generally, this option when used with nodal SPC's is *not recommended* since it can cause excursions in the energy balance because the constraint forces at the node may go through a displacement if the node is partially constrained.
DIR	Axis defined by node N2 moving from the origin node N1. The default direction is the x-axis.

Remarks:

The nodes N1, N2, and N3 must be separated by a reasonable distance and not collinear to avoid numerical inaccuracies.

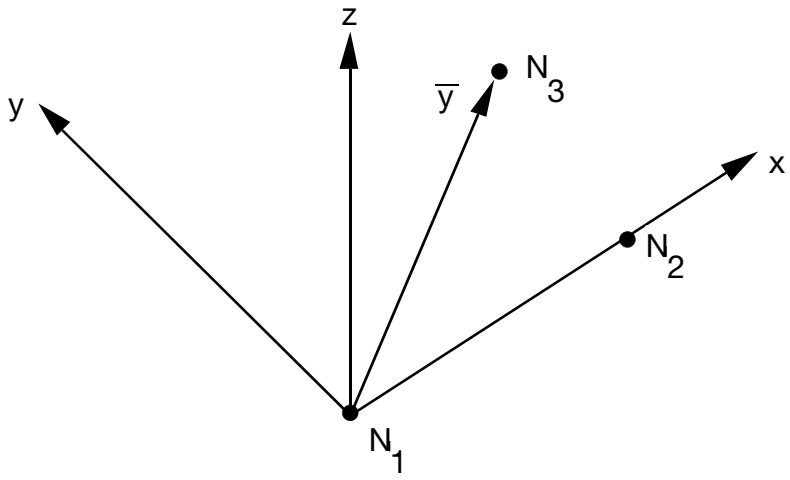

Figure 17-6. Definition of local coordinate system using three nodes when the node N2 lies along the *x*-axis.

*DEFINE_COORDINATE_SYSTEM_{OPTION}

Available options include:

<BLANK>

IGES

Purpose: Define a local coordinate system.

This card implements the same method as *DEFINE_COORDINATE_NODES; but, instead of reading coordinate positions from nodal IDs, it directly reads the three coordinates from its data cards as Cartesian triples.

When the IGES option is active, LS-DYNA will generate the coordinate system from an IGES file containing three straight curves representing the *x*-, *y*-, and *z*-axes. See Remark 4.

Card Summary:

Card 1. This card is included if and only if the keyword option is unset (<BLANK>).

CID	XO	YO	ZO	XL	YL	ZL	CIDL

Card 2. This card is included if and only if the keyword option is unset (<BLANK>).

XP	YP	ZP					

Card 3. This card is included if and only if the IGES keyword option is used.

FILENAME

Data Card Definitions:

Card 1 for <BLANK> Keyword Option.

Card 1	1	2	3	4	5	6	7	8
Variable	CID	XO	YO	ZO	XL	YL	ZL	CIDL
Type	I	F	F	F	F	F	F	I
Default	0	0.0	0.0	0.0	0.0	0.0	0.0	0

VARIABLE	DESCRIPTION
CID	Coordinate system ID. A unique number must be defined.
XO	*X*-coordinate of origin.
YO	*Y*-coordinate of origin.
ZO	*Z*-coordinate of origin.
XL	*X*-coordinate of point on local *x*-axis.
YL	*Y*-coordinate of point on local *x*-axis.
ZL	*Z*-coordinate of point on local *x*-axis.
CIDL	Coordinate system ID applied to the coordinates used to define the current system. The coordinates X0, Y0, Z0, XL, YL, ZL, XP, YP, and ZP are defined with respect to the coordinate system CIDL.

Card 2 for <BLANK> Keyword Option.

Card 2	1	2	3	4	5	6	7	8
Variable	XP	YP	ZP					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
XP	*X*-coordinate of point in local *xy*-plane.
YP	*Y*-coordinate of point in local *xy*-plane.
ZP	*Z*-coordinate of point in local *xy*-plane.

Card 1 for IGES Keyword Option.

Card 3	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	Name of the IGES file containing three curves (see Remark 4 below).

Remarks:

1. **Avoiding Numerical Inaccuracies.** The coordinates of the points must be separated by a reasonable distance and not co-linear to avoid numerical inaccuracies.

2. **Chains of Coordinate Transformations.** Care must be taken to avoid chains of coordinate transformations because there is no guarantee that they will be executed in the correct order.

3. **LS-PrePost.** A coordinate system can be created using the dialog box located at *Model* (main window) → *CreEnt* → *Define* (see the left pane) → *Coordinate*. This will activate a *Define Coordinate* dialog in the right pane. Select the *Cre* radio button at the top of the right pane and set the *type* dropdown to **SYSTEM*. The next set of radio buttons (below the title input box) sets the method used to define the coordinate system. See Figure 17-7.

   a) The *N+Xaxis* method generates a coordinate system from based on:

      i) a user specified origin,

      ii) one of the three global axes (this is a *severe* restriction), and

      iii) a 3rd point.

   The 3rd point, together with the specified global axis defines the new system's *xy*-plane. The remaining axes are derived using orthogonality and right-handedness. This method requires the user to pick two points which

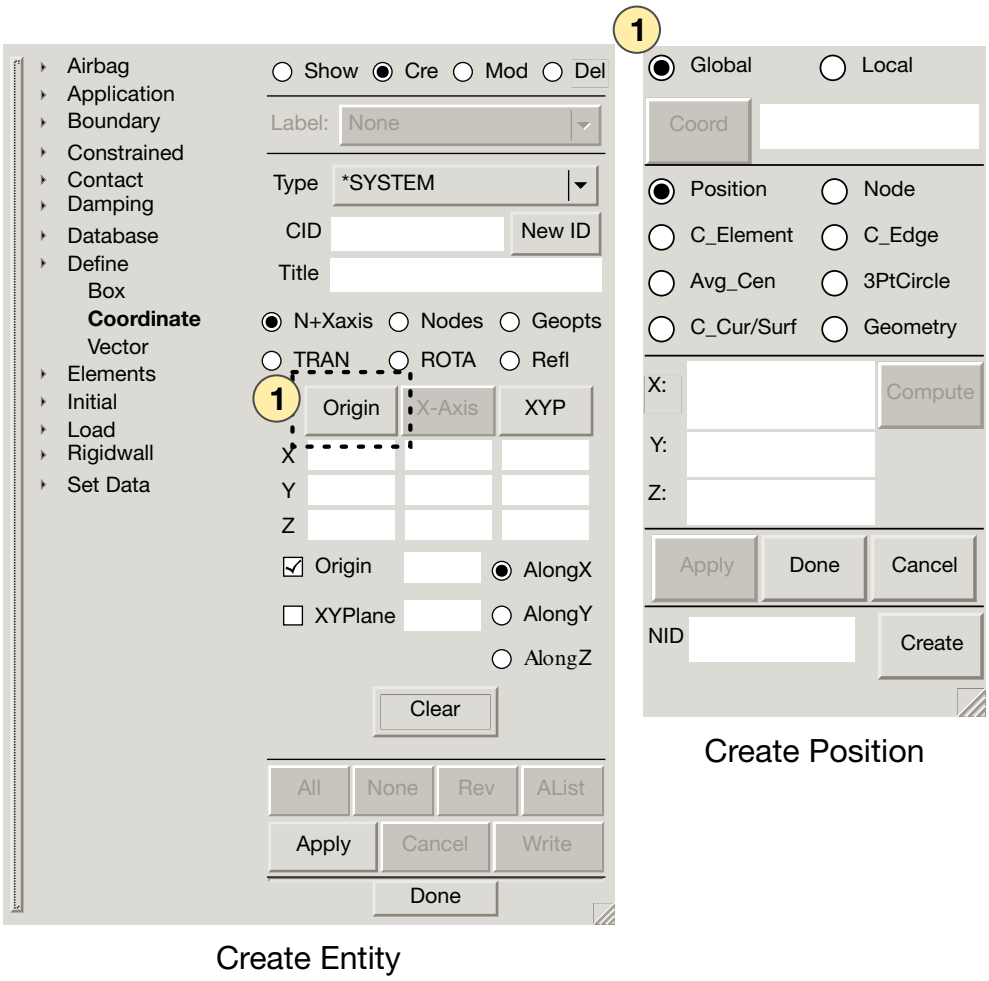

Figure 17-7. *LS-PrePost4.0* Dialog for defining a coordinate system.

involves the *Create Position* dialog box, as shown in the left frame of Figure 17-7.

NOTE: After defining each point in the *Create Position* dialog, it is *very important* to use the *done* button. The *Create Entity* dialog stays up and remains interactive while the *Create Position* dialog is also up and interactive. This can be confusing. Returning to the *Create Entity* dialog without choosing *done* is a common mistake.

b) The *node* method generates a coordinate system from three points:

i) The first point specifies the origin.

ii) The first and second points together specify the x-axis.

iii) The three points together specify the xy-plane of the new coordinate system. The y- and z-axis are derived from orthogonality and right-handedness.

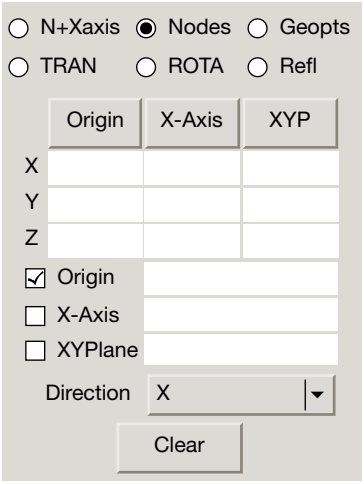

Figure 17-8. Subset of *Create Entity* dialog for both *Nodes* and *Geopts* methods.

c) The *Geopts* option generates the new coordinate system from a global axis and two points. With this method the new system's *z*-axis is set from the *Direction* drop-down. This new system's *xy*-plane is, then, orthogonal to the chosen direction. The remaining two points serve to define the origin and the *x*-axis (by projecting the second point). This option is useful for metal forming application, since, often times, only the *z*-axis is important while the while the *x*- and *y*-axes are not.

4. **IGES.** When option, IGES, is used, three curves in the IGES format will be used to define a local coordinate system. IGES curve entity types 126, 110 and 106 are currently supported. Among the three curves, the longest length will be made as local *Z*-axis, the mid-length will be *Y*-axis and the shortest length *X*-axis. Suggested *X*-, *Y*- and *Z*-axis lengths are 100 mm, 200 mm and 300 mm, respectively.

   All three curves must have one identical point and will be used for the origin of the new local coordinate system. The coordinate system ID for the local system will be based on the IGES file name. The IGES file name must start with a number, followed by an underscore "_", or by a dot. The number preceding the file name will be used as the new local coordinate system ID, which can then be referenced in *MAT_20 cards, for example.

   After the LS-DYNA run, three beam elements of a new PID will be created in place of the three curves representing the local *X*-, *Y*-, and *Z*-axes in the d3plot file for viewing in LS-PrePost. See Figure 17-9.

   The following partial input contains an example in which the keyword is used to create a local coordinate system (CID = 25) from IGES input. The IGES file named, 25_iges, contains three intersecting curves in one of the three supported IGES entity types. The example demonstrates using the IGES coordinate system (ID = 25) to specify the local coordinate system for a rigid body (PID = 2,

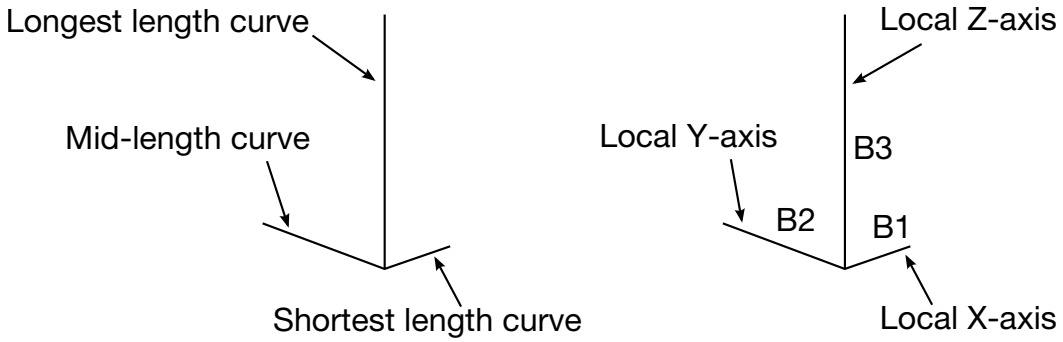

Figure 17-9. Input curves (left). The generated local coordinate system is written to the d3plot file as a part consisting of three beams (right).

MID = 2). The keyword, *BOUNDARY_PRESCRIBED_MOTION_RIGID_LOCAL, then uses this local coordinate system to assign velocities from load curves 3 and 5 for the rigid body motion in the local *x*-direction.

```

The keyword can be repeated for each new coordinate system if multiple coordinate systems are needed.

Revision information:

This option is available starting in LS-DYNA Revision 62798.

*DEFINE_COORDINATE_VECTOR

Purpose: Define a local coordinate system with two vectors, see Figure 17-10. The vector cross product, $\mathbf{z} = \mathbf{x} \times \mathbf{v}_{xy}$ where $\mathbf{v}_{xy}$ is a vector in the xy-plane, determines the z-axis. The y-axis is then given by $\mathbf{y} = \mathbf{z} \times \mathbf{x}$. If this coordinate system is assigned to a nodal point, then at each time step during the calculation, the coordinate system is incrementally rotated using the angular velocity of the nodal point to which it is assigned.

Card	1	2	3	4	5	6	7	8
Variable	CID	XX	YX	ZX	XV	YV	ZV	NID
Type	I	F	F	F	F	F	F	I
Default	0	0.0	0.0	0.0	0.0	0.0	0.0	0.

VARIABLE	DESCRIPTION
CID	Coordinate system ID. A unique number has to be defined.
XX	X-coordinate on local x-axis. Origin lies at $(0,0,0)$.
YX	Y-coordinate on local x-axis
ZX	Z-coordinate on local x-axis
XV	X-coordinate of local xy-vector
YV	Y-coordinate of local xy-vector
ZV	Z-coordinate of local xy-vector
NID	Optional nodal point ID. The coordinate system rotates with the rotation of this node. If the node is not defined, the coordinate system is stationary. See Remark 2.

Remarks:

1. **Numerical Inaccuracies.** These vectors should be separated by a reasonable included angle to avoid numerical inaccuracies.

2. **Rotation.** Ideally, this nodal point should be attached to a rigid body or a structural part where the nodal point angular velocities are meaningful. It should be

noted that angular velocities of nodes may not be meaningful if the nodal point is attached only to solid elements and even to shell elements where the drilling degree of freedom may be singular, which is likely in flat geometries.

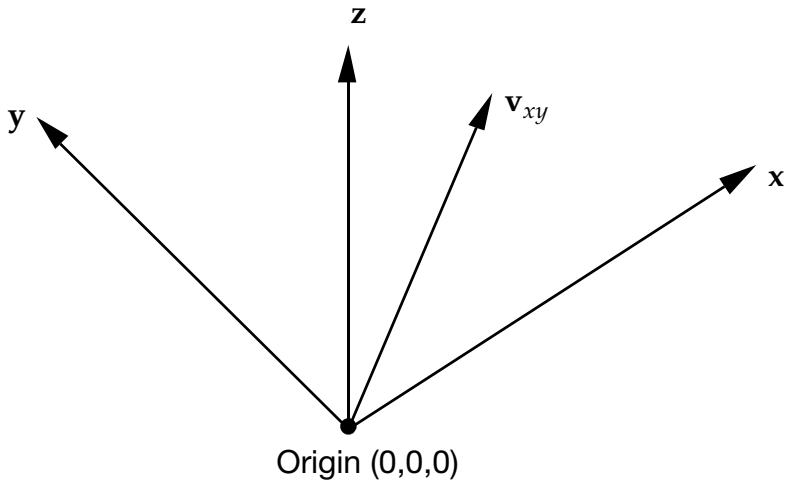

Figure 17-10. Definition of the coordinate system with two vectors.

*DEFINE_CPM_BAG_INTERACTION

Purpose: To model energy flow from a one airbag (the source) to another airbag (the sink). The source must be an active particle airbag and the sink a control volume (CV) airbag converted from a particle bag.

To track the flow of energy, LS-DYNA automatically determines which vent parts are common to both airbags. At each time step the energy that is vented through the common vents is subtracted from the source and added to the sink. In turn, the sink bag's pressure provides the downstream pressure value for the source bag's venting equation. While this model accounts for energy flow from source to sink, it ignores flow from sink to source.

If CHAMBER is used for the sink CV bag, see Remark 1.

Card 1	1	2	3	4	5	6	7	8
Variable	BAGID1	BAGID2	NSPEC					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
BAGID1	Airbag ID of source CPM particle bag
BAGID2	Airbag ID of sink CV bag switched from CPM bag
NSPEC	The location of the 1st gas component from the CPM bag to be filled in the CV bag. See Remark 2.

Remarks:

1. **Chambers.** Due to the complexity of the bookkeeping, the sink bag may have several chambers, but only one of the chambers may interact with the source bag. LS-DYNA finds this chamber automatically by looking at the commonly shared parts.

2. **NSPEC.** If NSPEC equals zero, the mass and energy vented out from the CPM bag will be directly fed into the CV bag. In this case the two bags are assumed to have the same gas species.

If the CPM bag and the CV bag contain different gas species initially, the gas species of the CPM bag must be listed after the inflator gas species of the CV bag (see NGAS on *AIRBAG_PARTICLE). The order of the gas components should be the same. NSPEC gives the first location of the CPM gas in the CV gas species list.

*DEFINE_CPM_CHAMBER

Purpose: To define airbag chambers for air particle initialization or chamber inter-action.

> **NOTE:** The part set that specifies the airbag, SID1, for *AIRBAG_-PARTICLE must include the parts that define the chambers, meaning SID1 for this keyword.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	NCHM						
Type	I	I						
Default	none	0						

Chamber Definition Card Sets:

Add NCHM chamber definition card sets. Each chamber definition card set consists of a Chamber Definition Card followed by NINTER Interaction Cards.

Chamber Definition Card.

Card 2	1	2	3	4	5	6	7	8
Variable	SID1	SID2	NINTER	CHM_ID				
Type	I	I	I	I				
Default	none	0	0	0				

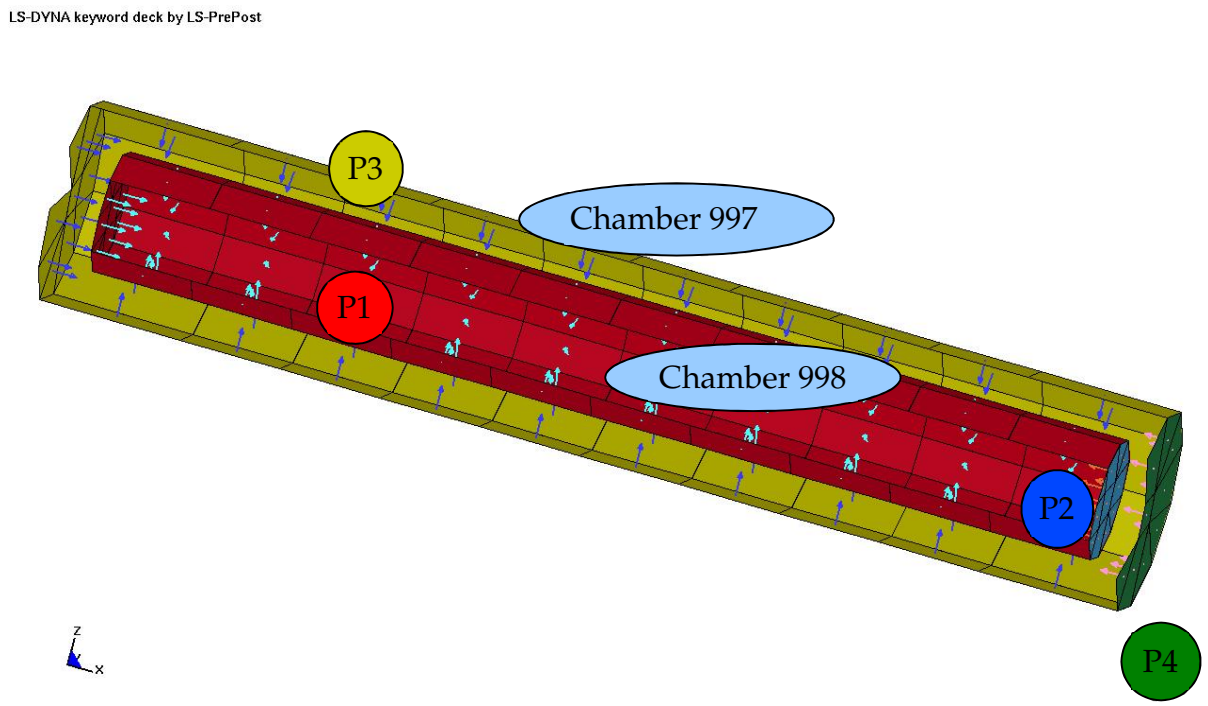

Figure 17-11. Illustration of the example in Remark 1

Interaction Cards. Add NINTER of these. If NINTER = 0, skip this card.

Card 3	1	2	3	4	5	6	7	8
Variable	SID3	ITYPE3	TOCHM					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
ID	Unique ID for this card
NCHM	Number of chambers defined in this card
SID1	Part set defining all parts that constitute the chamber volume. See Remark 1.
SID2	Part set defining the parts whose shell normal vectors need to be flipped, such as separation walls between chambers. See Remark 1.
NINTER	Number of vent hole definition for chamber interaction.

VARIABLE	DESCRIPTION
CHM_ID	Chamber ID (see Remark 2)
SID3	Set defining interaction between chambers
ITYPE3	Set type: EQ.0: Part EQ.1: Part set
TOCHM	Chamber ID of the connected chamber

Remarks:

1. **Normal Vectors.** Each chamber's volume is calculated based on the part normals pointed inwards. So SID1 would normally have parts with their shell normals pointing inwards. But in some cases, parts may be shared by more than one chamber. In this case, the shell orientation of certain part(s) may need to be flipped for the other chambers in question. In such cases, SID2 can be used to flip the shell normals for specific parts. An example of this is given below and illustrated in Figure 17-11.

```
*SET_PART_LIST

        20         0         1       998
$#    sid3    itype3     tochm
         2         0       997
$#    sid1      sid2    ninter    chm_id
         1        20         1       997
$#    sid3    itype3     tochm
         2         0       998
```

2. **Particle Collisions.** Particles with different chamber ID will not interact in particle to particle collision. This feature will allow program to distinguish particles separated by a thin wall.

3. **Output Files.** All chambers data are output to lsda binout database. The utility "l2a" can convert it into abstat_chamber ASCII file and process with LS-PrePost under abstat format.

*DEFINE_CPM_GAS_PROPERTIES

Purpose: Define extended gas thermodynamic properties.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	XMM	CP0	CP1	CP2	CP3	CP4	
Type	I	F	F	F	F	F	F	
Default	none	none	0.	0.	0.	0.	0.	

Card 2	1	2	3	4	5	6	7	8
Variable	MUT0	MUT1	MUT2	MUT3	MUT4	CHM_ID	VINI	
Type	F	F	F	F	F	I	F	
Default	0.	0.	0.	0.	0.	0	0.	

VARIABLE	DESCRIPTION
ID	Unique ID for this card
XMM	Molar mass
CP0, …, CP4	Coefficients of temperature-dependent specific heat with constant pressure $$C_p(T) = C_{p0} + C_{p1}T + C_{p2}T^2 + C_{p3}T^3 + C_{p4}T^4$$
MUT0, …, MUT4	Coefficients of temperature-dependent Joule-Thomson effect $$\mu_t(T) = \mu_{t0} + \mu_{t1}T + \mu_{t2}T^2 + \mu_{t2}T^3 + \mu_{t2}T^4$$
CHM_ID	Chamber ID (see Remark 1)
VINI	Initial volume for user-defined inflator (see Remark 1): EQ.0.0: User-defined inflator disabled GT.0.0: Initial volume

VARIABLE	DESCRIPTION
	LT.0.0: Calculate volume based on chamber geometry

Remarks:

1. **User Defined Routines.** If you define CHM_ID and VINI, the user_inflator routine uses this gas property. We provide this routine in the user-defined subroutine Fortran files of the general usermat package. LS-DYNA gives the current chamber volume, pressure, temperature, and time step to the subroutine and expects a return value of change of chamber, burned gas temperature, and mass flow rate to feedback for releasing particles. LS-DYNA outputs all state data for this chamber to the abstat_chamber section of binout.

Example:

```

This card is optional.

Card 2	1	2	3	4	5	6	7	8
Variable	HCINT							
Type	F							
Default	optional							

VARIABLE	DESCRIPTION
ID	Unique ID for this card (referred to by HCONV on *AIRBAG_PARTICLE)
HCONV	Convective heat transfer coefficient used to calculate heat loss from the airbag external surface to the ambient. See *AIRBAG_HYBRID developments (Resp. P.O. Marklund). LT.0: |HCONV| is a load curve ID defining the heat convection coefficient as a function of time.
PFRIC	Friction factor, F_r, if -1.0 < PFRIC ≤ 1.0. Defaults to FRIC from Card 1 on *AIRBAG_PARTICLE if undefined. Otherwise, LE.-1.0: |PFRIC| is the curve ID which defines F_r as a function of the part pressure. GT.1.0: PFRIC is the *DEFINE_FUNCTION ID that defines F_r.

VARIABLE	DESCRIPTION
SDFBLK	Scaling down factor for blockage factor (default = 1.0, no scaling down). The valid factor will be (0.0,1.0]. If 0.0, it will set to 1.0.
KP	Thermal conductivity of the part
INIP	Place initial air particles on surface: EQ.0: yes (default) EQ.1: no This feature excludes surfaces from initial particle placement. This option is useful for preventing particles from being trapped between adjacent fabric layers.
CP	Specific heat
PSFDCF	Additional scale factor for force decay constant. See Remark 1.
HCINT	Convective heat transfer coefficient between CPM particles and the part of interest. This feature is intended for analyses that couple the CPM and thermal solvers.

Remarks:

1. **Scale Factor for Force Decay Constant.** The particle impact force is gradually applied to an airbag segment by a special smoothing function with the following form:

$$F_{\text{apply}} = \left[1 - \exp\left(\frac{-dt}{\tau}\right)\right](F_{\text{current}} + F_{\text{stored}}) \ ,$$

where τ is the force decay constant. PSFDCF scales τ:

$$\tau = \tau \times \text{PSFDCF} \ .$$

*DEFINE_CPM_VENT

Purpose: To define extended vent hole options.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	C23	LCTC23	LCPC23	ENH_V	PPOP	C23UP	IOPT

Type	I	I	I	I	I	F	I	I
Default	0	0	0	0	0	0.0	0	0

This card is optional.

Card 4	1	2	3	4	5	6	7	8
Variable	JTND							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
ID	Unique ID for this card
C23	Vent hole coefficient. This is the Wang-Nefske leakage parameter.
LCTC23	Load curve defining vent hole coefficient as a function of time
LCPC23	Load curve defining vent hole coefficient as a function of pressure
ENH_V	Enhance venting option. The default is 0; however, if the Joule-Thomson effect is enabled, this field will be set to 1 automatically. EQ.0: Disable EQ.1: Enable
PPOP	Pressure difference between interior and ambient pressure to open the vent hole. Once the vent is open, it will stay open.
C23UP	Scale factor of C23 while switching from CPM to uniform pressure calculation.
IOPT	Directional venting: EQ.1: In shell normal EQ.2: Against shell normal One-way venting: EQ.10: In shell normal EQ.20: Against shell normal Special vent option: EQ.100: Enable compression seal vent. Vent area is adjusted according to the formula below (see Remark 1).

VARIABLE	DESCRIPTION
	$$A_{\text{vent}} = \max(A_{\text{current}} - A_0, 0)$$
	EQ.200: Enable push-out vent. Particle remains active while going through this external vent within the range of 2 times of its characteristic length, l_{vent}.
	$$l_{\text{vent}} = \sqrt{A_{\text{vent}}}$$
JT	Include the Joule-Thomson effect. When the Joule-Thomson effect is enabled, ENH_V is automatically set to 1 (enable). EQ.0: Disable EQ.1: Use part pressure EQ.2: Use chamber pressure
IDS1	JT's up stream condition part ID/chamber ID
IDS2	JT's downstream condition part ID/chamber ID
IOPT1	Upstream chamber ID for one-way vent hole. This will help the code to determine the probability function.
PID1, PID2	PID1 and PID2 indicate parts for determining the local part pressures that can be used to evaluate the vent probability function. Depending on if a chamber is defined, how the local part pressures are evaluated changes (see *DEFINE_CPM_CHAMBER). PID1 and PID2 are optional if a chamber is defined, otherwise they are required input. When a chamber is defined, specifying PID1 and PID2 causes the vent probability function to be evaluated from the difference of local part pressures between PID1 and PID2. Otherwise, the calculation involves the chamber pressure. This option is usually used for vents near a long sleeve which causes unrealistic venting using chamber pressure alone. When a chamber is not defined, the vent probability function is evaluated from the difference of local part pressures between PID1 and PID2, using the location of the part centers to help determine vent direction. If the part is an external part, the part pressure will be used. If the part is an internal part, the pressure on the shell's positive normal side will be used. If the vent is an external vent, PID1 should be the same as PID2 to avoid input error.

VARIABLE	DESCRIPTION
VANG	Cone angle in degrees. Particle going through this vent will be re-directed based on this angle. This option is only valid for an internal vent. GT.0.0: Cone angle (maximum 270°) EQ.0.0: Disabled (default) EQ.-1.0: Direction follows the vent normal (see Remark 2) EQ.-2.0: Direction follows local coordinates system defined by three nodes (see Remark 2)
LCRED	Time dependent probability curve to control CPM particle through the internal vent with VANG option (see Remark 3).
NID1-NID3	Three nodes define a moving coordinate system for the direction of flow through the vent when VANG = -2.
LCAC23	Load curve defining vent hole coefficient as a function of current vent area
PSETPV	|PSETPV| is a part set ID for internal airbag parts that interact with the push-out vent (IOPT = 200). The sign determines where the ambient pressure is applied: GT.0: Ambient pressure is applied to elements in these parts that are at least a distance of SFPV × CL away from the vent. LT.0: Ambient pressure is applied to elements in these parts that are within a distance of SFPV × CL of the vent. CL is defined as the $\sqrt{\text{element area}}$.
SFPV	Scale factor for element's characteristic length
LPATM	Load curve for ambient pressure of the external vent. This option only works for the CPM mode.
IBLKOFF	Flag for turning off blockage treatment. This flag only applies when IBLOCK is nonzero on *AIRBAG_PARTICLE. EQ.0: Use IBLOCK from *AIRBAG_PARTICLE (default). EQ.1: Turn off blockage treatment.
JTND	Node / node set for applying vent reaction force: GT.0: Node ID

VARIABLE	DESCRIPTION
	LT.0: Node Set ID. The average force is evenly applied among the nodes in the node set.

Remarks:

1. **Compression Seal Vent Model.** In order to evaluate bag state variables correctly, the CPM domain needs to be a closed surface for the volume to be well-defined. If the model contains a flap vent which is free to open and close, this option will correctly maintain the bag's integrity.

2. **VANG < 0.** When VANG < 0, all the particles passing through vent are in a collinear stream following the venting direction with no spread, effectively a zero degree angle. The particles disperse after the vent due to particle collisions.

3. **LCRED.** The application of the VANG option upon a particle passing through the vent at a given time depends on the time dependent probability function, LCRED, if defined. This option can be used to strengthen or weaken the directional vent stream.

Example:

```

***DEFINE_CURVE**_{OPTION}_

Purpose: Define a curve [for example, load (ordinate value) as a function of time (abscissa value)], often loosely referred to as a load curve. The ordinate may represent something other than a load however, as in the case of curves for constitutive models.

For most constitutive models, *DEFINE_CURVE curves are rediscretized internally with equal intervals along the abscissa for fast evaluation. Rediscretization is *not* used when evaluating loading conditions such as pressures, concentrated forces, or displacement boundary conditions (see Remark 1 for more details).

The curve rediscretization algorithm was enhanced for the 2005 release of version 970. In certain cases the new load-curve routines changed the final results enough to disrupt benchmarks. For validated models, such as barriers and occupants, requiring numerical consistency, there are keyword options for reverting to the older algorithms.

Available options include:

<OPTION>

3858

5434a

which correspond to the first releases of version 970 and the 2005 release, respectively.

Since input errors and wrong results are sometimes related to load curve usage, a "*Load curve usage*" table is printed in the d3hsp file after all the input is read. This table should be checked to ensure that each curve ID is referenced by the option for which the curve is intended.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	SIDR	SFA	SFO	OFFA	OFFO	DATTYP	LCINT
Type	A	I	F	F	F	F	I	I
Default	none	0	1.	1.	0.	0.	0	0

Point Cards. Put one pair of points per card (2E20.0). Input is terminated at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	A1		01					
Type	E20.0		E20.0					
Default	0.0		0.0					

VARIABLE	DESCRIPTION
LCID	Load curve identification. A unique number or label not containing "." must be specified. When defined by a number, tables (see *DEFINE_TABLE) and load curves may not share common IDs. If LCID is non-numeric, the LS-DYNA execution line should include "plabel = y" for proper (but unfortunately slower) input processing.
SIDR	Flag controlling use of curve during dynamic relaxation. SIDR set to 1 or 2 will activate a dynamic relaxation phase unless IDRFLG = -999 in *CONTROL_DYNAMIC_RELAXATION. EQ.0: load curve used in normal analysis phase only or for other applications, EQ.1: load curve used in dynamic relaxation phase but not the normal analysis phase, EQ.2: load curve applies to both dynamic relaxation phase and normal analysis phase.
SFA	Scale factor for abscissa value. This is useful for simple modifications. EQ.0.0: default set to 1.0.
SFO	Scale factor for ordinate value (function). This is useful for simple modifications. EQ.0.0: default set to 1.0.
OFFA	Offset for abscissa values, see Remark 2.
OFFO	Offset for ordinate values (function), see Remark 2.

VARIABLE	DESCRIPTION
DATTYP	Data type. This affects how offsets are applied (see Remark 3). EQ.-100: for defining the proxy, α, from experiments for the chemical shrinkage coefficient as a function of temperature (see *MAT_ADD_CHEM_SHRINKAGE for details) EQ.-2: for fabric stress as a function of strain curves (*MAT_FABRIC) as described below. EQ.0: general case for time dependent curves, force as a function displacement curves and stress strain curves EQ.1: for general (x,y) data curves whose abscissa values do not increase monotonically EQ.6: for general (r,s) data (coordinates in a 2D parametric space) whose values do not increase monotonically. Use for definition of trimming polygons for trimmed NURBS (*ELEMENT_SHELL_NURBS_PATCH, NL > 0).
LCINT	The number of discretization points to use for this curve. EQ.0: value of LCINT from *CONTROL_SOLUTION will be used.
A1, A2, …	Abscissa values. See Remark 2.
O1, O2, …	Ordinate (function) values. See Remark 2.

Remarks:

1. ***Warning* Concerning Rediscretization.** For constitutive models, unless noted otherwise in the material description, LS-DYNA internally rediscretizes the curve with uniform spacing to bypass searching during evaluations. The major drawback of this algorithm is that any detail in the curve on a scale finer than the uniform rediscretization grid will be smoothed-out and lost. *It is, therefore, important to avoid placing a single point off at some value approaching infinity.* The lone point at infinity will cause the resolution of the uniform grid to be coarse relative to the other points, causing the rediscretized curve to be, possibly, featureless.

   Therefore, when defining curves for constitutive models, points should generally be spaced as uniformly as possible. Also, since the constitutive model curves are extrapolated, it is important to ensure that extrapolation does not lead

to physically meaningless values, such as a negative flow stress. Conversely, extrapolation can be exploited to control the results of evaluations at points far from the input data.

The number of points in each rediscretized curve is controlled by the parameter LCINT in *CONTROL_SOLUTION. By changing LCINT to a value greater than the default of 100, the rediscretized curves may better resemble the input curves. The data points of the rediscretized curves are written to messag and d3hsp if the parameter IPCURV is set to 1 in *CONTROL_OUTPUT.

2. **Scaling.** The load curve values are scaled after the offsets are applied, that is:

$$\text{Abscissa value} = \text{SFA} \times (\text{Defined value} + \text{OFFA})$$
$$\text{Ordinate value} = \text{SFO} \times (\text{Defined value} + \text{OFFO})$$

3. **DATTYP.** The DATTYP field controls how the curve is processed during the calculation.

   a) For DATTYP = 0 positive offsets may be used when the abscissa represents time, since two additional points are generated automatically at time zero and at time 0.999 × OFFA with the function values set to zero.

   b) If DATTYP = 1, then the offsets do not create these additional points. Negative offsets for the abscissa simply shift the abscissa values without creating additional points.

   c) For material *MAT_FABRIC with FORM = 4, 14, -14, or 24, set DATYP = -2 to define stress as a function of strain curves using engineering stress and strain instead of 2nd Piola-Kirchhoff stress and Green strain.

   d) For adding chemical shrinkage effects with *MAT_ADD_CHEM_SHRINKAGE, setting DATYP = -100 signals to LS-DYNA that the load curve defines the proxy for the chemical shrinkage coefficient as a function of temperature. LS-DYNA then internally converts this proxy to the chemical shrinkage coefficient.

4. **Context Dependent Extrapolation.** Load curves are not extrapolated by LS-DYNA for applied loads such as pressures, concentrated forces, displacement boundary conditions, etc. Function values are set to zero if the time, etc., goes off scale. Therefore, extreme care must be observed when defining load curves. In the constitutive models, extrapolation is employed if the values on the abscissa go off scale.

5. **Restart.** The curve offsets and scale factors are ignored during restarts if the curve is redefined. See *CHANGE_CURVE_DEFINITION in the restart section.

*DEFINE_CURVE_BOX_ADAPTIVITY

Purpose: To define a polygon adaptive box for sheet metal forming. This keyword is applicable to shell elements. This keyword is used with *CONTROL_ADAPTIVE. This keyword is similar to *DEFINE_BOX_ADAPTIVE. It is only available for SMP.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	PID	LEVEL	DIST1				
Type	I	I	I	F				
Default	none	none	none	none				

Point Cards. Include as many as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	X		Y		Z			
Type	F		F		F			
Default	none		none		none			

VARIABLE	DESCRIPTION
ID	Curve ID; must be unique. The curve must be closed: its first and last point *must* coincide. See Examples.
PID	Sheet blank Part ID, as in *PART.
LEVEL	Adaptive refinement levels, similar to the field MAXLVL in *CONTROL_ADAPTIVE. See Remark 1.
DIST1	Depth in the Z-direction that the curve defined with Card 2 will be extruded. Currently this variable must be input as a negative value. The box depth in the Z-direction will be extended in the $-Z$-direction by $Z_{min} - \|DIST1\|$ and in $+Z$-direction by $Z_{max} + \|DIST1\|$, where Z_{min} and Z_{max} are the minimum and maximum Z coordinates in all the (X, Y, Z) data points input with Card 2. See Remark

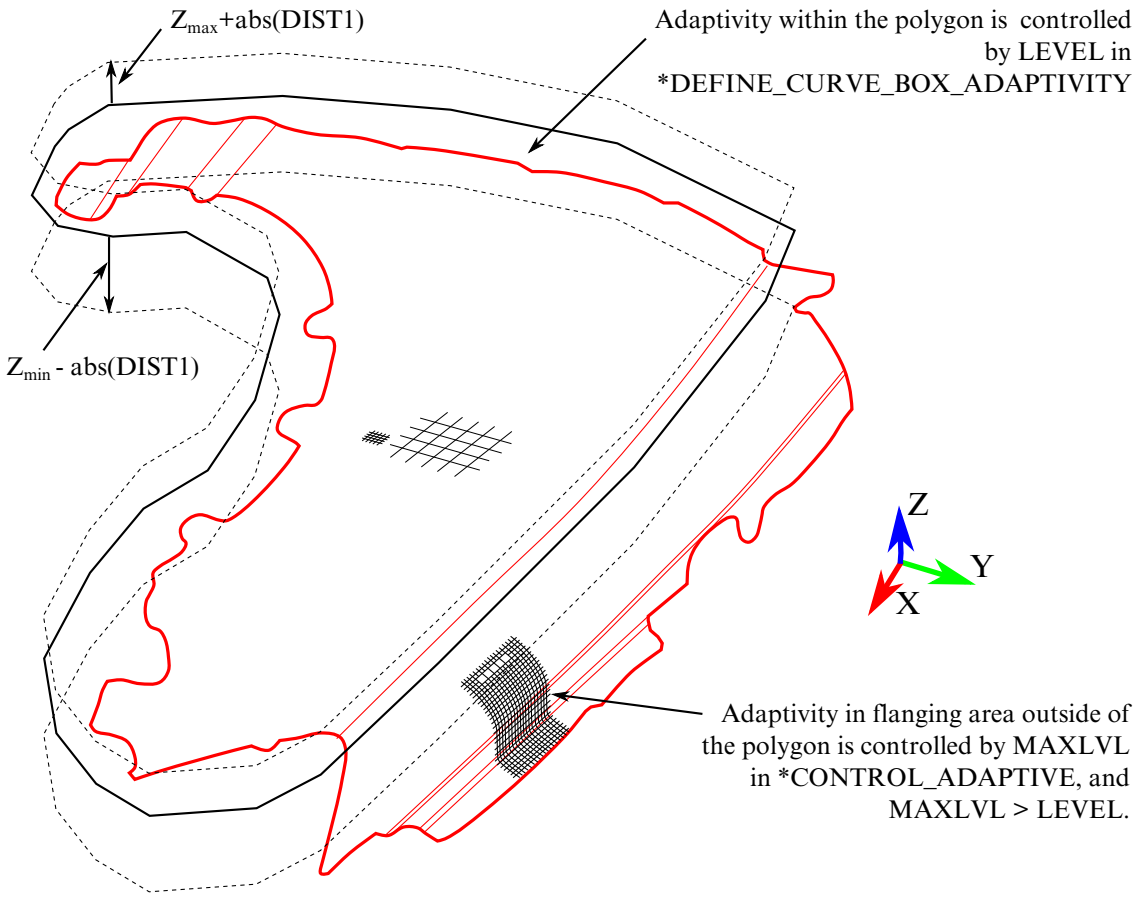

Figure 17-12. Defining an adaptive polygon box

VARIABLE	DESCRIPTION
	3 and Figure 17-12.
X	*X* coordinate of a point on the curve. See Remark 3.
Y	*Y* coordinate of a point on the curve. See Remark 3.
Z	*Z* coordinate of a point on the curve. See Remark 3.

Remarks:

1. **Mesh Refinement Definition.** Within the polygon, the variable LEVEL has priority over MAXLVL in *CONTROL_ADAPTIVE, but is limited by the minimum element size controlled by ADPSIZE. A larger LEVEL than MAXLVL value will enable more mesh refinement within the polygon, up to the size defined by ADPSIZE, than outside of the box. However, mesh refinement when LEVEL > MAXLVL is not recommended. This keyword (and *DEFINE_BOX_ADAPTIVE) is intended for the MAXLVL > LEVEL case in which the polygon box excludes the local areas of interest. For this case, refinement inside the local

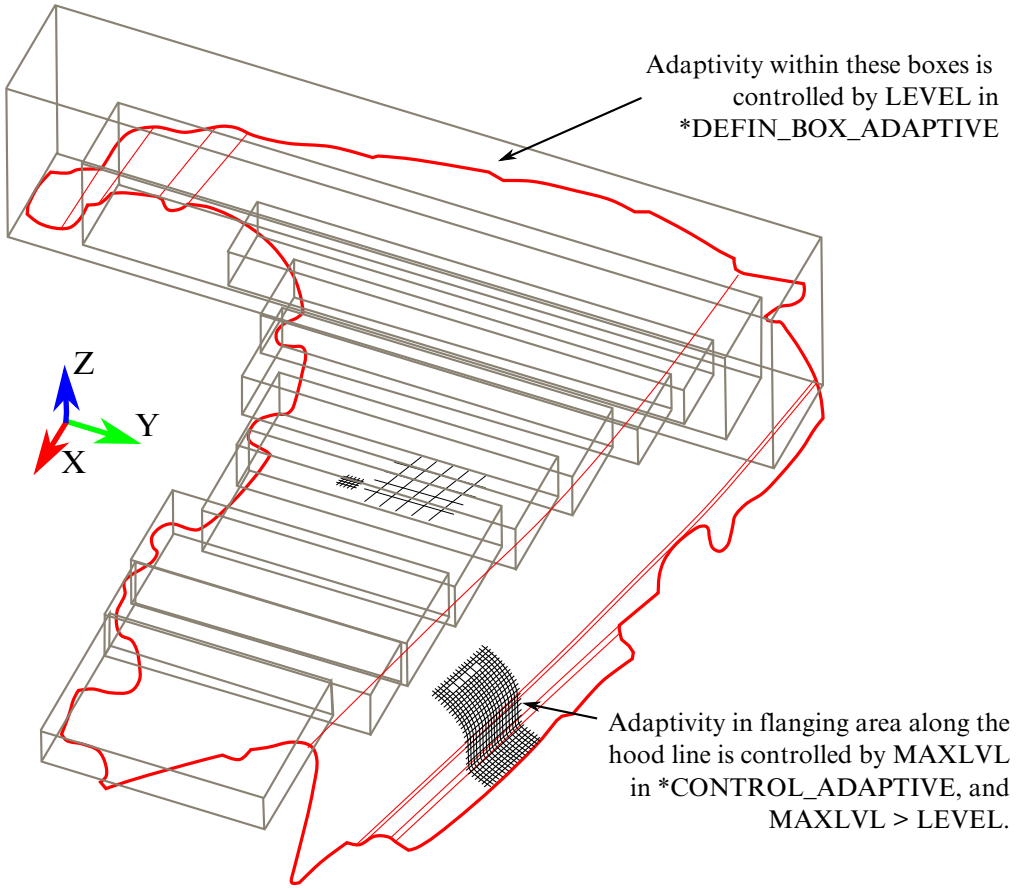

Figure 17-13. Defining adaptive boxes

areas will be controlled by MAXLVL while outside of the area will be controlled by LEVEL as shown in Figure 17-12.

2. **Advantages.** With this keyword only one box needs to be defined to specify the selected region while *DEFINE_ADAPTIVE_BOX requires multiple boxes to be defined for the same region as shown in Figure 17-13.

3. **Curve Location.** The 3D curve (closed polygon) defined by (X, Y, Z) data pairs should be near the sheet blank after the blank is auto-positioned in the beginning of a simulation. Similar to *DEFINE_BOX_ADAPTIVE, only the elements on the sheet blank initially within the polygon will be considered for use with this keyword. Local coordinate system is not supported at the moment.

4. **IGES Format.** The 3D curve can be converted from IGES format to the format required here following the procedure outlined in keyword *INTERFACE_BLANKSIZE.

Examples:

A partial keyword example is provided below, where inside the polygon mesh has no

refinement (LEVEL = 1), while outside of the box the mesh is refined 5 levels (MAXLVL = 5). The final minimum element size is defined as 0.4. It is noted that the first point and last point of the polygon are the same, closing the polygon box.

```

DEFINE_CURVE_COMPENSATION_CONSTRAINT_*OPTION

Purpose: Allow for the definition of a localized die face region for springback compensation of stamping tools. This keyword is only available for double precision.

Options available include:

BEGIN

END

> **NOTE:** *DEFINE_CURVE_COMPENSATION_CONSTRAINT_BEGIN and *DEFINE_CURVE_COMPENSATION_CONSTRAINT_END are not valid in the context of a general keyword input deck. Instead, they may only be used inside of an *INCLUDE_COMPENSATION_CURVE include file.

The required option, which must be either BEGIN or END, distinguishes between two different closed curves. When taken together, these curves identify a portion of the die for applying springback compensation, and a transition region for which compensation smoothly tapers off.

Card 1	1	2	3	4	5	6	7	8
Variable	CRVID	INOUT	TYPE					
Type	I	I	I					
Default	none	0	none					

Point Cards. Include as many cards as needed. This input ends at the next keyword ("*") card. Only the projection of this curve onto the *xy*-plane is used.

Card 2	1	2	3	4	5	6	7	8
Variable	X		Y		Z			
Type	F		F		F			
Default	0.0		0.0		0.0			

VARIABLE	DESCRIPTION
CRVID	Curve ID; must be unique. The curve must be closed: its first and last point *must* coincide.
INOUT	Flag to indicate local area to be compensated: EQ.0: For this option, the compensated region of the die consists of all points for which the projection onto the *xy*-plane is exterior to the projection of the BEGIN curve. The projection of the END curve is assumed exterior to the BEGIN curve. The transition region, then, consists of all die points for which the projection is between the BEGIN and END curves. All other points on the die are uncompensated. EQ.1: For this option, the compensated region of the die consists of all points for which the projection onto the *xy*-plane is interior to the projection of the BEGIN curve. The projection of the END curve is assumed exterior to the BEGIN curve. The transition region, then, consists of all die points for which the projection is between the BEGIN and END curves. All other points on the die are uncompensated. See Figure 17-14.
TYPE	Type code - must be "0".
X	*x*-coordinate of a point on the curve.
Y	*y*-coordinate of a point on the curve.
Z	*z*-coordinate of a point on the curve.

Motivation:

Sometimes springback occurs in a localized region of the die face. Since other parts of the die face are better left undisturbed, a localized compensation makes the most sense to bring the part shape back to the design intent. A typical example will be the front portion along the grill and headlamp or the rear portion along the windshield of a trimmed hood inner panel. A decklid (or trunk lid) inner also exhibits similar needs. Once the localized areas are identified, iterative compensation scheme may be employed within this localized region to bring the springback panel back to design shape.

Modeling Details:

Referring to Figure 17-14, the keywords *COMPENSATION_CONSTRAINT_BEGIN and

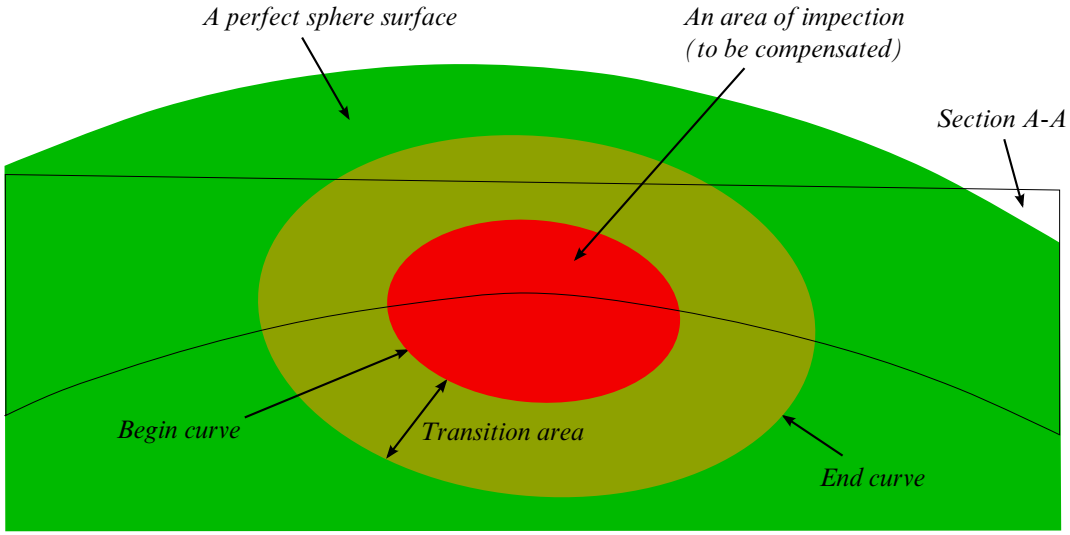

Figure 17-14. Local area compensation.

*COMPENSATION_CONSTRAINT_END must be used together in a file, which in turn will be included in keyword *INCLUDE_COMPENSATION_CURVE. The keyword "BEGIN" precedes the keyword "END;" each is defined by discrete points. In addition, each curve must form a closed loop. The area formed between the two curves is a transition area and will be affected in the compensated tooling. Multiple disconnected curves can be joined together and output in the .xyz format required here using *Curve* → *Merge* → *Multiple Method* in LS-PrePost4.0 and later.

The curve can be a 3D piecewise linear curve with coordinates in x, y and z. However, z-coordinates are ignored; meaning the tooling to be compensated must be positioned so the draw direction is in the global z-direction; otherwise an error will occur. In addition, it is assumed that both "blank before springback" and "blank after springback" will be smaller than rigid tools in dimension. Also, the rigid tool meshes should be discretized fine enough to provide enough degrees of freedom for the compensation.

Example – Single Region:

A complete input deck is provided below for a local compensation simulation. The keyword files state1.k and state2.k consist of model (nodes and elements) information for the blank before and after springback, respectively. If the blank is adaptively refined, the adaptive constraints must be included in the keyword files. The keyword file tools.k consists of the stamping tools (with PID 1, 2, 3 and 4) positioned in the home position. The keyword file curvesxy.xyz includes this keyword with both variations defining the two closed-loop curves used to define a localized area.

*END
```

Note that the first point and last point are exactly the same, forming a closed loop. In

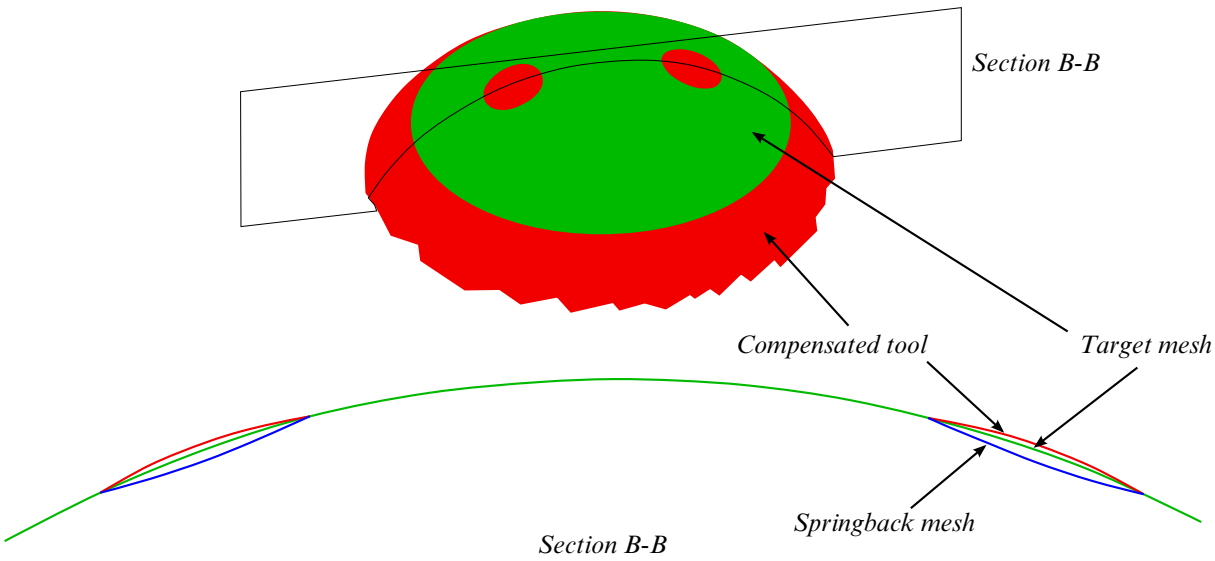

Figure 17-16. Multi-region local compensation.

Figure 17-14, local area compensation is to be performed in the center portion of a rigid sphere. Based on springback and target meshes, the compensated tool mesh is obtained, and smooth transition areas are achieved (see Figure 17-15). Here the compensation scale factor of 0.7 is used.

Example – Multiple Regions:

Multi-region localized compensation is also possible by defining multiple pairs of the BEGIN and END versions of this keyword, each forming a localized region. For example, for localized compensation of two regions, the file curvesxy.xyz will read as follows,

```
*KEYWORD
*DEFINE_CURVE_COMPENSATION_CONSTRAINT_BEGIN

         ⋮                ⋮              ⋮
*END
```

Figure 17-16 (top) shows an example of two localized areas of the sphere to be compensated. The compensation results are shown in Figure 17-16 (bottom). Again, a compensation scale factor of 0.7 was used and smooth transition areas are achieved.

*DEFINE_CURVE_DRAWBEAD

Purpose: This keyword simplifies the definition of a draw bead, which previously required the use of many keywords.

> **NOTE:** This option has been deprecated in favor of *DEFINE_MULTI_DRAWBEADS_IGES.

Card 1	1	2	3	4	5	6	7	8
Variable	CID	TCTYPE	VID	PID	BLKID	PERCT	LCID	
Type	I	I	I	I	I	F	I	
Default	none	none	none	none	none	0.0	none	

Point Cards. For TCTYPE = 1 define points on the curve. Input is terminated at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	CX	CY	CZ					
Type	F	F						
Default	0.0	0.0						

IGES Card. For TCTYPE = 2 set an IGES file.

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

VARIABLE	DESCRIPTION
CID	Draw bead curve ID; must be unique.
TCTYPE	Flag to indicate input curve data format: EQ.1: XYZ data, EQ.2: IGES format data.
VID	Vector ID, as defined by *DEFINE_VECTOR. This vector is used to project the supplied curves to the rigid tool, defined by the PID below.
PID	Part ID of a rigid tool to which the curves are projected and attached.
BLKID	Part ID of the blank.
PERCT	Draw bead lock percentage or draw bead force. GT.0: Percentage of the full lock force for the bead defined. This is the ratio of desired restraining force over the full lock force. The value should be between 0.0 and 100.0. LT.0: Absolute value is the draw bead force.
LCID	Load curve ID defining material hardening curve of the sheet blank, BLKID.
CX, CY, CZ	Points on the curve.
FILENAME	IGES file name.

Remarks:

1. This feature implements the following input algorithm for drawbeads:

   a) It reads a draw bead curve in either XYZ or IGES format

   b) projects the curve to the rigid tool specified

   c) creates extra node set and attaches it to the rigid tool.

   d) With supplied material hardening curve (LCID), full lock force is calculated.

   There is no need to define *CONTACT_DRAWBEAD and *CONSTRAINED_-RIGID_BODIES since they are treated internally within the code.

2. The "curve" menu in LS-PrePost can be used to break or join multiple disconnected curves, and output in either 'XYZ' or IGES format.

3. The following partial keyword example defines a draw bead curve ID 98 (IGES file "bead1.iges") to restrain blank part ID 63. Full lock force is calculated from the strain hardening curve ID 400. The draw bead is projected along vector ID 991, and is attached to a rigid tool of part ID 3.

Revision information:

This feature is available starting in LS-DYNA R5 Revision 62464.

*DEFINE_CURVE_DUPLICATE

Purpose: Define a curve by optionally scaling and offsetting the abscissa and ordinates of another curve defined by the *DEFINE_CURVE keyword.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	RLCID	SFA	SFO	OFFA	OFFO		
Type	I	I	F	F	F	F		
Default	none	none	1.	1.	0.	0.		

VARIABLE	DESCRIPTION
LCID	Load curve ID. Tables (see *DEFINE_TABLE) and load curve ID's must be unique.
RLCID	Reference load curve ID.
SFA	Scale factor for abscissa value of curve ID, RLCID. This value scales the SFA value defined for RLCID. EQ.0.0: default set to 1.0.
SFO	Scale factor for ordinate value (function) of curve ID, RLCID. This value scales the SFO value defined for RLCID. EQ.0.0: default set to 1.0.
OFFA	Offset for abscissa values. This value is added to the OFFA value defined for RLCID.
OFFO	Offset for ordinate values (function). This value is added to the OFFO value defined for RLCID.

*DEFINE_CURVE_ENTITY

Purpose: Define a curve of straight line segments and circular arcs that defines an axisymmetric surface. This curve can only be used with the keyword *CONTACT_ENTITY for the load curve entity GEOTYP = 11.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	SFA	SFO	SFR	OFFA	OFFO	OFFR	
Type	I	F	F	F	F	F	F	
Default	none	1.	1.	1.	0.	0.	0.	

Point Cards. Put one point per card. Include as many cards as needed. This input terminates at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	A*i*		O*i*		R*i*		IFLAG	
Type	F		F		F		I	
Default	0.0		0.0		optional		↓	

VARIABLE	DESCRIPTION
LCID	Load curve ID. Tables (see *DEFINE_TABLE) and load curves may not share common IDs. LS-DYNA allows load curve IDs and table IDs to be used interchangeably. A unique number has to be defined.
SFA	Scale factor for axis value. This is useful for simple modifications. EQ.0.0: default set to 1.0.
SFO	Scale factor for radius values. This is useful for simple modifications. EQ.0.0: default set to 1.0.

VARIABLE	DESCRIPTION
SFR	Scale factor for circular radius. This is useful for simple modifications. EQ.0.0: default set to 1.0.
OFFA	Offset for axis values. See Remark 1.
OFFO	Offset for radius values. See Remark 1.
OFFR	Offset for circular radius. See Remark 1.
A*i*	Z-axis coordinates along the axis of rotation.
O*i*	Radial coordinates from the axis of rotation
R*i*	Radius of arc between points (A_i, O_i) and (A_{i+1}, O_{i+1}). If zero, a straight line segment is assumed.
IFLAG	Defined if $\|Ri\| > 0.0$. Set to 1.0 if the center of the arc is inside the axisymmetric surface and to -1.0 if the center is outside the axisymmetric surface.

Remarks:

1. **Scaling.** The load curve values are scaled after the offsets are applied, that is:

$$\text{Axis value} = \text{SFA} \times (\text{Defined value} + \text{OFFA})$$
$$\text{Radius value} = \text{SFO} \times (\text{Defined value} + \text{OFFO})$$
$$\text{Circular value} = \text{SFR} \times (\text{Defined value} + \text{OFFR})$$

*DEFINE_CURVE_FEEDBACK

Purpose: Define information that is used as the solution evolves to scale the ordinate values of the specified load curve ID. This keyword is usually used in connection with sheet metal forming calculations.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	PID	BOXID	FLDID				
Type	I	I	I	I				
Default	none	none	0	none				

Card 2	1	2	3	4	5	6	7	8
Variable	FSL	TSL	SFF	SFT	BIAS			
Type	F	F	F	F	F			
Default	none	none	1.0	1.0	0.0			

VARIABLE	DESCRIPTION
LCID	ID number for load curve to be scaled.
PID	Active part ID for load curve control
BOXID	Box ID. Elements of specified part ID contained in box are checked. EQ.0: all elements of the active part are checked.
FLDID	Load curve ID which defines the flow limit diagram as shown in Figure 17-17.
FSL	If the ratio, $r = \varepsilon_{\text{major}_{\text{workpiece}}}/\varepsilon_{\text{major}_{\text{fld}}}$, exceeds FSL, then the scale factor for flow, SFF, is active.
TSL	Thickness strain limit. If the thickness strain limit is exceeded, then the scale factor for thickening, SFT, is active.

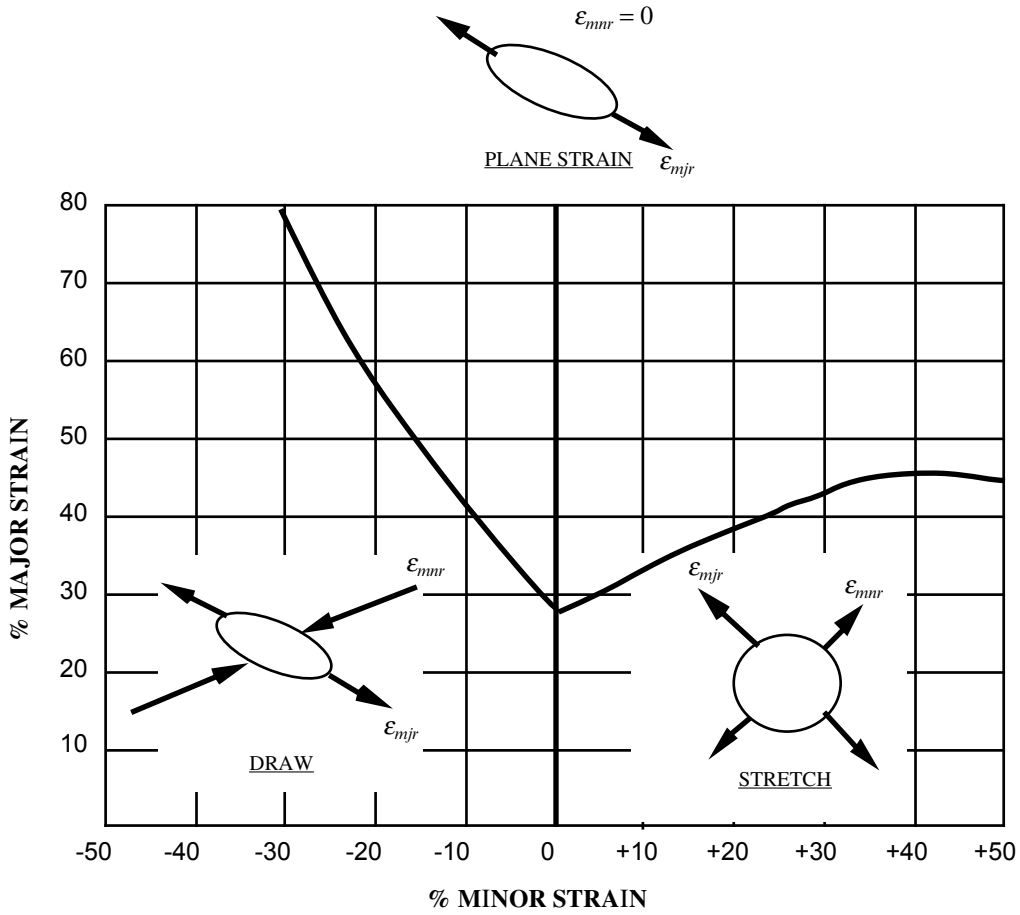

Figure 17-17. Flow limit diagram.

VARIABLE	DESCRIPTION
SFF	Scale factor for the flow limit diagram.
SFT	Scale factor for thickening.
BIAS	Bias for combined flow and thickening. Bias must be between -1 and 1.

Remarks:

This feature scales the ordinate values of a load curve according to a computed scale factor, S_f, that depends on both the major strain, r, and the through thickness, t. At each time step the load curve is scaled by S_f according to,

$$S^{n+1}_{\text{scaled load curve}} = S_f(r,t) \times S^{n}_{\text{load curve}},$$

where the superscript denotes the time step. The scale factor depends on r, which is a strain measure defined as,

$$r = \frac{\varepsilon_{\text{major}_{\text{workpiece}}}}{\varepsilon_{\text{major}_{\text{fld}}}}.$$

The scale factor, then, is given by,

$$S_f = \begin{cases} 1 & r < \text{FSL}, \quad t < \text{TSL} \\ \text{SFF} & r > \text{FSL}, \quad t < \text{TSL} \\ \text{SFT} & r < \text{FSL}, \quad t > \text{TSL} \\ \frac{1}{2}(1 - \text{BIAS}) \times \text{SFF} + \frac{1}{2}(1 + \text{BIAS}) \times \text{SFT} & r > \text{FSL}, \quad t > \text{TSL} \end{cases}$$

Usually SFF is slightly less than unity and SFT is slightly greater than unity so that $S_{\text{load curve}}$ changes insignificantly from time step to time step.

*DEFINE_CURVE_FLC

Purpose: This keyword allows for defining the Forming Limit Diagram (FLD) using sheet metal thickness t and strain hardening value n. This keyword is applicable to shell elements only.

This feature is available in LS-DYNA Revision 61435 and later releases.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	TH	TN					
Type	I	F	F					
Default	none	0.0	0.0					

VARIABLE	DESCRIPTION
LCID	Load curve ID.
TH	Sheet metal thickness.
TN	Strain hardening value of the sheet metal, as in power law (Swift).

Remarks:

1. **Related Keywords.** This keyword is used in conjunction with keyword *MAT_TRANSVERSELY_ANISOTROPIC_ELASTIC_PLASTIC_NLP_FAILURE and is for shell elements only. For detailed formula of calculating the FLD based on sheet metal thickness and n-value, please refer to the following paper: *Ming F. Shi, Shawn Gelisse, "Issues on the AHSS Forming Limit Determination", IDDRG 2006*.
2. **Material and Geometric Restrictions.** It is noted that this FLD calculation method is limited to sheet metal steels with thickness equal to or less than 2.5 mm, and it is not suitable for aluminum sheets. For aluminum sheets, *DEFINE_CURVE can be used to input the FLC for the field ICFLD in *MAT_TRANSVERSELY_ANISOTROPIC_ELASTIC_PLASTIC_NLP_FAILURE.

Example:

In a validation example shown in Figure 17-18, a single shell element is stretched in three typical strain paths (linear): uniaxial, plane strain and equi-biaxial. Strain limits for each

path are recovered when the history variable (Formability Index limit in *MAT_037) reaches 1.0, shown in Figure 17-19. The top most point (strain limit) of each strain path coincides with the FLC curve calculated according to the paper, indicating the FLC defined by this keyword is working correctly. As shown in a partial keyword file below, the FLC is defined using a thickness value of 1.5 and n-value of 0.159. The LCID of 891 is used in keyword *MAT_TRANSVERSELY_ANISOTROPIC_ELASTIC_PLASTIC_NLP_FAILURE.

*DEFINE_CURVE_FLD_FROM_TRIAXIAL_LIMIT

Purpose: Create a forming limit diagram (FLD) curve from a given stress triaxial limit curve, which can be referred to by material models utilizing a FLD curve, such as *MAT_-037_NLP_FAILURE or *MAT_260B. The conversion assumes plane stress and Von-Mises yield criterion. The converted FLD curve can be found in the ".o" file (a scratch file from batch queue run). A related keyword is *DEFINE_CURVE_TRIAXIAL_LIMIT_FROM_-FLD.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID							
Type	I							
Default	none							

Point Cards. Put one pair of points per card (2E20.0). Input is terminated at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	A1		O1					
Type	E20.0		E20.0					
Default	0.0		0.0					

VARIABLE	DESCRIPTION
LCID	The FLD curve ID to be created.
A1, A2, …	Abscissas represent stress triaxialities, typically ranging from -1/3 to 2/3.
O1, O2, …	Ordinates represent equivalent plastic strains to fracture.

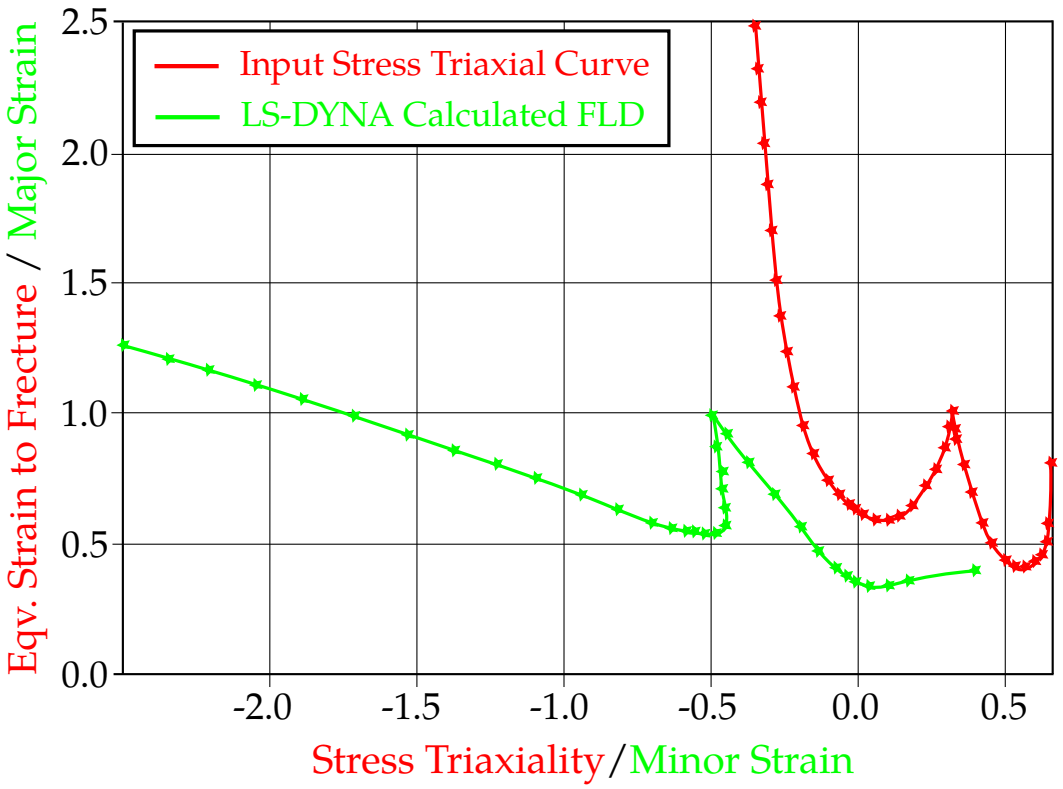

Figure 17-20. LS-DYNA calculated FLD from input stress triaxial curve [1].

Example:

The keyword input below includes the FLD limit curve obtained from Li et al. [1]. Figure 17-20 shows the calculated FLD curve from a uniaxial tension model on a single element using LS-DYNA, which matches the FLD curve from the paper.

*DEFINE_CURVE_FUNCTION

Purpose: Define a curve [for example, load (ordinate value) versus time (abscissa value)] where the ordinate is given by a function expression. The function can reference other curve definitions, kinematical quantities, forces, interpolating polynomials, intrinsic functions, and combinations thereof. Please note that many functions require the definition of a local coordinate system (see Remark 1 below). To output the curve to an ASCII database, see *DATABASE_CURVOUT. This command is not for defining curves for material models. Note that arguments appearing in square brackets "[ ]" are optional.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	SIDR						
Type	I	I						
Default	none	0						

Function Cards. Insert as many cards as needed. These cards are combined to form a single line of input. The next keyword ("*") card terminates this input.

Card 2	1	2	3	4	5	6	7	8
Variable	FUNCTION							
Type	A80							
Remarks	1							

VARIABLE	DESCRIPTION
LCID	Load curve ID. Tables (see *DEFINE_TABLE) and load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably. A unique number has to be defined.
SIDR	Stress initialization by dynamic relaxation: EQ.0: Load curve used in transient analysis only or for other applications, EQ.1: Load curve used in stress initialization but not transient analysis,

VARIABLE	DESCRIPTION
	EQ.2: Load curve applies to both initialization and transient analysis.
FUNCTION	Arithmetic expression involving a combination of the following possibilities.

Constants and Variables:

FUNCTION	DESCRIPTION
TIME	Current simulation time
TIMESTEP	Current simulation time step
PI	Proportionality constant relating the circumference of a circle to its diameter
DTOR	Degrees to radians conversion factor ($\pi/180$)
RTOD	Radians to degrees conversion factor ($180/\pi$)
NCYCLE	Current integration cycle
IDRFLG	Carries a value of 1 (unity) during dynamic relaxation and 0 (zero) in the transient phase

Intrinsic Functions:

FUNCTION	DESCRIPTION
ABS(a)	Absolute value of a
AINT(a)	Nearest integer whose magnitude is not larger than a
ANINT(a)	Nearest whole number to a
MOD(a_1, a_2)	Remainder when integer a_1 is divided by integer a_2
SIGN(a_1, a_2)	Transfer sign of a_2 to magnitude of a_1
MAX(a_1, a_2)	Maximum of a_1 and a_2
MIN(a_1, a_2)	Minimum of a_1 and a_2
SQRT(a)	Square root of a

FUNCTION	DESCRIPTION
EXP(a)	e raised to the power of a
LOG(a)	Natural logarithm of a
LOG10(a)	Log base 10 of a
SIN(a)	Sine of a
COS(a)	Cosine of a
TAN(a)	Tangent of a
ASIN(a)	Arc sine of a
ACOS(a)	Arc cosine of a
ATAN(a)	Arc tangent of a
ATAN2(a_1, a_2)	Arc tangent of a_1/a_2
SINH(a)	Hyperbolic sine of a
COSH(a)	Hyperbolic cosine of a
TANH(a)	Hyperbolic tangent of a

Load Curves:

FUNCTION	DESCRIPTION
LCn	Ordinate value of curve n defined elsewhere (see *DEFINE_-CURVE)
DELAY(LC$n, t_{\text{delay}}, y_{\text{def}}$)	Delays curve n, defined by *DEFINE_CURVE_FUNCTION, *DEFINE_FUNCTION or DEFINE_CURVE, by a constant t_{delay} when simulation time ≥ t_{delay}, and sets the delayed curve value to a constant y_{def} when time < t_{delay}, that is, $$f_{\text{delay}}(t) = \begin{cases} f(t - t_{\text{delay}}) & t \geq t_{\text{delay}} \\ y_{\text{def}} & t < t_{\text{delay}} \end{cases}$$ For a nonlinear curve, a t_{delay} equal to more than 5,000 time steps might compromise the accuracy and must be used with caution. When t_{delay} is a negative integer, delay time is input in terms

FUNCTION	DESCRIPTION
	of time step; $\|t_{delay}\|$ is the number of delay time steps. In this case, $\|t_{delay}\|$ is limited to a maximum of 100. For example, t_{delay} = -2 delays the curve by 2 time steps.

Coordinate Functions:

FUNCTION	DESCRIPTION
CX(n)	Value of x-coordinate for node n.
CY(n)	Value of y-coordinate for node n.
CZ(n)	Value of z-coordinate for node n.

Displacement Functions:

FUNCTION	DESCRIPTION
DM(n_1[,n_2])	Magnitude of translational displacement of node n_1 relative to node n_2. Node n_2 is optional and if omitted, the displacement is computed relative to ground.
DMRB(n)	Magnitude of translational displacement of rigid body having a part ID of n
DX(n_1[,n_2,n_3])	x-translational displacement of node n_1 relative to node n_2 expressed in the local coordinate system of node n_3. In other words, at any time t, the function returns the component of relative displacement that lies in the x-direction of the local coordinate system at time t. If node n_2 is omitted, it defaults to ground. If node n_3 is not specified, the displacement is reported in the global coordinate system.
DY(n_1[,n_2,n_3])	y-translational displacement of node n_1 relative to node n_2 expressed in the local coordinate system of node n_3. In other words, at any time t, the function returns the component of relative displacement that lies in the y-direction of the local coordinate system at time t. If node n_2 is omitted it defaults to ground. If node n_3 is not specified, the displacement is reported in the global coordinate system.
DZ(n_1[,n_2,n_3])	z-translational displacement of node n_1 relative to node n_2 expressed in the local coordinate system of node n_3. In other

FUNCTION	DESCRIPTION
	words, at any time t, the function returns the component of relative displacement that lies in the z-direction of the local coordinate system at time t. If node n_2 is omitted, it defaults to ground. If node n_3 is not specified, the displacement is reported in the global coordinate system.
DXRB(n)	x-translational displacement of rigid body having a part ID of n
DYRB(n)	y-translational displacement of rigid body having a part ID of n
DZRB(n)	z-translational displacement of rigid body having a part ID of n
AX(n_1[,n_2])	Rotational displacement of node n_1 about the local x-axis of node n_2. If n_2 is not specified, then it defaults to ground. In computing this value it is assumed that the rotation about the other two axes (y-, z-axes) of node n_2 is zero. See Remark 1.
AX2(n_1[,n_2])	Rotational displacement of node n_1 about the local x-axis of node n_2. If n_2 is not specified, then it defaults to the local x -axis of node n_1. This is recommended over AX, since it has fewer limitations. See Remark 1.
AY(n_1[,n_2])	Rotational displacement of node n_1 about the local y-axis of node n_2 . If n_2 is not specified, then it defaults to ground. In computing this value it is assumed that the rotation about the other two axes (x-, z-axes) of node n_2 is zero. See Remark 1.
AY2(n_1[,n_2])	Rotational displacement of node n_1 about the local y-axis of node n_2. If n_2 is not specified, then it defaults to the local y -axis of node n_1. This is recommended over AY, since it has fewer limitations. See Remark 1.
AZ(n_1[,n_2])	Rotational displacement of node n_1 about the local z-axis of node n_2. If n_2 is not specified, then it defaults to ground. In computing this value it is assumed that the rotation about the other two axes (x-, y-axes) of node n_2 is zero. See Remark 1.
AZ2(n_1[,n_2])	Rotational displacement of node n_1 about the local z-axis of node n_2. If n_2 is not specified, then it defaults to the local z-axis of node n_1. This is recommended over AZ, since it has fewer limitations. See Remark 1.

FUNCTION	DESCRIPTION
PSI(n_1[,n_2])	First angle in the body2:313 Euler rotation sequence which orients node n_1 in the frame of node n_2. If n_2 is omitted, it defaults to ground. See Remark 1.
THETA(n_1[,n_2])	Second angle in the body2:313 Euler rotation sequence which orients node n_1 in the frame of node n_2. If n_2 is omitted, it defaults to ground. See Remark 1.
PHI(n_1[,n_2])	Third angle in the body2:313 Euler rotation sequence which orients node n_1 in the frame of node n_2. If n_2 is omitted, it defaults to ground. See Remark 1.
YAW(n_1[,n_2])	First angle in the body3:321 yaw-pitch-roll rotation sequence which orients node n_1 in the frame of node n_2. If n_2 is omitted, it defaults to ground. See Remark 1.
PITCH(n_1[,n_2])	Second angle in the body3:321 yaw-pitch-roll rotation sequence which orients node n_1 in the frame of node n_2. If n_2 is omitted, it defaults to ground. See Remark 1.
ROLL(n_1[,n_2])	Third angle in the body3:321 yaw-pitch-roll rotation sequence which orients node n_1 in the frame of node n_2. If n_2 is omitted, it defaults to ground. See Remark 1.

Velocity Functions:

FUNCTION	DESCRIPTION
VM(n_1[,n_2])	Magnitude of translational velocity of node n_1 relative to node n_2. Node n_2 is optional and if omitted the velocity is computed relative to ground.
VR(n_1[,n_2])	Relative radial translational velocity of node n_1 relative to node. If node n_2 is omitted, it defaults to ground.
VX(n_1[,n_2,n_3])	x-component of the difference between the translational velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used.
VY(n_1[,n_2,n_3])	y-component of the difference between the translational velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted it defaults to ground. Node n_3 is

FUNCTION	DESCRIPTION
	optional and if not specified the global coordinate system is used.
VZ(n_1[,n_2,n_3])	z-component of the difference between the translational velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used.
WM(n_1[,n_2])	Magnitude of angular velocity of node n_1 relative to node n_2. Node n_2 is optional and if omitted the angular velocity is computed relative to ground.
WX(n_1[,n_2,n_3])	x-component of the difference between the angular velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1.
WY(n_1[,n_2,n_3])	y-component of the difference between the angular velocity vectors of node n_1 and node $n_2$in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1.
WZ(n_1[,n_2,n_3])	z-component of the difference between the angular velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node $n_2$is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1.

Acceleration Functions:

FUNCTION	DESCRIPTION
ACCM(n_1[,n_2])	Magnitude of translational acceleration of node n_1 relative to node n_2. Node n_2 is optional and if omitted the acceleration is computed relative to ground. See Remark 1.
ACCX(n_1[,n_2,n_3])	x-component of the difference between the translational acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1.

FUNCTION	DESCRIPTION
ACCY(n_1[,n_2,n_3])	y-component of the difference between the translational acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node $n_3$is optional and if not specified the global coordinate system is used. See Remark 1.
ACCZ(n_1[,n_2,n_3])	z-component of the difference between the translational acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1.
WDTM(n_1[,n_2])	Magnitude of angular acceleration of node n_1 relative to node n_2. Node n_2 is optional and if omitted the angular acceleration is computed relative to ground. See Remark 1.
WDTX(n_1[,n_2,n_3])	x-component of the difference between the angular acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1.
WDTY(n_1[,n_2,n_3])	y-component of the difference between the angular acceleration vectors of node $n_1$and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1.
WDTZ(n_1[,n_2,n_3])	z-component of the difference between the angular acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3. If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1.

Generic Force Functions:

FUNCTION	DESCRIPTION
FM(n_1[,n_2])	Magnitude of the SPC force acting on node n_1 minus the force acting on node n_2. Node n_2 is optional; if omitted the force acting only on n_1 is returned. See Remark 1.
FX(n_1[,n_2,n_3])	x-component of SPC force acting on node n_1 as computed in the optional local system of node n_3. If n_2 is specified, the force acting

FUNCTION	DESCRIPTION
	on n_2 is subtracted from the force acting on n_1. See Remark 1.
FY(n_1[,n_2,n_3])	y-component of SPC force acting on node n_1 as computed in the optional local system of node n_3. If n_2 is specified, the force acting on n_2 is subtracted from the force acting on n_1. See Remark 1.
FZ(n_1[,n_2,n_3])	z-component of SPC force acting on node n_1 as computed in the optional local system of node n_3. If n_2 is specified, the force acting on n_2 is subtracted from the force acting on n_1. See Remark 1.
TM(n_1[,n_2])	Magnitude of SPC torque acting on node n_1 minus the torque acting node n_2. Node n_2 is optional; if omitted the torque acting only on n_1 is returned. See Remark 1.
TX(n_1[,n_2,n_3])	x-component of the SPC torque acting on node n_1 as computed in the optional local system of node n_3. If n_2 is specified, the torque acting on n_2 is subtracted from the torque acting on n_1. See Remark 1.
TY(n_1[,n_2,n_3])	y-component of the SPC torque acting on node n_1 as computed in the optional local system of node n_3. If n_2 is specified, the torque acting on n_2 is subtracted from the torque acting on n_1. See Remark 1.
TZ(n_1[,n_2,n_3])	z-component of the SPC torque acting on node n_1 as computed in the optional local system of node n_3. If n_2 is specified, the torque acting on n_2 is subtracted from the torque acting on n_1. See Remark 1.

Sensor Functions:

FUNCTION	DESCRIPTION
SENSOR(n)	Returns a value of 1.0 if *SENSOR_CONTROL of control ID n has a status of "on". If the sensor has a status of "off", then the returned value is equal to the value of the TYPEID field on *SENSOR_CONTROL when the TYPE field is set to "function", otherwise SENSOR(n) returns zero.
SENSORD(n,*idflt*)	Returns the current value of *SENSOR_DEFINE sensor having ID n. Idflt is the optional filter ID defined using *DEFINE_FILTER.

Contact Force Functions:

FUNCTION	DESCRIPTION
RCFORC(*id*, *iba*, *comp*, *local*)	Returns the component *comp* (see description below) of contact interface *id* (see *CONTACT_..._ID) as calculated in the local coordinate system *local* (see *DEFINE_COORDINATE_...). If *local* equals zero, then forces are reported in the global coordinate system. Forces are reported for the SURFA side when *iba* = 1 or SURFB side when *iba* = 2. The admissible values of *comp* and their corresponding force component are as follows: comp.EQ.1: *x* force component comp.EQ.2: *y* force component comp.EQ.3: *z* force component comp.EQ.4: Resultant force

Element Specific Functions:

FUNCTION	DESCRIPTION
BEAM(*id*, *jflag*, *comp*, *rm*)	Returns the force component *comp* (see description below) of beam *id* as calculated in the local coordinate system *rm*. Forces are reported in the global coordinate system if *rm* is zero. If *rm* equals -1 the beam's *r*, *s*, and *t* force/moment is returned. If *jflag* is set to zero, then the force/torque acting on n_1 end of the beam is returned; otherwise if *jflag* is set to 1, the force/torque on the n_2 end of the beam is returned. See *ELEMENT_BEAM for the nodal connectivity rule defining n_1 and n_2. Admissible values of *comp* are 1-8 and correspond to the following components: comp.EQ.1: Force magnitude comp.EQ.2: *x* force (axial *r*-force, rm = -1) comp.EQ.3: *y* force (*s*-shear force, rm = -1) comp.EQ.4: *z* force (*t*-shear force, rm = -1) comp.EQ.5: Torque magnitude

FUNCTION	DESCRIPTION
	comp.EQ.6: *x* torque (torsion, rm = -1) comp.EQ.7: *y* torque (*s*-moment, rm = -1) comp.EQ.8: *z* torque (*t*-moment, rm = -1)
ELHIST(*eid*, *etype*, *comp*, *ipt*, *local*)	Returns the elemental quantity *comp* (see description below) of element e*id* as calculated in the local coordinate system *local*. Quantities are reported in the global coordinate system if *local* is zero. The parameter *ipt* specifies whether the quantity is for a particular integration point or maximum, minimum, or averaging is applied across the integration points. The following element classes, specified with *etype*, are supported: etype.EQ.0: Solid etype.EQ.2: Thin shell Following are admissible values of *comp* and the corresponding elemental quantity: comp.EQ.1: *x* stress comp.EQ.2: *y* stress comp.EQ.3: *z* stress comp.EQ.4: *xy* stress comp.EQ.5: *yz* stress comp.EQ.6: *zx* stress comp.EQ.7: Effective plastic strain comp.EQ.8: Hydrostatic pressure comp.EQ.9: Effective stress comp.EQ.11: *x* strain comp.EQ.12: *y* strain comp.EQ.13: *z* strain comp.EQ.14: *xy* strain comp.EQ.15: *yz* strain comp.EQ.16: *zx* strain Integration point options, specified with *ipt*, are:

FUNCTION	DESCRIPTION
	ipt.GE.1: Quantity is reported for integration point number ipt ipt.EQ.-1: Maximum of all integration points (default) ipt.EQ.-2: Average of all integration points ipt.EQ.-3: Minimum of all integration points ipt.EQ.-4: Lower surface integration point ipt.EQ.-5: Upper surface integration point ipt.EQ.-6: Middle surface integration point The local coordinate option *local* currently defaults to the global coordinate system for solid elements and other coordinate system options are unavailable. In the case of thin shell elements the quantity is reported only in the element local coordinate system. local.EQ.1: Global coordinate system (solid elements) local.EQ.2: Element coordinate system (thin shell elements)
JOINT(*id*, *jflag*, *comp*, *rm*)	Returns the force component *comp* (see description below) due to rigid body joint *id* as calculated in the local coordinate system *rm*. If *jflag* is set to zero, then the force/torque acting on n_1 end of the joint is returned. The force/torque on the n_2 end of the joint is returned if jflag is set to 1. See *CONSTRAINED_JOINT for the rule defining n_1 and n_2. Admissible values of *comp* are 1-8 and correspond to the following components: comp.EQ.1: Force magnitude comp.EQ.2: x force comp.EQ.3: y force comp.EQ.4: z force comp.EQ.5: Torque magnitude comp.EQ.6: x torque

FUNCTION	DESCRIPTION
	comp.EQ.7: y torque
	comp.EQ.8: z torque

Nodal Specific Functions:

FUNCTION	DESCRIPTION
TEMP(n)	Returns the temperature of node n
DIST(n)	Returns distance traveled by node n
EPOT(n)	Returns the electric potential of node n of a piezoelectric material
ECHG(n)	Returns the reactive electric charge of node n of a piezoelectric material, conjugate to prescribed nodal electric potential.
ECHGBC(n)	Returns the summation of the reactive electric charges of all nodes associated with a prescribed electric potential boundary condition (see *BOUNDARY_PZEPOT) with an ID = n.

General Functions

FUNCTION	DESCRIPTION
CHEBY($x, x_0, a_0, \ldots, a_{30}$)	Evaluates a Chebyshev polynomial at the user specified value x. The parameters $x_0, a_0, a_1, \ldots, a_{30}$ are used to define the constants for the polynomial defined by: $$C(x) = \sum a_j T_j(x - x_0)$$ where the functions T_j is defined recursively as $$T_j(x - x_0) = 2(x - x_0)T_{j-1}(x - x_0) - T_{j-2}(x - x_0)$$ where $$T_0(x - x_0) = 1$$ $$T_1(x - x_0) = x - x_0$$
FORCOS($x, x_0, \omega[, a_0, \ldots, a_{30}]$)	Evaluates a Fourier cosine series at the user specified value x. The parameters $x_0, a_0, a_1, \ldots, a_{30}$ are used to define the constants for the series defined by: $$F(x) = \sum a_j T_j(x - x_0)$$ where

FUNCTION	DESCRIPTION
	$T_j(x - x_0) = \cos[j\omega(x - x_0)]$
FORSIN$(x, x_0, \omega[, a_0, \ldots, a_{30}])$	Evaluates a Fourier sine series at the user specified value x. The parameters $x_0, a_0, a_1, \ldots, a_{30}$ are used to define the constants for the series defined by: $F(x) = \sum a_j T_j(x - x_0)$ where $T_j(x - x_0) = \sin[j\omega(x - x_0)]$
IF(a_1, a_2, a_3, a_4)	Arithmetic if conditional where a_i can be a constant or any legal expression described in *DEFINE_CURVE_-FUNCTION. For example, a_1='CX(100)' sets the first argument to be the x-coordinate of node 100. $\text{IF} = \begin{cases} \text{the value of } a_2 & \text{if the value of } a_1 < 0 \\ \text{the value of } a_3 & \text{if the value of } a_1 = 0 \\ \text{the value of } a_4 & \text{if the value of } a_1 > 0 \end{cases}$
MORLET(*freq, mag)*	Evaluates Morlet wavelet function with central frequency of *freq* and peak value of *mag*: $M(t) = mag \times e^{-0.5 \times g^2(t)} \times \cos(5 \times f(t) - 20)$ where $f(t) = 1.25 \times \text{freq} \times t$ and $g(t) = f(t) - 4.$
PIDCTL(*meas, ref, kp, ki, kd, tf, ei0, sint, umin, umax*)	Evaluates the control signal of a PID controller $u(t) = kp \times e(t) + ki \times \int_0^t e(\tau)d\tau + kd \times \frac{\mathrm{d}e(t)}{\mathrm{d}t}$ where $e(t)$ is the control error defined as the difference between the reference value *ref* and the measured value, *meas* $e(t) = ref - meas$ The control parameters are proportional gain *kp*, integral gain *ki*, derivative gain *kd* and low-pass filter *tf* for the derivative calculation $\frac{\mathrm{d}e(t_n)}{\mathrm{d}t} = \frac{\mathrm{d}e(t_{n-1})}{\mathrm{d}t}\frac{tf}{\Delta t + tf} + \frac{\Delta t}{\Delta t + tf} \times \frac{e(t_n) - e(t_{n-1})}{\Delta t}$

FUNCTION	DESCRIPTION
	ei0 is the initial integral value at time = 0. *sint* is the sampling interval. *umin* and *umax*, the lower and upper limit of a control signal, can be used to represent the saturation limits of an actuator. When the signal is not within the limits, it is clipped to the saturation limit, that is, integration is skipped to avoid integrator wind-up. Input parameter can be a constant or any legal expression described in *DEFINE_CURVE_FUNCTION. For example, *meas = 'CX(100)'* measures the *x*-coordinate of node 100, *ref* = 'LC200' uses curve 200 as the reference value.
POLY$(x, x_0, a_0, \dots, a_{30})$	Evaluates a standard polynomial at the user specified value x. The parameters x_0, a_0, a_1, …, a_{30} are used to define the constants for the polynomial defined by: $$P(x) = a_0 + a_1(x - x_0) + a_2(x - x_0)^2 + \cdots + a_n(x - x_0)^n$$
RICKER(*freq*, *mag*)	Evaluates Ricker wavelet function with central frequency of *freq* and peak value of *mag*: $$R(t) = mag \times (1 - 2 \times g(t))/e^{g(t)} \ ,$$ where $$f(t) = \text{PI} \times freq \times (t - 1/freq)$$ and $$g(t) = f^2(t)$$
SHF$(x, x_0, a, \omega[, \phi, b])$	Evaluates a Fourier sine series at the user specified value x. The parameters x_0, a_0, a_1, …, a_{30} are used to define the constants for the series defined by: $$\text{SHF} = a\sin[\omega(x - x_0) - \phi] + b$$
STEP(x, x_0, h_0, x_1, h_1)	Approximates the Heaviside function with a cubic polynomial using the equation: $$\text{STEP} = \begin{cases} h_0 & \text{if } x \le x_0 \\ h_0 + (h_1 - h_0)\left[\dfrac{(x - x_0)}{(x_1 - x_0)}\right]^2 \left\{3 - 2\left[\dfrac{(x - x_0)}{(x_1 - x_0)}\right]\right\} & \text{if } x_0 < x < x_1 \\ h_1 & \text{if } x \ge x_1 \end{cases}$$

Electromagnetic solver (EM) Functions

FUNCTION	DESCRIPTION
EM_ELHIST(*iele*, *ifield*, *idir*)	Returns the elemental quantity of element *iele* in the global reference frame.
EM_NDHIST(*inode*, *ifield*, *idir*)	Returns the nodal quantity of node *inode* in the global reference frame.
EM_PAHIST(*ipart*, *ifield*, *idir*)	Returns the value integrated over the whole part given by *ipart*. *ifield* can be 7, 8 and 11 only. Admissible values of *ifield* are 1-10 and correspond to the following variables: EQ.1: Scalar potential EQ.2: Vector potential EQ.3: Electric field EQ.4: **B** field EQ.5: **H** field EQ.6: Current density EQ.7: Lorentz force EQ.8: Joule heating EQ.9: Conductivity EQ.10: Relative permeability EQ.11: Magnetic energy (in the conductor only) Admissible values of *idir* are 1-4 and correspond to the following components: EQ.1: *x*-component EQ.2: *y*-component EQ.3: *z*-component EQ.4: norm

Remarks:

1. **Local Coordinate Systems Required for Rotational Motion.** A local coordinate system *must* be attached to nodes if they are referenced by functions involving rotational motion, for example, angular displacement or angular velocity.

The local coordinate system is attached to the node using *DEFINE_COORDINATE_NODES and FLAG = 1 is a requirement. Furthermore, the three nodes which comprise the coordinate system must lie on the same body. Similarly, a local coordinate system must also be attached to node n_3 if n_3 is referenced in functions: DX, DY, DZ, VX, VY, VZ, WX, WY, WZ, ACCX, ACCY, ACCZ, WDTX, WDTY, WDTZ, FX, FY, FZ, TX, TY, or TZ.

2. **Default is Radians.** Unless otherwise noted units of radians are always used for the arguments and output of functions involving angular measures.

3. **Reserved Variable Names.** See Appendix U for a list of variable names reserved internally by LS-DYNA.

The following examples serve only as an illustration of syntax.

Example 1:

Define a curve 10 whose ordinate is,

$$f(x) = \frac{1}{2}(\text{ordinate of load curve 9}) \times (\text{magnitude of translation velocity at node 22})^3.$$

```
*DEFINE_CURVE_FUNCTION
10
0.5*lc9*vm(22)**3
```

Example 2:

Define a curve 101 whose ordinate is,

$$f(x) = -2(\text{z translational displacement of node 38}) \times \sin(20\pi t).$$

```
*DEFINE_CURVE_FUNCTION
101
-2.*dz(38)*sin(2.*pi*10.*time)
```

Example 3:

Define a curve 202 whose ordinate is,

$$f(x) = \begin{cases} \cos(4\pi t) \; if \; t \leq 5. \\ 0. \; if \; t > 5. \end{cases}$$

```
*DEFINE_CURVE_FUNCTION
202
If(TIME-5.,COS(4.*PI*TIME),COS(4.*PI*TIME),0.)
```

*DEFINE_CURVE_SMOOTH

Purpose: Define a smoothly varying curve using few parameters. This shape is useful for velocity control of tools in metal forming applications.

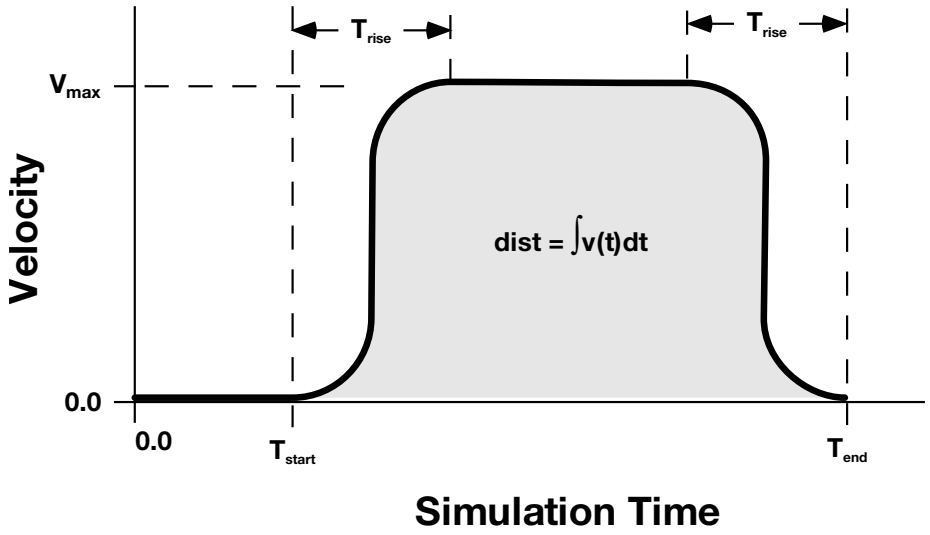

Figure 17-21. Smooth curve created automatically using *DEFINE_CURVE_-SMOOTH. This shape is commonly used to control velocity of tools in metal forming applications as shown in this figure but can also be used for other applications in place of any standard load curve.

Card	1	2	3	4	5	6	7	8
Variable	LCID	SIDR	DIST	TSTART	TEND	TRISE	VMAX	
Type	I	I	F	F	F	F	F	
Default	none	none	none	none	none	none	none	

VARIABLE	DESCRIPTION
LCID	Load curve ID, must be unique
SIDR	Stress initialization by dynamic relaxation: EQ.0: Load curve is used in transient analysis only or for other applications, EQ.1: Load curve is used in stress initialization but not transient analysis.

VARIABLE	DESCRIPTION
	EQ.2: Load curve applies to both initialization and transient analysis.
DIST	Total distance tool will travel (area under curve).
TSTART	Time curve starts to rise
TEND	Time curve returns to zero. If TEND is nonzero, VMAX will be computed automatically to satisfy required travel distance DIST. Input either TEND or VMAX.
TRISE	Rise time
VMAX	Maximum velocity (maximum value of curve). If VMAX is non-zero, TEND will be computed automatically to satisfy required travel distance DIST. Input either TEND or VMAX.

*DEFINE_CURVE_STRESS

Purpose: This keyword defines a material hardening curve based on a few commonly used material hardening laws. The hardening curve can also be a weighted combination of some of the laws. The load curve ID for this curve can be referenced in the load curve ID field used by a specific material model. This feature is applicable to all material models with a hardening curve that can be defined by a load curve using *DEFINE_CURVE.

Curve Definition Card(s). Only one card is needed unless ITYPE = 11. When ITYPE = 11, a second card with the form of CARD 1 is needed with the same LCID as the first card. See Remark 2.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	ITYPE	P1	P2	P3	P4	P5	P6
Type	I	I	F	F	F	F	F	F
Default	none	none	none	1	none	none	none	none

VARIABLE	DESCRIPTION
LCID	Load curve ID for the stress-strain curve to be generated.
ITYPE	Type of hardening law:

EQ.1: Swift power law:

$$\sigma = K\left(e_0 + \epsilon_p\right)^n ,$$

where σ is true effective stress, e_0 is the residual plastic strain at the initial yield point, K is a strength coefficient, ϵ_p is true effective plastic strain, and n is the work hardening coefficient.

EQ.2: Voce law with form:

$$\sigma = \sigma_0 + R_{\text{sat}}\left(1.0 - e^{-\zeta\epsilon_p}\right) ,$$

where σ_0 is the initial yield stress, R_{sat} is the stress differential between σ_0 and the saturated stress, and ζ is a strain coefficient.

EQ.3: Voce law with form:

$$\sigma = A - Be^{-C\epsilon_p} ,$$

where A, B, and C are material constants.

VARIABLE **DESCRIPTION**

EQ.4: Hockett-Sherby law:

$$\sigma = A - Be^{-C\epsilon_p^H},$$

where A, B, C, and H are material constants.

EQ.5: Stoughton-Yoon hardening law:

$$\sigma = A - Be^{-C\epsilon_p^m} + D\epsilon_p,$$

where A, B, C, m and D are material constants, such that $0 < m < 1.0$ and $D \geq 0.0$. According to Stoughton-Yoon, "with the exception of metals exhibiting Yield Point Elongation (YPE) effects, this function can represent the stress-strain response for both mild and AHSS steel and aluminum, from the initial yield point, throughout the small strain range, up to the highest strains realized in bulge tests". Note that if $D = 0.0$, this law reduces to the Hockett-Sherby law (ITYPE = 4). Also note that if $m = 1.0$ and $D = 0.0$, this law reduces to the ITYPE = 3 Voce law.

EQ.11: A weighted combination of ITYPE = 1 and any of the other ITYPEs. See Remark 2.

P1, P2, P3
P4, P5, P6

ITYPE	P1	P2	P3	P4	P5	P6
1	K	n	e_0			
2	σ_0	R_{sat}	ζ	w_2		
3	A	B	C	w_2		
4	A	B	C	H	w_2	
5	A	B	C	M	D	w_2
11	K	n	e_0	w_1		

Where w_1 and w_2 are the weighting factors used for ITYPE = 11; see Remark 2.

Remarks:

1. **Default for P2.** For ITYPE = 1, the default value (also the minimum) for P2 is 0.000001.

2. **Combining Hardening Laws.** With ITYPE = 11, the Swift power law (ITYPE = 1) can be combined with another law through a weighted sum. To do this two cards are needed with the same LCID. The first card has ITYPE = 11 in place of ITYPE = 1. This card also requires a weight, w_1, in the P4 field which is the weight applied to the Swift power law in the sum. The second card has the ITYPE of the law that is being summed to the Swift power law. This card also requires a weight, w_2, in the P*i* field specified for that ITYPE. The following example generates a hardening curve (LCID 90903) that is the sum of 0.5 (w_1) times the Swift power law and 0.8 (w_2) times the Hockett-Sherby law (ITYPE = 4). This curve then has the equation

$$\sigma = 0.5\left(350.0\left(0.01 + \epsilon_p\right)^{0.22}\right) + 0.8\left(162.2 - 72.2e^{-4.34\epsilon_p^{1.2}}\right).$$

Revision Information:

This feature is available starting from Revision 113640. ITYPE = 5 (Stoughton-Yoon) is available starting from Revision 114803.

*DEFINE_CURVE_TRIAXIAL_LIMIT_FROM_FLD

Purpose: Create a stress triaxial limit curve from a given forming limit diagram (FLD) curve, which can be referred to by material models utilizing a stress triaxial limit curve, such as *MAT_ADD_EROSION or *MAT_260B, or by keywords, such as *CONTROL_-FORMING_ONESTEP. The conversion assumes plane stress and Von-Mises yield criterion. The converted stress triaxial curve can be found in the ".o" file (a scratch file from batch queue run). A related keyword is *DEFINE_CURVE_FLD_FROM_TRIAXIAL_-LIMIT.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID							
Type	I							
Default	none							

Point Cards. Put one pair of points per card (2E20.0). Input is terminated at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	A1		O1					
Type	E20.0		E20.0					
Default	0.0		0.0					

VARIABLE	DESCRIPTION
LCID	The stress triaxial limit curve ID to be created.
A1, A2, …	Abscissas represent minor true strains of a FLD curve.
O1, O2, …	Ordinates represent major true strains of a FLD curve.

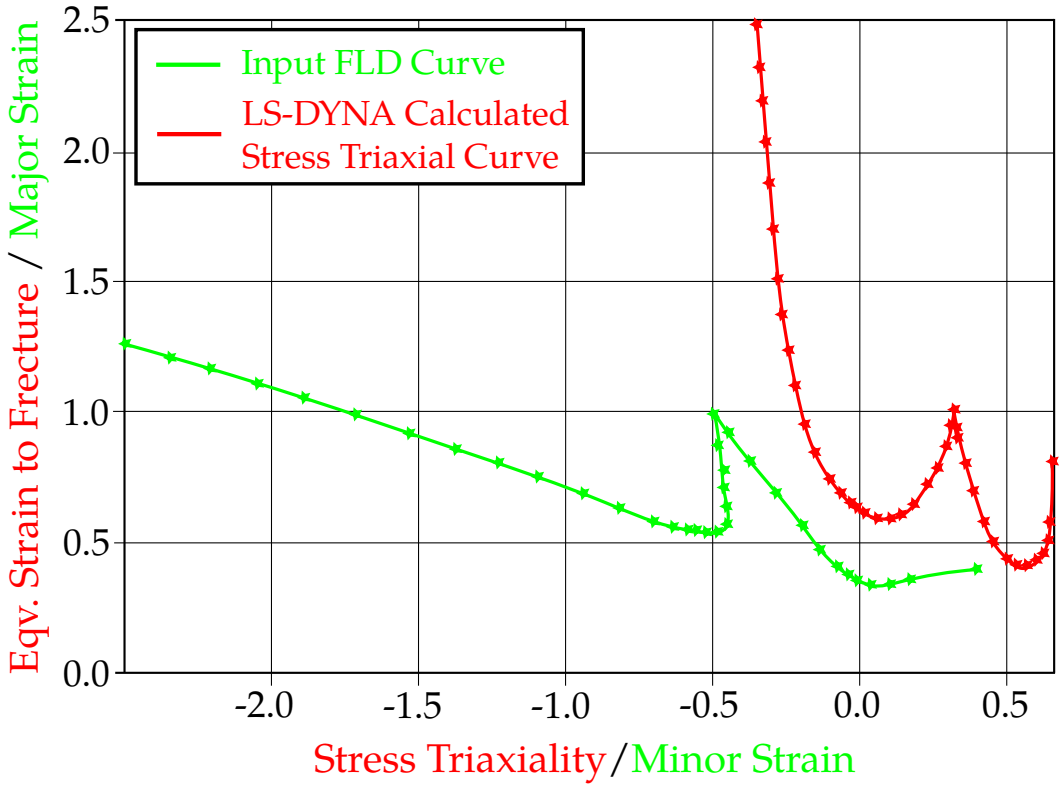

Figure 17-22. LS-DYNA calculated stress triaxial curve from FLD curve [1].

Example:

The keyword input below includes the FLD limit curve obtained from Li et al. [1]. Using a uniaxial tension model on a single element, Figure 17-22 shows the calculated stress triaxial curve from LS-DYNA, which matches the triaxial curve from the paper.

***DEFINE_CURVE_TRIM**_{OPTION}_

Available options include:

<BLANK>

3D

2D

Purpose: Define curves and controls for sheet blank trimming in sheet metal forming. This keyword can also be used to define mesh adaptivity along a curve within a band prior to the start of a simulation, using the variable TCTOL in this keyword and *CONTROL_ADAPTIVE_CURVE.

> **NOTE:** The option NEW was replaced by 2D starting in Revision 115518.

The three keyword options for *DEFINE_CURVE_TRIM cause different trimming algorithms to be used. The <BLANK> (or no option) case is the oldest method. It is used for 2D trimming. However, it is not recommended because it is slow due to each node on the blank being checked to determine if it is inside the curve or not. Because this method is not recommended, the remarks section will only discuss the 2D and 3D keyword options. When the keyword option 3D is used, the trimming is processed based on the element normal, meaning that the trimming curve is projected to the nearest element using the element normal. The option 2D is used to trim in a fixed direction specified by a vector, that is, the curve is projected onto the model using the same vector. This option is also a 2D trimming. Currently this keyword applies to:

- 2D and 3D adaptive trimming of adaptive shell elements,
- 2D and 3D adaptive trimming of non-adaptive solids,
- 2D and 3D adaptive trimming of adaptive-meshed sandwiched parts (limit to a core of one layer of solid elements with outer layers of shell elements; see "IFSAND" under *CONTROL_ADAPTIVE),
- 2D and 3D adaptive trimming of adaptive-meshed sandwiched parts (a core of multiple layers of solid elements with outer layers of shell elements),
- 2D and 3D adaptive trimming (in conjunction with *CONTROL_FORMING_TRIMMING_SOLID_REFINEMENT) of adaptive-meshed sandwiched parts (a core of multiple layers of solid elements with outer layers of shell elements), and,
- 2D trimming of thick shell elements (TSHELL).

This keyword is not applicable to axisymmetric solids or 2D plane strain/stress elements. Related keywords include *ELEMENT_TRIM, *CONTROL_FORMING_TRIMMING, *CONTROL_FORMING_TRIMMING_SOLID_REFINEMENT, *CONTROL_ADAPTIVE_CURVE, *INCLUDE_TRIM, and *INCLUDE. Another closely related keyword is

*CONTROL_FORMING_TRIM_MERGE, which automatically closes an open-ended trim curve within a user-specified tolerance.

> **NOTE:** Trimming of shell and solid elements in LS-PrePost is supported starting with LS-PrePost 4.0, under *Application* → *MetalForming* → *Easy Setup*.

Card Summary:

Card 1a. Include this card if the keyword option is not used.

TCID	TCTYPE			TCTOL			

Card 1b. Include this card for the 2D keyword option.

TCID	TCTYPE	TFLG	TDIR	TCTOL	DEPTH	NSEED1	NSEED2

Card 1c. Include this card for the 3D keyword option.

TCID	TCTYPE		TDIR	TCTOL	TOLN	NSEED1	NSEED2

Card 2a. Include as many of this card as needed if TCTYPE = 1. The next keyword ("*") card terminates this input.

CX	CY	CZ		

Card 2b. Include this card if TCTYPE = 2.

FILENAME

Data Card Definitions:

No Keyword Option Card. Include this card if not using a keyword option.

Card 1a	1	2	3	4	5	6	7	8
Variable	TCID	TCTYPE			TCTOL			
Type	I	I			F			
Default	none	1			0.25			

VARIABLE	DESCRIPTION
TCID	ID number for trim curve
TCTYPE	Trim curve type: EQ.1: Curve data in XYZ format, obtained following procedures outlined in Figures under *INTERFACE_BLANKSIZE. In addition, only this format is allowed in *INTERFACE_-COMPENSATION_3D. EQ.2: IGES trim curve
TCTOL	Tolerance limiting size of small elements created during trimming (see Figure 17-24). LT.0: "Simple" trimming, producing jagged edge mesh When used together with *CONTROL_ADAPTIVE_CURVE, it is a distance from the curve out (both sides). Within this distance the blank mesh will be refined, as stated in remarks below.

2D Keyword Option Card. Including this card if using the 2D keyword option.

Card 1b	1	2	3	4	5	6	7	8
Variable	TCID	TCTYPE	TFLG	TDIR	TCTOL	DEPTH	NSEED1	NSEED2
Type	I	I	I	I	F	F	I	I
Default	none	1	none	0	0.25	0.0	none	none

VARIABLE	DESCRIPTION
TCID	ID number for trim curve
TCTYPE	Trim curve type: EQ.1: Curve data in XYZ format, obtained following procedures outlined in Figures under *INTERFACE_BLANKSIZE. In addition, only this format is allowed in *INTERFACE_-COMPENSATION_3D. EQ.2: IGES trim curve
TFLG	Element removal option:

VARIABLE	DESCRIPTION
	EQ.-1: Remove material outside curve. EQ.1: Remove material inside curve.
TDIR	ID of a vector (*DEFINE_VECTOR) giving the trim direction (see Figure 17-23). EQ.0: Default vector (0.0,0.0,1.0) is used. The curve is defined in global *XY*-plane and projected onto the mesh in the global *Z*-direction to define trim line.
TCTOL	Tolerance limiting size of small elements created during trimming (see Figure 17-24). LT.0: "Simple" trimming, producing jagged edge mesh When used together with *CONTROL_ADAPTIVE_CURVE, it is a distance from the curve out (both sides). Within this distance the blank mesh will be refined, as stated in remarks below.
DEPTH	The trimming depth is DEPTH – 1. If the distance between the element and the curve is larger than this value, then it will not be cut. This feature prevents trimming through to the opposite side of the part.
NSEED1/ NSEED2	A node ID on the blank in the area that remains after trimming: LT.0: |NSEED*i*| is a node which may not necessarily be on the blank. See Remark 6.

3D Keyword Option Card. Include this card for the 3D keyword option.

Card 1c	1	2	3	4	5	6	7	8
Variable	TCID	TCTYPE	TFLG	TDIR	TCTOL	TOLN	NSEED1	NSEED2
Type	I	I	I	I	F	F	I	I
Default	none	1	0	1	0.25	2.0	none	none

VARIABLE	DESCRIPTION
TCID	ID number for trim curve

VARIABLE	DESCRIPTION
TCTYPE	Trim curve type: EQ.1: Curve data in XYZ format, obtained following procedures outlined in Figures under *INTERFACE_BLANKSIZE. In addition, only this format is allowed in *INTERFACE_-COMPENSATION_3D. EQ.2: IGES trim curve
TFLG	Side of surface for which trimming will start for sandwich parts: EQ.1: Top surface (default) EQ.2: Bottom surface
TDIR	Indicate whether the trim curve is near the top or bottom surface of the solids or laminates (>Revision 101964); see 3D (normal) trimming of solid elements. EQ.1: Trim curve is located near the top surface (default). EQ.-1: Trim curve is located near the bottom surface.
TCTOL	Tolerance limiting size of small elements created during trimming (see Figure 17-24). LT.0: "Simple" trimming, producing jagged edge mesh When used together with *CONTROL_ADAPTIVE_CURVE, it is a distance from the curve out (both sides). Within this distance the blank mesh will be refined, as stated in remarks below.
TOLN	Maximum gap between the trimming curve and the mesh. If the gap is bigger than this value, this section in the curve will not be used.
NSEED1 / NSEED2	A node ID on the blank in the area that remains after trimming: LT.0: |NSEED*i*| is a node which may not necessarily be on the blank. See Remark 6.

Point Cards. Additional cards for TCTYPE = 1. Put one point per card (2E20.0). Input is terminated at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	CX		CY		CZ			
Type	F		F		F			
Default	0.0		0.0		0.0			

VARIABLE	DESCRIPTION
CX, CY, CZ	*X*, *Y*, *Z*-coordinates of trim curve.

IGES File Card. Additional card for TCTYPE = 2.

Card 2b	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

VARIABLE	DESCRIPTION
FILENAME	Name of IGES database containing trim curve(s).

Trimming Capability Summary:

This keyword and its options deal with trimming of the following scenarios:

	2D (along one direction)	3D (element normal)	2D & 3D Double Trim	Adaptive mesh
Shell	Yes	Yes	Yes	Yes
Solids	Yes	Yes	Yes	N/A
Sandwiched Parts (Laminates)	Yes	Yes	Yes	Yes
TSHELL	Yes	N/A	N/A	N/A

Remarks:

1. **IGES Trim Curve.** Only IGES entities 110 and 106 are supported when using TCTYPE = 2. The eZ-Setup for trimming function ensures correct IGES files are written for a trimming simulation.

2. **Trim Curve Requirements.** Enclosed trimming curves (same start and end points) are required for all options. Also, for each enclosed trimming curve, only one curve segment is acceptable for the option 3D; while several curve segments are acceptable with the option 2D. Curves can be manipulated through the *Merge* and *break* features in LS-PrePost4.0, found under *Curve/Merge* (always select *piecewise* under *Merge*) and *break*.

   For 3D trimming, trim curves need to be sufficiently close to the part. Trim curves can be processed using curve projection onto the mesh in LS-PrePost. This feature is accessible under *GeoTol/Project/Closest Proj/Project to Element/By Part*. Using a double precision LS-DYNA executable may also help in this situation.

   For the option 2D, Revision 68643 and later releases enable trimming of a part where trim lines go beyond the part boundary. This is illustrated in Figure 17-29.

3. **Order of Trimming.** This keyword in combination with *ELEMENT_TRIM trims the requested parts before a job starts (pre-trimming). This combination can also handle an adaptive mesh. If the keyword *ELEMENT_TRIM is not included, the parts are trimmed after the job is terminated (post-trimming).

4. **TCTOL.** The trimming tolerance TCTOL limits the size of the smallest element created during trimming. A value of 0.0 places no limit on element size. A value of 0.5 restricts new elements to be at least half of the size of the parent element. A value of 1.0 allows no new elements to be generated, only repositioning of existing nodes to lie on the trim curve. A negative tolerance value activates "simple" trimming, where entire elements are removed, leaving a jagged edge.

5. **Mesh Refinement along the Trim Curve for Shell Elements.** When large elements are along the trim curve, the blank mesh can be pre-adapted along the trim curve before trimming by adding the keyword *CONTROL_ADAPTIVE_CURVE for a better quality trim edge. Care should be taken when using this keyword since an excessive number of elements can be created when setting the fields. Note that this keyword can only be used for shell elements.

   The variable TCTOL can be used to control the mesh refinement along a curve when used together with *CONTROL_ADAPTIVE_CURVE. In this scenario, it is the distance of the entire refinement width. The mesh will be refined in the beginning of the simulation. This method offers greater control on the number of elements to be generated during mesh refinement. A detailed description and

example are provided under the manual section under *CONTROL_ADAPTIVE_CURVE.

Sometimes it is helpful to conduct a check of the trimmed mesh along the edge in the same trimming input deck using the keyword *CONTROL_CHECK_SHELL. This is especially useful for the next continued process simulation. For detailed usage, see that manual page.

6. **Seed Nodes.** A seed node is used to define which side of the drawn panel will be kept after trimming. With the frequent application of adaptive re-meshing, the seed node for trimming is often unknown until the draw forming is complete. When NSEED*i* is negative, an extra node unrelated to the blank and tools can be used as the seed node, enabling simulating a trimming process independent of the previous process simulation results. The extra node can be defined using keyword *NODE. If the seed node is too far away from the blank, it will be projected onto the blank and the new position will be used as the seed node. Typically, this node can be selected from the stationary tool in its home position. Selecting a seed node is quite easy in *Trimming* process of LS-PrePost4.0 eZSetup for metal forming application.

   A partial keyword input example for the trimming of a double-attached *NUMISHEET2002 fender outer* with the option 2D is listed below, where a 2D trimming is performed with IGES file doubletrim.iges in the global *Z*-axis, with two nodes of negative ID 43356 and 18764 assigned to the variables NSEED1 and NSEED2, respectively. The two seed nodes are defined off the stationary lower post and do not necessarily need to be a part of the post as shown in Figure 17-25. The drawn panels in the wire frame are shown in Figure 17-26, along with the thickness/thinning contour (Figure 17-27). In Figure 17-28, the drawn panels are trimmed and separated.

```

7. **Nodal Temperature.** Starting in Revision 81105, trimming of blank with nodal temperature (related to hot and warm stamping) is available. At the end of the trimming, the file new_temp_ic.inc will be output along with the usual dynain file. Furthermore, the keyword *CONTROL_CHECK_SHELL can be used together when trimming with nodal temperature.

8. ***INCLUDE_TRIM.** We recommend using the keyword *INCLUDE_TRIM at all times, either for trimming or for mesh refinement purposes, except in the case where the to-be-trimmed sheet blank has no stress and strain information (no *INITIAL_STRESS_SHELL, and *INITIAL_STRAIN_SHELL cards present in the sheet blank keyword or dynain file). In that case the keyword *INCLUDE must be used. For solid element and thick shell element trimming, the keyword *INCLUDE_TRIM *must* be used. A check box to indicate that the blank is free of stress and strain information is provided in the Trimming process in the eZ-Setup for users to set up a trimming input deck under the circumstance.

2D and 3D trimming of solid elements and laminates:

In all trimming of solids and laminates, only a dynain file is written out (no d3plot files will be output).

2D trimming of solid elements

As of Revision 92088, 2D (option 2D) trimming in any direction (defined by a vector) of solid elements is available. An illustration of the 2D trim is shown in Figure 17-30. A partial keyword example is provided below, where trim curves in trimcurves2d.iges are being used to perform a solid element trimming along a vector defined along the global Z-axis.

*END
```

Currently, 2D trimming of solids in some cases may be approximate. The trimming will trim the top and bottom sides of the elements, not crossing over to the other sides. This can be seen, for instance, in trimming involving a radius.

3D (normal) trimming of solid elements

As of Revision 93467 3D trimming (option 3D) of solid elements is available. The trim curve should be created based on the solid element normal. The field TDIR indicates whether the curve is closer to the top (TDIR = 1) or bottom (TDIR = -1) surface of the solid; see Figure 17-32. The projection of trim curves onto either the top or bottom surface of the blank is important to ensure a smooth and successful trimming.

To change the example in the 2D case to the 3D case, the option 2D is changed to 3D, and trimcurves3d.iges is used. The field TDIR is set to "1" since the trim curve is on the positive side of the element normal (Figure 17-32). Since 3D trimming is along the element normal directions, *DEFINE_VECTOR is no longer needed.

```
*DEFINE_CURVE_TRIM_3D
$#     tcid    tctype      tflg      tdir     tctol      toln    nseed1    nseed2
         2         2         0         1   0.10000  1.000000         0         0
$# filename
trimcurves3d.iges
```

2D and 3D trimming of non-adaptive-meshed sandwiched parts (laminates)

2D and 3D trimming of non-adaptive-meshed laminates are available starting in Revision 92289. The laminates can have multiple layers of solid elements, sandwiched by a top and a bottom layer of shell elements. Note that the nodes of the shell elements must share the nodes with the solid elements at the top and bottom layers. See Figure 17-31 as an example. The input deck is similar to those used for trimming of solid elements, except the variable ITYP under *CONTROL_FORMING_TRIMMING should be set to "1" to activate the trimming of laminates in both 2D and 3D conditions:

```
*CONTROL_FORMING_TRIMMING
$---+----1----+----2----+----3----+----4----+----5----+----6----+----7----+----8
$     PSID                ITYP
   &blksid                   1
```

Again, in the case of 3D trimming, the projection of trim curves onto either the top or bottom surface of the blank is important to ensure a smooth and successful trim.

2D and 3D trimming of adaptive-meshed sandwiched parts - one core layer of solids

2D and 3D trimming of adaptive-meshed laminates with one core layer of solid elements sandwiched by shell elements are available starting in Revision 108770. The shell elements must share the same nodes as the solid elements.

*Note elements are refined automatically along the trim curves until no dependent nodes (see *CONSTRAINED_ADAPTIVITY) would be cut by the trim curves. In addition, the keyword *CONTROL_ADAPTIVE_CURVE must not be used since it is only applied to shell elements and would cause error termination otherwise.* This trimming unlike for shell elements

requires no additional adaptivity-related keyword inputs for mesh refinement. An example of the trimming on the 2005 NUMISHEET Cross Member is shown in Figure 17-33.

2D and 3D trimming of adaptive-meshed sandwiched parts - multiple layers of solids:

This capability is available starting in Dev 134513 when used with the keyword *CONTROL_FORMING_TRIMMING_SOLID_REFINEMENT. This keyword allows for the elements along the trim curves to be refined. Please refer to the corresponding manual pages.

2D trimming of thick shell elements (TSHELL):

2D trimming of thick shells supported starting from Revision 107957. Note that, by definition, thick shells have only one layer of solid elements, and is defined by keyword Note also *INCLUDE_TRIM (not *INCLUDE) must be used to include the dynain file to be trimmed. The input deck for 2D trimming of TSHELL is similar to what is used for trimming of solid elements.

2D and 3D trimming of double-attached solids and laminates:

These features are available starting in Revision 110140. Both seed point coordinates can be specified in *DEFINE_TRIM_SEED_POINT_COORDINATES to define a seed coordinate for each part, as shown below:

```
*DEFINE_TRIM_SEED_POINT_COORDINATES
$    NSEED        X1        Y1        Z1        X2        Y2        Z2
         2  -184.565    84.755    78.392  -1038.41   119.154    78.375
```

In Figure 17-34, a 2D double-trimming example on a sandwiched part is shown using the 2005 NUMISHEET cross member. Two trim curves and two seed nodes are defined for each to be trimmed portion.

Note again, *INCLUDE_TRIM (not *INCLUDE) must be used to include the dynain file to be trimmed.

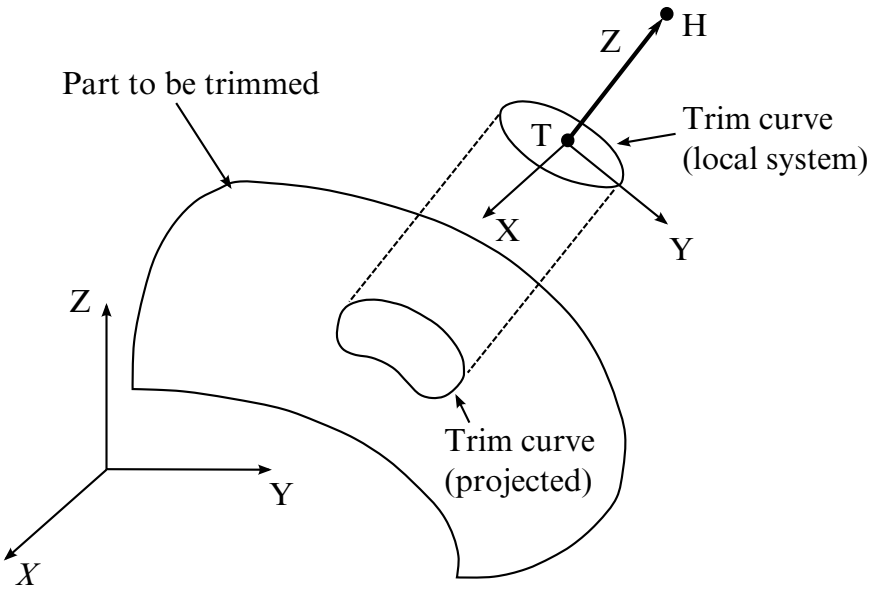

Figure 17-23. Trimming Orientation Vector. The tail (**T**) and head (**H**) points define a local coordinate system (x, y, z). The global coordinate system is named (X, Y, Z). The local x-direction is constructed in the Xz-plane. If X and z nearly coincide ($|X \cdot z| > 0.95$), then the local x-direction is instead constructed in the Yz-plane. Trim curve data is input in the xy-plane and projected in the z-direction onto the deformed mesh to obtain the trim line.

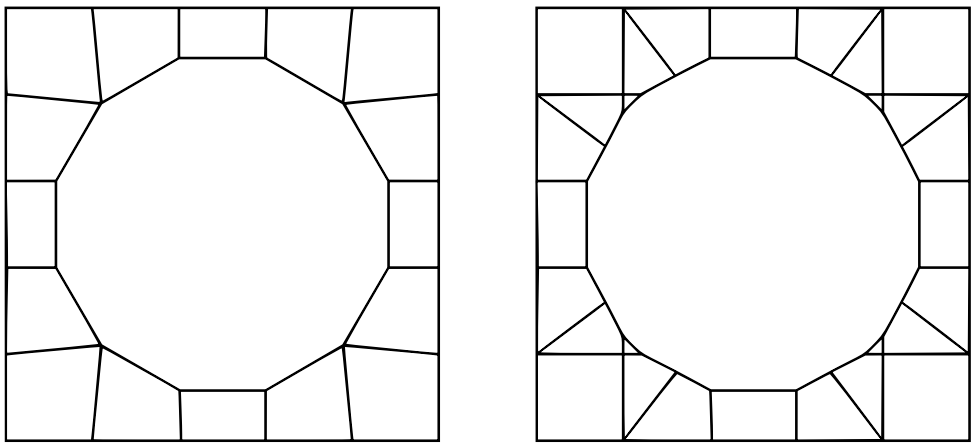

Figure 17-24. Trimming Tolerance. The tolerance limits the size of the small elements generated during trimming. The default tolerance (left) produces large elements. Using a tolerance of 0.01 (right) allows smaller elements and more detail in the trim line.

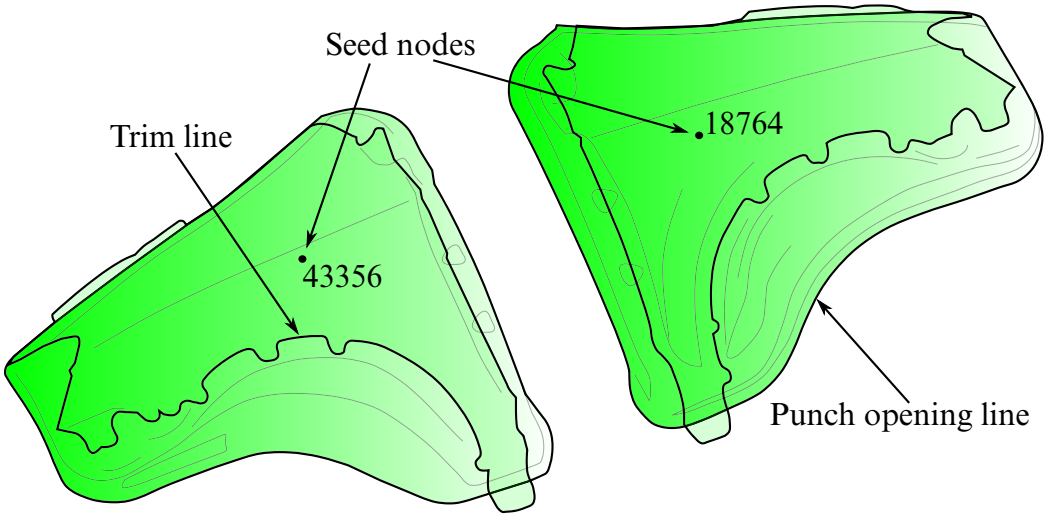

Figure 17-25. Trimming of a double-attached part (NUMISHEET2002 Fender Outer).

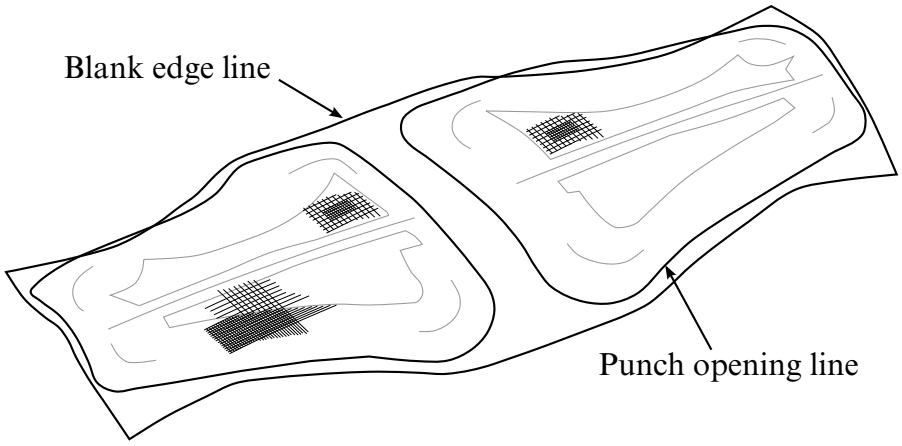

Figure 17-26. The fender outer (draw complete) in wireframe mode.

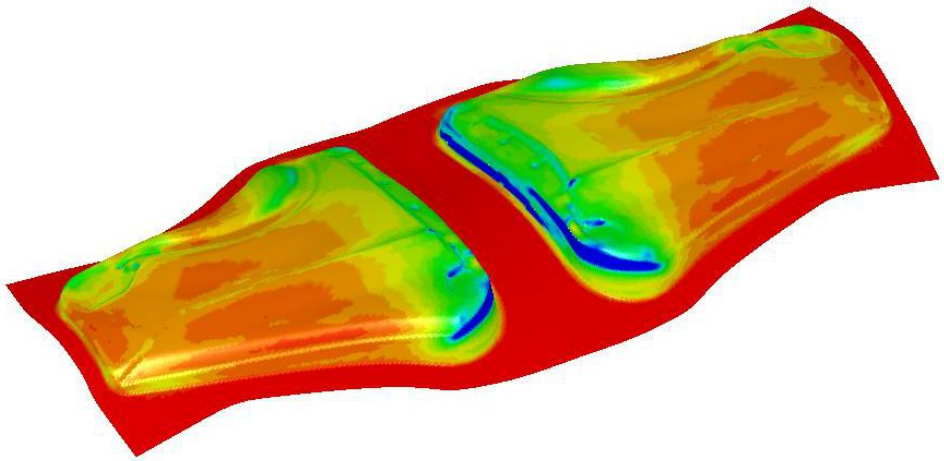

Figure 17-27. The fender outer - thickness/thinning plot on the drawn panel.

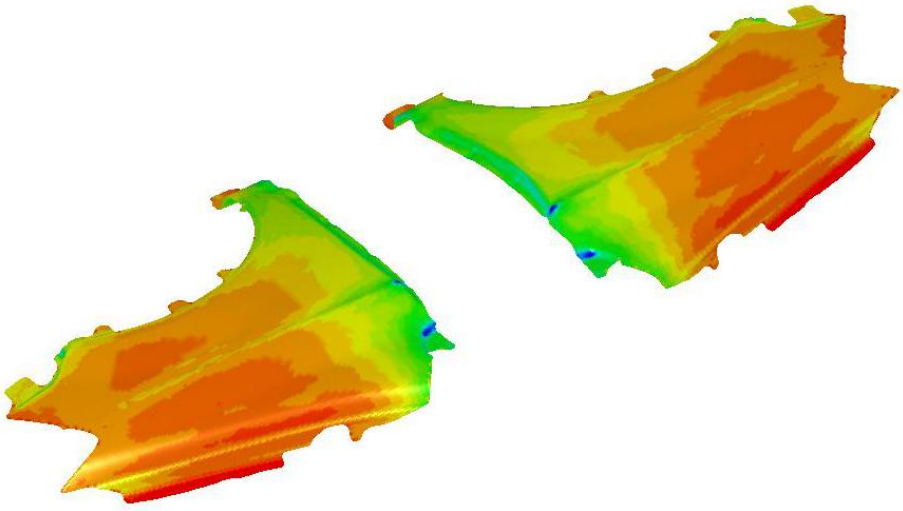

Figure 17-28. The fender outer trim complete using the NSEED1/NSEED2 feature.

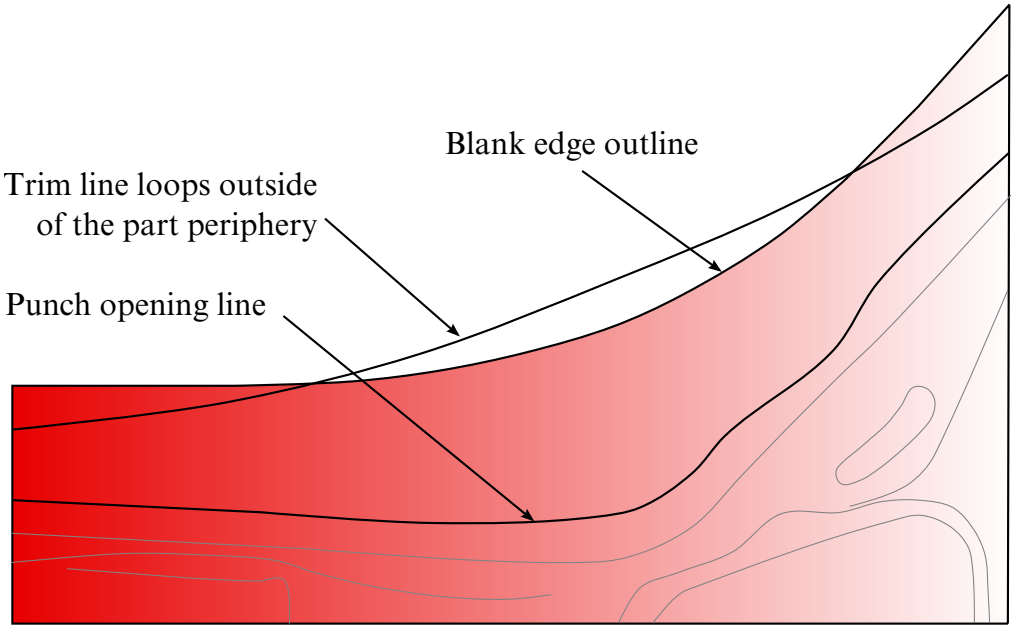

Figure 17-29. Revision 68643 deals with trim curves going beyond part boundary.

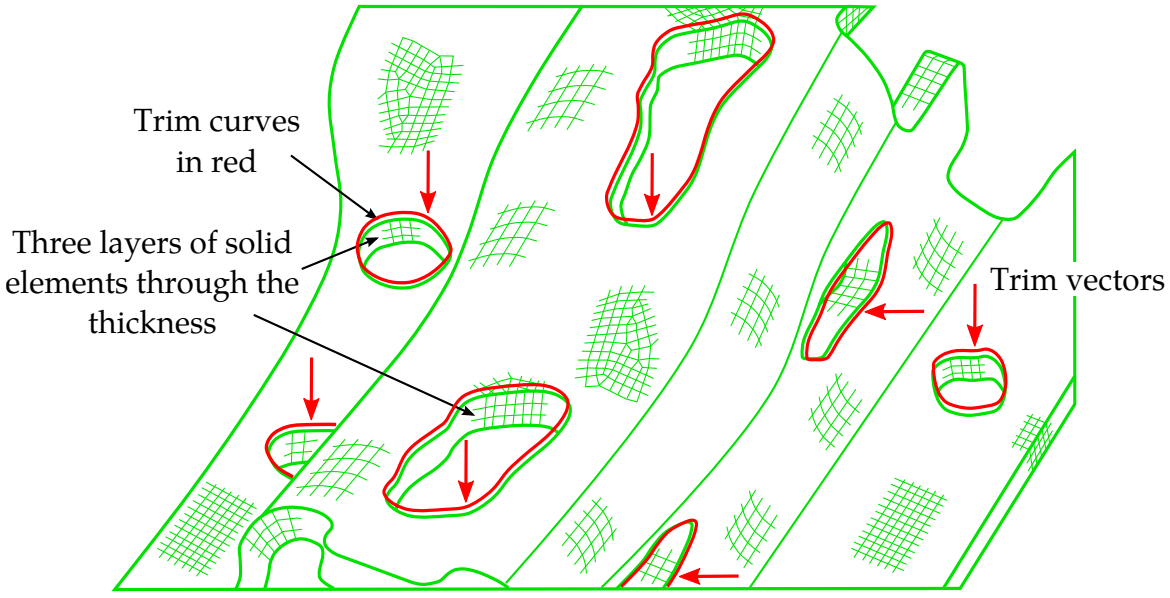

Figure 17-30. 2D trimming of solids using *DEFINE_CURVE_TRIM_2D

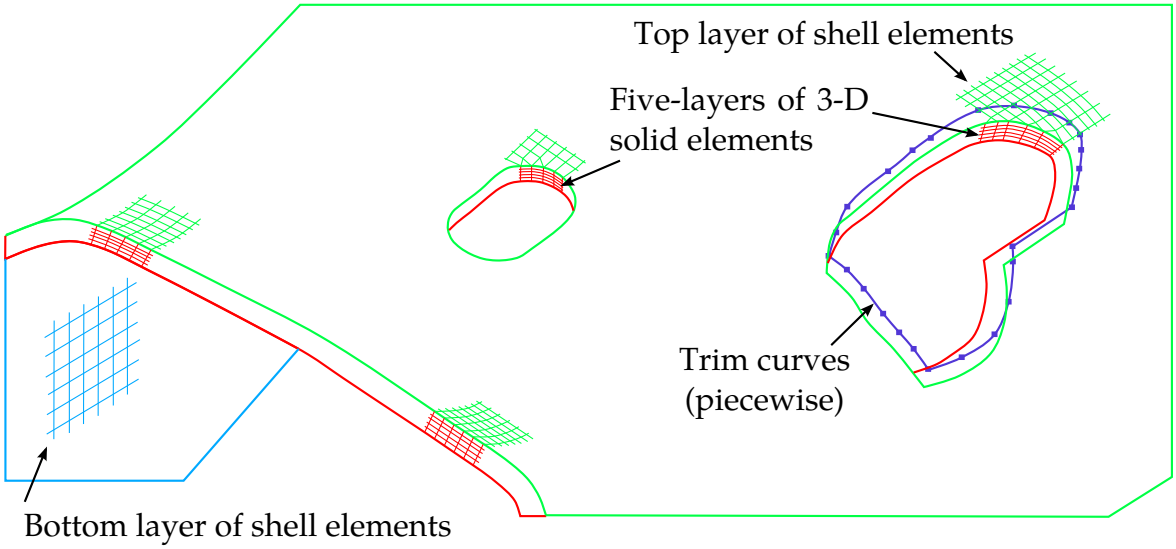

Figure 17-31. 3D trimming of laminates (a core of multiple-layers of solid elements with top and bottom layers of shell elements) using *DEFINE_CURVE_TRIM_3D. Note that shell elements must share the same nodes with the solid elements at the top and bottom layer.

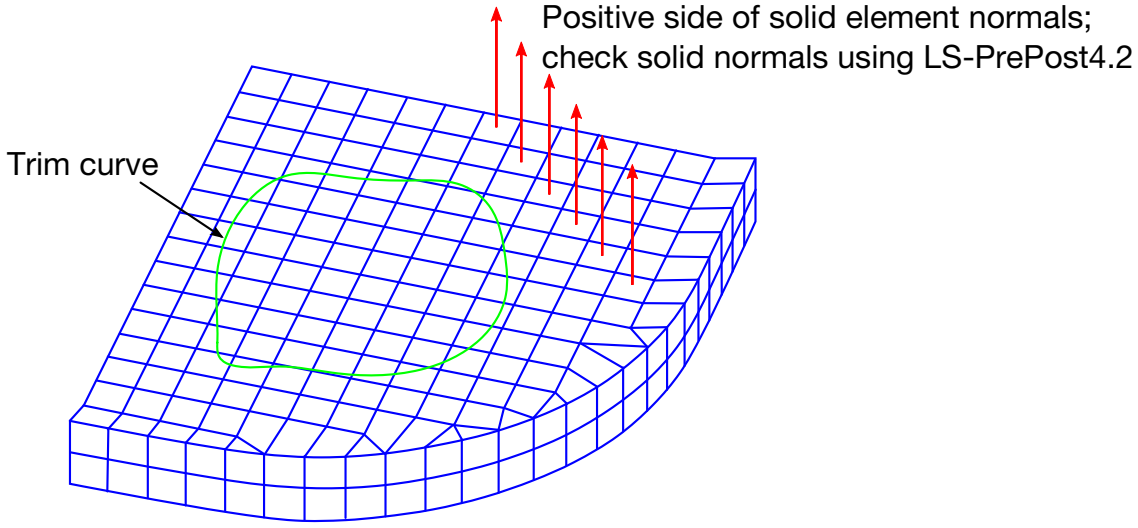

All solid element normals must be consistent. If trim curve is close to the positive normal side, set TDIR=1; otherwise set TDIR=-1. Respacing the curve with more points, project the respaced curve to the top or bottom solid surface may help the trimming.

Figure 17-32. Define trim curve for 3D trimming of solid and laminates.

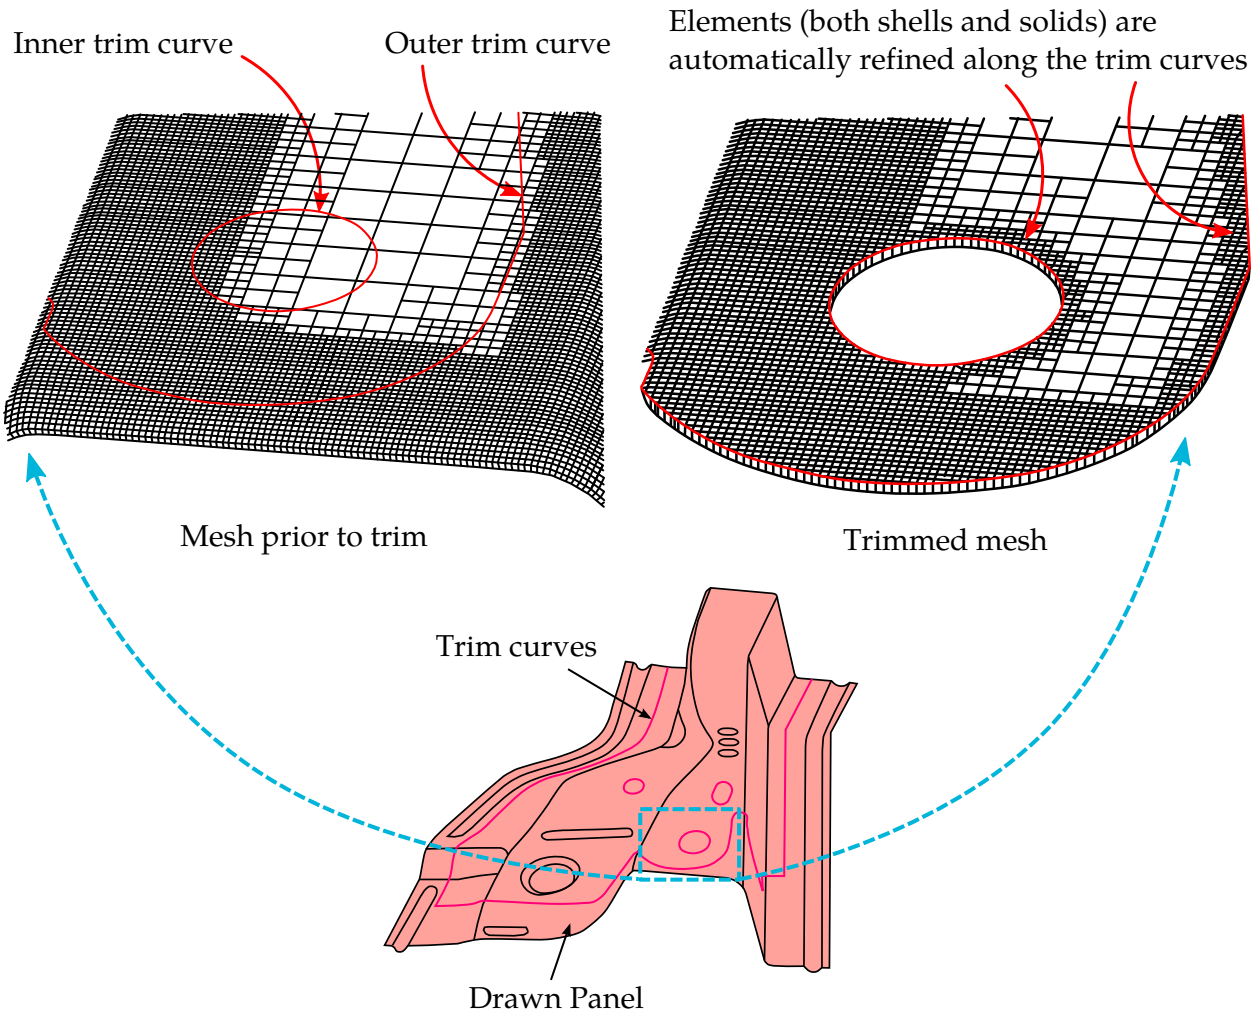

Figure 17-33. Trimming of an adaptive mesh on a sandwiched part. Meshes are automatically refined along the trim curves. Note that only one layer of solid element as a core is allowed for adaptive-meshed sandwich parts without CONTROL_FORMING_TRIMMING_SOLID_REFINEMENT. Also, the top and bottom layer of shells must share the same nodes as the solid elements.

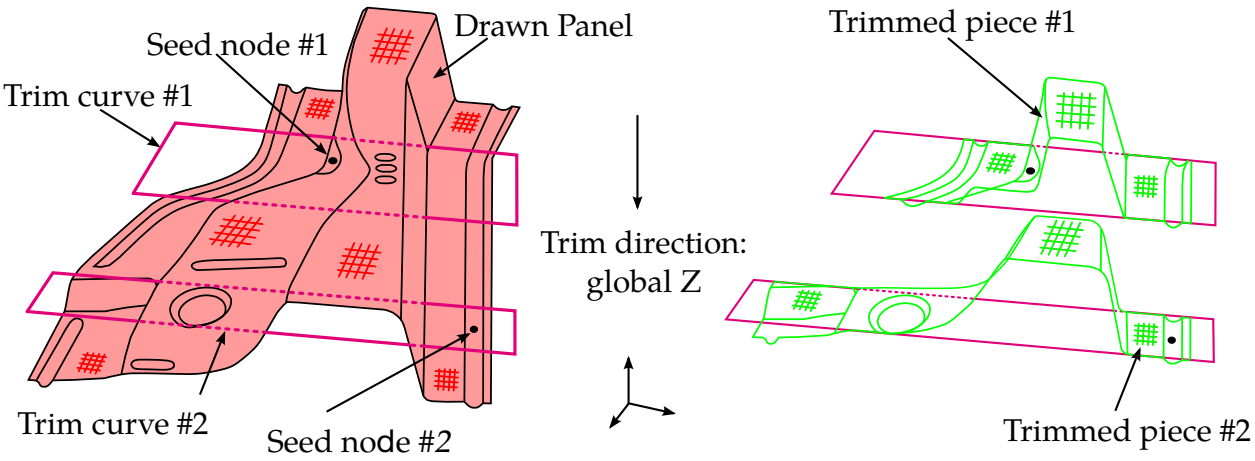

Figure 17-34. An example of 2D trimming of sandwiched part (laminates) from
2005 NUMISHEET benchmark - cross member.

*DEFINE_DE_ACTIVE_REGION

Purpose: To define an interested region for Discrete Elements (DE) for high efficiency collision pair searching. Any DE leaving this domain will not be considered in the future DE searching and will also be disabled in the contact algorithm.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYPE	XM/R	YM	ZM	TBIRTH	TDEATH	NFREQ
Type	I	I	F	F	F	F	F	I
Default	none	0	0.	0.	0.	0.	10^{20}	1

VARIABLE	DESCRIPTION
ID	Set ID/Box ID/Node ID
TYPE	Type for ID: EQ.0: Part set ID EQ.1: Box ID EQ.2: Node ID (moving sphere) EQ.3: Node ID (box-shaped region that moves with this node)
XM, YM, ZM	For TYPE = 0 or 1, factor for region's margin on each direction based on region length. The static coordinates limits are determined either by the part set or box. To provide a buffer zone, these factors, XM, YM, and ZM, can be used. The margin in each direction is calculated in the following way: Let X_{max} and X_{min} be the limits in the x-direction given by the set or box. Then, $$\Delta X = X_{max} - X_{min} \ .$$ The margin is, then, computed from the input as, $$X_{margin} = XM \times \Delta X$$ Then the corresponding limits for the active region are, $$X'_{max} = X_{max} + X_{margin}$$ $$X'_{min} = X_{min} - X_{margin}$$

VARIABLE	DESCRIPTION
	For TYPE = 3, the region is a box that moves with the node. The node is also the region's center. The location of the region is updated every NFREQ cycles. XM, YM, and ZM give the distance in each direction that the region extends from the node. For instance, let X_{node} be the position of the node in the x-direction. Let X_{max} and X_{min} be minimum and maximum x values defining the region. X_{max} and X_{min} are then calculated as: $$X_{max} = X_{node} + XM$$ $$X_{min} = X_{node} - XM$$
R	Radius of the region which is centered at the Node ID for TYPE = 2
TBIRTH, TDEATH	Birth and death times for the active region when Node ID is used (TYPE = 2)
NFREQ	Number of cycles between updates of the region's location for TYPE = 3 (default = 1)

*DEFINE_DE_BOND

Purpose: Define a bond model for bonds between discrete element spheres (DES). Note that the bond properties between DES may be overridden with *DEFINE_DE_BOND_-OVERRIDE.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	STYPE	BDFORM					
Type	I	I	I					
Default	none	0	1					

VARIABLE	DESCRIPTION
SID	Node set, part set, or part ID for which bond properties apply
STYPE	SID type: EQ.0: DES node set EQ.2: DES part set EQ.3: DES part
BDFORM	Bond formulation: EQ.1: Linear bond formulation

Card 2 for BDFORM = 1.

Card 2	1	2	3	4	5	6	7	8
Variable	PBN	PBS	PBN_S	PBS_S	SFA	ALPHA		MAXGAP
Type	F	F	F	F	F	F		F
Default	none	none	none	none	1.0	0.0		10^{-4}

VARIABLE	DESCRIPTION
PBN	Parallel-bond modulus [Pa]. See Remarks 1 and 2.

VARIABLE	DESCRIPTION
PBS	Parallel-bond stiffness ratio. shear stiffness/normal stiffness. See Remark 2.
PBN_S	Parallel-bond maximum normal stress. A zero value defines an infinite maximum normal stress.
PBS_S	Parallel-bond maximum shear stress. A zero value defines an infinite maximum shear stress.
SFA	Bond radius multiplier
ALPHA	Numerical damping, $0.0 \leq \text{ALPHA} \leq 1.0$
MAXGAP	Maximum gap between two bonded spheres: GT.0.0: Defines the ratio of the smaller radius of two bonded spheres as the maximum gap, that is, MAXGAP $\times \min(r_1, r_2)$. LT.0.0: Absolute value is used as the maximum gap.

Remarks:

1. **Normal Force.** The normal force between two bonded discrete elements with radii r_1 and r_2 is calculated as

$$\Delta f_{\text{n}} = \frac{\text{PBN}}{(r_1 + r_2)} \times \text{A} \times \Delta u_n \ ,$$

where

$$A = \pi r_{\text{eff}}^2$$
$$r_{\text{eff}} = \min(r_1, r_2) \times \text{SFA}$$

2. **Shear Force.** The shear force is calculated as

$$\Delta f_{\text{s}} = \text{PBS} \times \frac{\text{PBN}}{(r_1 + r_2)} \times \text{A} \times \Delta u_s \ .$$

*DEFINE_DE_BOND_OVERRIDE

Purpose: Override the bond values specified with *DEFINE_DE_BOND for bonds between certain discrete element spheres. This feature allows you to define heterogeneous bonds.

Unless *DEFINE_DE_BOND_OVERRIDE is required for defining heterogeneous bonds, we recommend not using it. The algorithms invoked by including *DEFINE_DE_BOND_OVERRIDE require more data passing during the calculation. Thus, it is more computationally expensive.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	STYPE		IRAND				
Type	I	I		I				
Default	none	0		0				

Card 2	1	2	3	4	5	6	7	8
Variable	PBN	PBS	PBN_S	PBS_S	SFA	ALPHA		
Type	F	F	F	F	F	F		
Default	none	none	none	none	1.0	0.0		

Additional card if IRAND = 1

Card 3	1	2	3	4	5	6	7	8
Variable	PBNMAX	PBSMAX	PBN_SMX	PBS_SMX				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
SID	Node set, part set, or part for which the bond properties will be overridden
STYPE	SID type: EQ.0: DES node set EQ.2: DES part set EQ.3: DES part
IRAND	Random distribution of bond properties: EQ.0: Single property (default) EQ.1: Uniform distribution
PBN	Parallel-bond modulus [Pa]. For IRAND = 1, this is the minimum value in the distribution. See Remarks 1 and 2.
PBS	Parallel-bond stiffness ratio. shear stiffness/normal stiffness. For IRAND = 1, PBS is the minimum value of the parallel-bond stiffness ratio in the distribution. See Remark 2.
PBN_S	Parallel-bond maximum normal stress. A zero value defines an infinite maximum normal stress. For IRAND = 1, PBN_S is the minimum value used for the parallel-bond maximum normal stress in the distribution.
PBS_S	Parallel-bond maximum shear stress. A zero value defines an infinite maximum shear stress.
SFA	Bond radius multiplier
ALPHA	Numerical damping
PBNMAX	Maximum value of PBN. Used for random distribution.
PBSMAX	Maximum value of PBS. Used for random distribution.
PBN_SMAX	Maximum value of PBN_S. Used for random distribution.
PBS_SMAX	Maximum value of PBS_S. Used for random distribution.

Remarks:

1. **Normal Force.** The normal force between two bonded discrete elements with radii r_1 and r_2 is calculated as

$$\Delta f_{\mathrm{n}} = \frac{\mathrm{PBN}}{(r_1 + r_2)} \times \mathrm{A} \times \Delta u_n \ ,$$

where

$$A = \pi r_{\mathrm{eff}}^2$$
$$r_{\mathrm{eff}} = \min(r_1, r_2) \times \mathrm{SFA}$$

For IRAND = 1, PBN is selected from the uniform distribution.

2. **Shear Force.** The shear force is calculated as

$$\Delta f_{\mathrm{s}} = \mathrm{PBS} \times \frac{\mathrm{PBN}}{(r_1 + r_2)} \times \mathrm{A} \times \Delta u_s \ .$$

For IRAND = 1, PBN and PBS are selected from their uniform distributions.

3. **Maximum Gap Between Bonded Spheres.** The maximum gap between bonded spheres is inherited from MAXGAP on *DEFINE_DE_BOND and thus not specified with this keyword.

*DEFINE_DE_BY_PART

Purpose: To define control parameters for discrete element sphere by part ID. This card overrides the values set in *CONTROL_DISCRETE_ELEMENT.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	NDAMP	TDAMP	FRICS	FRICR	NORMK	SHEARK	
Type	I	F	F	F	F	F	F	
Default	none	0.	0.	0.	0.	0.01	2/7	

Card 2	1	2	3	4	5	6	7	8
Variable	GAMMA	VOL	ANG					
Type	F	F	F					
Default	0.	0.	0.					

Card 3 is optional.

Card 3	1	2	3	4	5	6	7	8
Variable	LNORM	LSHEAR		FRICD	DC			
Type	I	I		F	F			
Default	0.	0.		FRICS	0.			

VARIABLE	DESCRIPTION
PID	Part ID of DES nodes
NDAMP	Normal damping coefficient
TDAMP	Tangential damping coefficient

VARIABLE	DESCRIPTION
FRICS	Static coefficient of friction (see Remarks): EQ.0.0: 3 DOF NE.0.0: 6 DOF (consider rotational DOF)
FRICR	Rolling friction coefficient
NORMK	Optional scale factor of normal spring constant (Default = 0.01)
SHEARK	Optional ratio between SHEARK/NORMK (Default = 2/7)
GAMMA	Liquid surface tension
VOL	Volume fraction
ANG	Contact angle
LNORM	Load curve ID of a curve that defines normal stiffness as a function of norm penetration ratio
LSHEAR	Load curve ID of a curve that defines shear stiffness as a function of norm penetration ratio
FRICD	Dynamic coefficient of friction. By default, FRICD = FRICS. See Remarks.
DC	Exponential decay coefficient. See Remarks.

Remarks:

The frictional coefficient is assumed to be dependent on the relative velocity $v_{\text{rel}}$of the two DEM in contact

$$\mu_c = \text{FRICD} + (\text{FRICS} - \text{FRICD})e^{-\text{DC}\times|v_{\text{rel}}|}.$$

*DEFINE_DE_COHESIVE

Purpose: Define a cohesive force mode for discrete element spheres. This keyword overrides the values set in *CONTROL_DISCRETE_ELEMENT.

Card 1	1	2						
Variable	SID	STYPE						
Type	I	I						
Default	0	0						

Card 2	1	2	3	4				
Variable	GAMMA	VOL	ANG	GAP				
Type	F	F	F	F				
Default	0.	0.	0.	0.				

VARIABLE	DESCRIPTION
SID	Node set ID, part set ID or part ID defining DES with cohesive force
STYPE	SID type: EQ.0: node set EQ.1: part set EQ.2: part
GAMMA	Liquid surface tension
VOL	Volume fraction
ANG	Contact angle

VARIABLE	DESCRIPTION
GAP	Spatial limit for the existence of liquid bridge between particles. A liquid bridge will exist when the distance between two particles is less or equal to $\min(\text{GAP}, d_{\text{rup}})$ where d_{rup} is the rupture distance of the bridge automatically calculated by LS-DYNA. EQ.0.0: maximum radius of DES NE.0.0: value of spatial limit

*DEFINE_DE_FLOW_DRAG

Purpose: Apply drag force to discrete element spheres (DES).

Card Summary:

Card 1. This card is required.

CD	RHO	MU	VX	VY	VZ	TBIRTH	TDEATH

Card 2. This card is required.

VS	DFLAG	SFN	SFS				

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	CD	RHO	MU	VX	VY	VZ	TBIRTH	TDEATH
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	10^{20}

VARIABLE	DESCRIPTION
CD	Drag coefficient, C_d EQ.-1: C_d determined based on Morrison 2013. See Remark 2. EQ.-2: C_d determined based on Allen 2018. See Remark 2. Card 1.1 must be included.
RHO	Flow density, ρ
MU	Dynamic viscosity
VX, VY, VZ	Flow velocity
TBIRTH	Birth time
TDEATH	Death time

Card 2	1	2	3	4	5	6	7	8
Variable	VS	DFLAG	SFN	SFS				
Type	F	I	F	F				
Default	0.0	1	1.0	1.0				

VARIABLE	DESCRIPTION
VS	Sound speed, V_s for CD = -2. See Remark 2.
DFLAG	Influence of neighbors on drag treatment: EQ.1: Consider only shadowing effect (default) EQ.2: See Remark 3. EQ.3: See Remark 3.
SFN, SFS	Scale factors for $C_{d1_\text{eff}}$and C_{d2_eff} respectively when DFLAG = 2.

Remarks:

1. **Drag Force.** The drag force is calculated as:

$$f_{\text{drag}} = \frac{1}{2} C_d \rho v^2 \frac{\pi D^2}{4} \quad .$$

Here C_d is the drag coefficient and D is the diameter of the DES.

2. **Drag Coefficient.** For CD = -1 and -2, the drag coefficient is found using predefined correlations.

If CD = -1, the drag coefficient is determined by the following correlation (Morrison 2013):

$$C_d = \frac{24}{\text{Re}} + \frac{2.6\left(\frac{\text{Re}}{5.0}\right)}{1+\left(\frac{\text{Re}}{5.0}\right)^{1.52}} + \frac{0.411\left(\frac{\text{Re}}{2.63\times 10^5}\right)^{-7.94}}{1+\left(\frac{\text{Re}}{2.63\times 10^5}\right)^{-8.00}} + \frac{0.25\frac{\text{Re}}{10^6}}{1+\frac{\text{Re}}{10^6}} \quad .$$

Re is the Reynolds number which for a sphere is defined as:

$$\text{Re} = \frac{\rho v D}{\mu} \quad .$$

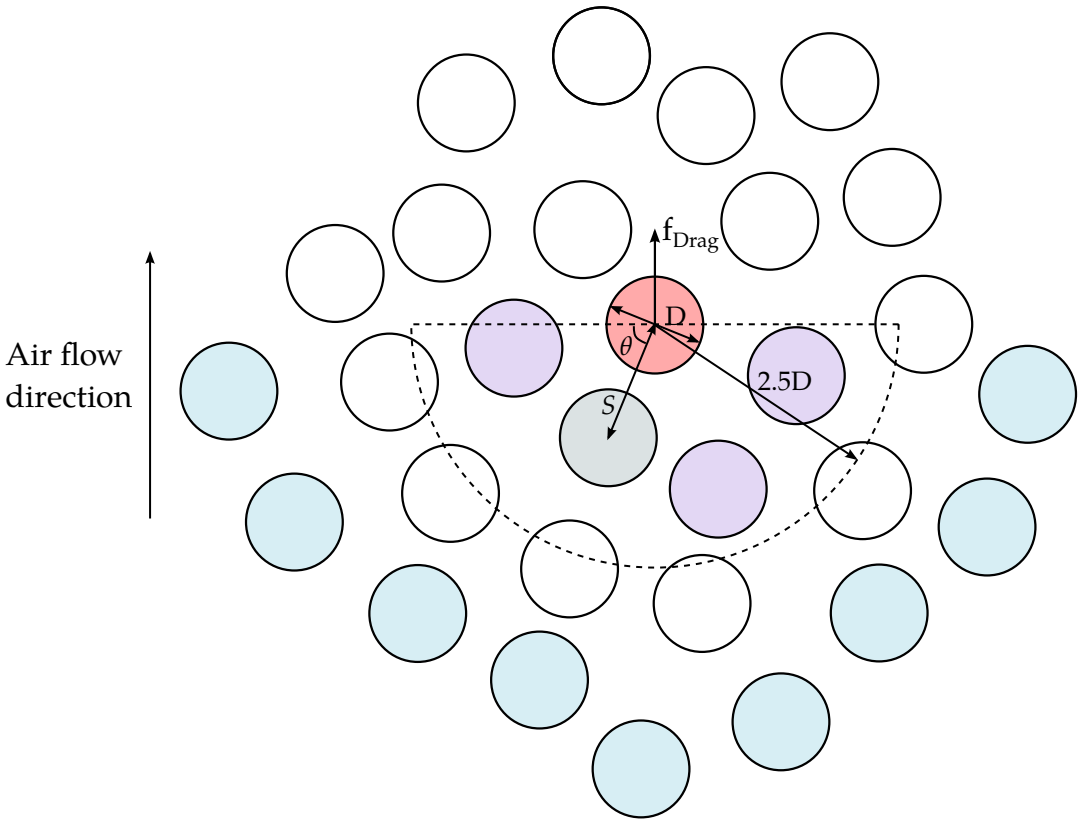

Figure 17-35. Schematic of how neighboring particles affect the drag treatment for DFLAG = 2 and 3. In this schematic the particles in blue are the leading particles that move at supersonic speed. We have developed two different two different methods for how the coefficient of drag is influenced by neighboring particles for particles that are not leading particles. In both methods, LS-DYNA checks for particles in the hemisphere in front of a given particle. In this schematic, the given particle is in red. The neighboring particles in the hemisphere are purple and grey. For DFLAG = 2, the grey particle is the closest neighbor of the red particle.

where ρ is the fluid density, v is the flow speed, D is the particle diameter, and μ is the dynamic viscosity of the fluid. C_d as obtained from this correlation is valid between $0.1 < \mathrm{Re} < 10^6$.

If CD = -2, the drag coefficient is determined by the following correlation (Allen 2018):

$$C_d = \begin{cases} 0.995 & \text{for} \quad M \geq 2.0 \\ 0.920 + 0.0375M & \text{for} \quad 1.2 \leq M < 2.0 \\ -0.163 + 0.9400M & \text{for} \quad 0.7 \leq M < 1.2 \\ 0.418 + 0.1100M & \text{for} \quad 0.2 \leq M < 0.7 \\ 0.440 & \text{for} \quad M < 0.2 \end{cases}$$

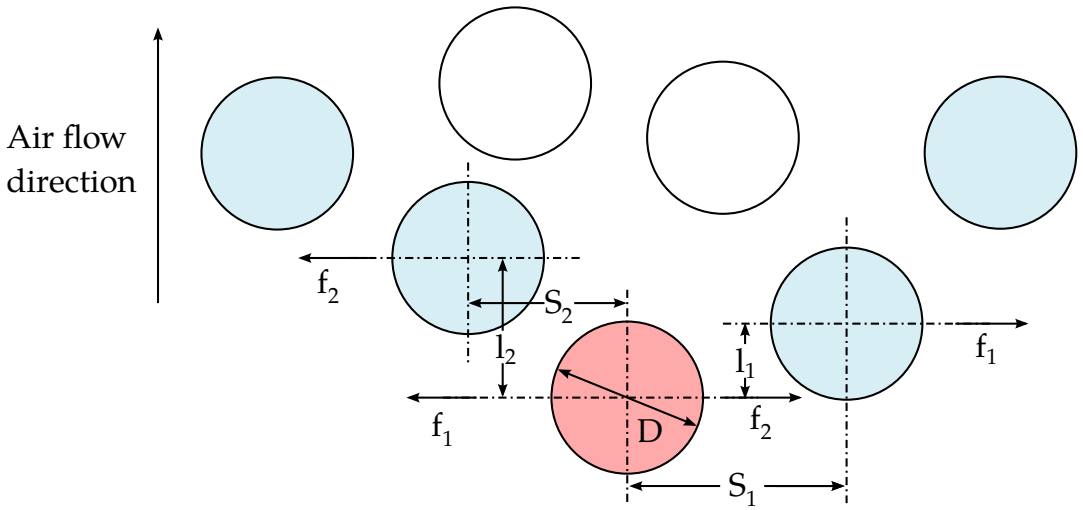

Figure 17-36. Illustration of perpendicular drag force in the lead particles for DFLAG = 2 and 3. In this schematic, the red particle interacts with both of its neighbors.

Here, M is the Mach number defined as:

$$M = \frac{V}{V_s},$$

where V is the pellet velocity and V_s is the sound speed.

3. **Influence of Neighbors on Drag Treatment.** The influence of neighboring particles on the drag treatment of a DES depends on the setting of DFLAG. By default, LS-DYNA only considers the shadowing effect (DFLAG = 1). We have implemented two other treatments.

   For DFLAG = 2 and 3, consider a group of particles as shown in Figure 17-35. The particles in blue are the leading particles in the flow. These particles travel with supersonic speed. They create a shock wave in front of them. Because of the shock wave, the leading particles may experience drag side forces perpendicular to the traveling direction from their neighboring leading particles (see Figure 17-36). For the particles in the layers behind the leading particles, their drag coefficient may be influenced by the particles in front of them. DFLAG = 2 and 3 are intended to model these two phenomena.

   For both DFLAG = 2 and 3, we model the perpendicular side force with the same equation. These side forces are only from leading particle interactions and thus only apply to leading particles. The side drag coefficient is given by:

$$\frac{C_{\text{dperp\_eff}}}{C_d} = \left(7.20e^{-2.644\frac{S}{D}}\right)(1-\frac{l}{D}), for\ l \le D\ and\ S < 2.5D$$

C_d in this equation is the normal drag coefficient, and D is the diameter of the particle. l and S are as indicated in Figure 17-36, where l_1 and l_2 are examples of l, and S_1 and S_2 are examples of S.

For the drag force in the traveling direction, the coefficient of drag for the leading particles will be CD as specified in Card 1. The leading particles have the largest drag coefficient. The coefficient of drag for all the other particles are modified based on the value of DFLAG. For this modification, LS-DYNA looks at the hemisphere with radius $2.5D$ in front of a given particle in the flow as shown in Figure 17-35.

a) *DFLAG* = *2*. The coefficient of drag is first determined with the following equation:

$$\frac{C_{d\text{trav\_eff}}}{C_d} = \left(1.0 + 4.644e^{-2.225\frac{S}{D}}\right)\cos\theta + \left(1 - e^{-0.5\frac{S}{D}}\right)\sin\theta\,, \text{ for } S < 2.5D$$

S is the distance from the center of the particle to its closest neighbor in the hemisphere. In Figure 17-35, the particle of interest is red and its closest neighbor is grey. θ is defined as shown in the figure. C_d is the coefficient given in CD. This coefficient is then scaled down by considering the number of particles, NHP, in the hemisphere to get the traveling direction coefficient of drag:

$$C_{\text{dtrav}} = \max(0, 1.0 - 0.02 \times \text{NHP})C_{\text{dtrav\_eff}}$$

Note that if the particle has no neighboring particles, then the coefficient of drag is that given by Card 1.

b) *DFLAG* = *3*. The coefficient of drag is determined with the following equation (Numerical Investigation of Drag Forces on Particle Clouds in Non-Newtonian Flow, Efe Kinaci, Johannes Kepler University Linz, September 2015):

$$\frac{C_{\text{dtrav\_eff}}}{C_d} = \alpha^{1-\chi}, \text{ for } S < 2.5D$$

Here,

$$C_d = \left(0.63 + \frac{4.8}{\text{Re}_i^{0.5}}\right)^2$$

$$\chi = 3.7 - 0.65e^{\frac{(1.5-\log_{10}\text{Re}_i)^2}{2}}$$

$$\text{Re}_i = \frac{\alpha\rho v D}{\mu}$$

In the above equations, α is the void fraction, ρ is the fluid density, v is the flow velocity, D is the diameter of the particle, and μ is dynamic viscosity of the fluid.

If there is no neighboring particle within 2.5*D*, the drag coefficient is based on the logic of CD = -1.

*DEFINE_DE_HBOND

Purpose: To define a heterogeneous bond model for discrete element sphere (DES). (This command, along with *INTERFACE_DE_HBOND, are no longer being developed.)

Card Summary:

Card 1. This card is required

SID	STYPE	HBDFM	IDIM				

Card 1.1. This card is included if and only if HBDFM = 2.

PBK_SF	PBS_SF	FRGK	FRGS	BONDR	ALPHA	DMG	FRMDL

Card 2. This card is optional.

PRECRK	CKTYPE		ITFID				

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	STYPE	HBDFM	IDIM				
Type	I	I	I	I				
Default	none	0	1	3				

VARIABLE	DESCRIPTION
SID	DES nodes
STYPE	Set type for SID: EQ.0: DES node set EQ.1: DES node EQ.2: DES part set EQ.3: DES part

VARIABLE	DESCRIPTION
HBDFM	Bond formulation: EQ.1: (Reserved) EQ.2: Nonlinear heterogeneous bond formulation for fracture analysis based on the general material models defined in the material cards. DES elements with different material models can be defined within one bond.
IDIM	Space dimension for DES bonds: EQ.2: For 2D plane strain problems EQ.3: For 3D problems

Nonlinear Heterogeneous Bond Card. Include this card if and only if HBDFM = 2.

Card 1.1	1	2	3	4	5	6	7	8
Variable	PBK_SF	PBS_SF	FRGK	FRGS	BONDR	ALPHA	DMG	FRMDL
Type	F	F	F	F	F	F	F	I
Default	1.0	1.0	none	none	none	0.0	1.0	1

VARIABLE	DESCRIPTION
PBK_SF	Scale factor for volumetric stiffness of the bond.
PBS_SF	Scale factor for shear stiffness of the bond.
FRGK	Critical fracture energy release rate for volumetric deformation due to the hydrostatic pressure. EQ.0: A zero value specifies an infinite energy release rate for unbreakable bonds. LT.0: A negative value defines the energy release rate under volumetric compression (i.e. positive pressure) and FRGS defined below is used under volumetric expansion (i.e. negative pressure).

VARIABLE	DESCRIPTION
FRGS	Critical fracture energy release rate for shear deformation. EQ.0: A zero value specifies an infinite energy release rate for unbreakable bonds. FRGK.LT.0: See description for FRGK.
BONDR	Influence radius of the DES nodes.
ALPHA	Numerical damping
DMG	Continuous parameter for damage model. EQ.1.0: The bond breaks if the fracture energy in the bond reaches the critical value. Microdamage is not calculated. GT.0.5.and.LT.1.0: Microdamage effects being once the fracture energy reaches DMG × FMG[K,S]. Upon the onset of microdamage, the computed damage ratio will increase (monotonically) as the fracture energy grows. Bond weakening from microdamage is modeled by reducing the bond stiffness in proportion to the damage ratio.
FRMDL	Fracture model: EQ.1: Fracture energy of shear deformation is calculated based on deviatoric stresses. EQ.2: Fracture energy of shear deformation is calculated based on deviatoric stresses, *excluding the axial component (along the bond).* EQ.3,4: Same as 1&2, respectively, but FRGK and FRGS are read as the total failure energy density and will be converted to the corresponding critical fracture energy release rate. The total failure energy density is calculated as the total area under uniaxial tension stress-strain curve. EQ.5,6: Same as 3&4, respectively, as FRGK and FRGS are read as the total failure energy density but will not be converted. Instead, the failure energy within the bond will be calculated.

VARIABLE	DESCRIPTION
	Models 1&2 are more suitable for brittle materials, and Models 5&6 are easier for ductile materials. Models 3&4 can be used for moderately ductile fracture accordingly. This is the default fracture model applied to all DES parts, even if they have different material models. More fracture models can be defined for different materials by specifying an interface ID (ITFID) in the optional card.

Pre-Crack Card. This card is optional.

Card 2	1	2	3	4	5	6	7	8
Variable	PRECRK	CKTYPE		ITFID				
Type	I	I		I				
Default	none	0		0				

VARIABLE	DESCRIPTION
PRECRK	Shell set, define 3D surfaces of the pre-crack
CKTYPE	EQ.0: Part set EQ.1: Part
ITFID	ID of the interface *INTERFACE_DE_HBOND, which defines different failure models for the heterogeneous bonds within each part and between two parts respectively.

*DEFINE_DE_INJECT_BONDED_{OPTION}

Available options include:

<BLANK>

ELLIPSE

Purpose: This keyword injects bonded discrete element spheres (DES) from a specified region at a flow rate given by a user defined curve. Like *DEFINE_DE_INJECTION, when the option is blank, the region from which the DES emanate is assumed rectangular; the ELLIPSE option indicates that the region is elliptical. The first two cards are very similar to *DEFINE_DE_INJECTION. In contrast to *DEFINE_DE_INJECTION, this keyword contains additional cards to inject the bonded patterns. The bond properties of Card 3 are the same as the properties of Card 2 in *DEFINE_DE_BOND. In conjunction with the keyword *DEFINE_DE_INJECT_-SHAPE, this keyword randomly selects different shape patterns and injects them at the mass flow rate (RMASS) defined in Card 2.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	SID	XC	YC	ZC	XL	YL	CID
Type	I	I	F	F	F	F	F	I
Default	none	none	0.0	0.0	0.0	0.0	0.0	0

Card 2	1	2	3	4	5	6	7	8
Variable	RMASS	VX	VY	VZ	TBEG	TEND		
Type	F	F	F	F	F	F		
Default	none	0.0	0.0	0.0	0.0	10^{20}		

Card 3	1	2	3	4	5	6	7	8
Variable	PBN	PBS	PBN_S	PBS_S	SFA	ALPHA	MAXGAP	
Type	F	F	F	F	F	F	F	
Default	none	none	0.0	0.0	1.0	0.0	10^{-4}	

Card 4	1							
Variable	NSHAPE							
Type	I							
Default	0							

Bonded Shape Patterns. Additional cards for NSHAPE ≠ 0. Define NSHAPE patterns, requiring ceil(NSHAPE/8) cards.

Card 5	1	2	3	4	5	6	7	8
Variable	ISHAPE	ISHAPE	ISHAPE	ISHAPE	ISHAPE	ISHAPE	ISHAPE	ISHAPE
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
PID	Part ID of new generated DES nodes
SID	Node set ID. Nodes and DES properties are generated automatically during input phase based on the user input and assigned to this SID.
XC, YC, ZC	x, y, z coordinates of the center of injection plane

VARIABLE	DESCRIPTION
XL	For rectangular planes XL specifies the planar length along the x-axis in the coordinate system specified by CID. For elliptical planes XL specifies the length of the major axis.
YL	For rectangular planes YL specifies the planar length along the y-axis in the coordinate system specified by CID. For elliptical planes YL specifies the length of the minor axis.
CID	Optional local coordinate system ID, see *DEFINE_COORDINATE_SYSTEM
RMASS	Mass flow rate GE.0.0: Constant mass flow rate LT.0.0: |RMASS| is a curve ID defining the mass flow rate as a function of time.
VX, VY, VZ	Vector components defining the initial velocity of injected DES specified relative the coordinate system defined by CID.
TBEG	Birth time; time for injection to begin
TEND	Death time; time for injection to end
PBN	Parallel-bond modulus [Pa].
PBS	Parallel-bond stiffness ratio. Shear stiffness/normal stiffness.
PBN_S	Parallel-bond maximum normal stress. A zero value defines an infinite maximum normal stress.
PBS_S	Parallel-bond maximum shear stress. A zero value defines an infinite maximum shear stress.
SFA	Bond radius multiplier.
ALPHA	Numerical damping.
MAXGAP	Maximum gap between two bonded spheres GT.0.0: When MAXGAP is positive, the maximum allowed gap is determined on a bond-by-bond basis as a function of the radii of the two involved spheres. The maximum gap is determined by multiplying the minimum of the two radii by the value of MAXGAP.

VARIABLE	DESCRIPTION
	LT.0.0: Absolute value is used as the maximum gap.
NSHAPE	Number of shape patterns.
ISHAPE	The pattern ID defined in *DEFINE_DE_INJECT_SHAPE. Only the first NSHAPE number of IDs will be used.

*DEFINE_DE_INJECT_SHAPE

Purpose: Define the bonded shape patterns. When used with *DEFINE_DE_INJECT_-BONDED, these shape patterns will be injected with equal probability. Each pattern contains several discrete elements, and the pattern can be in any direction.

There are two options to specify a desired bonded injection pattern:

1. Give the position and radius of each DE in the pattern (IAUTO = 0). The relative positions and radii of the DEs should be carefully defined to generate bonds between the neighboring DEs; see the field MAXGAP in *DEFINE_DE_INJECTED_BONDED.

2. Select the shape from predefined pattern types (IAUTO = 1). This method requires the length of the desired shape in all directions and a particle radius. All the particles will have the same radius. The patterns are restricted to lines, prisms with equilateral triangle faces, and cuboids.

Card Summary:

Card Sets: Include as many sets of Cards 1 and 2a/b as desired. Each set defines one shape pattern. This input terminates at the next keyword ("*") card.

Card 1. This card is required.

ID	NDE	IAUTO	ITYPE				

Card 2a. If IAUTO = 0, include NDE of this card, one for each DE in the pattern.

X	Y	Z	R				

Card 2b. Include this card if IAUTO = 1.

LX	LY	LZ	R				

Data Card Definitions:

Card 1	1	2	3	4				
Variable	ID	NDE	IAUTO	ITYPE				
Type	I	I	I	I				
Default	none	none	0	0				

VARIABLE	DESCRIPTION
ID	ID of the shape pattern
NDE	Number of DEs in this pattern
IAUTO	Flag for how to specify the bonded shape patterns: EQ.0: Give each particle's relative position and radius EQ.1: Use predefined pattern types
ITYPE	Bond particles patterns when IAUTO = 1: EQ.1: Line EQ.2: Cuboid EQ.3: Prism with equilateral triangle faces

Card 2 for IAUTO = 0. Include one card for each DE in the pattern (NDE total cards for each Card 1).

Card 2a	1	2	3	4				
Variable	X	Y	Z	R				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
X, Y, Z	Coordinates of the DEs in this pattern
R	Radii of the DEs in this pattern

Card 2 for IAUTO = 1. Include this card to define the length of the bonded pattern as well as the radius for each DE in the pattern.

Card 2b	1	2	3	4				
Variable	LX	LY	LZ	R				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
LX, LY, LZ	Length of bonded pattern in *X*, *Y*, and *Z*-directions
R	Radius of each DE in this pattern. All DEs in the pattern have the same radius.

*DEFINE_DE_INJECTION_{OPTION}

Available options include:

<BLANK>

ELLIPSE

Purpose: This keyword injects discrete element spheres (DES) from specified a region at a flow rate given by a user defined curve. When the option is blank, the region from which the DES emanate is assumed rectangular. The ELLIPSE keyword option indicates that the region is to be elliptical.

Card Summary:

Card 1. This card is required.

PID	SID	XC	YC	ZC	XL	YL	CID

Card 2. This card is required.

RMASS	RMIN	RMAX	VX	VY	VZ	TBEG	TEND

Card 3. This card is optional.

IFUNC	NID	IMULTI	LCVX	LCVY	LCVZ	IRAND	

Card 3.1. Include this card when IMULTI > 1.

R1	P1	R2	P2	R3	P3	R4	P4

Card 1	1	2	3	4	5	6	7	8
Variable	PID	SID	XC	YC	ZC	XL	YL	CID
Type	I	I	F	F	F	F	F	I
Default	none	none	0.0	0.0	0.0	0.0	0.0	0

VARIABLE	DESCRIPTION
PID	Part ID of generated DES nodes

VARIABLE	DESCRIPTION
SID	Node set ID. Nodes and DES properties are generated automatically during input phase based on the user input and assigned to this SID.
XC, YC, ZC	x, y, z coordinate of the center of injection plane
XL	For rectangular planes XL specifies the planar length along the x-axis in the coordinate system specified by CID. For elliptical planes XL specifies the length of the major axis.
YL	For rectangular planes YL specifies the planar length along the y-axis in the coordinate system specified by CID. For elliptical planes YL specifies the length of the minor axis.
CID	Optional local coordinate system ID; see *DEFINE_COORDINATE_SYSTEM or *DEFINE_COORDINATE_NOTES

Card 2	1	2	3	4	5	6	7	8
Variable	RMASS	RMIN	RMAX	VX	VY	VZ	TBEG	TEND
Type	F	F	F	F	F	F	F	F
Default	none	none	RMIN	0.0	0.0	0.0	0.0	10^{20}

VARIABLE	DESCRIPTION
RMASS	Mass flow rate (see Remark 2) LT.0: Curve ID
RMIN	Minimum DES radius (ignored if IMULTI > 1)
RMAX	Maximum DES radius (ignored if IMULTI > 1)
VX, VY, VZ	Vector components defining the initial velocity of injected DES specified relative the coordinate system defined by CID.
TBEG	Birth time
TEND	Death time

Optional card 3.

Card 3	1	2	3	4	5	6	7	8
Variable	IFUNC	NID	IMULTI	LCVX	LCVY	LCVZ	IRAND	
Type	I	I	I	I	I	I	I	
Default	0	0	1	0	0	0	0	

VARIABLE	DESCRIPTION
IFUNC	Distribution of particle radii (ignored if IMULTI > 1): EQ.0: Uniform distribution (default) EQ.1: Gaussian distribution (see Remark 1)
NID	An optional node ID. If defined, the center of injection plane follows the motion of this node.
IMULTI	Flag for giving a specified mass distribution of injected particles with given radii: EQ.1: Inject the particles with distribution IFUNC using the radii specified with RMIN and RMAX (default). GT.1: Inject particles with IMULTI different radii, R*i*, with each different size having a specified mass distribution, P*i*, given in Card 3.1. IMULTI cannot be greater than 4.
LCVX	Load curve defining initial injection velocity in the *x*-direction
LCVY	Load curve defining initial injection velocity in the *y*-direction
LCVZ	Load curve defining initial injection velocity in the *z*-direction
IRAND	Enable a more randomized injection patten with IRAND = 1.

Included when IMULTI > 1.

Card 3.1	1	2	3	4	5	6	7	8
Variable	R1	P1	R2	P2	R3	P3	R4	P4
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
R*i*	Injected particle radius. IMULTI radii may be specified.
P*i*	Mass percentage of injected particle with radius R*i*

Remarks:

1. **Gaussian Distribution of Particle Radii.** The distribution of particle radii for IFUNC = 1 follows a Gaussian distribution:

$$(r|r_0,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(r-r_0)^2}{2\sigma^2}} ,$$

where the mean radius is given by

$$r_0 = \frac{1}{2}(r_{\max} + r_{\min})$$

and the standard deviation is

$$\sigma = \frac{1}{2}(r_{\max} - r_{\min}) .$$

2. **Maximum Estimated Mass Flow Rate.** The maximum estimated mass flowrate injected through plane (XL,YL) is:

$$Q_{\max} = 0.9 \times \pi \times \rho \times \mathrm{XL} \times \mathrm{YL} \times \frac{1}{6}\mathrm{V}_{\max}$$

where

$$V_{\max} = \sqrt{\mathrm{VX}^2 + \mathrm{VY}^2 + \mathrm{VZ}^2}$$

If RMASS > $Q_{\max}$, LS-DYNA issues the warning message: "input mass flowrate may exceed the maximum estimated rate."

3. **Restrictions for Rebalancing.** Dynamic rebalancing does not work with injections. Thus, NCRB in *CONTROL_DISCRETE_ELEMENT should be set to zero

when using this feature. Instead, you can use *CONTROL_MPP_DECOMPOSITION_REDECOMPOSITION for rebalancing purposes.

*DEFINE_DE_INTERNAL_SKIP

Purpose: DES defined in PID will ignore internal particle to particle interaction force.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	TYPE						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
PID	Part set ID or part ID. TYPE below indicates the ID type.
TYPE	PID type: EQ.0: Part set EQ.1: Part

*DEFINE_DE_MASSFLOW_PLANE

Purpose: Measure DES mass flow rate across a defined plane. See also the accompanying keyword *DATABASE_DEMASSFLOW which controls the output frequency.

Card 1	1	2	3	4	5	6	7	8
Variable	PRTCLSID	SURFSID	PTYPE	STYPE				
Type	I	I	I	I				
Default	0	0	0	0				

VARIABLE	DESCRIPTION
PRTCLSID	Node set ID, node ID, part set ID or part ID specifying DES to be measured. PTYPE below indicates the ID type specified by PRTCLSID.
SURFSID	Part set ID or part ID defining the surface. STYPE below indicates the ID type specified by SURFSID.
PTYPE	PRTCLSID type: EQ.0: Node set EQ.1: Node EQ.2: Part set EQ.3: Part
STYPE	SURFSID type: EQ.0: Part set EQ.1: Part

*DEFINE_DE_MESH_BEAM

Purpose: Generate and place discrete element sphere (DES) elements along the axis of beam elements. By default, the generated DES is treated as a shadow (inactive) element on the beam element. It only transfers forces between the ICFD element and beam element to make ICFD coupling easier.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	TYPE	NQUAD	DESPID	DESXID	NSID	RSF	IACTIVE
Type	I	I	I	I	I	I	F	I
Default	none	none	1	Rem 1	Rem 1	0	1.0	0

Card 2	1	2	3	4	5	6	7	8
Variable	MASS	INERTIA	RADIUS					
Type	F	F	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
SID	Part or part set ID for the region of the mesh upon which the DES elements will be placed
TYPE	SID type: EQ.0: Part set ID EQ.1: Part ID
NQUAD	Number of equally spaced DES elements created along the axis of beam element (maximum NQUAD = 4)
DESPID	Part ID for generated DES elements
DESXID	Section ID for generated DES elements

VARIABLE	DESCRIPTION
NSID	Create a node set with ID NSID (see *SET_NODE) for the nodes generated by this keyword. By default, no node set is created.
RSF	Scale factor of DES radius
IACTIVE	Activate DES: EQ.0: DES is inactive and used as a shadow (default). EQ.1: DES is active.
MASS	DES Mass: GT.0: DES mass EQ.-1: The DES particle radius (r) is $0.5 \times$ Beam Length/NQUAD, the DES mass (m) is $4\pi\rho r^3/3$, and the moment of inertia is $2mr^2/5$. Input fields INERTIA and RADIUS are ignored.
INERTIA	Mass moment of inertia (ignored if MASS = -1)
RADIUS	Particle radius (ignored if MASS = -1)

Remarks:

1. **DESPID and DESXID.** The part ID and/or section ID will be generated by this card if they are not provided in the input.

*DEFINE_DE_MESH_SURFACE

Purpose: Generate and place discrete element sphere (DES) elements on the surface of shell elements. By default, the generated DES is treated as a shadow (inactive) element on the surface. It only transfers forces between the ICFD element and shell element to make ICFD coupling easier.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	TYPE	NQUAD	DESPID	DESXID	NSID	RSF	IACTIVE
Type	I	I	I	I	I	I	F	I
Default	none	none	1	Rem 1	Rem 1	0	1.0	0

VARIABLE	DESCRIPTION
SID	Part or part set ID for the region of the mesh upon which the DES elements will be placed
TYPE	SID type: EQ.0: Part set ID EQ.1: Part ID
NQUAD	Number of equally spaced DES elements created on a shell element in each local shell direction. For instance, NQUAD × NQUAD DES elements will be created on the surface a quad shell. (Maximum NQUAD = 4)
DESPID	Part ID for generated DES elements
DESXID	Section ID for generated DES elements
NSID	If defined, this card creates a node set with ID NSID (see *SET_-NODE) for the nodes generated by this card.
RSF	Scale factor for determining the DES radius: GE.0.0: Scale factor on the internally determined radius based on shell thickness. LT.0.0: DES radius is $0.5 \times \lvert RSF \rvert \times (\text{maximum diagonal length})/NQUAD$

VARIABLE	DESCRIPTION
	for rectangular segments and $0.5 \times \lvert RSF \rvert \times (\text{maximum side length})/NQUAD$ for triangular segments.
IACTIVE	Activate DES: EQ.0: DES is inactive and used as a shadow (default). EQ.1: DES is active.

Remarks:

1. **DESPID and DESXID.** Part ID and/or section ID will be generated by this card if they are not provided in the input.

*DEFINE_DE_PATTERN_OUTPUT

Purpose: Output when DES cross specified planes and what their coordinates are when they cross the planes. This feature is for visualizing the pattern of shotgun pellets at various locations during post-processing. The data is output to dem_pattern. With this keyword, you specify the line to which the planes are orthogonal and where the plane is along the line from an origin point.

Card Summary:

Card 1. This card is required.

PID	PTYPE	XO	YO	ZO	XH	YH	ZH

Card 2. This card is required.

NSET							

Card 2.1. Include NSET/8 of this card.

DIST1	DIST2	DIST3	DIST4	DIST5	DIST6	DIST7	DIST8

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PID	PTYPE	XO	YO	ZO	XH	YH	ZH
Type	I	I	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
PID	Part ID/part set ID of the DES
PTYPE	Type for PID: EQ.0: Part EQ.1: Part set
XO, YO, ZO	Coordinates of the origin from which the distance to the planes is measured along the vector (XH,YH,ZH) – (XO,YO,ZO)

VARIABLE	DESCRIPTION
XH, YH, ZH	Head of the direction to which the planes are orthogonal

Card 2	1	2	3	4	5	6	7	8
Variable	NSET							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
NSET	Number of planes for which patterns will be recorded

Include NSET/8 of this card to specify the distance of each plane from the origin

Card 2.1	1	2	3	4	5	6	7	8
Variable	DIST1	DIST2	DIST3	DIST4	DIST5	DIST6	DIST7	DIST8
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
DIST1, . .	Distance of each plane from (XO, YO,ZO)

*DEFINE_DE_TO_BEAM_COUPLING

Purpose: To define a coupling interface between discrete element spheres (DES) and beams.

Card 1	1	2	3	4	5	6	7	8
Variable	DESID	BEAMID	DESTYP	BEAMTYP				
Type	I	I	I	I				
Default	0	0	0	0				

Card 2	1	2	3	4	5	6	7	8
Variable	FRICS	FRICD	DAMP	BSORT				
Type	F	F	F	I				
Default	0	0	0	100				

VARIABLE	DESCRIPTION
DESID	Node set ID, node ID, part set ID or part ID specifying the DES in the coupling. DESTYP below indicates the ID type.
BEAMID	Part set ID or part ID specifying the beams in the coupling. BEAMTYP below indicates the ID type.
DESTYP	Type for DESID: EQ.0: Node set EQ.1: Node EQ.2: Part set EQ.3: Part
BEAMTYP	Type for BEAMID: EQ.0: Part set EQ.1: Part

VARIABLE	DESCRIPTION
FRICS	Friction coefficient
FRICD	Rolling friction coefficient
DAMP	Damping coefficient
BSORT	Number of cycles between bucket sorts

*DEFINE_DE_TO_SURFACE_COUPLING_{OPTION}

Purpose: To define a non-tied coupling interface between discrete element spheres (DES) and a surface defined by shell part(s) or solid part(s). This coupling is currently not implemented for tshell part(s).

Available options include:

<BLANK>

TRANSDUCER

The TRANSDUCER keyword option creates a force transducer for measuring the coupling interface forces. With this option, LS-DYNA outputs the translational forces from the active surface coupling interfaces to dem_rcforc. The *only* fields read when using this option are SURFID, SURFTYP and CID_RCF. See Remark 5.

Card 1	1	2	3	4	5	6	7	8
Variable	DESID	SURFID	DESTYP	SURFTYP				
Type	I	I	I	I				
Default	none	none	0	0				

Card 2	1	2	3	4	5	6	7	8
Variable	FRICS	FRICD	DAMP	BSORT	LCVX	LCVY	LCVZ	WEARC
Type	F	F	F	I	I	I	I	F
Default	0.0	0.0	0.0	100	0	0	0	0.

User Defined Wear Parameter Cards. Additional card for WEARC < 0.

Card 3	1	2	3	4	5	6	7	8
Variable	W1	W2	W3	W4	W5	W6	W7	W8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

This card is optional

Card 4	1	2	3	4	5	6	7	8
Variable	SFP	SFT			IDEACT	CID_RCF	BT	DT
Type	F	F			I	I	F	F
Default	1.0	1.0			0	0	0.0	10^{20}

VARIABLE	DESCRIPTION
DESID	Node set ID, node ID, part set ID or part ID specifying DES in the coupling. DESTYP below indicates the ID type.
SURFID	Part set ID or part ID specifying the surface. SURFTYP below indicates the ID type.
DESTYP	DESID type: EQ.0: Node set EQ.1: Node EQ.2: Part set EQ.3: Part
SURFTYP	SURFID type: EQ.0: Part set EQ.1: Part EQ.2: Segment set (TRANSDUCER keyword option only; see Remark 5)

VARIABLE	DESCRIPTION
FRICS	Friction coefficient
FRICD	Rolling friction coefficient
DAMP	Damping coefficient (unitless). If a discrete element sphere impacts a rigid surface with a velocity v_{impact}, the rebound velocity is $$v_{\text{rebound}} = (1 - \text{DAMP})v_{\text{impact}}$$
BSORT	Number of cycle between bucket sorts; default value is 100. For blast simulation with very high DEM particles velocity, it is suggested to set BSORT = 20 or smaller. LT.0: |BSORT| is the minimum number of cycle between bucket sorts. This value can be increased during runtime by tracking the velocity of potential coupling pair. This feature only works with MPP currently.
LVCX	Load curve defines surface velocity in x-direction
LVCY	Load curve defines surface velocity in y-direction
LVCZ	Load curve defines surface velocity in z-direction
WEARC	WEARC is the wear coefficient: GT.0: Archard's Wear Law; see Remark 1. EQ.-1: Finnie Wear Law, additional card is required EQ.-100: User defined wear model, additional card is required
W1-W8	For WEARC = -1, W1 is the yield stress of the target material. For WEARC = -100, Wi are user defined wear parameters.
SFP	Scale factor on contact stiffness. By default, SFP = 1.0. The contact stiffness is calculated as $$K_n = \text{SFP} \times \begin{cases} K \times r \times \text{NormK} & \text{if NormK} > 0 \\ \lvert\text{NormK}\rvert & \text{if NormK} < 0 \end{cases}$$ where K is bulk modulus, r is discrete element radius, NormK is the scale factor of the spring constant defined in *CONTROL_DISCRETE_ELEMENT.
SFT	Scale factor for surface thickness (scales true thickness). This option applies only to contact with shell elements. True thickness is the element thickness of the shell elements.

VARIABLE	DESCRIPTION
IDEACT	DES particles will be automatically deactivated after contacting with surface when IDEACT = 1.
CID_RCF	Coordinate system ID. Force resultants are output to the demforc file in a local system.
BT	Birth time
DT	Death time

Remarks:

1. **Archard's Wear Law.** If WEARC > 0, then the wear on the shell surface is calculated using Archard's wear law

$$\dot{h} = \frac{\text{WEARC} \times f_n \times v_t}{A}$$

where,

h = wear depth
f_n = normal contact force from DE
v_t = tangential sliding velocity of the DE on shell
A = area of contact segment

The wear depth is output to the interface force file.

2. **Finnie's Wear Law.** If WEARC = -1, then the wear on the shell surface is calculated using Finnie's wear law. The model of Finnie relates the rate of wear to the rate of kinetic energy of particle impact on a surface as:

$$Q = \begin{cases} \dfrac{mv^2}{8p}\left(\sin 2\alpha - 3\sin^2\alpha\right) & \text{if } \tan\alpha < \dfrac{1}{3} \\ \dfrac{mv^2}{24p}\cos^2\alpha & \text{if } \tan\alpha > \dfrac{1}{3} \end{cases}$$

where, Q is the volume of the material removed from surface, m is particle mass, α is the impact angle, and p is the yield stress of the target material input in field W1.The wear depth is output to the interface force file.

3. **Interface Force File.** *DATABASE_BINARY_DEMFOR controls the output interval of the coupling forces to the DEM interface force file. This interface force file is activated by the command line option "dem=", for example,

lsdyna i=**inputfilename.k** … dem=**interfaceforce_filename**

The DEM interface force file can be read into LS-PrePost for plotting of coupling pressure and forces on the surface segments.

4. **Coupling Force Output.** *DATABASE_RCFORC controls the output interval of the coupling forces to the ASCII demrcf file. This output file is analogous to the rcforc file for *CONTACT.

5. **TRANSDUCER.** The TRANSDUCER keyword option causes LS-DYNA to collect and record the translational forces from a section of the surface side of an active surface coupling interface. With this option, the *only input not ignored* is SURFID, SURFTYP and CID_RCF. The collected forces are from surface nodes instead of surface segments. Therefore, total force may be a little different from the parent interface.

*DEFINE_DE_TO_SURFACE_TIED

Purpose: To define a tied-with-failure coupling interface between discrete element spheres (DES) and a surface defined by shell part(s) or solid part(s). This coupling is currently not implemented for tshell part(s).

Card 1	1	2	3	4	5	6	7	8
Variable	DESID	SURFID	DESTYP	SURFTYP				
Type	I	I	I	I				
Default	0	0	0	0				

Card 2	1	2	3	4	5	6	7	8
Variable	NFLF	SFLF	NEN	MES	LCID	NSORT	MAXGAP	
Type	F	F	F	F	I	I	F	
Default	none	none	2.	2.	0	100	0.0	

VARIABLE	DESCRIPTION
DESID	Node set ID, node ID, part set ID or part ID specifying DES in the tied interface. DESTYP below indicates the ID type.
SURFID	Part set ID or part ID specifying the surface. SURFTYP below indicates the ID type.
DESTYP	DESID type: EQ.0: Node set EQ.1: Node EQ.2: Part set EQ.3: Part
SURFTYP	SURFID type: EQ.0: Part set

VARIABLE	DESCRIPTION
	EQ.1: Part
NFLF	Normal failure force. Only tensile failure, that is, tensile normal forces, will be considered in the failure criterion
SFLF	Shear failure force
NEN	Exponent for normal force
MES	Exponent for shear force. Failure criterion: $$\left(\frac{\lvert f_n \rvert}{\text{NFLF}}\right)^{\text{NEN}} + \left(\frac{\lvert f_s \rvert}{\text{SFLF}}\right)^{\text{MES}} \geq 1.$$ Failure is assumed if the left side is larger than 1. f_n and f_s are the normal and shear interface force.
LCID	Optional curve ID defining a scale factor as a function of time. The scale factor is applied to NFLF and SFLF, making the failure forces time-dependent.
NSORT	Number of cycles between bucket sorts
MAXGAP	Determines maximum gap between DES and the surface: GT.0.0: The maximum gap is determined by scaling the DES radius by MAXGAP, that is, MAXGAP × r_{DES} LT.0.0: |MAXGAP| is used as the maximum gap.

Remarks:

Both NFLF and SFLF must be defined. If failure in only tension or shear is required, then set the other failure force to a large value (10^{10}).

DEFINE_DEATH_TIMES_*OPTION

Available options include:

NODES

SET

RIGID

Purpose: To dynamically define the death times for *BOUNDARY_PRESCRIBED_MOTION based on the locations of nodes and rigid bodies. Once a node or rigid body moves past a plane or a geometric entity, the death time is set to the current time. The input in this section continues until the next keyword ("*") card is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	GEO	N1	N2	N3				
Type	I	I	I	I				
Default	none	0	0	0				

Card 2	1	2	3	4	5	6	7	8
Variable	X_T	Y_T	Z_T	X_H	Y_H	Z_H	R	FLAG
Type	F	F	F	F	F	F	F	I
Default	Rem 1	Rem 1	Rem 1	Rem 2	Rem 2	Rem 2	none	1

ID Cards. Set the list of nodes and rigid bodies affected by this keyword. This input terminates at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	NSID1	NSID2	NSID3	NSID4	NSID5	NSID6	NSID7	NSID8
Type	I	I	I	I	I	I	I	I

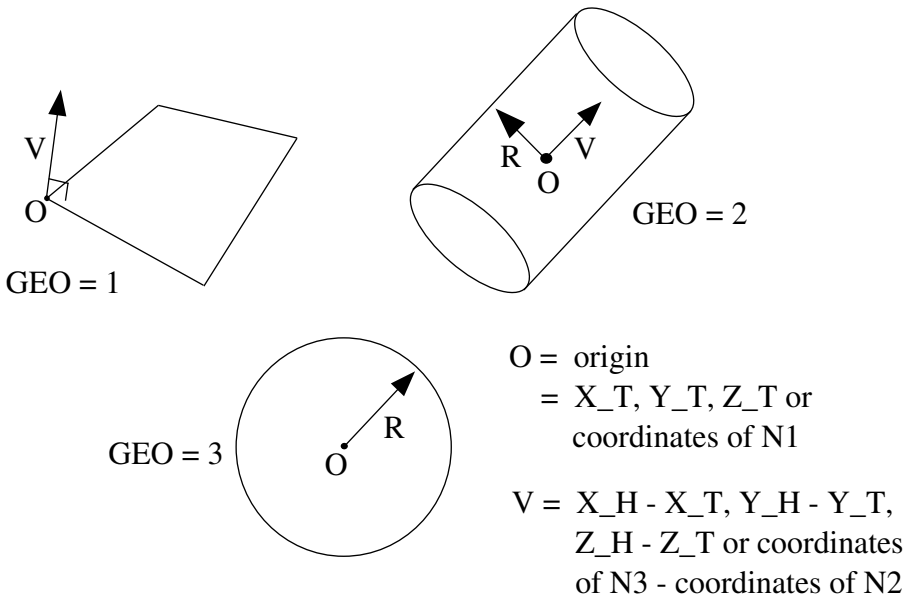

Figure 17-37. Geometry types.

VARIABLE	DESCRIPTION
GEO	Geometric entity type: EQ.1: Plane EQ.2: Infinite cylinder EQ.3: Sphere
N1	Node defining the origin of the geometric entity. See Remark 1.
N2	Node defining the tail of the orientation vector. See Remark 2.
N3	Node defining the head of the orientation vector. See Remark 2.
X_T	*x*-coordinate of the origin of the geometric entity and the tail of the orientation vector. See Remark 1.
Y_T	*y*-coordinate of the origin of the geometric entity and the tail of the orientation vector. See Remark 1.
Z_T	*z*-coordinate of the origin of the geometric entity and the tail of the orientation vector. See Remark 1.
X_H	*x*-coordinate of the head of the orientation vector. See Remark 2.
Y_H	*y*-coordinate of the head of the orientation vector. See Remark 2.

VARIABLE	DESCRIPTION
Z_H	z-coordinate of the head of the orientation vector. See Remark 2.
R	Radius of cylinder or sphere.
FLAG	Flag for where the node or rigid body must be with respect to the geometric entity for the death time to be set to the current time: EQ.1: The node or rigid body is outside of the geometric entity or on the positive side of the plane as defined by the normal direction. EQ.-1: Node or rigid body is inside the geometric entity or on the negative side of the plane.
NSIDi	i^{th} node, node set, or rigid body

Remarks:

1. **Origin.** Either N1 or X_T, Y_T, and Z_T should be specified, but not both.

2. **Orientation Vector.** Either N2 and N3 or X_H, Y_H, and Z_H should be specified, but not both. Specifying N2 and N3 is equivalent to setting the head of the vector equal to the tail of the vector (X_T,Y_T, Z_T) plus the vector from N2 to N3.

*DEFINE_DRIFT_REMOVE

Purpose: Minimize the drift of a structure over a loop by modifying the curves for specifying accelerations and forces.

Card 1	1	2	3	4	5	6	7	8
Variable	OPTION							
Type	I							
Default	none							

Curve Card. Include as many of this card as needed. Input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
OPTION	Specifies how curves are handled. EQ.0: no changes are made to the curves. EQ.1: modify to minimize the drift.
ID[N]	ID of Nth curve to be modified

Remarks:

When data from an accelerometer is integrated to obtain velocities and displacements numerical noise leads to drift. For signals that are necessarily periodic, like data collected as a car drives around a track, the resulting quadrature loses its periodicity. This keyword activates an algorithm that approximately restores periodicity.

Because its chief property is *not* being periodic we approximate noise, a_{noise}, by a function that is not periodic, namely, a parabola (or possibly a straight line)

$$a_{\text{noise}}(t) = a_0 + a_1 t + a_2 t^2 \ .$$

Since a_{noise} cannot be allowed in the context of periodicity we seek to find an $a_{\text{corrected}}$

$$a_{\text{corrected}} = a_{\text{data}} - a_{\text{noise}}$$

that removes as much "noise" as possible. We therefore find the a_i that minimize the norm of the corrected velocity,

$$\int_{t_0}^{t_1} [v_{\text{corrected}}(t)]^2 \text{dt} \ ,$$

where the corrected velocity is the quadrature of the corrected noise,

$$v_{\text{corrected}}(t) = \int_{t_0}^{t} [a_{\text{data}}(\tau) - a_{\text{noise}}(\tau)] \, \text{d}\tau = v_{\text{data}}(t) - \left(a_0 t + \frac{1}{2} a_1 t^2 + \frac{1}{3} a_2 t^3 \right).$$

For each curve listed on the data cards LS-DYNA approximately removes the drift by numerically solving the above minimization problem.

DEFINE_ELEMENT_DEATH_*OPTION

Available options include:

SOLID

SOLID_SET

BEAM

BEAM_SET

SHELL

SHELL_SET

THICK_SHELL

THICK_SHELL_SET

Purpose: Set a time or space condition for deleting an element or element set during a simulation. This keyword is only for deformable elements, not rigid body elements.

Card 1	1	2	3	4	5	6	7	8
Variable	EID/SID	TIME	BOXID	INOUT	IDGRP	CID	PERCENT	
Type	I	F	I	I	I	I	F	
Default	none	0.0	{∅}	0	0	global	0.0	

VARIABLE	DESCRIPTION
EID/SID	Element ID or element set ID identifying elements that are considered for deletion, either by meeting the BOXID/INOUT criterion or the independent TIME/IDGRP/PERCENT criterion.
TIME	Deletion time for elimination of the element or element set. If BOXID is nonzero, a TIME value of zero is reset to 10^{16}.
BOXID	An optional box ID; see CID below and *DEFINE_BOX. An element is immediately deleted upon meeting the condition of being inside the box (or outside the box, depending on INOUT), without regard to TIME, IDGRP, or PERCENT. For an element set, only the element (or elements) in the set meeting the condition is deleted at

VARIABLE	DESCRIPTION
	each time step. Before R11, the elements in a single IDGRP were all deleted when one element in the group met the condition despite the value of PERCENT. As of R11, all the elements in the group are deleted when PERCENT of the elements in the group meet the condition.
INOUT	Flag pertaining to BOXID: EQ.0: Elements inside the box EQ.1: Elements outside the box
IDGRP	Group ID. Elements sharing the same positive value of IDGRP are considered to be in the same group. All elements in a group will be simultaneously deleted one cycle after a percentage of the elements (specified in PERCENT) fail. There is no requirement that each *DEFINE_ELEMENT_DEATH command have a unique IDGRP. In other words, elements in a single group can come from multiple *DEFINE_ELEMENT_-DEATH commands. Elements in which IDGRP = 0 are not assigned to a group and thus deletion of one element does not cause deletion of the other elements.
CID	Coordinate ID for transforming box BOXID. If CID is not specified, the box is in the global coordinate system. The box rotates and translates with the coordinate system only if the coordinate system is flagged for an update every time step.
PERCENT	Deletion percentage. EQ.0.0: When one element fails, all elements in the group will be deleted (default). GT.0.0: Percentage of elements failed before elements in group IDGRP are deleted.

DEFINE_ELEMENT_EROSION_*OPTION

Available options include:

IGA

SHELL

TSHELL

Purpose: Defines the number of failed integration points per layer that fails a layer and the number of failed layers that triggers element deletion (erosion) during the simulation. This keyword is only for deformable shells and deformable thick shells. This keyword must be used in conjunction with a material model that has a failure option, or else with *MAT_ADD_EROSION. The criteria specified on this card will override other criteria related to the number of failed integration points for element deletion, such as NUMFIP on *MAT_ADD_EROSION or NUMINT on other *MAT cards.

Either the SHELL option or the TSHELL option is required, except for in the case of isogeometric analysis. Isogeometric analysis requires the IGA option and currently only supports isogeometric shell elements for STYP = 3 or 4.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	STYP	NUMFIP	NIPF				
Type	I	I	F	I				
Default	none	none	-100.	1				

VARIABLE	DESCRIPTION
SID	Element ID, element set ID, part ID, or part set ID; see *PART, *SET_PART or *SET_T/SHELL_*OPTION*.
STYP	ID type of SID: EQ.1: Shell or tshell element ID EQ.2: Shell or tshell element set ID EQ.3: Part ID EQ.4: Part set ID

VARIABLE	DESCRIPTION
NUMFIP	Number of layers which must fail prior to element deletion. LT.0.0: |NUMFIP| is the percentage of layers which must fail prior to element deletion.
NIFP	Number of integration points within one layer that need to fail to indicate a failed layer

*DEFINE_ELEMENT_GENERALIZED_SHELL

Purpose: Define a general 3D shell formulation to be used in combination with *ELEMENT_GENERALIZED_SHELL. The objective of this feature is to allow the rapid prototyping of new shell element formulations by adding them through the keyword input file.

All necessary information, like the values of the shape functions and their derivatives at various locations (at the integration points and at the nodal points), must be defined using this keyword. An example for a 9-noded generalized shell element with 4 integration points in the plane is given in Figure 17-38 to illustrate the procedure. The element formulation ID (called ELFORM) used in this keyword needs to be greater or equal than 1000 and will be referenced through *SECTION_SHELL (see Figure 19-4 in *ELEMENT_GENERALIZED_SHELL).

Card 1	1	2	3	4	5	6	7	8
Variable	ELFORM	NIPP	NMNP	IMASS	FORM			
Type	I	I	I	I	I			
Default	none	none	none	none	none			

Weights and Shape Function Values/Derivatives at Gauss Points:

These cards are read according to the following pseudo code:

```
for i = 1 to NIPP {
        read Card 2(i)
        for k = 1 to NMNP {
                read Card 3(i,k)
        }
} // comment: Read in NIPP × (1 + NMNP) cards
```

Weight Cards. Provide weight for integration point *i*.

(Card 2)$_i$	1	2	3	4	5	6	7	8
Variable	WI							
Type	F							

Integration Point Shape Function Value/Derivatives Cards. Provide the value of the k^{th} shape function and its derivative at the i^{th} integration point.

(Card 3)$_{ik}$	1	2	3	4	5	6	7	8
Variable	NKI		DNKIDR		DNKIDS			
Type	F		F		F			

For FORM = 0 or FORM = 1, Shape Function Derivatives at Nodes:

These cards are read according to the following pseudo code:

```
for l = 1 to NMNP {
        for k = 1 to NMNP {
                read Card 4a(l,k)
        }
} // comment: Read in NMNP × NMNP cards
```

Nodal Shape Function Derivative Cards. The value of the k^{th} shape function's derivative at the l^{th} nodal point.

(Card 4a)$_{lk}$	1	2	3	4	5	6	7	8
Variable	DNKLDR		DNKLDS					
Type	F		F					

For FORM = 2 or FORM = 3, Shape Function 2nd derivative at Gauss Points:

> NOTE: For FORM = 2 and FORM = 3 it is assumed that the shape functions are at least C1 continuous (having a continuous derivative).

The cards for this method are read according to the following pseudo code:

```
for i = 1 to NIPP {
        for k = 1 to NMNP {
                read Card 4b(i,k)
        }
} // comment: Read in NGP × NMNP cards
```

Nodal Shape Function Second Derivative Cards. The value of the k^{th} shape function's second derivative at the i^{th} integration point.

(Card 4b)*ik*	1	2	3	4	5	6	7	8
Variable	D2NKIDR2		D2NKIDRDS		D2NKIDS2			
Type	F		F		F			

VARIABLE	DESCRIPTION
ELFORM	Element Formulation ID which is referenced by *SECTION_SHELL to connect *ELEMENT_GENERALIZED_SHELL with the appropriate shell formulation. The chosen number needs to be greater or equal than 1000.
NIPP	Number of in-plane integration points.
NMNP	Number of nodes for this element formulation.
IMASS	Option for lumping of mass matrix: EQ.0: row sum EQ.1: diagonal weighting.
FORM	Shell formulation to be used EQ.0: shear deformable shell theory with rotational DOFs (shell normal evaluated at the nodes) EQ.1: shear deformable shell theory without rotational DOFs (shell normal evaluated at the nodes) EQ.2: thin shell theory without rotational DOFs (shell normal evaluated at the integration points) EQ.3: thin shell theory with rotational DOFs (shell normal evaluated at the integration points)
WI	Integration weight at integration point *i*.

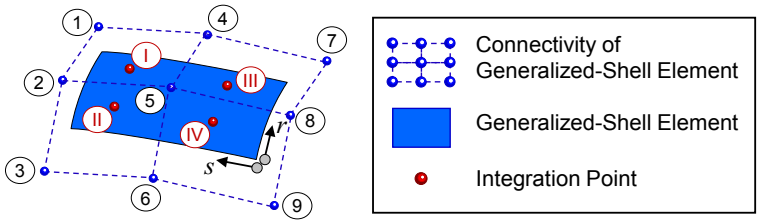
VARIABLE	DESCRIPTION
NKI	Value of the shape function N_k evaluated at integration point i.
DNKIDR	Value of the derivative of the shape function N_k with respect to the local coordinate r at the integration point i $\left(\frac{\partial N_k^i}{\partial r}\right)$.
DNKIDS	Value of the derivative of the shape function N_k with respect to the local coordinate s at the integration point i $\left(\frac{\partial N_k^i}{\partial s}\right)$.
DNKLDR	Value of the derivative of the shape function N_k with respect to the local coordinate r at the nodal point l $\left(\frac{\partial N_k^l}{\partial r}\right)$.
DNKLDS	Value of the derivative of the shape function N_k with respect to the local coordinate s at the nodal point l $\left(\frac{\partial N_k^l}{\partial s}\right)$.
D2NKIDR2	Value of the second derivative of the shape function N_k with respect to the local coordinate r at the integration point i $\left(\frac{\partial^2 N_k^i}{\partial r^2}\right)$.
D2NKIDRDS	Value of the second derivative of the shape function N_k with respect to the local coordinates r and s at the integration point i $\left(\frac{\partial^2 N_k^i}{\partial r \partial s}\right)$.
D2NKIDS2	Value of the second derivative of the shape function N_k with respect to the local coordinate s at the integration point i $\left(\frac{\partial^2 N_k^i}{\partial s^2}\right)$.

Remarks:

1. **Interpolation Shell Elements.** For post-processing and the treatment of contact boundary conditions, the use of interpolation shell elements (see *ELEMENT_-INTERPOLATION_SHELL and *CONSTRAINED_NODE_INTERPOLATION) is necessary.

2. **Input Order.** Data input order for the NMNP nodal points must match the definition of the connectivity of the element in *ELEMENT_GENERALIZED_-SHELL.

Example:



```
*DEFINE_ELEMENT_GENERALIZED_SHELL
$#  elform      nipp      nmnp     imass      form

Figure 17-38. Example of a generalized shell formulation with *DEFINE_ELEMENT_GENERALIZED SHELL.

*DEFINE_ELEMENT_GENERALIZED_SOLID

Purpose: Define a general 3D solid formulation to be used in combination with *ELEMENT_GENERALIZED_SOLID. New solid element formulations may be rapidly prototyped in the input deck using this feature.

All necessary information, like the values of the shape functions and their derivatives at all integration points, must be defined using this keyword. The example shown in Figure 17-39 illustrates this procedure by prototyping an 18-noded generalized solid element with 8 integration points. The element formulation ID (called ELFORM) used in this keyword needs to be greater or equal than 1000 and will be referenced through *SECTION_SOLID (see Figure 19-5 in *ELEMENT_GENERALIZED_SOLID).

Card 1	1	2	3	4	5	6	7	8
Variable	ELFORM	NIP	NMNP	IMASS				
Type	I	I	I	I				
Default	none	none	none	none				

Weights and Shape Function Values/Derivative at Gauss Points:

These cards are read according to the following pseudo code:

```
for i = 1 to NIP {
        read Card 2(i)
        for k = 1 to NMNP {
                read Card 3(i,k)
        }
} // comment: Read in NIP × (1 + NMNP) cards
```

Weight Cards. Provide weight for integration point *i*.

(Card 2)*i*	1	2	3	4	5	6	7	8
Variable	WI							
Type	F							

Integration Point Shape Function Value/Derivatives Cards. Provide the value of the k^{th} shape function and its derivative at the i^{th} integration point.

(Card 3)$_{ik}$	1	2	3	4	5	6	7	8
Variable	NKI		DNKIDR		DNKIDS		DNKIDT	
Type	F		F		F		F	

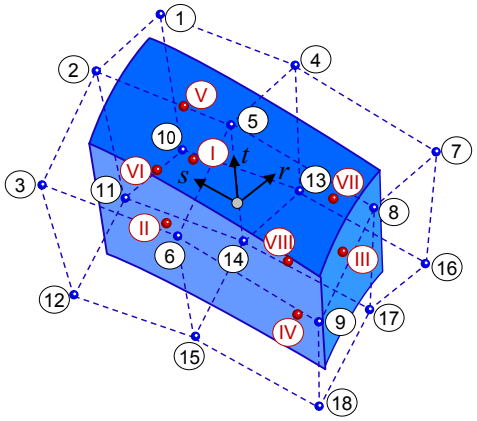
VARIABLE	DESCRIPTION
ELFORM	Element Formulation ID referenced by *SECTION_SOLID to connect *ELEMENT_GENERALIZED_SOLID with the appropriate solid formulation. The chosen number needs to be greater or equal than 1000.
NIP	Number of integration points.
NMNP	Number of nodes for this element formulation.
IMASS	Option for lumping of mass matrix: EQ.0: row sum EQ.1: diagonal weighting.
WI	Integration weight at integration point i.
NKI	Value of the shape function N_k evaluated at integration point i.
DNKIDR	Value of the derivative of the shape function N_k with respect to the local coordinate r at the integration point i $\left(\frac{\partial N_k^i}{\partial r}\right)$.
DNKIDS	Value of the derivative of the shape function N_k with respect to the local coordinate s at the integration point i $\left(\frac{\partial N_k^i}{\partial s}\right)$.
DNKIDT	Value of the derivative of the shape function N_k with respect to the local coordinate t at the integration point i $\left(\frac{\partial N_k^i}{\partial t}\right)$.

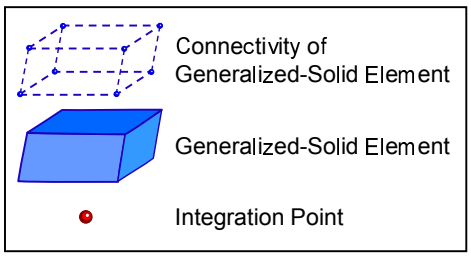
Remarks:

1. **Post-Processing.** For post-processing the use of interpolation solid elements (see *ELEMENT_INTERPOLATION_SOLID and *CONSTRAINED_NODE_INTERPOLATION) is necessary.

2. **Input Order.** Data input order for the NMNP nodal points must correlate with the definition of the connectivity of the element in *ELEMENT_GENERALIZED_SOLID.

Example:





```
*DEFINE_ELEMENT_GENERALIZED_SOLID
$#   elform       nip      nmnp     imass

Block A

Figure 17-39. Example of a generalized solid formulation with *DEFINE_ELEMENT_GENERALIZED_SOLID

*DEFINE_FABRIC_ASSEMBLIES

Purpose: Define lists of part sets to properly treat fabric bending between parts.

Define as many cards as needed for the assemblies, using at most 8 part sets per card. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SPID1	SPID2	SPID3	SPID4	SPID5	SPID6	SPID7	SPID8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
SPID*n*	Part set ID that comprises an assembly.

Remarks:

The materials *MAT_FABRIC and *MAT_FABRIC_MAP are equipped with an optional coating feature to model the fabric's bending resistance. See the related parameters ECOAT, SCOAT and TCOAT on these material model manual entries.

The default behavior for these coatings, *which this keyword changes*, excludes T-interesections, and, furthermore requires that all fabric elements must have a consistently oriented normal vector. In Figure 17-40, the left connection of fabric elements is permitted by the default functionality while the right one is not. However, with using this keyword the proper bending treatment for the right connectivity can be activated by adding the following input to the deck

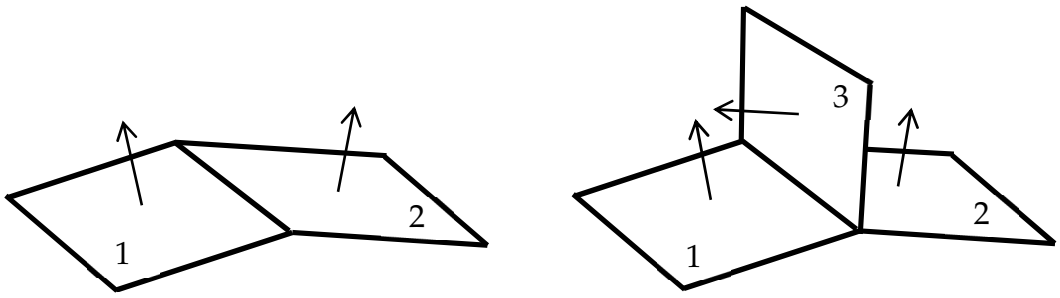

Figure 17-40. Bending in fabric, intended use of *DEFINE_FABRIC_ASSEMBLIES. The numbers indicate the parts the elements belong to.

```
*SET_PART_LIST
1
1,2
*SET_PART_LIST
2
3
*DEFINE_FABRIC_ASSEMBLIES
1,2
```

which decouples part 3 from the other two parts in terms of bending, thus creating a moment free hinge along the edge between part sets 1 and 2. Bending between parts 1 and 2 is unaffected since these are contained in the same fabric assembly.

For several instances of this keyword in an input deck, the list of assemblies is appended. If assemblies are defined and there happens to be fabric parts that do not belong to any of the specified assemblies, then these parts are collected in a separate unlisted assembly. The restriction on consistent normal vectors and on having no T-intersections applies to all elements within an assembly.

*DEFINE_FIBERS

Purpose: Define carbon fibers and their related properties in a matrix for a one-step inverse forming simulation. This keyword works *only* with the keyword *CONTROL_FORMING_ONESTEP. This keyword requires a double precision executable. We developed this feature with Ford Motor Company.

Fiber ID and Property Card.

Card 1	1	2	3	4	5	6	7	8
Variable	IDF	IDP	NUMF	N1	N2	EFB	SHR	HRGLS
Type	I	I	I	I	I	F	F/I	F
Default	none	none	none	optional	optional	none	none	1.0

Fiber Orientation Card.

Card 2	1	2	3	4	5	6	7	8
Variable	ALPHA1	ALPHA2	ALPHA3					
Type	F	F	F					
Default	none	none	none					

Reference Fiber Orientation Card. Define this card if N1 and N2 in Card 1 are undefined or zero.

Card 2	1	2	3	4	5	6	7	8
Variable	X1	Y1	Z1	X2	Y2	Z2		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
IDF	ID of a fiber set to be defined. It must be unique number; see Figure 17-41.
IDP	Part ID of the matrix material associated with the fiber set; see Figure 17-41.
NUMF	Number of fiber orientations; see Figure 17-41.
N1, N2	Direction from Node 1 (N1) to Node 2 (N2) defines the reference fiber orientation; see Figure 17-41. If not defined or zero, Card 3 is required.
EFB	Effective stiffness of the fiber in its orientation which typically equals Young's Modulus times fiber cross sectional area fraction. Fiber cross sectional area fraction is typically between 0.25 and 0.5.
SHR	Shear stiffness of the fiber: GT.0: shear stiffness, LT.0: |SHR| is the load curve ID defining shear stiffness as a function of shear strain.
HRGLS	Hourglass coefficient for stiffness type hourglass control.
ALPHA1, ALPHA2, ALPHA3	Initial orientation angles of the first, second and third fibers relative to reference fiber orientation defined by N2 − N1, respectively.
X1, Y1, Z1, X2, Y2, Z2	If N1 and N2 are undefined, or zero, Card 3 is required to define the coordinates for N1 and N2. The Z1 and Z2 coordinate values must be defined close to the part. Based on the coordinate inputs, LS-DYNA will find the nearest nodes to define N1 and N2 from the model. See Figure 17-41.

Remarks:

1. **Matrix Material.** *MAT_024 is supported to define the matrix material.

2. **Predicted Flat Blank Orientation.** The method of orienting the unfolded blank with three nodes defined in *CONTROL_FORMING_ONESTEP_AUTO_CONSTRAINT is disabled when *DEFINE_FIBERS is used. Use the dynain (not repositioned.k) file for the predicted flat blank.

3. **Coulomb Friction.** Coulomb friction can be specified with *CONTROL_FORMING_ONESTEP_FRICTION.

4. **Draw Bead Forces.** Use of *CONTROL_FORMING_ONESTEP_DRAWBEAD is not recommended.

5. **Matrix Element Direction.** Element direction of the matrix must be consistent. The directions can be displayed in LS-PrePost4.6, under *EleTol* → *EleEdit* → *Direction* → *Shell* → *Vector* → *Apply*. To align all element directions with an existing element direction, use *EleTol* → *EleEdit* → *Direction* → *Shell* → *Orient* → *Pick seed* → *Apply*.

6. **Output for Visualization.** *ELEMENT_FIBER_INFO and *ELEMENT_BEAM (new part IDs) are automatically created and output in onestepresult file to display the fiber orientations after forming in LS-PrePost; see Figure 17-41.

   Additional history variables are written in the onestepresult file to display various angles in color contours (see Figure 17-41):

   a) History variable #1: the angle between two fibers,

   b) History variable #2: the angle between the first fiber and the element direction,

   c) History variable #3: the angle between the second fiber and the element direction.

   These color contour fringe plots can be overlaid with beam elements to verify the fiber orientations. To request history variable output, set NEIPS in *DATABASE_EXTENT_BINARY to a minimum of 3.

Example:

A partial keyword example below defines a fiber set ID 1 in a matrix material with part ID 121. The first and second fiber orientations are at 45° and 135°, respectively, from the reference fiber direction.

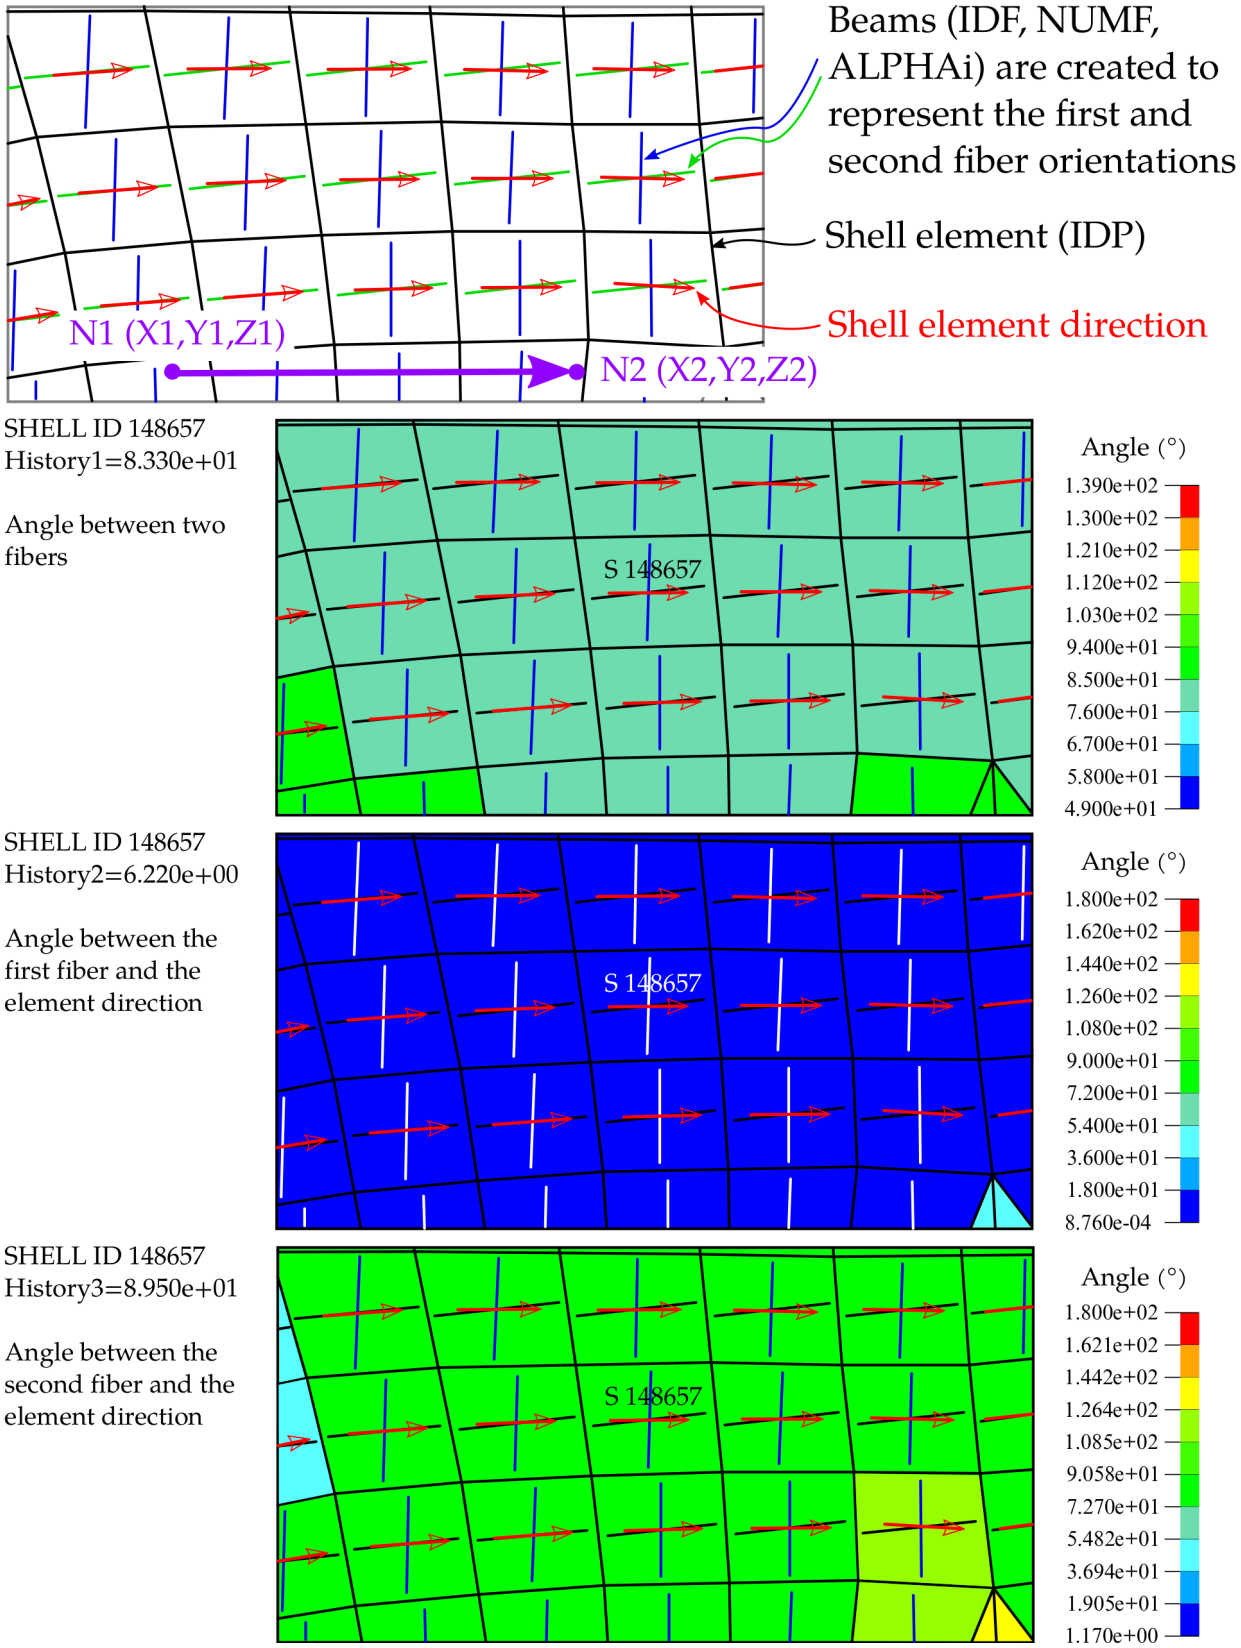

Figure 17-41. *DEFINE_FIBERS inputs and outputs.

***DEFINE_FIELD**_*{OPTION}*

Available options include:

<BLANK>

TITLE

Purpose: Define a field associated with a point cloud; see *DEFINE_POINT_CLOUD. Field data, defined on a point cloud, are automatically interpolated at required locations for the purpose of analysis. The interpolation is performed through radial basis functions. The interpolation is controlled by parameters defined on *DEFINE_FIELD.

Card Summary:

Card Title. This card is included if the TITLE keyword option is used.

TITLE

Card 1. This card is required.

FID	PCID	NV	LMTSRC	SRCRAD	REFLEN		

Card 2. This card is required. Include ceil[NV × number of points/8] cards. This input ends if an empty field is found OR at the next keyword ("*") card.

V1	V2	V3	V4	V5	V6	V7	V8

Data Card Definitions:

Title Card. Additional card for the TITLE keyword option.

Card Title	1	2	3	4	5	6	7	8
Variable	TITLE							
Type	A80							

VARIABLE	DESCRIPTION
TITLE	Name or description of the field defined in this keyword.

Card 1	1	2	3	4	5	6	7	8
Variable	FID	PCID	NV	LMTSRC	SRCRAD	REFLEN		
Type	I	I	I	I	F	F		
Default	none	none	none	0	0	0		

VARIABLE	DESCRIPTION
FID	Field ID. A unique ID number must be used.
PCID	ID of the point cloud referenced by this field. See *DEFINE_POINT_CLOUD.
NV	Number of data specified for each point of the point cloud PCID. See Remark 1.
LMTSRC	Flag to restrict the interpolation domain to a subset of data points of the point cloud PCID. This flag activates a search algorithm that restricts the interpolation domain based on a point-to-element distance criterion. For any element associated with a *PART_FIELD that references this field FID: EQ.0: Perform global interpolation by interpolating field data from all data points of point cloud PCID. EQ.1: Restrict the interpolation domain and search for all data points of point cloud PCID whose distance from centroid of the element is ≤ a distance determined by SRCRAD.
SRCRAD	Radius of the interpolation domain. If LMTSRC = 0, this parameter is disregarded. If LMTSRC = 1, this parameter restricts the interpolation domain. Based on the value of SRCRAD, the interpolation domain is restricted to all data points whose distance from element centroid is: LT.0: Less than or equal to |SRCAD| × REFLEN EQ.0: Less than or equal to REFLEN GT.0: Less than or equal to SRCRAD
REFLEN	Reference length used for scaling of radial basis functions, and, if required, to restrict the interpolation domain:

VARIABLE	DESCRIPTION
	EQ.0: For any element, the solver automatically computes a reference length based on the maximum distance of all its integration points.
	GT.0: User-defined reference length. Any value can be specified.

Field Data Cards. Include ceil[NV × number of points/8] cards. This input ends at the first missing field or the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	V1	V2	V3	V4	V5	V6	V7	V8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
V*i*	Field data specified at points of the point cloud PCID. See Remark 2. NV × number of points defined in PCID should be defined. The data should be input such that first NV data are for the first point, the second NV data are for the second point, etc.

Remarks:

1. **Field Dimension**. The format of *DEFINE_FIELD is general in the sense that no distinction is made between scalar, vector, or tensor data at the keyword level.

2. **Data Type.** A field represents a consistent set of data associated with one physical property or parameter.

3. **Precision.** If you need to specify more significant digits for the field data, it is possible to invoke the "long format" for this keyword, meaning *DEFINE_FIELD_*{OPTION}*+. In case the "long format" is invoked, the format of Card 1 is (4I20,2F20), while the format of Card(s) 2 is (8F20). The precision of the executable may also limit the actual number of significant digits of the input field data used for the analysis. See Long Format Input in the section General Card Format of Getting Started in this manual for more details regarding the number of significant digits and the "long format".

*DEFINE_FILTER

Purpose: Define a general purpose filter, currently used by this option:

SENSOR_SWITCH

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TITLE						
Type	I	A70						

Card 2	1	2	3	4	5	6	7	8
Variable	TYPE	DATA1	DATA2	DATA3	DATA4	DATA5	DATA6	DATA7
Type	A10							

VARIABLE	DESCRIPTION
ID	Identification number.
TITLE	Title for this filter.
TYPE	One of the 3 currently defined filter types: DISCRETE, CONTINUOUS, or CHAIN
DATA1-7	Filter type specific data, which determines what the filter does.

Filter Types:

FILTER	DESCRIPTION
DISCRETE	The discrete filter operates on a fixed number of values of the input data. The first data field is an A10 character field, which gives the type of operation the filter performs: MIN, MAX, and AVG are the available options. The second data field is an I10 field, giving the number of input values over which the minimum, maximum, or average is computed.

FILTER	DESCRIPTION
CONTINU-OUS	Like the DISCRETE filter, except that it operates over a fixed time interval. The first data field is exactly the same as for the DISCRETE option. The second data field is an F10 field, indicating the duration of the filter. For example, if AVG is given, and the duration is set to 0.1, a running timestep weighted average is computed over the last 0.1 time of the simulation.
CHAIN	Here, data fields 1-7 are all I10 fields, and give the IDs of a list of other filters (including other CHAIN filters, if desired), each of which will be applied in order. So the raw data is fed to the filter indicated by DATA1. The output of that is fed to the next filter, and so on, with up to 7 filters in the chain. List only as many filters as you need.

*DEFINE_FORMING_BLANKMESH

Purpose: A rectangular sheet metal blank can be defined with square elements and an arbitrary mesh orientation. This blank can, then, be trimmed with *ELEMENT_BLANKING and *DEFINE_CURVE_TRIM_2D into a developed blank with a complex periphery and inner hole cutouts. This keyword is renamed from the previous keyword *CONTROL_FORMING_BLANKMESH.

Card 1	1	2	3	4	5	6	7	8
Variable	IDMSH	ELENG	LENG1	LENG2	ANGLE	NPLANE	CID	
Type	I	F	F	F	F	I	I	
Default	none	0.0	0.0	0.0	0.0	1	0	

Card 2	1	2	3	4	5	6	7	8
Variable	PIDBK	NID	EID	XCENT	YCENT	ZCENT	SHIFT1	SHIFT2
Type	I	I	I	F	F	F	F	F
Default	1	1	1	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
IDMSH	A unique ID for the blank mesh (not the blank PID) to be generated
ELENG	The edge length of the square element to be generated.
LENG1	First edge length of the rectangular blank along the following axis in the coordinate system (CID) defined: NPLANE.EQ.1: X-axis NPLANE.EQ.2: Y-axis NPLANE.EQ.3: Z-axis

VARIABLE	DESCRIPTION
LENG2	Second edge length of the rectangular blank along the following axis in the coordinate system (CID) defined: NPLANE.EQ.1: *Y*-axis NPLANE.EQ.2: *Z*-axis NPLANE.EQ.3: *X*-axis
ANGLE	An angle about the following axis of the CID defined, starting from its respective axis, to rotate the blank (the orientation of the mesh) to be generated. The sign of the rotation angle follows the right-hand rule. NPLANE.EQ.1: about *Z*-axis, starting from the positive *X*-axis NPLANE.EQ.2: about *X*-axis, starting from the positive Y-axis NPLANE.EQ.3: about *Y*-axis, starting from the positive *Z*-axis
NPLANE	A plane in which a flat blank to be generated, in reference to the coordinate system defined (CID): EQ.1: *XY*-plane (default) EQ.2: *YZ*-plane EQ.3: *XZ*-plane
CID	ID of a local coordinate system defined by *DEFINE_COORDINATE_SYSTEM. Default is 0 representing the global coordinate system.
PIDBK	Part ID of the blank, as defined by *PART
NID	Starting node ID of the blank to be generated
EID	Starting element ID of the blank to be generated
XCENT	*X*-coordinate of the center of the blank
YCENT	*Y*-coordinate of the center of the blank
ZCENT	*Z*-coordinate of the center of the blank
SHIFT1	First shift distance of the blank in the following axis in the coordinate system (CID) defined. NPLANE.EQ.1: *X*-axis

VARIABLE	DESCRIPTION
	NPLANE.EQ.2: Y-axis NPLANE.EQ.3: Z-axis
SHIFT2	Second shift distance of the blank in the following axis in the coordinate system (CID) defined: NPLANE.EQ.1: Y axis NPLANE.EQ.2: Z-axis NPLANE.EQ.3: X-axis

About the Keyword:

A flat and rectangular blank can be defined and meshed, which can be trimmed with IGES curves to a desired blank shape with complex periphery and inner cutouts. The mesh orientation is always parallel to the rectangular blank edge and can be changed by defining the field ANGLE. The blank outlines and inner holes can be defined using IGES curves and included in *DEFINE_CURVE_TRIM_2D (not_3D). This feature is very useful for interactive input deck set up of metal forming simulation.

Example:

A complete keyword example of generating a flat blank with PID 1 is provided blow. Referring to Figure 17-42, the rectangular blank mesh is generated in the global XY-plane with its center at the global origin and a size of 1100.0×1050.0 mm. The square element edge length is 12 mm. The node and element ID numbers start at 8000 and 9000, respectively. An inner cut-out curve is provided by the IGES file innerholes.iges, and the blank outer line is defined with the IGES file outerlines.iges. Both files are included in the keyword *DEFINE_CURVE_TRIM_2D. A seed point is defined indicating the portion that remains after trimming.

The blank and mesh orientation can be rotated about a particular axis. Following the right-hand rule, the blank in this case is rotated about *Z*-axis for a positive 30° (ANGLE=30.0) starting from the positive *X*-axis, as shown in Figure 17-43.

Revision information:

This feature is available in LS-DYNA starting in Revision 59165. This keyword name was changed from *CONTROL_FORMING_BLANKMESH to *DEFINE_FORMING_BLANKMESH in Revision 69074. The variable NPLANE is available in Revision 69128. Some important updates are available in Revision 123603.

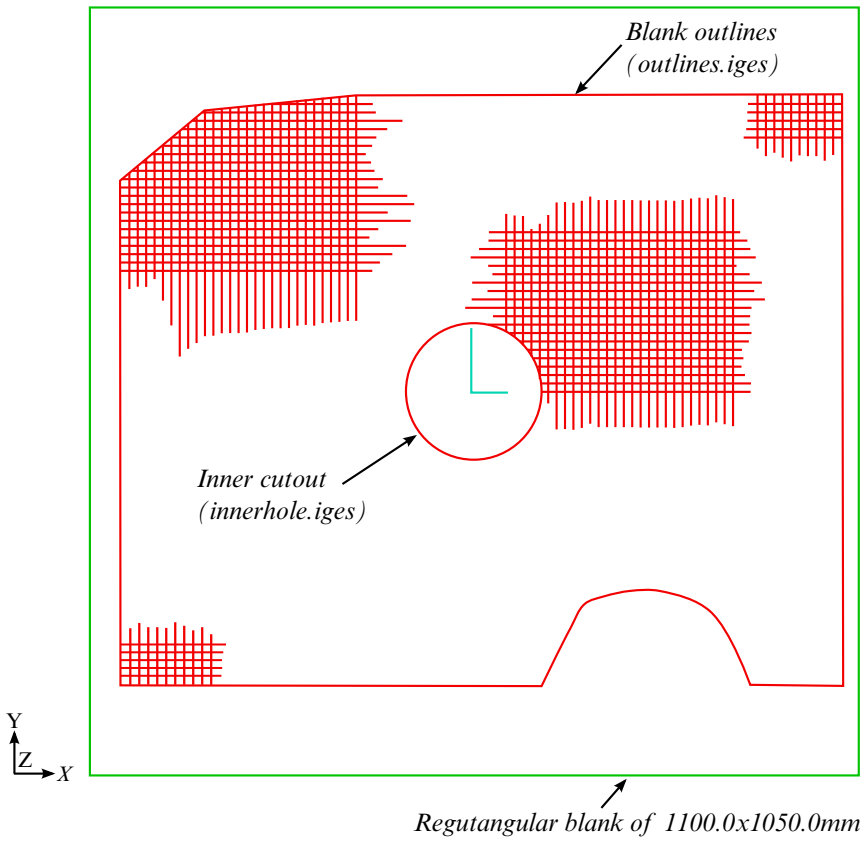

Figure 17-42. A rectangular blank mesh is generated and trimmed into a developed blank shape, with an inner cutout defined by innerhole.iges and outline defined by outlines.iges.

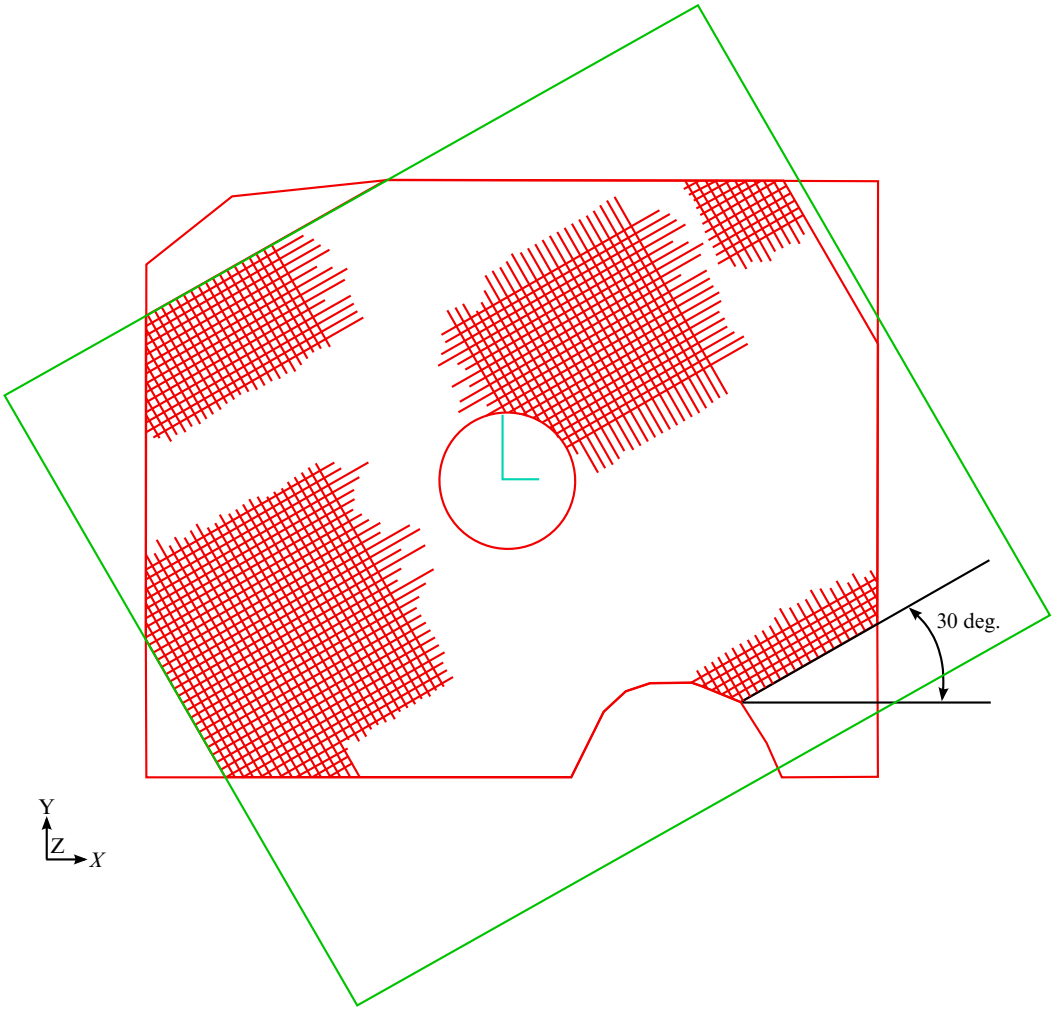

Figure 17-43. A rectangular blank mesh is generated in an angle (ANGLEX = 30) and trimmed into a developed blank shape, with an inner cutout defined by innerhole.iges and outline defined by outlines.iges. Note the blank mesh orientation is always parallel to the rectangular blank boundary.

*DEFINE_FORMING_CLAMP

Purpose: This keyword acts as a macro that replaces the combination of cards required to model a clamping process. It is available for double precision executables with the implicit solver. A related keyword is *DEFINE_FORMING_CONTACT.

Define Clamp Card. Define one card for each clamp set. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	CLP1	CLP2	VID	GAP	AT	DT		
Type	I	I	I	F	F	F		
Default	none	none	none	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
CLP1	Part ID of a moving rigid body clamp, defined by *PART and *MAT_020 (*MAT_RIGID).
CLP2	Part ID of a fixed rigid body clamp, defined by *PART and *MAT_-020. This is sometimes called "net pad".
VID	Define CLP1 moving direction: GT.0: Vector ID from *DEFINE_VECTOR, specifying the moving direction of CLP1 LT.0: Absolute value is a node ID, whose normal vector will be used to define the moving direction of CLP1.
GAP	Final desired distance between CLP1 and CLP2 at the end of clamping.
AT	Begin time for CLP1's move.
DT	Duration of CLP1's move.

About the keyword:

One typical application of this keyword is to estimate springback during the clamping of a formed panel on a checking fixture. Net pads (lower fixed regular or square pads) of a

few millimeters thick are placed according to GD&T (*Geometry Dimensioning and Tolerancing*) requirements on a support platform, typically taking shape of the nominal product. Each net pad (CLP2, see Figure 17-44) has a corresponding moving clamp (CLP1).

The movable clamp (CLP1) is initially open so that the formed panel can be loaded onto the net pads. Four-way and two-way position gaging pins are used to initially locate and load the panel in the fixture before CLP1 is moved to close with the net pad (CLP2). A white light scan is then performed on the panel, and scan data is processed to ascertain the degree of panel conformance to the required nominal shape. Even with the clamps fully closed, some severely distorted panels will significantly deviate from the nominal shape when the residual stresses from the forming process are too great.

Although, unrelated to this keyword another common method to determine the panel springback amount is the *free state* check which involves a white light scan on the panel secured on a platform but with no additional forces (clamps – CLP1s) applied to deform the panel (to the net pads CLP2s, for example). LS-DYNA can model both methods and job setups can be easily done by selecting *Implicit Static Flanging* process in LS-PrePost 4.2's *Metal Forming Application* → *eZ-Setup*. Furthermore, once springback has been determined, die compensation (*INTERFACE_COMPENSATION_3D) can then be performed to minimize or eliminate the springback; the resulting compensated die shapes can be surfaced, re-machined to produce panels that are within dimensional tolerance.

Since the clamp is, typically, modeled with a much coarser mesh than that on a blank, *CONTACT_FORMING_SURFACE_TO_SURFACE should be used. Rotating-type of clamps are currently not supported.

Application example:

A partial keyword example of using the feature is listed below. Referring to Figure 17-44, the drawn and trimmed blank is positioned between the clamps CLP1 and CLP2. The implicit termination "time" is set at 1.0, with a stepping size of 0.25, for a total of four steps – two steps each for the two CLP1. With the original blank thickness of 1.0 mm, the CLP1s are set to close with the lower CLP2s at "time" of 1.0, leaving a total GAP of 1.02 mm. Note the VIDs are defined as "-46980", indicating that the moving clamps (CLP1) will move in the normal direction defined by Node #46980. The contact definition between the panel and the clamps are defined using *DEFINE_FORMING_CONTACT.

*END
```

Note with this keyword, the formed panel needs to be pre-positioned properly with respect to the clamps by users, and auto-position (*CONTROL_FORMING_AUTOPOSITION) cannot be used. Furthermore, prescribed motions and clamp motion curves do not need to be defined for the clamps.

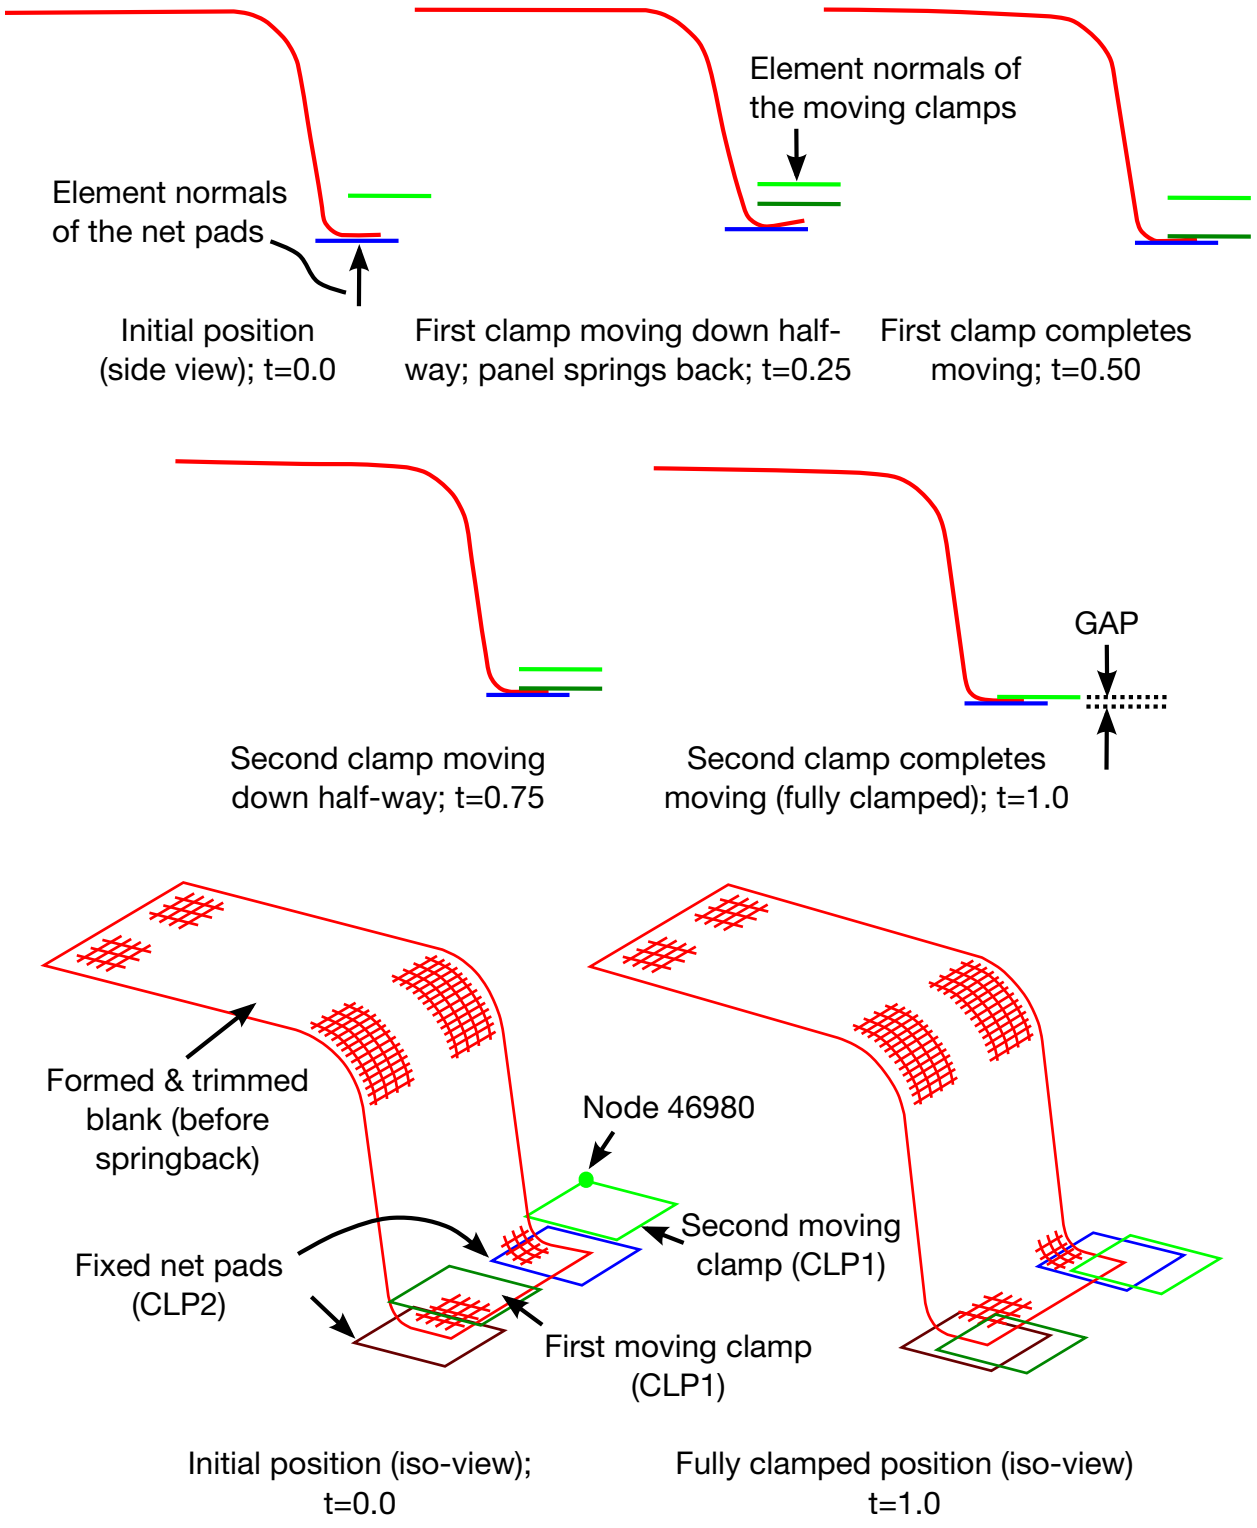

Figure 17-44. Variable definitions and an example of using the negative VID.

*DEFINE_FORMING_CONTACT

Purpose: This keyword works as a macro for the FORMING_(ONE_WAY)_SURFACE_-TO_SURFACE keyword. It adds one contact definition to the model per data card. Each data card consists of a reduced set of fields compared with the full *CONTACT keyword. The omitted fields take their default values. A related keyword is *DEFINE_FORMING_-CLAMP.

Define Contact Card. Define one card for each contact interface. Define as many cards in the following format as desired. The input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	IPSA	IPSB	FS	ONEWAY				
Type	I	I	F	I				
Default	none	none	none	0				

VARIABLE	DESCRIPTION
IPSA	Part ID of a SURFA sliding member, typically a deformable sheet metal blank.
IPSB	Part ID of a SURFB sliding member, typically a tool or die defined as a rigid body.
FS	Coulomb friction coefficient
ONEWAY	Define FORMING contact type: EQ.0: The contact is FORMING_ONE_WAY_SURFACE_TO_-SURFACE. EQ.1: The contact is FORMING_SURFACE_TO_SURFACE.

Application example:

A partial keyword example that defines contact between a deformable part and two pairs of clamps is given below. In Figure 17-45, a blank (PID 1) is defined to have FORMING_-SURFACE_TO_SURFACE contact with rigid body clamps (PIDs 2, 3, 4, and 5) with coefficient of frictions for each interface as 0.125, 0.100, 0.125, and 0.100, respectively. Only a total of four lines are needed to define four contact interfaces, as opposed to at least three cards for each interface using the contact keywords.

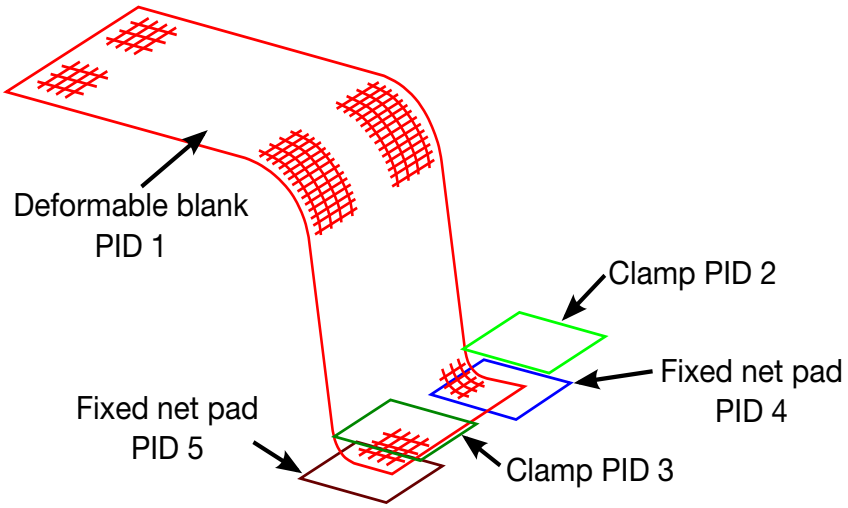

Figure 17-45. Define contact interfaces.

*DEFINE_FORMING_ONESTEP_PRIMARY

> **NOTE:** This keyword was previously named *DEFINE_-FORMING_ONESTEP_MASTER. The old name is supported for backward compatibility. *DEFINE_-FORMING_ONESTEP_PRIMARY is the preferred name starting with R13.

Purpose: Define a primary blank to which a second (constrained) blank is connected using *CONSTRAINED_SPOTWELD. Such a configuration is often called "patch-welded blanks." Note this keyword must be used together with *CONTROL_FORMING_ONESTEP.

Card 1	1	2	3	4	5	6	7	8
Variable	SLPID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
SLPID	Part ID of the primary blank to which a constrained blank is welded using *CONSTRAINED_SPOTWELD

Example:

A partial keyword example is given below. Two patches, with PIDs 2 and 3, are spot-welded onto the primary blank (PID 1) using multiple *CONSTRAINED_SPOTWELD keywords. The primary blank is specified using *DEFINE_FORMING_ONESTEP_PRIMARY. The spot welds can be generated using LS-PrePost.

Revision Information:

This feature is available starting in LS-DYNA Dev Revision 134771 for SMP and double precision only.

*DEFINE_FP_TO_SURFACE_COUPLING

Purpose: Define a tied coupling interface between fluid particles modeled with implicit smoothed particle Galerkin (ISPG) and a surface.

Card 1	1	2	3	4	5	6	7	8
Variable	FP	SURF	FPTYPE	SURFTYPE				
Type	I	I	I	I				
Default	none	none	1	0				

Card 2	1	2	3	4	5	6	7	8
Variable	SBC	SCA				SFP		
Type	I	F				F		
Default	0	0.5				0.1		

VARIABLE	DESCRIPTION
FP	Part ID for the fluid particles
SURF	Segment set ID specifying the surface. Currently the segment set should be generated from the 8-noded hexahedral elements.
FPTYPE	Type for FP: EQ.0: Part set ID EQ.1: Part ID
SURFTYPE	Type for SURF: EQ.0: Segment set ID
SBC	Type of boundary condition. EQ.0: Free-slip boundary EQ.1: Non-slip boundary

VARIABLE	DESCRIPTION
SCA	Static (equilibrium) contact angle in radians
SFP	Stiffness coefficient along the normal direction of the contact interface. SFP should be less than 1.0. If SFP is too small, large penetrations can occur.

*DEFINE_FRICTION

Purpose: Define friction coefficients between parts for use with the contact options:

SINGLE_SURFACE

AIRBAG_SINGLE_SURFACE

AUTOMATIC_GENERAL

AUTOMATIC_SINGLE_SURFACE

AUTOMATIC_SINGLE_SURFACE_MORTAR

AUTOMATIC_NODES_TO_SURFACE

AUTOMATIC_SURFACE_TO_SURFACE

AUTOMATIC_SURFACE_TO_SURFACE_MORTAR

AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE

ERODING_SINGLE_SURFACE

The input ends at the next keyword ("*"). Default friction values are used for any part ID pair that is not defined. Contact interfaces that are defined with SOFT = 2 on optional card A may use this part data for any keyword that is supported by the segment-to-segment contact.

The coefficient tables specified by the following cards are activated when FS (see second card of *CONTACT) is set to -2.0. This feature overrides the coefficients defined in *PART_CONTACT (which are turned on only when FS is set to -1.0).

When only *one* friction table is defined, it is used for *all* contacts having FS set to -2.0. Otherwise, for each contact with FS equal to -2.0, the keyword reader assigns a table to each *CONTACT by matching the value of FD from *CONTACT with an ID from Card 1 below. Failure to match FD to an ID causes error termination.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	FS_D	FD_D	DC_D	VC_D	ICNEP		
Type	I	F	F	F	F	I		
Default	none	0.0	0.0	0.0	0.0	0		

Friction *ij* card. Sets the friction coefficients between parts (or part sets) *i* and *j*. Add as many of these cards to the deck as necessary. The next keyword ("*") card terminates the friction definition.

Card 2	1	2	3	4	5	6	7	8
Variable	PID*i*	PID*j*	FS*ij*	FD*ij*	DC*ij*	VC*ij*	PTYPE*i*	PTYPE*j*
Type	I	I	F	F	F	F	A	A
Default	none	none	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
ID	Identification number. Only one table is allowed.
FS_D	Default value of the static coefficient of friction. The frictional coefficient is assumed to depend on the relative velocity v_{rel} of the surfaces in contact, $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$ Default values are used when part pair are undefined. For mortar contact $\mu_c = \text{FS}$, that is, dynamic effects are ignored.
FD_D	Default value of the dynamic coefficient of friction. The frictional coefficient is assumed to depend on the relative velocity v_{rel} of the surfaces in contact, $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$ Default values are used when part pair are undefined. For mortar contact $\mu_c = \text{FS}$, that is, dynamic effects are ignored.

VARIABLE	DESCRIPTION
DC_D	Default value of the exponential decay coefficient. The frictional coefficient is assumed to be depend on the relative velocity v_{rel} of the surfaces in contact, $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$ Default values are used when part pair are undefined. For mortar contact $\mu_c = \text{FS}$, that is, dynamic effects are ignored.
VC_D	Default value of the coefficient for viscous friction. This is necessary to limit the friction force to a maximum. A limiting force is computed $$F_{\text{lim}} = \text{VC} \times A_{\text{cont}} \ ,$$ where A_{cont} is the area of the segment contacted by the node in contact. The suggested value for VC is to use the yield stress in shear $\text{VC} = \sigma_o/\sqrt{3}$ where σ_o is the yield stress of the contacted material. Default values are used when part pair are undefined.
ICNEP	Flag to check for non-existing parts, or part sets, (PID*i*, PID*j*) on Card 2: EQ.0: existence of parts or part sets is checked, and an error occurs when any is missing (default). EQ.1: existence of parts or part sets is checked and lines with non-existent parts will be ignored.
PID*i*	Part, or part set, ID *i*
PID*j*	Part, or part set, ID *j*
FS*ij*	Static coefficient of friction between parts *i* and *j*
FD*ij*	Dynamic coefficient of friction between parts *i* and *j*
DC*ij*	Exponential decay coefficient between parts *i* and *j*
VC*ij*	Viscous friction between parts *i* and *j*
PTYPE*i*, PTYPE*j*	EQ."PSET": when PTYPE*i* or PTYPE*j* refers to a *SET_PART.

*DEFINE_FRICTION_ORIENTATION

Purpose: Define different coefficients of friction (COF) for specific directions, specified using a vector and angles in degree. In addition, COF can be scaled according to the amount of pressure generated in the contact interface. This keyword works in SMP only with *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE, including the SMOOTH keyword option. In MPP it works with *CONTACT_FORMING_ONE_-WAY_SURFACE_TO_SURFACE_ORTHO_FRICTION, including the SMOOTH keyword option.

This feature is developed jointly with the Ford Motor Company.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	LCID	LCIDP	V1	V2	V3		
Type	I	I	I	F	F	F		
Default	none	0	0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
PID	Part ID to which directional and pressure-sensitive COF is to be applied. See *PART.
LCID	ID of the load curve defining COF as a function of orientation in degrees
LCIDP	ID of the load curve defining COF scale factor as a function of pressure
V1, V2, V3	Vector components of vector **V** defining zero-degree (rolling) direction

Remarks:

Load curves LCID and LCIDP are not extrapolated beyond what are defined. It is recommended that the definition is specified for the complete range of angle and pressure values expected. One edge of all elements on the sheet metal blank must align initially with the vector defined by V1, V2, and V3.

This feature was initially intended for use with *CONTACT_FORMING_ONE_WAY_-SURFACE_TO SURFACE in SMP. It later was further enhanced to be used in

combination with *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE_ORTHO_FRICTION for MPP applications. With this contact, the fields LCID and LCIDP are overridden by the friction factor input in ORTHO_FRICTION, while the vector **V** defines the first orthogonal direction. It furthermore allows the convenience of defining SURFA and SURFB in *CONTACT as part sets in which case the segment sets necessary for ORTHO_FRICTION are generated automatically with orientation according to vector **V**. A detailed keyword example is shown in Figure 17-52.

Example:

The following is a partial keyword input of using this feature to define directional frictions and pressure-sensitive COF scale factor.

```
*DEFINE_FRICTION_ORIENTATION
$      PID      LCID     LCIDP        V1        V2        V3

```

Referring to Figure 17-46, a deformable blank is clamped with 1000 N of force between two rigid plates and is pulled 90 mm in the X-direction using displacement control. Initial and final positions of the blank are shown in Figure 17-47. The normal force is recovered from the RCFORC file, as shown in Figure 17-48, which agrees with what is applied. The frictional force (pulling force) in the X-direction is 89 N, as shown in Figure 17-49. A hand calculation from the input verifies this result:

$$\underbrace{[\text{clamping force}]}_{1000N} \times \underbrace{[X\text{-dir coefficient}]}_{0.3} \times \underbrace{[\text{coefficient scale factor at 0.27 pressure}]}_{0.3} = 90N$$

The interface pressure can be output from an LS-DYNA run when 'S=filename' is included in the command line. The binary output can be viewed from LS-PrePost.

The element directions are automatically aligned with the vector **V**. The left side of Figure 17-50 shows the element directions of the incoming sheet blank. The keyword will re-orient the element directions based on the vector **V** specified, which has the component of (1.0,0.0,0.0) in this case. The re-oriented element directions for the blank are shown on the right side of the figure.

Following the numeric directions provided in Figure 17-51, LS-PrePost4.0 can be used to check the element directions of a sheet blank.

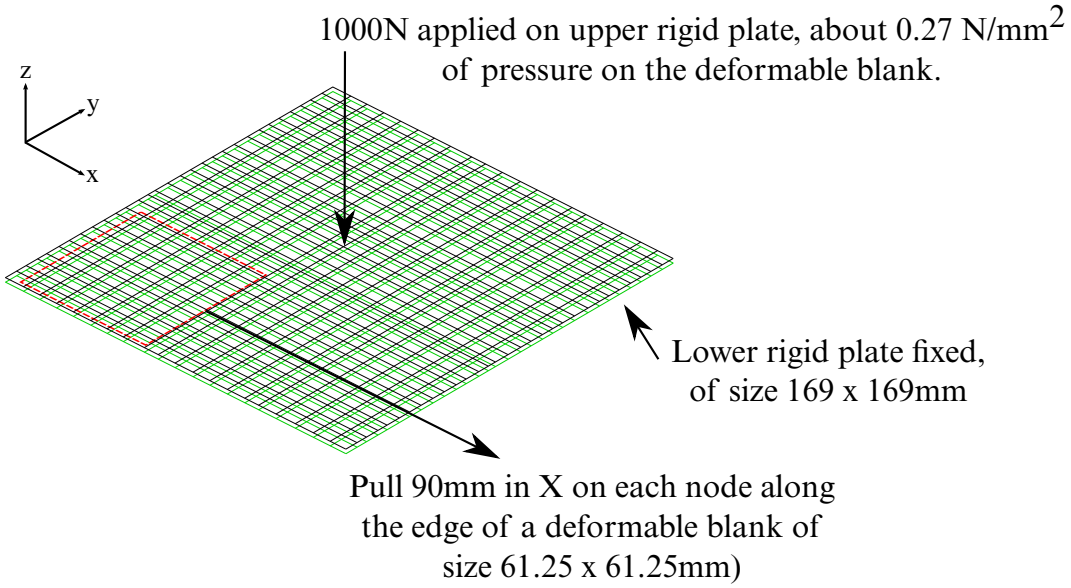

Figure 17-46. Boundary and loading conditions of a small test model.

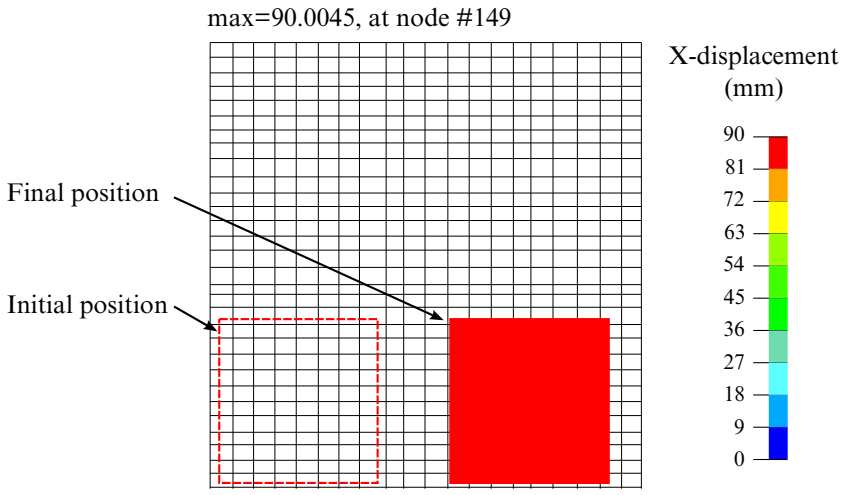

Figure 17-47. Initial and final position of the blank.

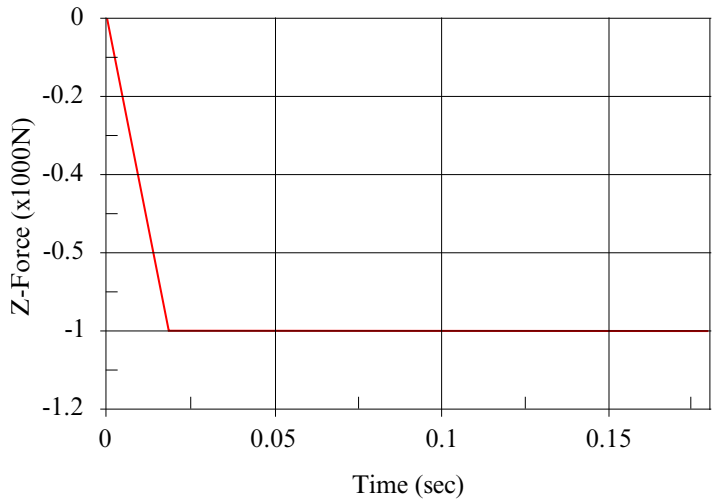

Figure 17-48. Normal force from RCFORC file.

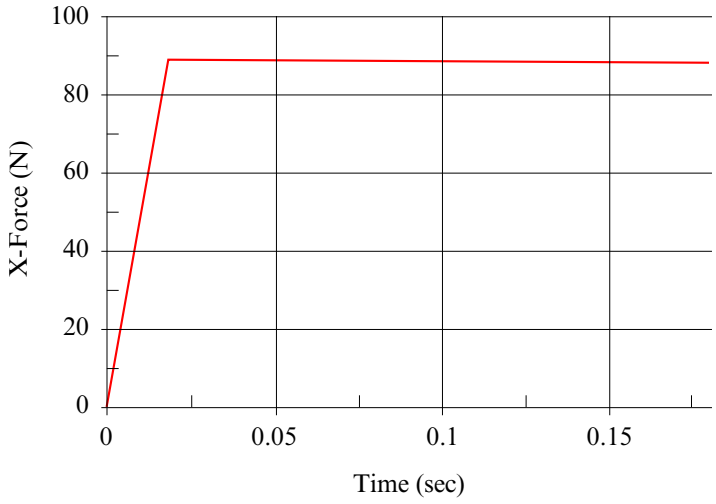

Figure 17-49. Pulling force (frictional force) from RCFORC file.

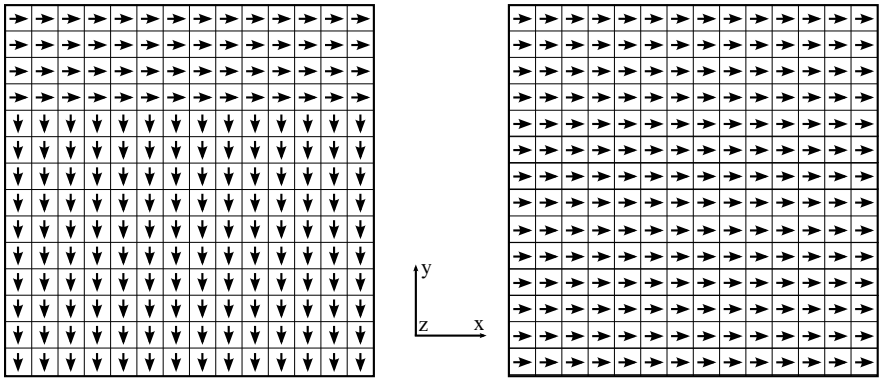

Figure 17-50. Element directions (N1-N2) of an incoming sheet blank (left) and directions after re-orientation.

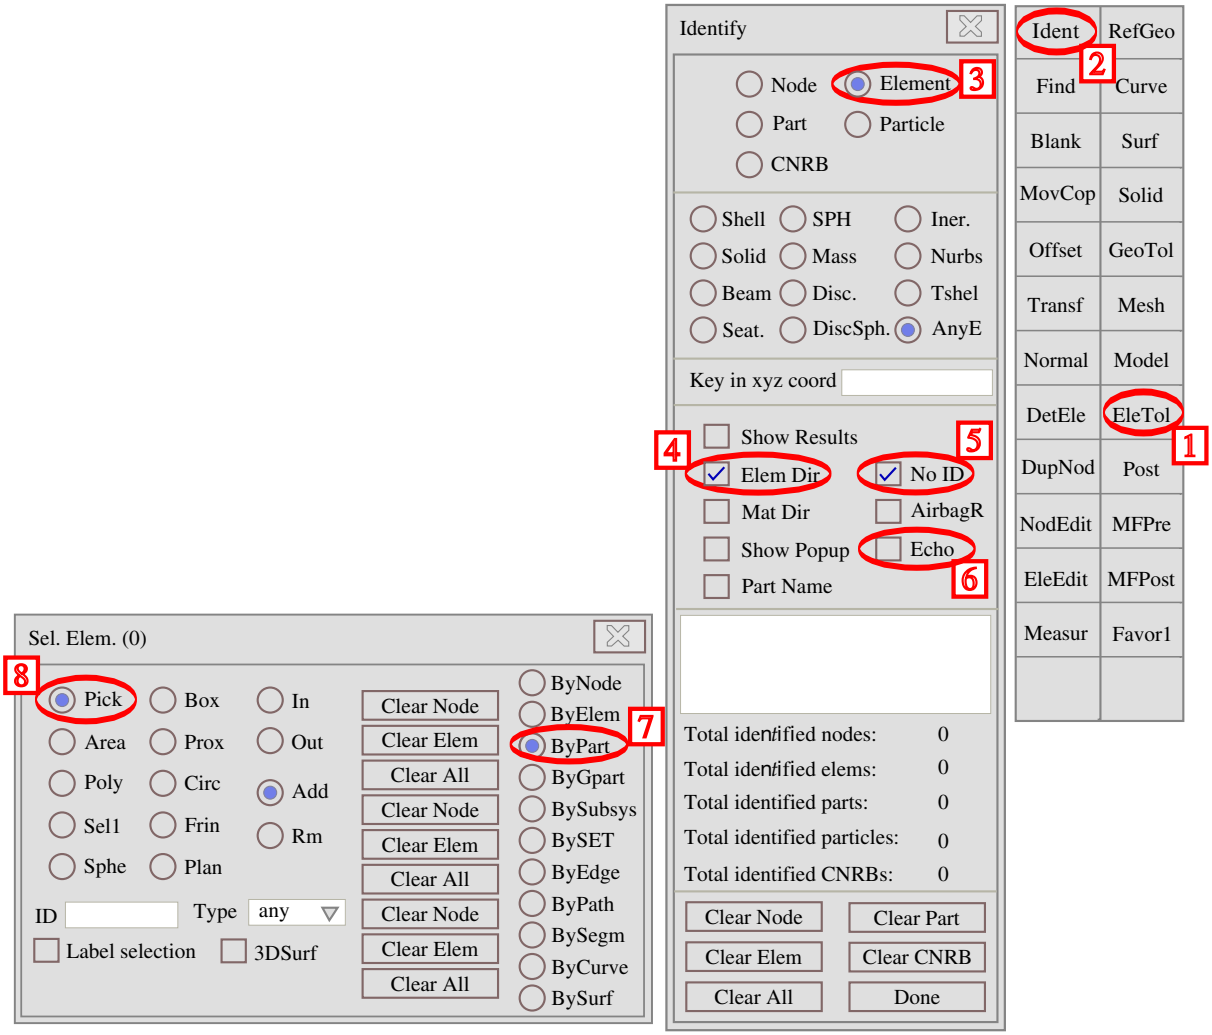

Figure 17-51. Checking element directions (N1-N2) by part using LS-PrePost

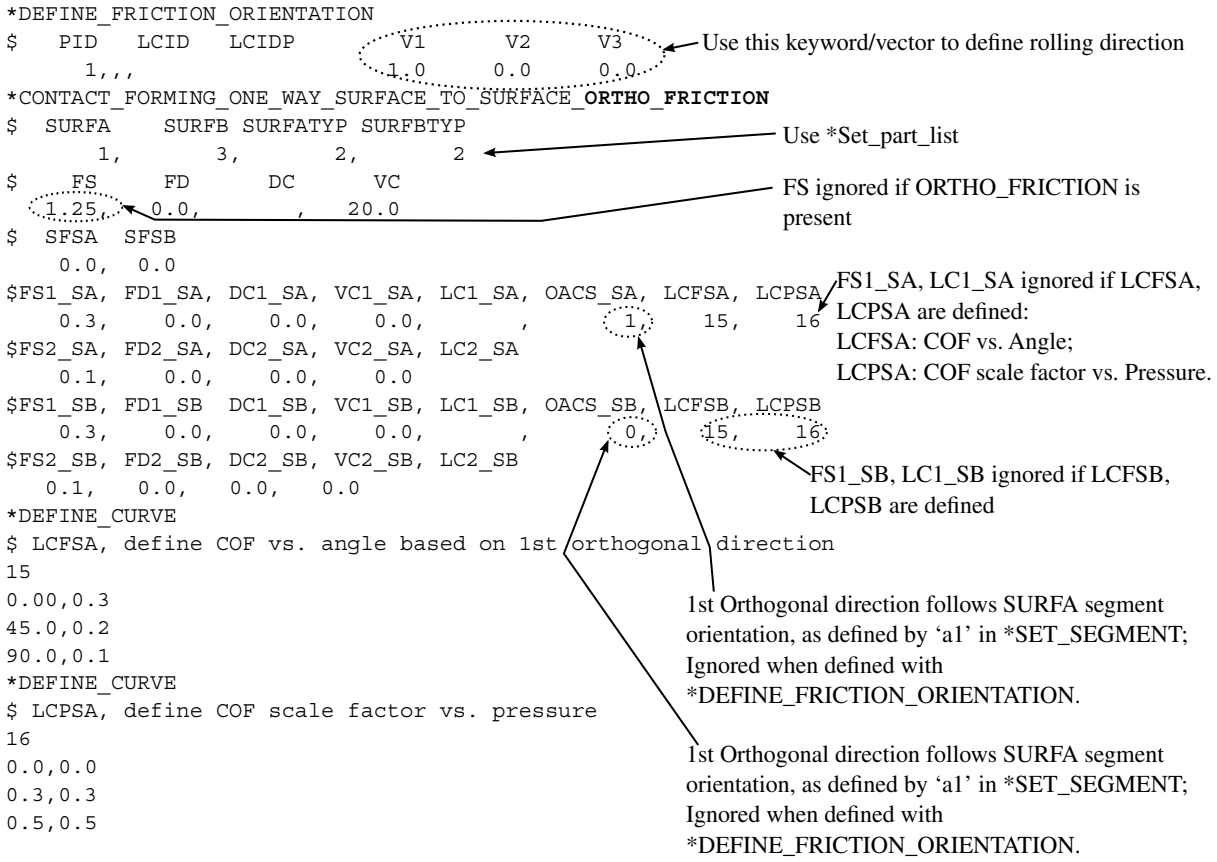

Figure 17-52. Use of this keyword with _ORTHO_FRICTION for MPP.

*DEFINE_FRICTION_SCALING

Purpose: Define scale factors for contact friction for the inner and outer surfaces of shell contact segments. This option is currently only available for contact interfaces that have SOFT set to 2 on optional card A of the *CONTACT input data.

Include as many of Card 1 as desired. The next keyword ("*") card terminates this input. Default friction values are used for any part ID pair that is not defined.

Card 1	1	2	3	4	5	6	7	8
Variable	FSID	CID	PSID	SCALEI	SCALEO			
Type	I	F	F	F	F			
Default	none	0.0	0.0	1.0	1.0			

VARIABLE	DESCRIPTION
FSID	Friction scaling ID number. Each friction scaling definition should have a unique ID which is used for output messages only.
CID	Contact ID. Optional input to limit friction scaling to one contact interface with this ID number.
PSID	Part set ID. Optional input to limit friction scaling to parts in the set.
SCALEI	Friction scale factor for the inner surface of shell segments
SCALEO	Friction scale factor for the outer surface of shell segments

Remarks:

Some materials, such as fabrics, have friction coefficients on one side that differ from the other side. To enable the contact friction to mimic this behavior, separate scale factors can be defined for the inner and outer surface of contact segments that are attached to thin shell elements. The inner and outer surfaces are defined by using the right hand rule with node numbering of the segments. Segment node numbering is consistent with shell element numbering if the contact surface is defined by part or part set.

When modeling an airbag, the inner and outer surface may not be consistent with element or segment numbering, but will depend on how the airbag is defined. When an airbag is

defined using the particle method (see *AIRBAG_PARTICLE), then the SCALEO parameter will scale the friction on the inner surface of the bag, and SCALEI will scale the outer surface. When defined by control volumes (see *AIRBAG), the SCALEI parameter will scale friction on the inner surface of the bag and SCALEO the scale the outer surface.

This option is compatible with all other options to define the friction coefficients as the scale factors are applied after the Coulomb coefficient, μ_c, has been calculated.

*DEFINE_FUNCTION

Purpose: Define a function that can be referenced by a limited number of keyword options. The function arguments are different for each keyword that references *DEFINE_FUNCTION. Unless stated otherwise, all the listed argument(s) in their correct order must be included in the argument list. Some usages of *DEFINE_FUNCTION allow random ordering of arguments and argument dropouts. See the individual keywords for the correct format. Some examples are shown below.

NOTE: Unless the type of the function is explicitly given (as in Example 2 below), the function will return an integer value if the name of the function starts with a letter in the range of i - n. Otherwise it will return a real value. For example, if a function is defined as "ifunc(x) = sqrt(x)," then ifunc(2.0) will return 1, not 1.414.

The TITLE option is not allowed with *DEFINE_FUNCTION.

Card 1	1	2	3	4	5	6	7	8
Variable	FID	HEADING						
Type	I	A70						

Function Cards. Insert as many cards as needed. These cards are combined to form a single line of input. The next keyword ("*") card terminates this input.

Card	1	2	3	4	5	6	7	8
Variable	FUNCTION							
Type	A80							

VARIABLE	DESCRIPTION
FID	Function ID. Functions, tables (see *DEFINE_TABLE), and load curves may not share common IDs. A unique number must be defined.
HEADING	An optional descriptive heading
FUNCTION	Arithmetic expression involving a combination of independent variables and other functions, that is, "f(a,b,c)=a*2+b*c+sqrt(a*c)," where a, b, and c are the independent variables. The function name, "f(a,b,c)," must be unique since other functions can then use

VARIABLE	DESCRIPTION
	and reference this function. For example, "g(a,b,c,d)=f(a,b,c)**2+d." In this example, two *DEFINE_FUNCTION definitions are needed to define functions f and g.

Remarks:

1. **Reserved Names for Variables and Constants.** Certain useful constants are intrinsic and available through reserved names. For example, PI is the proportionality constant relating the circumference of a circle to its diameter, while DTOR and RTOD are, respectively, used to convert from degrees to radians and from radians to degrees. Also, TIME stores the current simulation time. See Appendix U for a complete list of variable names reserved internally by LS-DYNA.

2. **Trigonometric and Other Intrinsic Functions.** Most trigonometric and other mathematical functions available in the Fortran and C programming languages are valid in *DEFINE_FUNCTION, such as SIN, COS, ABS, and MAX. Please see a more complete list under "Intrinsic Functions" in *DEFINE_CURVE_FUNCTION.

3. **Units of Angular Measures.** Unless otherwise noted units of radians are always used for the arguments and output of functions involving angular measures.

4. **Dynamic Relaxation.** Unlike *DEFINE_CURVE and *DEFINE_CURVE_FUNCTION, *DEFINE_FUNCTION is always active in dynamic relaxation phase.

The following examples serve only as an illustration of syntax.

Example 1:

Prescribe sinusoidal *x*-velocity and *z*-velocity for some nodes.

```
*BOUNDARY_PRESCRIBED_MOTION_SET
$#    nsid       dof       vad      lcid        sf
         1         1         0         1
         1         3         0         2
*DEFINE_FUNCTION
1,x-velo
x(t)=1000*sin(100*t)
*DEFINE_FUNCTION
2,z-velo
a(t)=x(t)+200
```

Example 2:

Ramp up a hydrostatic pressure on a submerged surface.

```
*comment
units: mks

Apply a hydrostatic pressure ramped up over a finite time = trise.

pressure on segment = rho * grav * depth of water
where depth of water is refy - y-coordinate of segment
and refy is the y-coordinate of the water surface

*DEFINE_FUNCTION
10
float hpres(float t, float x, float y, float z, float x0, float y0, float
      z0)
{
  float  fac, trise, refy, rho, grav;
  trise = 0.1; refy = 0.5; rho = 1000.; grav = 9.81;
  fac = 1.0;
  if(t<=trise) fac = t/trise;
  return fac*rho*grav*(refy-y);
}
*LOAD_SEGMENT_SET
1,10
```

Example 2 illustrates that a programming language resembling C can be used to define a function. Before a variable or function is used, its type must be declared. For example, variable t is real, so it has "float" preceding it in the function declaration. The braces indicate the beginning and end of the function being programmed. Semicolons must appear after each statement but several statements may appear on a single line. Please refer to a C programming guide for more detailed information.

*DEFINE_FUNCTION_TABULATED

Purpose: Define a function of one variable using two columns of input data (in the manner of *DEFINE_CURVE) that can be referenced by a limited number of keyword options or by other functions defined via *DEFINE_FUNCTION. This command must appear in the keyword deck before the function it defines is used.

The TITLE option is not allowed with *DEFINE_FUNCTION_TABULATED.

Card 1	1	2	3	4	5	6	7	8
Variable	FID	HEADING						
Type	I	A70						

Card 2	1	2	3	4	5	6	7	8
Variable	FUNCTION							
Type	A80							

Point Cards. Put one pair of points per card (2E20.0). Add as many cards as necessary. Input is terminated when a keyword ("*") card is found.

Cards 3	1	2	3	4	5	6	7	8
Variable	A1		01					
Type	F		F					
Default	0.0		0.0					

VARIABLE	DESCRIPTION
FID	Function ID. Functions, tables (see *DEFINE_TABLE), and load curves may not share common ID's. A unique number has to be defined.
HEADING	An optional descriptive heading.

VARIABLE	DESCRIPTION
FUNCTION	Function name.
A1, A2, …	Abscissa values.
O1, O2, …	Ordinate (function) values.

Example:

```
*BOUNDARY_PRESCRIBED_MOTION_SET
$  function 300 prescribes z-acceleration of node set 1000
1000,3,1,300
*DEFINE_FUNCTION_TABULATED

tabfunc
0., 200
0.03, 2000.
1.0, 2000.
*DEFINE_FUNCTION
300
a(t)=tabfunc(t)*t
$ for t < 0.03, function 300 is equivalent to a(t)=(200. + 60000.*t)*t
$ for t >= 0.03, function 300 is equivalent to a(t)=(2000.)*t
```

*DEFINE_GROUND_MOTION

Purpose: Define an earthquake ground motion history using ground motion records provided as load curves, for use in conjunction with *LOAD_SEISMIC_SSI for dynamic earthquake analysis including nonlinear soil-structure interaction.

Card 1	1	2	3	4	5	6	7	8
Variable	GMID	ALCID	VLCID					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
GMID	Ground motion ID. A unique number has to be defined.
ALCID	Load curve ID of ground acceleration history.
VLCID	Load curve ID of ground velocity history.

Remarks:

1. **Earthquake Ground Motion Data.** Earthquake ground motion data is typically available either only as ground accelerations, or as a triple of ground accelerations, velocities and displacements. Usually, the velocities and the displacements are computed from the accelerations using specialized filtering and baseline correction techniques. Either input is accepted, with each quantity specified as a load curve. Only the acceleration and the velocity are required in the latter case; LS-DYNA does not require the ground displacement.

2. **Generated Velocity Load Curve.** If only the ground acceleration data is provided for a particular ground motion, LS-DYNA generates a corresponding load curve for the velocity by integrating the acceleration numerically. The generated load curves are printed out to the d3hsp file. It is up to the user to ensure that these generated load curves are satisfactory for the analysis.

*DEFINE_HAZ_PROPERTIES

Purpose: To model the heat-affected zone in a welded structure, the yield stress and failure strain are scaled in shell models as a function of their distance from spot welds and the nodes specified in *DEFINE_HAZ_TAILOR_WELDED_BLANK. *DEFINE_HAZ_-PROPERTIES currently supports spot welds defined with *CONSTRAINED_INTERPOLATION_SPOTWELD. It also supports spot welds defined with beam or solid elements using *MAT_SPOTWELD. *CONSTRAINED_SPOTWELD is not currently supported.

Card 1	1	2	3	4	5	6	7	8
Variable	ID_HAZ	IOP	PID	PID_TYP				
Type	I	I	I	I				
Default	0	0	0	0				

Card 2	1	2	3	4	5	6	7	8
Variable	ISS	IFS	ISB	IFB	ISC	IFC	ISW	IFW
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
ID_HAZ	Property set ID. A unique ID number must be used.
IOP	Activate scaling flag: EQ.0: Scaling not activated. EQ.1: Scaling activated.
PID	Part or part set ID
PID_TYP	PID type: EQ.0: Part ID EQ.1: Part set ID

VARIABLE	DESCRIPTION
ISS	Curve ID for scaling the yield stress based on the distance to the closest solid element spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2.
IFS	Curve ID for scaling the failure strain based on the distance to the closest solid element spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2.
ISB	Curve ID for scaling the yield stress based on the distance to the closest beam element spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2.
IFB	Curve ID for scaling the failure strain based on the distance to the closest beam element spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2.
ISC	Curve ID for scaling the yield stress based on the distance to the closest constrained spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2.
IFC	Curve ID for scaling the failure strain based on the distance to the closest constrained spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2.
ISW	Curve ID for scaling the yield stress based on the distance to the closest tailor welded blank node. Use a negative ID for curves normalized by the spot weld diameter as described in in Remark 2.
IFW	Curve ID for scaling the failure strain based on the distance to the tailor welded blank node. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2.

Remarks:

1. **Scaling.** The yield stress and failure strain are assumed to vary radially as a function of the distance of a point to its neighboring spot welds. Since larger spot welds may have a larger radius of influence, the smallest scale factor for the yield stress from all the neighboring spot welds is chosen to scale the yield stress at a particular point. The failure strain uses the scaling curve for the same weld.

2. **Weld Diameter Normalization.** Curve IDs may be input as negative values to indicate that they are normalized by the diameter of the spot weld to compensate for the effects of the spot weld size. When this option is used, the scale factor is

calculated based on the distance divided by the spot weld diameter for the spot weld that is closest to the element.

3. **Distance Measurement.** The distance from a spot weld (or node for the blank) is measured along the surface of the parts in the part set. This prevents the heat softening effects of a weld from jumping across empty space.

4. **Material Restrictions.** The HAZ capability only works with parts with materials using the STOCHASTIC option. It may optionally be simultaneously used with *DEFINE_STOCHASTIC_VARIATION to also account for the spatial variations in the material properties. See *DEFINE_STOCHASTIC_VARIATION for more details.

5. **Extra History Variables.** The scale factors on yield stress and failure strain may be stored as extra history variables as follows:

Material Model	History Variable # for Scaling Factor on Yield Stress	History Variable # for Scaling Factor on Failure Strain
10	5	6
15	7	8
24	6	7
81	6	7
98	7	8
123 (shells only)	6	7

When the HAZ capability is used in combination with *DEFINE_STOCHASTIC_VARIATION, the history variables shown in the table above represent the net scale factors due to HAZ and stochastic variation.

*DEFINE_HAZ_TAILOR_WELDED_BLANK

Purpose: Specify nodes of a line weld such as in a Tailor Welded Blank. The yield stress and failure strain of the shell elements in the heat affected zone (HAZ) of this weld are scaled according to *DEFINE_HAZ_PROPERTIES.

Card 1	1	2	3	4	5	6	7	8
Variable	IDTWB	IDNS	IDP	IPFLAG	IMONFLAG			
Type	I	I	I	I	I			
Default	0	0	0	0	0			

VARIABLE	DESCRIPTION
IDTWB	Tailor Welded Blank ID
IDNS	Node Set ID defining the location of the line weld.
IDP	Part or part set ID. Applies to all HAZ parts if IDP = 0 (default).
IPFLAG	IDP type: EQ.0: part ID (default) EQ.1: part set ID
IMONFLAG	Monotonicity flag for load curves ISW and IFW on *DEFINE_-HAZ_PROPERTIES: EQ.0: ISW and IFW increase monotonically. EQ.1: ISW and IFW are allowed to be arbitrary load curves.

*DEFINE_HEX_SPOTWELD_ASSEMBLY_{OPTION}

Purpose: Define a list of hexahedral elements that make up a single spot weld for computing the force and moment resultants that are written into the swforc output file. A maximum of 16 elements may be used to define an assembly representing a single spot weld. See Figure 17-53. This table of element IDs is generated automatically when beam elements are converted to solid elements. See the input parameter RPBHX associated with the keyword *CONTROL_SPOTWELD_BEAM.

Available options for this command are:

<BLANK>

N

For the <BLANK> option, all solid elements specified on Card 2 make up the spot weld and no additional card is read. For the N option, N is an integer representing the total number of solid elements making up the spot weld. If N is greater than 8, the additional card beyond Card 2 is read. N may not exceed 16.

Card 1	1	2	3	4	5	6	7	8
Variable	ID_SW							
Type	I							
Default	0							

Card 2	1	2	3	4	5	6	7	8
Variable	EID1	EID2	EID3	EID4	EID5	EID6	EID7	EID8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

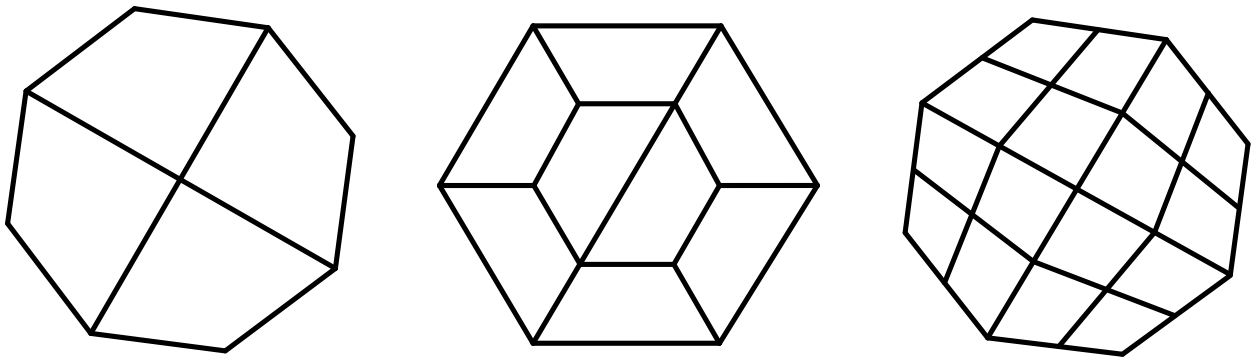

Figure 17-53. Illustration of four, eight, and sixteen element assemblies of solid hexahedron elements forming a single spot weld.

Additional card for N > 8.

Optional	1	2	3	4	5	6	7	8
Variable	EID9	EID10	EID11	EID12	EID13	EID14	EID15	EID16
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
ID_SW	Spot weld ID. A unique ID number must be used.
EID*n*	Element ID *n* for up to 16 solid hexahedral elements.

Remarks:

The elements comprising a spot weld assembly may share a part ID (PID) with elements in other spot weld assemblies defined using *DEFINE_HEX_SPOTWELD_ASSEMBLY but may not share a PID or even a material ID (MID) with elements that are not included in a *DEFINE_HEX_SPOTWELD_ASSEMBLY.

*DEFINE_LANCE_SEED_POINT_COORDINATES

Purpose: Define seed points that determine the portion of a part(s) that is not removed (not scraps) during the trimming portion of lancing. This keyword is to be used in conjunction with *ELEMENT_LANCING. See *ELEMENT_LANCING.

Card 1	1	2	3	4	5	6	7	8
Variable	NSEED	X1	Y1	Z1	X2	Y2	Z2	
Type	I	F	F	F	F	F	F	
Default	none	0.0	0.0	0.0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
NSEED	Number of seed points. Maximum value of "2" is allowed.
X1, Y1, Z1	Location coordinates of seed point #1.
X2, Y2, Z2	Location coordinates of seed point #2.

Remarks:

1. **Trimming Restrictions.** This keyword will remove all scraps during or after lancing, depending on how the parameter AT is defined in *ELEMENT_LANCING. Lancing curves must form a closed loop, meaning the first and last point coordinates must be coincident. Scraps are the portions that are exclusive of the portions whose seed points are defined by this keyword.

2. **Example.** The following input defines two sets of seed point coordinates, where a double-attached part may be lanced and trimmed:

```
*DEFINE_LANCE_SEED_POINT_COORDINATES
$    NSEED        X1        Y1         Z1        X2        Y2         Z2
         2    -289.4     98.13   2354.679    -889.4     91.13    255.679
```

Revision Information

This feature is available starting with LS-DYNA Revision 107262.

*DEFINE_MATERIAL_HISTORIES_{OPTION}

The available options include:

<BLANK>

NAMES

Purpose: To control the content of the history variables in the d3plot database. This feature is supported for solid, shell, and integrated beam elements. See Motivation below for the rationale behind this keyword and How this Keyword Works for a description of how the history variables are output.

If the NAMES keyword option is active, you can give each specified history variable a corresponding name. These names will be reflected in d3hsp and a post-processing file containing the history variable names if HISNOUT > 0 on *CONTROL_OUTPUT.

> **NOTE:** Whenever this keyword is included in the input file, the effective plastic strain output will be zero for all materials for which there is no plastic strain (see Remark 3 for more details).

Card Summary:

Card Sets. Define as many instantiations of Card 1 or sets of Card 1 and Card 2 for the NAMES keyword option as needed to define the extra history variables. This input ends at the next keyword ("*") card. This keyword can be defined without any data cards; see Remark 3 below for details of when this should be used.

Card1. Include as many of this card or sets of this card with Card 2 for the names keyword option as needed.

LABEL	A1	A2	A3	A4

Card 2. This card is included in sets with Card 1 when the NAMES keyword option is used.

NAME	

Data Card Definitions:

History Variable Card. Define as many cards as needed to define the extra history variables. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	LABEL				A1	A2	A3	A4
Type	A40				F	F	F	F
Default	none				0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
LABEL	String identifying history variable type. Labels are *case-sensitive*. See section LABEL below and Remark 4. By prefixing the label with (capital letter) 'X', the current history variable will not be printed to the binary database. See Example 4.
A*n*	Attributes. See section LABEL below.

User-Defined Name Card. Additional card for the NAMES keyword option. Define this card in sets with Card 1. See Example 2.

Card 2	1	2	3	4	5	6	7	8
Variable	NAME							
Type	A70							

VARIABLE	DESCRIPTION
NAME	User-defined name for history variable

LABEL:

The permitted LABELs (*case-sensitive*) are

Instability	A number between 0 and 1 that indicates how close an element or integration point is to failure or to initiate damage, whatever happens first (see Remark 1). Attributes apply to the DIEM

damage model (see *MAT_ADD_DAMAGE_DIEM) and add erosion model (see *MAT_ADD_EROSION) only. In those cases, the following apply

A1 Value	Description
-12	Instability value for FAILTM on *MAT_ADD_EROSION. FAILTM is assumed nonzero.
-10	Instability value for SIGTH and IMPULSE on *MAT_ADD_EROSION. SIGTH and IMPULSE are assumed nonzero.
-9	Instability value for EPSSH on *MAT_ADD_EROSION. EPSSH is assumed nonzero.
-8	Instability value for MXEPS on *MAT_ADD_EROSION. MXEPS is assumed nonzero.
-7	Instability value for SIGVM on *MAT_ADD_EROSION. SIGVM is assumed nonzero.
-6	Instability value for SIGP1 on *MAT_ADD_EROSION. SIGP1 is assumed nonzero.
-5	Instability value for MNPRES on *MAT_ADD_EROSION. MNPRES is assumed nonzero.
-4	Instability value for VOLEPS on *MAT_ADD_EROSION. VOLEPS is assumed nonzero.
-3	Instability value for EFFEPS on *MAT_ADD_EROSION. EFFEPS is assumed nonzero.
-2	Instability value for MNEPS on *MAT_ADD_EROSION. MNEPS is assumed nonzero.
-1	Instability value for MXPRES on MAT_ADD_EROSION. MXPRES is assumed nonzero.
1	Max instability value in any integration point and any criterion for DIEM

2	Location (isoparametric z-coordinate between -1 and 1) of max instability value for DIEM
3	Criterion attaining max instability value for DIEM (integer value)
4	Stress triaxiality η for evaluating instability criterion value for the ductile (DITYP = 0) criterion in DIEM
5	Shear influence θ for evaluating instability criterion value for the shear (DITYP = 1) criterion in DIEM
6	Ratio of principal strain rates α for evaluating instability criterion value for the MSFLD (DITYP = 2) criterion in DIEM
7	Ratio of principal strain rates α for evaluating instability criterion value for the FLD (DITYP = 3) criterion in DIEM
8	Stress state parameter β for evaluating instability criterion value for the weighted ductile (DITYP = 4) criterion in DIEM

Damage

A number between 0 and 1 indicating the damage level of the element or integration point (see Remark 1). Attributes apply to the GISSMO damage model (see *MAT_ADD_DAMAGE_GISSMO) only. In those cases, the following apply

A1 Value	Description
0	GISSMO's effective damage value $\widetilde{D}$ (ND+18)
1	GISSMO's damage value D (ND)

Plastic Strain Rate

Effective plastic strain rate, calculated generically for "all" plastic materials from the evolution of effective plastic strain. No attributes apply to this label.

Effective Stress

Effective, or equivalent, stress. If not specifically stated in the material section for the material in question, this will be the von Mises stress. For selected anisotropic materials (such as the

Barlat models), it is the stress value that is conjugate to the effective plastic strain rate with respect to energy density rate.

Effective Tresca Stress Effective, or equivalent, stress according to Tresca (maximum shear stress):

$$\sigma_e^T = \max[|\sigma_1 - \sigma_2|, |\sigma_2 - \sigma_3|, |\sigma_3 - \sigma_1|] \ ,$$

where σ_1, σ_2 and σ_3 are the principal stresses.

Plastic Energy Density Plastic work per unit volume. It is only nonzero for materials deemed as plastic materials. This is evaluated as $\int_0^t \sigma \dot{\varepsilon}_{\text{eff}}^p$, where σ is the von Mises effective stress and $\varepsilon_{\text{eff}}^p$ is the work equivalent plastic strain. Thus, the result will not be entirely correct for anisotropic materials. Upon request, we will improve the calculation for the asked for anisotropic materials.

Effective Creep Strain Effective creep strain for material models with creep. In particular it will provide the effective creep strain for *MAT_ADD_INELASTICITY if creep is one of the selected inelasticity laws; see this keyword for more details.

History Fetch a history variable at a known place for a given material type, element type and part set (see Example 1). The following attributes apply:

Attribute	Description
A1	Mandatory (no defaults) GT.0: History variable location LT.0: Load curve ID = (-A1); see below for a complete description
A2	Material type. By default, it applies to all materials.
A3	Element type: 0 for all element types, 1 for solids, 2 for shells and 3 for beams
A4	Part set. History will only be fetched from the parts in the given part set. The default is all parts in the model.

When A1 < 0, then |A1| refers to a *DEFINE_CURVE. In this curve definition you specify an 'operation' that you would like

to perform over a certain list of history variables within an element.

Operation	Description
1	Maximum value
2	Layer where the maximum value occurs
3	History variable that attains the max value

Only the ordinate values of the load curve are used, but we suggest defining the abscissa value using increasing integer numbers starting with 0. Furthermore, you should use DATTYP = 6 in the curve definition to make sure that the data is not transformed in any way. Here is an example:

```
*DEFINE_CURVE
ID, 0, 1., 1., 0., 0., 6, 0
0, 1 (operation)
1, 12 (location of 1st history variable)
2, 17 (location of 2nd history variable)
3, 22 (location of 3rd history variable)
```

In this particular case, you will receive the maximum value of the history variables 12, 17 and 22 at any integration point within one element.

Operator

Perform an operation on a given history variable or quantity. The following attributes apply:

Attribute	Description
A1	Type of operator: EQ.0: Maximum value over time EQ.1: Point in time when maximum value over time was attained. EQ.2: Minimum value over time EQ.3: Point in time when minimum value over time was attained. EQ.5: Absolute value, |A2| EQ.6: Addition, A2 + A3 EQ.7: Subtraction, A2 - A3 EQ.8: Multiplication, A2 × A3

	EQ.9: Division, A2/A3 (assuming A3 > 0) EQ.10: Exponentiation, $A2^{A3}$ EQ.11: Maximum, max(A2, A3) EQ.12: Minimum, min(A2, A3) EQ.13: Natural logarithm, ln|A2|
A2 and A3	First and second argument to operator: EQ.-16: Real number given by A4 EQ.-9: *x*-stress EQ.-8: *y*-stress EQ.-7: *z*-stress EQ.-6: *xy*-stress EQ.-5: *yz*-stress EQ.-4: *zx*-stress EQ.-3: Mid principal stress EQ.-2: Minor principal stress EQ.-1: Major principal stress EQ.0: Effective plastic strain GT.0: History variable # in list specified here

A4	Parameter for operator A1:
	If A2 or A3 are EQ.-16 then
	Real number (see Example 4)
	Else
	If 0.LE.A1.LE.3 then
	GT.0: Time at which min/max will be reset
	LT.0: |A4| is ID to load curve whose ordinate contains time points when min/max will be reset. Even though only the ordinate values are used, DATTYP = 6 is recommended.
	Else

	LT.0: Shell stress will be rotated to global coordinates. **Endif** **Endif**

The stress components used as arguments (A2 and A3) are for solid elements in global coordinates and for shell elements in element-local (co-rotated) coordinates. However, by setting A4 to a negative value, shell element stresses will be rotated to global coordinates.

See Examples 3 and 4.

Principal Stress Range

Compute the maximum (principal) stress amplitude. This feature is a scanning tool intended for fatigue analysis. Currently only shell elements are supported. See Remark 5 for details about how it is determined.

The following attributes apply:

Attribute	Description
A1	GT.0: Reset time LT.0: |A1| is ID to load curve whose ordinate contains time points when min/max will be reset. Even though only the ordinate values are used, DATTYP = 6 is recommended.
A2	Number of buckets (NBKTS) each 90° sector is divided into. Default value is 65 buckets.
A3	(not used)
A4	Part set. Stress range will only be computed in the parts in the given part set. The default is all parts in the model.

Max Stress Range

As label *Principal Stress Range* above but not specifically considering the principal stresses; see Remark 5. The drawback of this approach is that close to twice the amount of storage is needed. Therefore, the default number of buckets (NBKTS) is 45.

The same attributes apply as for label *Principal Stress Range.*

Motivation:

Material models in LS-DYNA have history variables that are specific to the constitutive model being used. For most materials, 6 are reserved for the Cauchy stress components and 1 for the effective plastic strain, but many models have more than that. The history variables may include physical quantities like material damage, material phase compositions, strain energy density and strain rate, as well as nonphysical quantities like material direction cosines and scale factors.

By using NEIPS, NEIPB and NEIPH on *DATABASE_EXTENT_BINARY, these extra history variables can be exported to the d3plot database *in the order that they are stored*, and in LS-PrePost the variables may then be plotted (Hist button) or fringed (Misc menu). This approach has a few drawbacks. You must, for instance, have knowledge of the storage location of a certain history variable for a given material model and element type. While this information can be retrieved either in the LS-DYNA manual, on LS-DYNA support sites or in LS-PrePost itself, it is not always convenient.

Furthermore, the same physical quantity may be stored in different locations for different materials and different element types, meaning that history variable #1 will correspond to different things in different parts which complicates post-processing of large models. You may also be interested in a certain material specific quantity that is not necessarily stored as a history variable; this quantity is not retrievable using this approach. Finally, if the history variable of interest happens to be stored in a bad location, that is, among the last ones in a long list, it would be necessary to set NEIPS, NEIPB and/or NEIPH large enough to access this variable in LS-PrePost. This could result in unnecessarily large binary plot files.

How this Keyword Works:

This keyword attempts to organize the extra history variables with the goal of obtaining an output that is reasonably small and easy to interpret. The input is very simple: use the keyword *DEFINE_MATERIAL_HISTORIES in the keyword input deck, followed by lines that specify the history variables of interest using predetermined labels and attributes. *NEIPS, NEIPB and NEIPH on *DATABASE_EXTENT_BINARY will then be overridden by the number of history variables, that is, number of lines, requested on this card*. As an example

```
*DEFINE_MATERIAL_HISTORIES
Instability
Damage
```

would mean that two extra history variables are output to the d3plot database, so NEIPS, NEIPB and NEIPH will internally be set to 2 regardless of the user input. History variable #1 will correspond to an instability measure (between 0 and 1) and history variable #2 will correspond to a material damage (between 0 and 1). Thus, the history variables are output in the order they are listed. If there are several instances of this keyword in an

input deck, then the order of the history variables will follow the order that the cards are read by the keyword reader.

In the d3hsp file you may find the complete list by searching for the string "M a t e r i a l H i s t o r y L i s t." For a material that does not store or calculate an "instability" or "damage" history variable, the output will be zero and thus the output will not be cluttered by unwanted data. Note that this keyword does not necessarily require that the history variable be stored, as long as it can be calculated when LS-DYNA outputs a plot state (see Remark 7 regarding storage). Thus, you can possibly request quantities that are not available by just using NEIPS, NEIPB and/or NEIPH on *DATABASE_EXTENT_BINARY.

Remarks:

1. **Damage and Instability.** For large models with many different parts and materials, the *Instability* and *Damage* variables should provide a comprehensive overview and understanding of the critical areas in terms of failure that otherwise may not be assessable. Note that *Damage* can only be nonzero after *Instability* reaches 1, and thereafter the integration point fails when *Damage* reaches 1. If the material has no damage evolution law (which is the case in many of the *MAT_ADD_EROSION features for which failure of the integration point occurs immediately upon reaching the failure criterion without any stress softening), then in general *Damage* will jump from 0 to 1 exactly when *Instability* reaches 1.

2. **History Variable Requests from *DATABASE_EXTENT_BINARY.** As discussed in How this Keyword Works, NEIPS, NEIPB, and NEIPH set in *DATABASE_EXTENT_BINARY will be ignored when *DEFINE_MATERIAL_HISTORIES is included in the input deck. The number of extra history variables output to d3plot will be determined by how many instantiations of Card 1 are included in the input deck. For instance, if only instability and damage are specified with this keyword, then two extra history variables will be output.

3. **Effective Plastic Strain.** Whenever *DEFINE_MATERIAL_HISTORIES is present in the input file, the effective plastic strain output will be zero for all materials for which there is no plastic strain. Thus, this slot in the d3plot database is in this case *not* taken over by something else, but rather occupied by zero data. For instance, for *MAT_ELASTIC it will be a null field while it will be the effective plastic strain field for *MAT_PIECEWISE_LINEAR_PLASTICITY. For a part that uses *MAT_ADD_INELASTICITY with a plastic model, the effective plastic strain will be the one pertaining to this inelasticity law. Thus, *DEFINE_MATERIAL_HISTORIES may be used without any cards if this behavior is desired for the effective plastic strain.

4. **Requestable History Variables Types.** At the end of the remarks for a material model in Volume II, the history variable types (other than *History*) available are listed in a table similar to the one below. *History* is available for all materials, but retrievable ones depend on the model. Also, whether mentioned in such a table or not, *Plastic Strain Rate* and *Plastic Energy Density* available for any material model that calculates plastic strain as the 7th standard history variable.

**DEFINE_MATERIAL_HISTORIES Properties*

Label	Attributes	Description
Instability	- - - -	Failure indicator $\varepsilon^p_{\text{eff}}/\varepsilon^p_{\text{fail}}$, see FAIL
Plastic Strain Rate	- - - -	Effective plastic strain rate $\dot{\varepsilon}^p_{\text{eff}}$
Plastic Energy Density	- - - -	Plastic energy density $\int_0^t \sigma \dot{\varepsilon}^p_{\text{eff}}$

Label in the table states what the string LABEL on *DEFINE_MATERIAL_HISTORIES must be, *a1* to *a4* will list attributes A1 to A4 if necessary, and *Description* will be a short description of what is output with this option, including possible restrictions.

5. **Calculating Principal Stress Range.** Assuming plane stress ($\sigma_z = 0$), the normal stress at an angle φ to the local element x-axis is

$$\sigma(\varphi) = \frac{\sigma_x + \sigma_y}{2} + \frac{\sigma_x - \sigma_y}{2}\cos 2\varphi + \tau_{xy}\sin 2\varphi.$$

Specifically, the major principal stress and its direction are

$$\sigma_1 = \frac{\sigma_x + \sigma_y}{2} \pm \sqrt{\left(\frac{\sigma_x - \sigma_y}{2}\right)^2 + \tau_{xy}^2}$$
$$\varphi_1 = \frac{1}{2}\tan^{-1}\frac{2\tau_{xy}}{\sigma_x - \sigma_y}$$

Using the equations above, the range of angles $\varphi \in [-90°, 90°]$ is divided into $2 \times$ NBKTS buckets with each bucket covering $90°/$NBKTS degrees. In each bucket the minimum stress over time is stored. At the same time the over-time maximum major principal stress and its direction is stored. The stress range is then computed as the difference between the major principal stress and the minimum stress in the corresponding direction (i.e., bucket). Output to the binary database is the over-time maximum stress range.

The computed principal stress range is exact in the case when the angle of the minimum minor principal stress is the same as the angle of the maximum major principal stress. In most other cases the computed stress range is an

overestimate. It is estimated that the worst overestimate would be close to $2\cos(90^\circ - 90^\circ/\text{NBKTS}) \times 100\%$ of the minimum minor principal stress in size.

Please note that besides the maximum stress range, $2 \times \text{NBKTS} + 2$ values will be stored for each integration point. Therefore, we recommend limiting the number of elements for which this label is used.

The alternative label *Max Stress Range* does not consider the direction of the major principal stress. Instead, in each bucket the stress range is computed as the difference of the over-time maximum and minimum normal stress. Output to the binary database is the over-time maximum stress range of all buckets. For this label, besides the maximum stress range, $4 \times \text{NBKTS}$ values will be stored for each integration point.

6. **Future Developments and Feature Requests.** Further development of this keyword will mainly be driven by customer requests submitted to *LstSuggestions@ansys.com*. Currently only solid, shell, and integrated beam elements are supported for the binary d3plot format. Future developments may include adding output for thick shells to d3plot and supporting ASCII/binout.

7. **Storage allocation.** In many cases (e.g, *Instability*, *History*, *Effective Stress*), no additional storage (by the element or material) beyond the already occupied slots in the internal data array is needed. However, some requested quantities on this card will require additional storage. In most cases only one slot, but in other cases more. For example, requesting the *Operator* 'Point in time when maximum value over time was attained' (A1 = 1) will require two slots: one containing the maximum value and one for the time it occurred. Note that only one value (the time) will be output to the d3plot database. Below is a list of the *additional* data storage required for each label.

Label	Additional storage slots
Instability	0
Damage	0
Plastic Strain Rate	1
Effective Stress	0
Effective Tresca Stress	0
Plastic Energy Density	1
Effective Creep Strain	0

Label	Additional storage slots
History	1
Operator	2 if A1 = 1 or 3 1 otherwise
Principal Stress Range	3 + NBKTS × 2
Max Stress Range	1 + NBKTS × 4

Examples:

1. **History Label.** The History label is for when you know where history variables of interest are stored and want to use this to compress or simplify the output. For example, the following input

```
*DEFINE_MATERIAL_HISTORIES
History,4,272,1,23
History,1,81
*SET_PART_LIST
23
2,3
```

will make a list of two history variables in the output. History variable #1 will fetch the 4th history variable and output it only for the RHT concrete model (material 272) solid elements in parts 2 and 3. History variable #2 will fetch the 1st history variable and output it only for the plasticity with damage model (material 81) but for any element and part. Both of these requested variables happen to be the damage in the respective materials, so an alternative to do something similar would be to use

```
*DEFINE_MATERIAL_HISTORIES
Damage
```

for which the damage for all materials will be displayed in history variable #1.

2. **History Variable Names.** The NAMES keyword options allows you to give the history variables labels in d3hsp and the post-processing file (if HISNOUT > 0 on *CONTROL_OUTPUT). For example, the following

```
*DEFINE_MATERIAL_HISTORIES_NAMES
History,1,24
Effective strain rate
History,4,47
my_own_history
```

gives the first history variable corresponding to history variable 1 of MAT_024 the label "Effective strain rate" and the second history variable corresponding to the fourth history variable of user material 47 the label "my_own_history".

3. **Operator Label.** The Operator label is for performing specific operations on stress or a history variable listed in *DEFINE_MATERIAL_HISTORIES. For example,

```
*DEFINE_MATERIAL_HISTORIES
Effective Stress
Operator,0,1,0,0.1
Operator,1,1,0,0.1
Operator,0,-1,0,-99
Operator,1,-1,0,-99
Operator,2,-2
Operator,3,-2
*DEFINE_CURVE
-99
0.0,0.1
0.0,0.3
0.0,0.7
```

will lead to the following history variables in d3plot:

History Variable #	Description
1	Effective stress
2	Maximum value over time of effective stress, reset at time 0.1.
3	Time when maximum value in time of effective stress was attained, reset at time 0.1.
4	Maximum value in time of major principal stress, reset at times 0.1, 0.3, and 0.7.
5	Time when maximum value in time of major principal stress was attained, reset at times 0.1, 0.3, and 0.7.
6	Minimum value in time of minor principal stress
7	Time when minimum value in time of minor principal stress was attained.

4. **Operator Label for Creating Expressions.** The Operator label can be used to create user-defined expressions. For example,

```
*DEFINE_MATERIAL_HISTORIES
$ 1 (1):
Effective Tresca Stress
$ 2 (-): s1-s2
XOperator,7,-1,-3
$ 3 (-): s2-s3
XOperator,7,-3,-2
$ 4 (-): s3-s1
XOperator,7,-2,-1
$ 5 (-): abs(s1-s2)
XOperator,5,2
$ 6 (-): abs(s2-s3)
XOperator,5,3
$ 7 (-): abs(s3-s1)
XOperator,5,4
$ 8 (-): max(abs(s1-s2),abs(s2-s3))
XOperator,11,5,6
$ 9 (2): max(abs(s1-s2),abs(s2-s3),abs(s3-s1))
Operator,11,7,8
$ 10 (-): hsv 1 + hsv 9
XOperator,6,1,9
$ 11 (3): hsv 10 * 0.5
Operator,8,10,-16,0.5
```

will lead to the following history variables in d3plot:

History Variable #	Description
1	Effective Tresca stress
2	Effective Tresca stress (computed using operators)
3	Mean value of Tresca expressions above

*DEFINE_MULTI_DRAWBEADS_IGES

Purpose: Simplify the definition and creation of draw beads, which previously required the use of many keywords.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	DBID	VID	PID	BLKID	NCUR			
Type	I	I	I	I	I			
Default	none	none	1	1	none			

IGES Curve ID Cards. For multiple draw bead curves include as many cards as necessary. Input is terminated at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	CRVID	BFORCE						
Type	I	F						
Default	none	0.0						

VARIABLE	DESCRIPTION
FILENAME	IGES file that has the draw bead curve segment definitions
DBID	Draw bead set ID, which may consist of many draw bead segments.

VARIABLE	DESCRIPTION
VID	Vector ID, as defined by *DEFINE_VECTOR. This vector is used to project the supplied curves to the rigid tool, defined by PID.
PID	Part ID of a rigid tool to which the curves are projected and attached.
BLKID	Part ID of the sheet blank with which created draw beads will contact.
NCUR	Number of draw bead curve segments (in the IGES file defined by FILENAME) to be defined.
CVRID	IGES curve ID for each segment.
BFORCE	Draw bead force for each segment.

Revision information:

This feature is available in LS-DYNA R5 Revision 62840 and later releases.

*DEFINE_MULTI_SHEET_CONNECTORS

Purpose: Define a multi-sheet connection with up to four shell element sheets. The individual sheets can be joined with up to three connection elements. Currently, for the connection elements, only single hexahedron elements with *MAT_SPOTWELD_DAIMLERCHRYSLER (*MAT_100_DA) are supported. Also, PRUL must be ≥ 2 in *DEFINE_CONNECTION_PROPERTIES. In addition to the standard definition of *MAT_100_DA between two sheets, it is possible with this keyword to define the material behavior of the joining elements as functions of the geometric and material properties of all sheets involved.

Card Summary:

Card Sets. Include as many sets of the following cards as desired. This input ends with the next keyword ("*") card.

Card 1. This card is required.

ID	ITYP	NSHEETS					

Card 2. This card is required.

PID1	JNT12	PID2	JNT23	PID3	JNT34	PID4	

Card 3. This card is required.

PARM1	PARM2	PARM3	PARM4	PARM5	PARM6	PARM7	PARM8

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	ID	ITYP	NSHEETS					
Type	I	I	I					
Default	none	1	none					

VARIABLE	DESCRIPTION
ID	Multi sheet connector ID

VARIABLE	DESCRIPTION
ITYP	Material model of joint elements: EQ.1: *MAT_SPOTWELD_DAIMLERCHRYSLER.
NSHEETS	Number of sheets connected with this multi sheet connector

Card 2	1	2	3	4	5	6	7	8
Variable	PID1	JNT12	PID2	JNT23	PID3	JNT34	PID4	
Type	I	I	I	I	I	I	I	
Default	none	none	none	optional	optional	optional	optional	

VARIABLE	DESCRIPTION
PID1	Part ID of sheet number one
JNT12	ID of joining element between sheet one and two
PID2	Part ID of sheet number two
JNT23	ID of joining element between sheet two and three (optional)
PID3	Part ID of sheet number three (optional)
JNT34	ID of joining element between sheet three and four (optional)
PID4	Part ID of sheet number four (optional)

Card 3	1	2	3	4	5	6	7	8
Variable	PARM1	PARM2	PARM3	PARM4	PARM5	PARM6	PARM7	PARM8
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
PARM*i*	Set of user parameters additionally available in *DEFINE_FUNCTION. See Remark 1.

Remarks:

1. **Failure Rule from *DEFINE_FUNCTION.** The elements referenced through JNT12, JNT23 and JNT34 should be hexahedral solid elements with material *MAT_100_DA and PRUL must be ≥ 2on *DEFINE_CONNECTION_PROPERTIES. Therefore, the following eleven variables in the respective *DEFINE_CONNECTION_PROPERTIES must be defined as function IDs: DSIGY, DETAN, DDGPR, DSN, DSB, DSS, DEXSN, DEXSB, DEXSS, DGFAD, and DSCLMRR.

   These functions depend on:

   (t1,t2,t3,t4) = thicknesses of the sheets
   (sy1,sy2,sy3,sy4) = initial yield stresses at plastic strain
   (sm1,sm2,sm3,sm4) = maximum engineering yield stresses
   r = strain rate of joining element
   a = area of joining element
   s = number of sheets
   n = internal number of joining element (1, 2, or 3)
   (p1, p2, p3, p4, p5, p6, p7, p8) = parameters defined in card 3
   fn = normal term in failure function
   fb = bending term in failure function
   fs = shear term in failure function

   For DSIGY = 100, such a function could look like:

```
*DEFINE_FUNCTION
            100
func(t1,t2,t3,t4,sy1,sy2,sy3,sy4,sm1,sm2,sm3,sm4,…
…,r,a,s,n,p1,p2,p3,p4,p5,p6,p7,p8,fn,fb,fs)=0.5*(sy1+sy
2)
```

   All the listed arguments in their correct order must be included in the argument list, even if you are not using 4 sheets. Note that this argument list is longer than the one listed in the remarks for the manual page of *DEFINE_CONNECTION_PROPERTIES. Also, PRUL = 2 and 3 are the same for this keyword because the order of the sheets is determined by this keyword. Since material parameters must be identified from the weld partners during initialization, this feature is only available for a subset of material models now, namely material types 3, 24, 36, 81, 120, 123, 124, 133, 187, 224, 243, 251, and 258.

*DEFINE_MULTISCALE

Purpose: Associate beam sets with multiscale local model IDs for modeling detailed local model failure through the multiscale method.

Local model/Beam Set and Coupling Type Association Cards. Provide as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	BSET	CTYPE					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
ID	Multiscale local model ID to use. See *INCLUDE_MULTISCALE.
BSET	Beam set which uses this multiscale local model ID for failure modeling.
CTYPE	Coupling type (see Remark 2): EQ.0: Weak coupling (default) EQ.1: Strong coupling

Remarks:

1. **Explanation of capability.** See *INCLUDE_MULTISCALE for a detailed explanation of this capability.

2. **Coupling type.** When CTYPE is 0 or not specified, this multiscale feature generates the solid local models for the defined beams and uses a weak coupling algorithm (used in *INCLUDE_MULTISCALE) for the multiscale calculation. When CTYPE equals to 1, it generates the solid local models for the defined beams and uses a strong coupling algorithm (algorithm used in *INCLUDE_COSIM; see *INCLUDE_COSIM for details) for the calculation.

*DEFINE_NURBS_CURVE

Purpose: Define a NURBS curve using a univariate knot vector, a control polygon, and optionally a set of control weights. The knot vector defines the necessary shape functions and parameterizes the curve.

There is no limit on the size of the input data. Hence, the total number of keyword cards depends on the parameters defined on the first card. The total number of cards is 1 + ceil[(N + P + 1)/8] + N, where N and P designate the number of control points forming the control polygon and the polynomial degree, respectively.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	N	P		TYPE	WFL		
Type	I	I	I		I	I		
Default	none	none	none		0	0		

Knot Vector Cards. The knot vector of length N+P+1 is given below, requiring ceil[(N + P + 1)/8] cards in total. The knot vector must be normalized to the [0,1] interval.

Card 2	1	2	3	4	5	6	7	8
Variable	K1	K2	K3	K4	K5	K6	K7	K8
Type	F	F	F	F	F	F	F	F

Control Point Cards. The spatial coordinates of the control points and the control weights are listed on N cards. Control weight entries are disregarded unless WFL = 1 on Card 1.

Card 3	1	2	3	4	5	6	7	8
Variable	X	Y	Z	W				
Type	F	F	F	F				

VARIABLE	DESCRIPTION
ID	Curve ID. A unique number must be chosen.
N	Number of control points
P	Polynomial degree
TYPE	Coordinate type: EQ.0: Spatial EQ.1: Parametric
WFL	Flag for user defined control weights: EQ.0: Control weights are assumed to be uniform and positive, that is, the curve is a B-spline curve. The fourth column of Card 3 is disregarded. EQ.1: Control weights are defined on the fourth entry of Card 3.
Kn	Values of the univariate knot vector define in Card 2 with $n = 1, \ldots, \text{N} + \text{P} + 1$.
Xk	Spatial coordinates in the global X-direction defined in Card 3 with $k = 1, \ldots, \text{N}$.
Yk	Spatial coordinates in the global Y-direction defined in Card 3 with $k = 1, \ldots, \text{N}$.
Zk	Spatial coordinates in the global Z-direction defined in Card 3 with $k = 1, \ldots, \text{N}$.
Wk	Control weights defined in Card 3 with $k = 1, \ldots, \text{N}$.

Remarks:

1. **Trimming Curves.** While the keyword is meant to store NURBS curves in two or three spatial dimensions, it is also employed to describe trimming curves that define trimmed NURBS elements/surfaces; see *ELEMENT_SHELL_NURBS_-PATCH for further details. In the latter case, the control point coordinates are in fact parametric coordinates of the surface to be trimmed, that is, $(x, y, z, w) = (r, s, 0, w)$ and TYPE = 1 on Card 1.

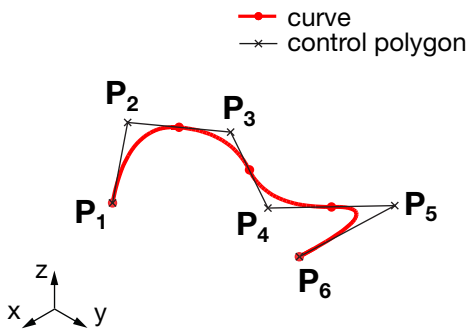

Figure 17-54. An example quadratic NURBS curve.

Example:

See Figure 17-54.

```
$ Define quadratic nurbs curve.
*DEFINE_NURBS_CURVE

```

*DEFINE_PART_FROM_LAYER

Purpose: This keyword creates new blank(s) from an existing sheet blank. It is often used to model composite layers. This keyword applies to shell elements only. The new blanks cannot be adaptively refined.

Multiple layers can be defined. Input ends with the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	LAYER	PIDSRCE	LAYOLD	MID	THICK		
Type	I	I	I	I	I	F		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
PID	The part ID to be created.
LAYER	The layer ID of the PID, see Figure 17-55.
PIDSRCE	The part ID of the existing blank to be copied from.
LAYOLD	The layer ID of the existing blank.
MID	The material ID of the PID.
THICK	The thickness of the PID.

Remarks:

1. **Required Input Deck Cards.** *PART and *SECTION_SHELL do not need to be defined for the to-be created composite layer, but *MAT and contact cards still need to be defined.

2. **Contact.** Contact between outer layer of composites and the tools can be modeled using *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE, while *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_COMPOSITE, or *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE can be used to model the interactions between two composite layers.

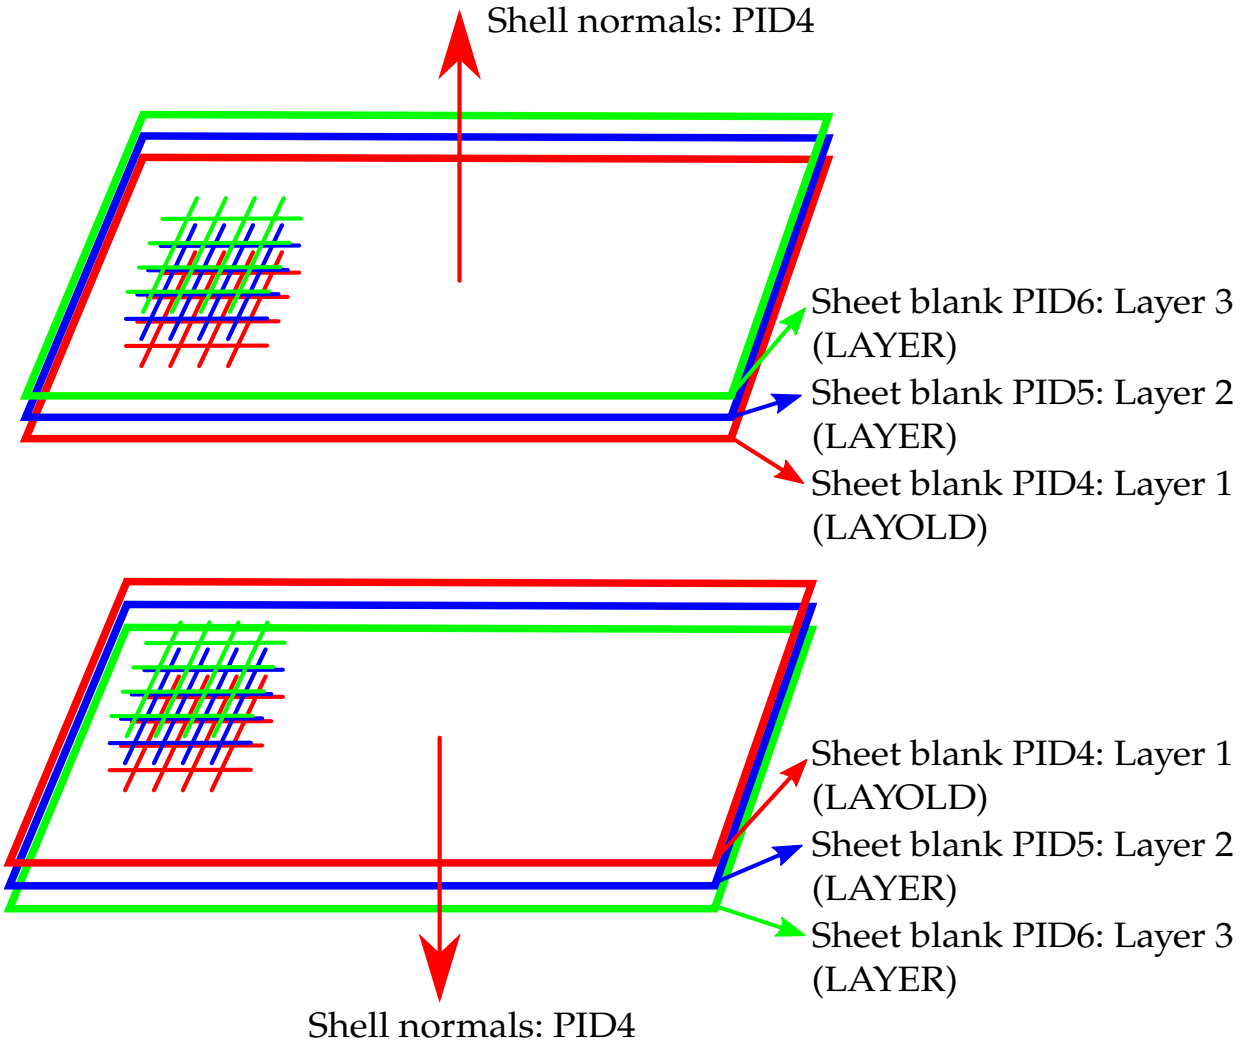

Figure 17-55. Defining the variables LAYER and LAYOLD.

Starting in Dev Revision 124300, contact definitions will be automatically defined between all adjacent layers using *CONTACT_SURFACE_TO_SURFACE during the simulation.

3. The following keyword defines new sheet metal blanks with part IDs 5 and 6 from an existing sheet blank with PID 4. It positions PID 5 on top of PID4 and PID6 on top of PID5.

```
*DEFINE_PART_FROM_LAYER
$---+----1----+----2----+----3----+----4----+----5----+----6----+----7----+----8
$       PID     lAYER   PIDSRCE    LAYOLD       MID     THICK
          5         2         4         1         5      0.10
          6         3         4         1         5      0.10
$---+----1----+----2----+----3----+----4----+----5----+----6----+----7----+----8
```

Revision Information:

This feature is available starting from Dev Revision 117590. Automatic contact is available in Dev Revision 124300.

*DEFINE_PARTICLE_BLAST

Purpose: To define control parameters for particle based blast loading. This keyword was formerly called *PARTICLE_BLAST in versions R11 and earlier.

Card 1	1	2	3	4	5	6	7	8
Variable	LAGSID	LAGSTYPE	NODID	NODTYPE	HECID	HECTYPE	AIRCID	
Type	I	I	I	I	I	I	I

Type	I	F	F	F	F	F		
Default	0	0.	0.	0.	0.	0.		

Card 4	1	2	3	4	5	6	7	8
Variable	DETX	DETY	DETZ	TDET	BTEND	NID		
Type	F	F	F	F	F	I		
Default	0.	0.	0.	0.	0.	0		

Card 5	1	2	3	4	5	6	7	8
Variable	BCX0	BCX1	BCY0	BCY1	BCZ0	BCZ1		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

Card 6	1	2	3	4	5	6	7	8
Variable	IBCX0	IBCX1	IBCY0	IBCY1	IBCZ0	IBCZ1	BC_P	
Type	I	I	I	I	I	I	I	
Default	0	0	0	0	0	0	0	

VARIABLE	DESCRIPTION
LAGSID	Structure ID for particle structure interaction
LAGSTYPE	Structure type: EQ.0: Part Set EQ.1: Part
NODID	Discrete element sphere (DES) or Smooth particle hydrodynamics (SPH) ID for the interaction between particles and nodes.

VARIABLE	DESCRIPTION
NODTYPE	Nodal type: EQ.0: Node Set EQ.1: Node EQ.2: Part Set EQ.3: Part
HECID	Initial container for high explosive particle
HECTYPE	Structure type: EQ.0: Part Set EQ.1: Part EQ.2: Geometry, see *DEFINE_PBLAST_GEOMETRY
AIRCID	Initial geometry for air particles: EQ.0: Filled air particles to entire domain defined by Card 5 GT.0: Reference to *DEFINE_PBLAST_AIRGEO ID
NPHE	Number of high explosive particles
NPAIR	Number of air particles
IUNIT	Unit System EQ.0: Kg-mm-ms-K EQ.1: SI Units EQ.2: Ton-mm-s-K EQ.3: g-cm-us-K EQ.4: blob-in-s-K, where $[\text{blob}] = [\text{lbf}][\text{s}]^2/[\text{in}]$
IHETYPE	High Explosive type (see Remark 1): EQ.0: User defined EQ.1: TNT EQ.2: C4
DENSITY	High Explosive density for user defined explosive (see Remark 1).

VARIABLE	DESCRIPTION
ENERGY	High Explosive energy per unit volume for user defined explosive (see Remark 1).
GAMMA	High Explosive fraction between C_p and C_v for user defined explosive (see Remark 1).
COVOL	High Explosive co-volume for user defined explosive (see Remark 1).
DET_V	High Explosive detonation velocity for user define explosive (see Remark 1).
DETX	Detonation point x
DETY	Detonation point y
DETZ	Detonation point z
TDET	Detonation time
BTEND	Blast end time
NID	An optional node ID defining the position of the detonation point. If defined, its coordinates will overwrite the DETX, DETY, and DETZ defined above.
BCX0	Global domain x-min
BCX1	Global domain x-max
BCY0	Global domain y-min
BCY1	Global domain y-max
BCZ0	Global domain z-min
BCZ1	Global domain z-max
IBCX0	Boundary conditions for global domain x-min: EQ.0: Free EQ.1: Rigid reflecting boundary

VARIABLE	DESCRIPTION
IBCX1	Boundary conditions for global domain x-max: EQ.0: Free EQ.1: Rigid reflecting boundary
IBCY0	Boundary conditions for global domain y-min: EQ.0: Free EQ.1: Rigid reflecting boundary
IBCY1	Boundary conditions for global domain y-max: EQ.0: Free EQ.1: Rigid reflecting boundary
IBCZ0	Boundary conditions for global domain z-min: EQ.0: Free EQ.1: Rigid reflecting boundary
IBCZ1	Boundary conditions for global domain z-max: EQ.0: Free EQ.1: Rigid reflecting boundary
BC_P	Pressure ambient boundary condition for global domain: EQ.0: Off (Default) EQ.1: On (Remark 2)

Remarks:

1. **Material Constants for Commonly used High Explosives.** If the explosive material is TNT or C4, then the parameters DENSITY (ρ), ENERGY (e_0), GAMMA (γ), COVOL (COV), and DET_V (D) are set automatically to the values in the table below by LS-DYNA. Otherwise, the user must provide those values to define the explosive material.

IHE-TYPE	ρ	e_0	γ	COV	D
TNT	$1630\frac{\text{kg}}{\text{m}^3}$	$7\frac{\text{GJ}}{\text{m}^3}$	1.35	0.6	$6930\frac{\text{m}}{\text{s}}$
C4	$1601\frac{\text{kg}}{\text{m}^3}$	$9\frac{\text{GJ}}{\text{m}^3}$	1.32	0.6	$8193\frac{\text{m}}{\text{s}}$

2. **Pressure Boundary Conditions.** If pressure boundary conditions are used, particles will not escape from the global domain when the pressure in the domain is lower than the ambient. The ambient is automatically assumed as 1 ATM by default inside LS-DYNA.

*DEFINE_PBLAST_AIRGEO

Purpose: To define a simple geometry for initial air domain.

Card 1	1	2	3	4	5	6	7	8
Variable	GID	GTYPE1	GTYPE2					
Type	I	I	I					
Default	0	0	0					

Card 2	1	2	3	4	5	6	7	8
Variable	XA	YA	ZA	XB	YB	ZB		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

Card 3	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	G1	G2	G3		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

Card 4	1	2	3	4	5	6	7	8
Variable	XC	YC	ZC	G4	G5	G6		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
GID	ID of a GEOMETRY defining initial air particle domain.
GTYPE1 GTYPE2	Geometry type EQ.1: box EQ.2: sphere EQ.3: cylinder EQ.4: ellipsoid EQ.5: hemisphere (see Remark 1)
XA, YA, ZA	(XA, YA, ZA) defines a vector of the *x*-axis
XB, YB, ZB	(XB, YB, ZB) defines a vector of the *y*-axis
X0, Y0, Z0	Center coordinates of air domain
G1	Dimension value depending on GTYPE. GTYPE.EQ.1: length of *x* edge GTYPE.EQ.2: Radius of sphere GTYPE.EQ.3: Radius of cross section GTYPE.EQ.4: length of *x*-axes GTYPE.EQ.5: Radius of hemisphere
G2	Dimension value depending on GTYPE. GTYPE.EQ.1: length of *y* edge GTYPE.EQ.3: length of cylinder GTYPE.EQ.4: length of *y*-axes
G3	Dimension value depending on GTYPE. GTYPE.EQ.1: length of *z* edge GTYPE.EQ.4: length of *z*-axes
XC, YC, ZC	Center coordinates of domain excluded from the air domain
G4, G5, G6	See definition of G1, G2, G3

Remarks:

1. If GTYPE1/GTYPE2 is 5, the hemisphere is defined in negative z direction defined by the cross product of the y and x axis.

*DEFINE_PBLAST_GEOMETRY

Purpose: To define a simple geometry for high explosives domain.

Card 1	1	2	3	4	5	6	7	8
Variable	GID	GTYPE						
Type	I	I						
Default	0	none						

Card 2	1	2	3	4	5	6	7	8
Variable	XA	YA	ZA	XB	YB	ZB	ITYPE	
Type	F	F	F	F	F	F	I	
Default	0.	0.	0.	0.	0.	0.	0	

Card 3	1	2	3	4	5	6	7	8
Variable	XC	YC	ZC					
Type	F	F	F					
Default	0.	0.	0.					

Card 4	1	2	3	4	5	6	7	8
Variable	G1	G2	G3					
Type	F	F	F					
Default	0.	0.	0.					

VARIABLE	DESCRIPTION
GID	ID of a GEOMETRY defining high explosive particle domain.
GTYPE	Geometry type EQ.1: Box EQ.2: Sphere EQ.3: Cylinder EQ.4: Ellipsoid EQ.5: Hemisphere (see Remark 1)
XA, YA, ZA	ITYPE.EQ.0: Local x-axis ITYPE.EQ.0: Starting coordinate of the charge used to internally calculate the local coordinate system
XB, YB, ZB	ITYPE.EQ.0: Local y-axis ITYPE.EQ.1: Ending coordinate of the charge used to internally calculate the local coordinate system
ITYPE	Flag for determining how the domain geometry of the high explosive particles is generated: EQ.0: Particles are generated in the given geometry with the local coordinate system provided with XA, YA, ZA, XB, YB, and ZB (default). EQ.1: Particles are generated in the given geometry using starting and ending coordinates given with XA, YA, ZA, XB, YB, and ZB.
XC	X-coordinate of charge center
YC	Y-coordinate of charge center
ZC	Z-coordinate of charge center

VARIABLE	DESCRIPTION
G1	GTYPE.EQ.1: Length of x edge GTYPE.EQ.2: Radius of sphere GTYPE.EQ.3: Radius of cross section GTYPE.EQ.4: Length of x-axes GTYPE.EQ.5: Radius of hemisphere
G2	GTYPE.EQ.1: Length of y edge GTYPE.EQ.3: Length of cylinder GTYPE.EQ.4: Length of y-axes
G3	GTYPE.EQ.1: Length of z edge GTYPE.EQ.4: Length of z-axes

Remarks:

1. **Hemisphere.** If GTYPE is 5, the hemisphere is defined in the negative z-direction given by the cross product of the y- and x-axes.

*DEFINE_PLANE

Purpose: Define a plane with three non-collinear points. The plane can be used to define a reflection boundary condition for problems like acoustics.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	X1	Y1	Z1	X2	Y2	Z2	CID
Type	I	F	F	F	F	F	F	I
Default	0	0.0	0.0	0.0	0.0	0.0	0.0	0

Card 2	1	2	3	4	5	6	7	8
Variable	X3	Y3	Z3					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
PID	Plane ID. A unique number has to be defined.
X1	*X*-coordinate of point 1.
Y1	*Y*-coordinate of point 1.
Z1	*Z*-coordinate of point 1.
X2	*X*-coordinate of point 2.
Y2	*Y*-coordinate of point 2.
Z2	*Z*-coordinate of point 2.
CID	Coordinate system ID applied to the coordinates used to define the current plane. The coordinates X1, Y1, Z1, X2, Y2, Z2, X3, Y3 and Z3 are defined with respect to the coordinate system CID.
X3	*X*-coordinate of point 3.

VARIABLE	DESCRIPTION
Y3	*Y*-coordinate of point 3.
Z3	*Z*-coordinate of point 3.

Remarks:

1. **Setup Suggestions.** The coordinates of the points must be separated by a reasonable distance and not collinear to avoid numerical inaccuracies.

*DEFINE_POINT_CLOUD_{OPTION}

Available options include:

<BLANK>

TITLE

Purpose: Define a set of points in the physical space. A point cloud is referenced by one or more fields to define spatially varying data on a set of points; see *DEFINE_FIELD.

Card Summary:

Card Title. This card is included if the TITLE keyword option is used.

TITLE

Card 1. This card is required.

PCID							

Card 2. This card is required. Include as many instantiations of this card as needed. This input ends at the next keyword ("*") card. See Remarks 1 and 2.

X	Y	Z		

Data Card Definitions:

Title Card. Additional card for the TITLE keyword option.

Card Title	1	2	3	4	5	6	7	8
Variable	TITLE							
Type	A80							

VARIABLE	DESCRIPTION
TITLE	Name or description of the point cloud defined in this keyword.

Card 1	1	2	3	4	5	6	7	8
Variable	PCID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PCID	Point cloud ID. A unique ID number must be used.

Point Coordinates Card. Include as many instantiations of this card as needed, one for each point in the point cloud. This input ends at the next keyword ("*") card. See Remarks 1 and 2.

Card 2	1	2	3	4	5	6	7	8
Variable	X		Y		Z			
Type	F		F		F			
Default	0.0		0.0		0.0			

VARIABLE	DESCRIPTION
X	x-coordinate of the i^{th} point in the point cloud in the global coordinate system
Y	y-coordinate of the i^{th} point in the point cloud in the global coordinate system
Z	z-coordinate of the i^{th} point in the point cloud in the global coordinate system

Remarks:

1. **Data Consistency**. Each instance of Card 2 allows you to define a single point in the point cloud. You may define an arbitrary number of instantiations of Card 2. However, the number of points in the point cloud must be consistent with the number of field data included in *DEFINE_FIELD, meaning that the

number of points × NV must equal the total number of input field data (NV is the number of data input for each point). See *DEFINE_FIELD for details.

2. **Point ID**. Points defined with *DEFINE_POINT_CLOUD are not associated with an ID. Therefore, these points cannot be explicitly referenced by other keywords, such as *SET.

DEFINE_POROUS_*OPTION

Available options include:

ALE

LAGRANGIAN

Purpose: The *DEFINE_POROUS_ALE card defines the Ergun porous coefficients for ALE elements. It is to be used with *LOAD_BODY_POROUS. This card with the LAGRANGIAN option, *DEFINE_POROUS_LAGRANGIAN, defines the porous coefficients for Lagrangian elements and is to be used with *CONSTRAINED_LAGRANGE_IN_SOLID (Lagrangian structure parts with CTYPE = 11 or 12).

Default	0.0	0.0	0.0	0.0	0.0	0.0		

VARIABLE **DESCRIPTION**

EIDBEG, EIDEND

EIDBEG, EIDEND > 0: Range of thick porous element IDs. These are solids in 3D and shells in 2D.

EIDBEG, EIDEND < 0: Range of thin porous element IDs. These are shells in 3D and beams in 2D. The ALE option does *not* support thin porous elements.

EIDBEG > 0, EIDEND $= 0$: EIDBEG is a set of thick porous elements

EIDBEG > 0, EIDEND < 0: EIDBEG is a set of thin porous elements

LOCAL

Flag to activate an element coordinate system:

EQ.0: The forces are applied in the global directions.

EQ.1: The forces are applied in a local system attached to the element. The system is consistent with DIREC = 1 and CTYPE = 12 in *CONSTRAINED_LAGRANGE_IN_SOLID. For CTYPE = 11, LOCAL is always 1 and the x-axis is aligned with the element normal while the y-axis passes through the element center and the first node in the element connectivity (*ELEMENT_BEAM in 2D or *ELEMENT_SHELL in 3D)

VECID1, VECID2

*DEFINE_VECTOR IDs to define a specific coordinate system. VECID1 and VECID2 give the x- and y-direction respectively. The z-vector is a cross product of VECID1 and VECID2. If this latter is not orthogonal to VECID1, its direction will be corrected with a cross-product of z- and x-vectors. The vectors are stored as isoparametric locations to update their directions if the element deforms or rotates.

VARIABLE	DESCRIPTION
USERDEF	Flag to compute A*ij* and B*ij* with a user defined routine in the file dyn21.F called lagpor_getab_userdef. The file is part of the general package usermat.
A*ij*	Viscous matrix for the porous flow Ergun equation (see Remark 1)
B*ij*	Inertial matrix for the porous flow Ergun equation (see Remark 1)

Remarks:

1. **Ergun Equation.** The Ergun equation computing the pressure gradient along each direction $i = x, y, z$ can be written as follows:

$$\frac{dP}{dx_i} = \sum_{j=1}^{3} \left[\mu A_{ij} V_j + \rho B_{ij} |V_j| V_j \right]$$

where,

a) V_i is the relative velocity of the flow in the porous media

b) A_{ij} are the viscous coefficients of the Ergun-type porous flow equation in the i^{th} direction.. This matrix is similar to the viscous coefficients used in *LOAD_BODY_POROUS.

c) B_{ij} are the inertial coefficient of the Ergun-type porous flow equation in the i^{th} direction. This matrix is similar to the inertial coefficients used in *LOAD_BODY_POROUS.

If this keyword defines the porous properties of Lagrangian elements in *CONSTRAINED_LAGRANGE_IN_SOLID, the porous coupling forces are computed with the pressure gradient as defined above instead of the equations used for CTYPE = 11 and 12.

*DEFINE_PRESSURE_TUBE

Purpose: Define a gas filled tube for the simulation of interior pressure waves that result from changes in the tube cross section area over time. The tube is specified with tubular beam elements, and the initial gas volume is determined by beam cross section area and initial element lengths. Area changes are either given by beam contact penetration (only mortar contacts currently supported) or by deformation of automatically generated shell/solid elements. The pressure calculation is not coupled with the beam deformation and does not use any data from the material card. Pressure and tube area at the beam nodes are output through *DATABASE_PRTUBE.

Card Summary:

Card 1. This card is required.

PID	WS	PR	MTD	TYPE	GAMMA		

Card 2. This card is optional.

VISC	CFL	DAMP	BNDL	BNDR	CAVL	CAVR	SNODE

Card 3a. This card is only read if TYPE = 1.

NSHL	ELFORM	NIP	SHRF	BPID			

Card 3b. This card is only read if TYPE = 2.

NSLD	ELFORM	NTHK		BPID			

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PID	WS	PR	MTD	TYPE	GAMMA		
Type	I	F	F	I	I	F		
Default	0	0.0	0.0	0	0	1.0		

VARIABLE	DESCRIPTION
PID	Part ID of tube. All connected beam elements in the part will model a tube. Only tubular beam elements are allowed, that is,

VARIABLE	DESCRIPTION
	ELFORM = 1, 4, 5, and 11 with CST = 1 on *SECTION_BEAM. Initial tube cross sectional area is calculated using the beam inner diameter TT1/TT2 fields in the *SECTION_BEAM keyword. If no inner diameter is given, the outer diameter TS1/TS2 fields in the *SECTION_BEAM keyword is used. The beam elements may not contain junctions. Two different parts on which *DEFINE_PRESSURE_TUBE is defined may not share nodes. For MPP all elements in the part will be on a single processor.
WS	Speed of sound c_0 in the gas
PR	Initial gas pressure p_0 inside tube
MTD	Solution method (see Remark 2): EQ.0: Standard Galerkin FEM EQ.1: Discontinuous Galerkin EQ.2: Discontinuous Galerkin on isentropic Euler equations
TYPE	Tube element type: EQ.0: The tube is entirely simulated with beam elements. Cross section area is given from contact penetration of the beam elements. The mechanical response in radial direction of the beam elements is governed by contact stiffness. Only mortar contacts are supported. EQ.1: The tube is simulated by automatic generation of shell elements, which are assigned the beam part ID and the beam material model. A new part ID is given to the beam elements, and those are no longer part of the mechanical solution. Contacts and other properties associated with the old beam part ID will now apply to the new shell part. Cross sectional area is given by the shell element nodes, and the mechanical response is governed entirely by the shells. All contact definitions are supported. Constraints defined by *BOUNDARY_{SPC, PRESCRIBED_MOTION}, *CONSTRAINED_{EXTRA_NODES, NODAL_RIGID_BODY}, or nodes that are shared with a rigid body are moved to the new shell tube; see Figure 17-56. EQ.2: The tube is simulated by automatic generation of solid elements, similarly to TYPE = 1 above.

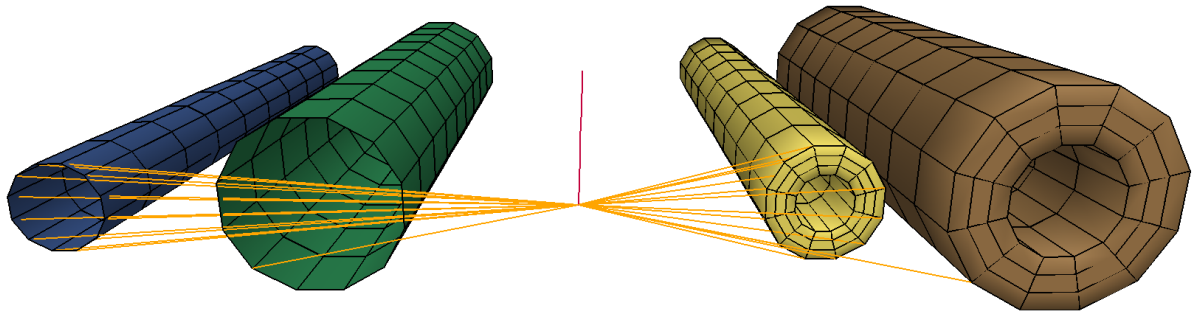

Figure 17-56. Automatically generated tubes using TYPE = 1, -1, 0, 2, and -2, from left to right. The beam tube ends are connected with *CONSTRAINED_NODAL_RIGID_-BODY, which applies differently to the generated shell/solid tubes, depending on the sign of TYPE.

VARIABLE	DESCRIPTION
	LT.0: Automatic generation of elements as above, but the beam nodes are given new nodal IDs. The old beam NIDs are moved to the automatically generated tube (one row of nodes along the length). Any nodal constraints will thus apply to the new tube instead of the beam element tube. See Figure 17-56 for an example of different values of TYPE and how they affect nodal constraints.
GAMMA	Adiabatic index, γ. It must be ≥ 1. It is only used for MTD = 2.

Card 2	1	2	3	4	5	6	7	8
Variable	VISC	CFL	DAMP	BNDL	BNDR	CAVL	CAVR	SNODE
Type	F	F	F	F	F	F	F	I
Default	1.0	0.9	0.0	0.0	0.0	0.0	0.0	0

VARIABLE	DESCRIPTION
VISC	MTD.EQ.0: Artificial viscosity multiplier (VISC > 0.0); see Remark 2. A smaller value gives a more resolved pulse at shorter wavelengths but may lead to instabilities. For typical automotive crash applications (tube length ~2m, diameter ~5mm, pressure pulse width ~5ms), we recommend the default value.

VARIABLE	DESCRIPTION
	MTD.GT.0: Slope limiter smoothing factor; see Remark 2. Smaller values give a more resolved pulse at shorter wavelengths but may lead to instabilities. Larger values lead to a smeared pulse.
CFL	Stability factor (CFL > 0.0); see Remark 2. A smaller value leads to increased stability at the expense of increased computational cost. For typical automotive crash applications, the default value is recommended.
DAMP	Linear damping (DAMP ≥ 0.0); see Remark 2.
BND*i*	Left/right boundary condition (0 ≤ BND*i* ≤ 1); see Remark 3. Special cases are: EQ.0.0: Closed tube end, that is, zero velocity boundary condition EQ:0.5: Non-reflecting boundary condition EQ:1.0: Open tube end, that is, constant pressure boundary condition Left/right tube end is automatically assigned to the lowest/highest beam node number on the tube, respectively.
CAV*i*	Left/right cavity; see Remark 4. GT.0.0: Elements near the end of the tube are replaced with a cavity. The integer part of CAV*i* determines the number of beam elements that belong to the cavity. The remainder of CAV*i* determines the boundary condition on the interface between the tube and the cavity. LT:0.0: The tube is extended with a cavity by adding new beam elements. The length of the added cavity is given by $L = \text{int}(\lvert\text{CAV}i\rvert)/100$ where $\text{int}(x)$ truncates the decimal portion of x (leaving an integer). The remainder of $\lvert\text{CAV}i\rvert$ determines the boundary condition on the interface between the tube and the cavity.
SNODE	Optional starting node. This node determines the left end of the tube. If not set, the tube starts at the lowest numbered beam node.

Automatically Generated Shells Card. This card is read if and only if TYPE = 1.

Card 3a	1	2	3	4	5	6	7	8
Variable	NSHL	ELFORM	NIP	SHRF	BPID			
Type	F	F	F	F	I			
Default	12.0	16.0	3.0	1.0	optional			

Automatically Generated Solids Card. This card is read if and only if TYPE = 2.

Card 3b	1	2	3	4	5	6	7	8
Variable	NSLD	ELFORM	NTHK		BPID			
Type	F	F	F		I			
Default	12.0	1.0	3.0		optional			

VARIABLE	DESCRIPTION
NSHL/NSLD	Number of automatically generated shells/solids on circumference of tube
ELFORM	ELFORM for automatically generated shells/solids; see *SECTION_SHELL/SOLID.
NIP	Number of through thickness integration points for automatically generated shells; see NIP in *SECTION_SHELL.
NTHK	Number of solid elements in thickness of tube for automatically generated solids
SHRF	Shear correction factor for automatically generated shells; see SHRF in *SECTION_SHELL.
BPID	Optional PID given to beam elements when automatically generating shells/solids.

Remarks:

1. **Pressure Tube Model.** The pressure tube is modeled with an acoustic approximation of the one-dimensional compressible Euler equations for pipes with varying thickness:

$$\frac{\partial}{\partial t}(\rho A) + \frac{\partial}{\partial x}(\rho u A) = 0$$
$$\frac{\partial}{\partial t}(\rho u A) + \frac{\partial}{\partial x}(\rho u^2 A + pA) = p\frac{\partial A}{\partial x}$$
$$\frac{\partial}{\partial t}(EA) + \frac{\partial}{\partial x}(u(E+p)A) = 0$$

where $A = A(x,t)$ is the cross-sectional area and ρ, p, u, and E are density, pressure, velocity, and energy per unit volume, respectively. The above system is closed under the constitutive relations

$$E = \rho e + \frac{\rho u^2}{2} \ , \qquad p = p(\rho, e) \ ,$$

where e is the internal energy per unit mass.

For an isentropic and isothermal flow, the pressure will be proportional to the density, that is,

$$p = c_0^2 \rho \ ,$$

and the energy equation can be dropped. This is a good approximation of the Euler equations for acoustic flows where the state variables are smooth perturbations around a background state. For such flows, no shocks will develop over time but may be present from initial/boundary values or source terms.

Assuming small perturbations, linearization around $\rho_0, p_0, u_0 = 0$ gives the acoustic approximation

$$\frac{\partial}{\partial t}(A\rho) + \rho_0 \frac{\partial y}{\partial x} = 0$$
$$\rho_0 \frac{\partial y}{\partial t} + c_0^2 \frac{\partial}{\partial x}(A\rho) = p\frac{\partial A}{\partial x}$$

where $y = Au$. Expressed in y and p we have

$$\frac{\partial p}{\partial t} + \frac{\partial \ln A}{\partial t} p + \frac{p_0}{A}\frac{\partial y}{\partial x} = 0$$
$$\frac{\partial y}{\partial t} + A\frac{c_0^2}{p_0}\frac{\partial p}{\partial x} = 0$$

2. **Solution Methods for the Pressure Tube.** We have two solution methods for the linearized system given in Remark 1 and one solution method for the isothermal nonlinear system. You can select the method with MTD on Card 1.

a) *Continuous Galerkin (MTD = 0).* The linearized system can be solved using the standard Continuous Galerkin finite element method, using piecewise linear basis functions and artificial viscosity. Linear damping is then added to model energy losses from friction between the gas and the tube walls. With artificial viscosity and damping, the linear system can be written as

$$\frac{\partial p}{\partial t} + \frac{\partial \ln A}{\partial t} p + \frac{p_0}{A}\frac{\partial y}{\partial x} = \epsilon \frac{\partial^2 p}{\partial x^2} - \text{DAMP} \times (p - p_0)$$
$$\frac{\partial y}{\partial t} + A\frac{c_0^2}{p_0}\frac{\partial p}{\partial x} = \epsilon \frac{\partial^2 y}{\partial x^2}$$

The artificial viscosity, ϵ, is proportional to the maximum initial beam element length, that is,

$$\epsilon = \text{VISC} \times c_0 \max_i \Delta x_i \ .$$

Small values of VISC may lead to convergence problems while large values smear out the solution. Time integration is independent of the mechanical solver and uses a step size less than or equal to the global time step, satisfying a CFL condition

$$\Delta t < \min_i \frac{\text{CFL} \times \Delta x_i}{\Delta x_i \left|\frac{\partial \ln A}{\partial t}\right| + 3c_0} \ .$$

b) *Discontinuous Galerkin (MTD = 1).* Alternatively, the linear system can be solved with the Discontinuous Galerkin method, using piecewise linear basis functions on each element, Lax-Friedrich flux, and a MUSCL flux limiter to limit spatial oscillations. Time integration is done with Heun's method which is a 2nd order TVD Runge Kutta method. In this case, linear damping is again added to the model.

$$\frac{\partial p}{\partial t} + \frac{\partial \ln A}{\partial t} p + \frac{p_0}{A}\frac{\partial y}{\partial x} = -\text{DAMP} \times (p - p_0)$$
$$\frac{\partial y}{\partial t} + A\frac{c_0^2}{p_0}\frac{\partial p}{\partial x} = 0$$

VISC > 0 is a smoothing factor for the MUSCL limiter with VISC = 0 indicating no smoothing. The Discontinuous Galerkin method gives less diffusion (smearing) than the Continuous Galerkin method.

c) *Discontinuous Galerkin with isentropic Euler equations (MTD = 2).* This method uses Discontinuous Galerkin to solve the damped nonlinear isentropic Euler equations

$$\frac{\partial}{\partial t}(\rho A) + \frac{\partial}{\partial x}(\rho u A) = -\text{DAMP} \times (\rho - \rho_0)A,$$
$$\frac{\partial}{\partial t}(\rho u A) + \frac{\partial}{\partial x}\left(\rho u^2 A + pA\right) = p\frac{\partial A}{\partial x},$$

with

$$p = \frac{{c_0}^2}{\gamma \rho_0^{\gamma-1}} \rho^\gamma,$$
$$\rho_0 = \frac{\gamma p_0}{{c_0}^2}.$$

VISC has the same meaning as for MTD = 1. This method may be beneficial for scenarios with large pressure/velocity perturbations, where the acoustic approximation is poor.

3. **Boundary Conditions.** The boundary conditions are

$$(p - p_0) = \pm Z u \ ,$$

where the sign depends on whether it is the left or right boundary. The impedance is defined as

$$Z = \frac{p_0}{c_0} \frac{\text{BND}i}{(1 - \text{BND}i)} \ .$$

A closed end, BNDi = 0, thus corresponds to $Z = 0$ and $u = 0$, meaning a zero-velocity condition. An open end, BNDi = 1, corresponds to $Z = \infty$ and $p = p_0$, that is, a constant-pressure condition. For the intermediate case, we note that if A is a constant, DAMP = 0, and $\epsilon = 0$, then the acoustic equations become

$$\frac{\partial p}{\partial t} + p_0 \frac{\partial u}{\partial x} = 0$$
$$\frac{\partial u}{\partial t} + \frac{c_0^2}{p_0} \frac{\partial p}{\partial x} = 0$$

which is equivalent to the acoustic wave equation

$$\frac{\partial^2 p}{\partial t^2} - c_0^2 \frac{\partial^2 p}{\partial x^2} = \left(\frac{\partial}{\partial t} - c_0 \frac{\partial}{\partial x} \right) \left(\frac{\partial}{\partial t} + c_0 \frac{\partial}{\partial x} \right) p = 0 \ .$$

Differentiation of the boundary condition (and assuming that the wave equation holds on the boundary) gives

$$\frac{\partial p}{\partial t} = \pm Z \frac{\partial u}{\partial t} = \pm \frac{p_0}{c_0} \frac{\text{BND}i}{(1 - \text{BND}i)} \frac{\partial u}{\partial t} = \mp \text{c}_0 \frac{\text{BND}i}{(1 - \text{BND}i)} \frac{\partial p}{\partial x} \ .$$

Setting BNDi = 0.5 implies

$$\frac{\partial p}{\partial t} = \mp \text{c}_0 \frac{\partial p}{\partial x} \ ,$$

which is the left/right travelling solution to the acoustic wave equation, that is, BNDi = 0.5 corresponds to $Z = Z_0 = p_0/c_0$ and a non-reflecting boundary condition.

The boundary condition can also be seen as jump in cross-section area of the tube, meaning if we have two tubes with area A_l and A_r, then a wave (p, u)

traveling from A_l to A_r can be split into a reflected part $(Rp, -Ru)$ and a transmitted part (Tp, Tu), with reflectance/transmission coefficients

$$R = \frac{A_l - A_r}{A_l + A_r} \quad , \qquad T = \frac{2A_l}{A_l + A_r} \quad .$$

Reflectance can also be expressed with respect to impedance at the interface

$$R = \frac{Z_0 - Z}{Z_0 + Z} \quad .$$

Combining the expressions for the reflectance, the boundary condition can thus be seen as an infinite extension of the original tube, with a jump from the tube area A_{in} at the boundary, to an outside area

$$A_{out} = \frac{\text{BND}i}{(1 - \text{BND}i)} A_{in} \quad .$$

BND$i = 0.5$ thus corresponds to $A_{out} = A_{in}$, BND$i = 0$ gives $A_{out} = 0$, and BND$i = 1$ gives $A_{out} = \infty$.

4. **Cavities.** Cavities close to the tube ends can be simulated in three ways:

   a) Altering tube thickness with *ELEMENT_BEAM_THICKNESS.

   b) Setting CAV$i > 0$.

      For CAV$i > 0$, the original tube geometry will be intact and $n = \text{int}(\text{CAV}i)$ (the integer portion of CAVi) elements from the end will belong to a cavity, that is, a different cross-section area (that can only be seen in binout/prtubeout). The cavity cross-section area is determined by the boundary condition, $\alpha = \text{CAV}i - n$, on the interface between the tube and the cavity. The n elements closest to the boundary will have the new area

      $$A_{\text{cav}} = \frac{\alpha}{(1 - \alpha)} A_{n+1} \quad ,$$

      where A_{n+1} is the initial cross-section the area of element $n + 1$ from the boundary. For example, for a tube with initial cross-section area $A = 10$, CAVL = 50.8 means that the 50 elements closest to the left end will have the constant cross-section area

      $$A_{\text{cav}} = \frac{0.8}{(1 - 0.8)} 10 = 40 \quad .$$

   c) Setting CAV$i < 0$.

      For CAV$i < 0$, a cavity of length $L = \text{int}(|\text{CAV}i|)/100$ is added at the end by creating new beam elements (at least 5 beam elements are used). These new beam elements will not be converted to shells/solids regardless of TYPE; thus, they are not part of the mechanical solution. The cavity cross-section

area is calculated as above using the boundary condition, $\alpha = |\text{CAV}i| - \text{int}(|\text{CAV}i|)$.

Note that when using CAV*i*, any cross-section area updates for the cavity elements resulting from physical deformation will be overridden by the area A_{cav}. Also, the boundary conditions set by BND*i* still holds at the outer ends of the (extended) tube.

*DEFINE_QUASAR_COUPLING

Purpose: Define LS-DYNA node/node set that interacts with Cadlm's QUASAR ROM model. Each coupling needs to have its own keyword card and will not accept multiple entries.

> **WARNING:** We added Card 2 in September of 2020. It breaks backward compatibility. Old input decks that include this keyword will not work with executables created September of 2020 and later.

Card 1	1	2	3	4	5	6	7	8

VARIABLE	DESCRIPTION
NODE	Coupled node/node set
TYPE	Region type: EQ.0: Node ID EQ.1: Node set ID
ROMID	Cadlm's ROM ID
PID	LS-DYNA part/part set ID
PTYPE	Type for PID: EQ.0: Part ID (Default) EQ.1: Part set ID
IOPT	Option for exchanging data between LS-DYNA/Cadlm Quasar: EQ.0: Default. LS-DYNA outputs nodal translational and rotational coordinates and receives nodal translational and rotational forces. EQ.1: LS-DYNA outputs nodal translational and rotational displacements and receives nodal translational and rotational forces. EQ.2: LS-DYNA outputs nodal translational coordinates and receives nodal translational forces. EQ.3: LS-DYNA outputs nodal translational displacements and receives nodal translational forces.
CID	Reference coordinate system needed to transform the data from the LS-DYNA global system to the Quasar local system

VARIABLE	DESCRIPTION
EX_ND	Node set to exclude from Quasar output. LS-DYNA still expects the complete set of data. (Quasar can predict the forces from a reduced data set.)
FRCFRQ	Number of cycles between QUASAR force updates for the coupling interface
FILENAME1	LS-DYNA output file to QUASAR
FILENAME2	QUASAR output file to LS-DYNA
VAR*i*	User defined constant

*DEFINE_REGION

Purpose: Define a volume of space, optionally in a local coordinate system.

Variable	XC1	YC1	ZC1	RMIN1	RMAX1			
Type	R	R	R	R	R			
Default	0.0	0.0	0.0	0.0	0.0			

VARIABLE	DESCRIPTION
XC1, YC1, ZC1	Coordinates of the center of the sphere
RMIN1, RMAX1	The inner and outer radii of the spherical shell. Set RMIN1 = 0 for a solid sphere

Cylinder. Use when TYPE = 2.

Card 3c.1	1	2	3	4	5	6	7	8
Variable	XC2	YC2	ZC2	AX2	AY2	AZ2	RMIN2	RMAX2
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

Cylinder. Use when TYPE = 2.

Card 3c.2	1	2	3	4	5	6	7	8
Variable	L2							
Type	F							
Default	∞							

VARIABLE	DESCRIPTION
XC2, YC2, ZC2	A point on the cylindrical axis
AX2, AY2, AZ2	A vector which defines the direction of the axis of the cylinder
RMIN2, RMAX2	The inner and outer radii of the cylindrical shell. Set RMIN2 = 0 for a solid cylinder.
L2	Length of the cylinder. If L2 = 0.0, an infinite cylinder is defined. Otherwise the cylinder has one end at the point (XC2, YC2, ZC2) and the other at a distance L2 along the axis in the direction of the vector (AX2, AY2, AZ2).

Ellipsoid. Use when TYPE = 3.

Card 3d.1	1	2	3	4	5	6	7	8
Variable	XC3	YC3	ZC3	AX3	AY3	AZ3	BX3	BY3
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

Ellipsoid. Use when TYPE = 3.

Card 3d.2	1	2	3	4	5	6	7	8
Variable	BZ3	RA3	RB3	RC3				
Type	F	F	F	F				
Default	0.0	0.0	0.0	0.0				

VARIABLE	DESCRIPTION
XC3, YC3, ZC3	Coordinates of the center of the ellipsoid
AX3, AY3, AZ3	A vector in the direction of the first axis of the ellipsoid (axis **a**)
BX3, BY3, BZ3	A vector, $\tilde{\mathbf{b}}$, in the plain of the first and second axes of the ellipsoid. The third axis of the ellipsoid (axis **c**) will be in the direction of $\mathbf{a} \times \tilde{\mathbf{b}}$ and finally the second axis $\mathbf{b} = \mathbf{c} \times \mathbf{a}$
RA3, RB3, RC3	The semi-axis lengths of the ellipsoid

*DEFINE_SD_ORIENTATION

Purpose: Define orientation vectors for discrete springs and dampers. These orientation vectors are optional for this element class. Four alternative options are possible. With the first two options, IOP = 0 or 1, the vector is defined by coordinates and is fixed permanently in space. The third and fourth option orients the vector based on the motion of two nodes, so that the direction can change as the line defined by the nodes rotates.

Card	1	2	3	4	5	6	7	8
Variable	VID	IOP	XT	YT	ZT	NID1	NID2	
Type	I	I	F	F	F	I	I	
Default	0	0	0.0	0.0	0.0	0	0	

VARIABLE	DESCRIPTION
VID	Orientation vector ID. A unique ID number must be used.
IOP	Option (see Remark 1): EQ.0: deflections/rotations are measured and forces/moments applied along the following orientation vector. EQ.1: deflections/rotations are measured and forces/moments applied along the axis between the two spring/damper nodes projected onto the plane normal to the following orientation vector. EQ.2: deflections/rotations are measured and forces/moments applied along a vector defined by the following two nodes. EQ.3: deflections/rotations are measured and forces/moments applied along the axis between the two spring/damper nodes projected onto the plane normal to the a vector defined by the following two nodes.
XT	x-value of orientation vector. Define if IOP = 0 or 1.
YT	y-value of orientation vector. Define if IOP = 0 or 1.
ZT	z-value of orientation vector. Define if IOP = 0 or 1.
NID1	Node 1 ID. Define if IOP = 2 or 3.

VARIABLE	DESCRIPTION
NID2	Node 2 ID. Define if IOP = 2 or 3.

Remarks:

1. **Orientation Vectors.** The orientation vectors defined by options 0 and 1 are fixed in space for the duration of the simulation. Options 2 and 3 allow the orientation vector to change with the motion of the nodes. Generally, the nodes should be members of rigid bodies, but this is not mandatory. When using nodes of deformable parts to define the orientation vector, care must be taken to ensure that these nodes will not move past each other. If this happens, the direction of the orientation vector will immediately change with the result that initiate severe instabilities can develop.

*DEFINE_SET_ADAPTIVE

Purpose: To control the adaptive refinement level by element or part set.

Card 1	1	2	3	4	5	6	7	8
Variable	SETID	STYPE	ADPLVL	ADPSIZE				
Type	I	I	I	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
SETID	Element set ID or part set ID
STYPE	Set type for SETID: EQ.1: element set EQ.2: part set
ADPLVL	Adaptive refinement level for all elements in SETID set.
ADSIZE	Minimum element size to be adapted based on element edge length for all elements in SETID set.

Remarks:

1. **Element Restrictions.** This option is for 3D-shell *h*-adaptivity only at the present time.

2. **Keyword Priority.** Three keywords control refinement level: *CONTROL_ADAPTIVE, *DEFINE_BOX_ADAPTIVE, and *DEFINE_SET_ADAPTIVE. *CONTROL_ADAPTIVE must be included in the keyword deck for any adaptivity to be done. If all three keywords are defined in a keyword deck, *DEFINE_BOX_ADAPTIVE defines the refinement within the box; it unlike the other two keywords does not control the minimum element size to be adapted. *DEFINE_SET_ADAPTIVE has the next highest priority for defining refinement level while *CONTROL_ADAPTIVE has the least priority. This keyword is useful for defining different refinement levels for different parts.

3. **Multiple Refinement Definitions.** If there are multiple definitions of refinement level or element size for any elements, the latter one will be used.

*DEFINE_SPG_TO_SURFACE_COUPLING

Purpose: Define a coupling interface between smoothed particle Galerkin (SPG) particles and a surface. Currently it is only available for SMP.

Card 1	1	2	3	4	5	6	7	8
Variable	SPGP	SURF	SPTYPE	SFTYPE				
Type	I	I	I	I				
Default	none	none	1	0				

Card 2	1	2	3	4	5	6	7	8
Variable	SBC	FS	FD	DC	SFP	THK	FRQ	
Type	I	F	F	F	F	F	I	
Default	0	0.	FS	0.	0.1	0.5	50	

VARIABLE	DESCRIPTION
SPGP	Part ID/Part set ID for the SPG particles
SURF	Segment set ID specifying the surface
SPTYPE	Type for SPGP: EQ.0: Part set ID EQ.1: Part ID
SFTYPE	Type for SURF: EQ.0: Segment set ID
SBC	Type of boundary condition: EQ.0: Free-slip boundary EQ.1: Non-slip boundary (tied after contact)

VARIABLE	DESCRIPTION
FS	Static coefficient of friction. If SBC = 1, then FS is not used.
FD	Dynamic coefficient of friction. It is set to the value of FS by default.
DC	Exponential decay of the friction coefficient
SFP	Scaling factor of the penetration stiffness coefficient along the normal direction of the contact interface. Default value is 0.1.
THK	Thickness scaling factor for contact search. During initialization, LS-DYNA searches for the particle that is closest to the surface. The distance of this particle from the surface at the beginning of the simulation is scaled by THK. This scaled distance is used as the contact thickness for the surface's segments. The default value of THK is 0.5.
FRQ	Bucket sorting frequency. Default is 50.

*DEFINE_SPH_ACTIVE_REGION

Purpose: The purpose of this keyword is to increase the efficiency of the SPH method's neighborhood search algorithm by specifying an *active region*. All SPH elements located outside of the active region are deactivated. This card supports active regions consisting of the volume bounded by two closed surfaces (boxes, centered cylinders, and centered spheres are currently supported). Once the SPH particle is deactivated, it will stay inactive.

Card Summary:

Card 1. This card is required.

ID	TYPE	STYPE	CYCLE	NID	ICID	IBUFF	

Card 2a.1. Include this card if STYPE = 0.

XIMIN	YIMIN	ZIMIN	XIMAX	YIMAX	ZIMAX		

Card 2a.2. Include this card if STYPE = 0.

XOMIN	XOMIN	ZOMIN	XOMAX	YOMAX	ZOMAX		

Card 2b.1. Include this card if STYPE = 1.

X0	Y0	Z0	XH	YH	ZH		

Card 2b.2. Include this card if STYPE = 1.

RMIN	ZMIN	RMAX	ZMAX				

Card 2c.1. Include this card if STYPE = 2.

X0	Y0	Z0					

Card 2c.2. Include this card if STYPE = 2.

RMIN	RMAX						

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYPE	STYPE	CYCLE	NID	ICID	IBUFF	
Type	I	I	I	I	I	I	I	
Default	none	0	0	1	0	0	0	

VARIABLE	DESCRIPTION
ID	Part Set ID/Part ID
TYPE	EQ.0: Part set EQ.1: Part
STYPE	Type of the region. EQ.0: Rectangular box EQ.1: Cylinder EQ.2: Sphere
CYCLE	Number of cycles between each check
NID	Referential nodal ID. The SPH box will move with this node.
ICID	Local coordinate system ID
IBUFF	Buffer zone flag (only used when STYPE = 0): EQ.0: Particles on the edge of the outer box do not get any special treatment. EQ.1: Particles on the edge of the outer box are frozen in space and act as neighbors for active particles inside the box. This option is mainly used for fluid simulations to prevent the fluid from spilling out of the activation box.

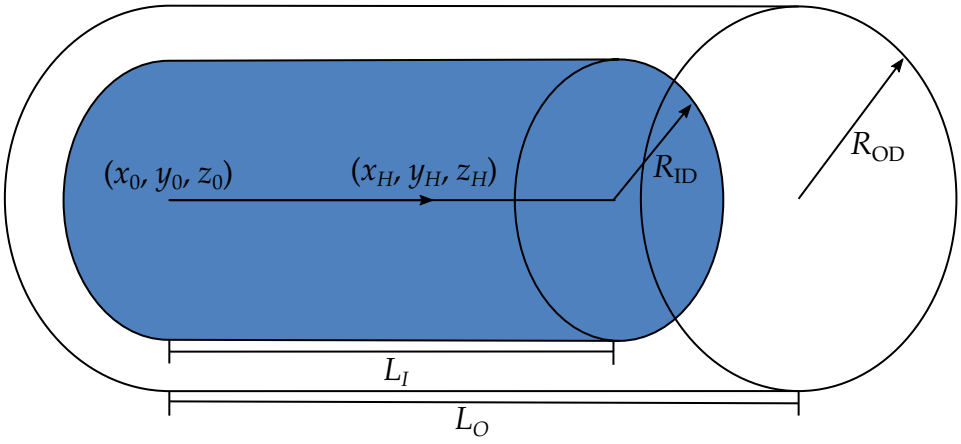
Interior Rectangular Box Card. This card is included if STYPE = 0.

Card 2a.1	1	2	3	4	5	6	7	8
Variable	XIMIN	YIMIN	ZIMIN	XIMAX	YIMAX	ZIMAX		
Type	F	F	F	F	F	F		
Default	none	none	none	None	none	none		

Outer Rectangular Box Card. This card is included if STYPE = 0.

Card 2a.2	1	2	3	4	5	6	7	8
Variable	XOMIN	XOMIN	ZOMIN	XOMAX	YOMAX	ZOMAX		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
XIMIN, YIMIN, ZIMIN	Minimum x, y, z coordinate of the inner box
XIMAX, YIMAX, ZIMAX	Maximum x, y, z coordinates of the inner box
XOMIN, YOMIN, ZOMIN	Minimum x, y, z coordinate of the outer box
XOMAX, YOMAX, ZOMAX	Maximum x, y, z coordinates of the outer box



```
*DEFINE_SPH_ACTIVE_REGION
1,1,1,100
x0,y0,z0,xH,yH,zH
RID,LI,ROD,LO
```

Figure 17-57. Example DEFINE_SPH_ACTIVE_REGION

Cylinder Axis Card. This card is included if STYPE = 1.

Card 2b.1	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	XH	YH	ZH		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

Cylinder Radii Card. This card is included if STYPE = 1.

Card 2b.2	1	2	3	4	5	6	7	8
Variable	RMIN	ZMIN	RMAX	ZMAX				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
X0, Y0, Z0	Coordinates of the center of the cylinder base. The nested cylinders share the same starting base plane. This point also serves as the tail for the vector specifying the direction of the cylinders' axis. See Figure 17-57.
XH, YH, ZH	Coordinates for the head of the cylinders' axial direction vector.
RMIN, ZMIN	Radius and length of the interior cylinder.
RMAX, ZMAX	Radius and length of the outer cylinder.

Center of Sphere Card. This card is included if STYPE = 2.

Card 2c.1	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0					
Type	F	F	F					
Default	none	none	none					

Sphere Radii Card. This card is included if STYPE = 2.

Card 2c.2	1	2	3	4	5	6	7	8
Variable	RMIN	RMAX						
Type	F	F						
Default	none	none						

VARIABLE	DESCRIPTION
X0, Y0, Z0	The spheres' center.
RMIN	Radius of the interior sphere
RMAX	Radius of the outer sphere

*DEFINE_SPH_AMBIENT_DRAG

Purpose: Add drag forces to SPH particles that use the implicit incompressible formulation (FORM = 13 in *CONTROL_SPH). For a wading simulation, this keyword sets air properties.

Card 1	1	2	3	4	5	6	7	8
Variable	ICID	VX	VY	VZ	RHOA	MUA	SFTENS	
Type	I	F	F	F	F	F	F	
Default	0	0.0	0.0	0.0	none	none	none	

VARIABLE	DESCRIPTION
ICID	Coupling with ICFD: EQ.0: No coupling
VX, VY, VZ	Velocity components of the ambient material
RHOA	Density of the ambient material
MUA	Viscosity of the ambient material
SFTENS	Surface tension coefficient for the interface between the SPH fluid and ambient material

*DEFINE_SPH_DE_COUPLING_{OPTION}

Purpose: Define a penalty based contact. This option is to be used for the node to node contacts to couple the SPH solver and the discrete element sphere (DES) solver.

The available options include:

<BLANK>

ID

ID Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	DID	HEADING						
Type	I	A80						
Default	none	none						

SPH Part Cards. Include as many of this card as desired. Input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SPHID	DESID	SPHTYP	DESTYP	PFACT	DFACT	SPHBOX	
Type	I	I	I	I	F	F	I	
Default	none	none	none	none	1.0	0.	none	

VARIABLE	DESCRIPTION
DID	Definition ID. This must be a unique number.
HEADING	Definition descriptor. It is suggested that unique descriptions be used.
SPHID	SPH part or part set ID.
DESID	DES part or part set ID.

VARIABLE	DESCRIPTION
SPHTYP	SPH part type: EQ.0: Part set ID, EQ.1: Part ID.
DESTYP	DES part type: EQ.0: Part set ID, EQ.1: Part ID.
PFACT	Penalty scale factor
DFACT	Penalty scale factor for contact damping coefficient
SPHBOX	BOX ID for SPH parts, See Remarks.

Remarks:

SPHBOX is used to define the box IDs for the SPH parts. Only the particles inside the boxes are defined for the node to node contacts.

*DEFINE_SPH_INJECTION

Purpose: Inject SPH elements from user defined grid points.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	NSID	CID	VX	VY	VZ	AREA	VMAG
Type	I	I	I	F	F	F	F	I
Default	none	none	none	0.0	0.0	0.0	0.0	0

Card 2	1	2	3	4	5	6	7	8
Variable	TBEG	TEND	NID	RADIUS	XLEN	YLEN	PSIZE	
Type	F	F	I	F	F	F	F	
Default	0.0	10^{20}	0	0.0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
PID	Part ID of newly generated SPH elements.
NSID	Node set ID. Nodes are used for initial injection position for the SPH elements. Ignored if RADIUS, XLEN or YLEN are defined below.
CID	Local coordinate system ID; see *DEFINE_COORDINATE_SYSTEM for example. The local x and y-directions define the injection plane, while the local z-direction defines the normal to the injection plane. A CID is always required. This coordinate system is used for the definition of injection velocity (VX,VY,VZ) as well.
VX, VY, VZ	Velocity of the injected particles: $\mathbf{v}$ = (VX, VY, VZ), defined in the local coordinate system from CID.

VARIABLE	DESCRIPTION
AREA	The area of initial injection surface. The density of injection flow comes from the material models; see *MAT definition. This parameter can be left blank if the nodes provided in NSID are uniformly distributed, or if RADIUS, XLEN or YLEN are defined below, in which case AREA will be automatically computed.
VMAG	Injected particle velocity multiplier: GT.0: The velocity of the injected particles is multiplied by VMAG. LT.0: |VMAG| is a curve ID defining the magnitude of the velocity vector with respect to time, for variable injection speed.
TBEG	Birth time
TEND	Death time
RADIUS	If this option is nonzero, the node set provided in NSID is ignored. Instead, this parameter defines the radius of a circular injection surface centered at the origin of the coordinate system defined in CID, using the local *Z*-axis of CID as normal to the injection plane. Particles are uniformly generated with a spacing of PSIZE.
XLEN	If this option is nonzero and RADIUS is zero, the node set provided in NSID is ignored. Instead, a rectangular injection surface is automatically created, centered at the origin of the coordinate system defined in CID, using the local *Z*-axis of CID as normal to the injection plane. This rectangular injection has dimensions of XLEN and YLEN in the local coordinate system defined by CID. Particles are uniformly generated with a spacing of PSIZE.
YLEN	See XLEN.
PSIZE	If RADIUS or XLEN / YLEN is defined, the particles are automatically placed on the defined injection geometry, with a spacing of PSIZE.

*DEFINE_SPH_MASSFLOW_PLANE

Purpose: To measure SPH mass flow rate across a defined plane. See also the accompanying keyword *DATABASE_SPHMASSFLOW which controls the output frequency.

Card 1	1	2	3	4	5	6	7	8
Variable	PRTCLSID	SURFSID	PTYPE	STYPE				
Type	I	I	I	I				
Default	0	0	0	0				

VARIABLE	DESCRIPTION
PRTCLSID	Node set ID, node ID, part set ID or part ID specifying the SPH particles to be measured. PTYPE below indicates the ID type specified by PRTCLSID.
SURFSID	Part set ID or part ID defining the surface across which the flow rate is measured. STYPE below indicates the ID type specified by SURFSID.
PTYPE	PRTCLSID type: EQ.0: Node set EQ.1: Node EQ.2: Part set EQ.3: Part
STYPE	SURFSID type: EQ.0: Part set EQ.1: Part

*DEFINE_SPH_MESH_BOX

Purpose: Generate SPH particles inside a given box.

Card 1	1	2	3	4	5	6	7	8
Variable	XMIN	YMIN	ZMIN	XLEN	YLEN	ZLEN		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

Card 2	1	2	3	4	5	6	7	8
Variable	IPID	NX	NY	NZ		IDSEG	SFSP	
Type	I	I	I	I		I	F	
Default	none	none	none	none		0	1.0	

VARIABLE	DESCRIPTION
XMIN	Minimum x-coordinate
YMIN	Minimum y-coordinate
ZMIN	Minimum z-coordinate
XLEN	Box length in the x-direction
YLEN	Box length in the y-direction
ZLEN	Box length in the z-direction
IPID	Part ID for generated SPH elements
NX	Number of SPH particles in the x-direction
NY	Number of SPH particles in the y-direction

VARIABLE	DESCRIPTION
NZ	Number of SPH particles in the z-direction
IDSEG	Segment set ID that can be used to removed generated SPH elements. segment set is used to split the box into two regions, one that has SPH elements and one without SPH (see Remark 2). The sign of IDSEG determines which region keeps the SPH elements. Also, to avoid sudden movement, elements that are "too close" to the segment set will be removed, regardless of the sign of IDSEG. Too close means the normal distance from the center of the SPH element to the nearest segment is smaller than the SPH smoothing length scaled by SFSP. EQ.0: No generated elements are removed. GT.0: Keep the SPH element if it lies nominally in the normal direction of the segments in the segment set. LT.0: Keep the SPH element if it lies nominally in the reverse normal direction of segments in the segment set.
SFSP	Scale factor for SPH smoothing length (active only when IDSEG ≠ 0). If the normal distance between an SPH particle and the nearest segment is smaller than this distance, the SPH element is removed.

Remarks:

1. **Interparticle Distances.** Interparticle distances are calculated as XLEN/NX, YLEN/NY, and ZLEN/NZ

2. **Region for Element Removal.** The region created by the segment set, IDSEG, must either define a closed volume in the box or intersect the box. If it defines an open surface in the box, the elements that are to be kept cannot be uniquely determined.

*DEFINE_SPH_MESH_OBJ

Purpose: Import an OBJ file whose geometry will follow a rigid body. Also include the OBJ geometry in d3plot and (if requested) ISPHFOR output files.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A							

Card 1	1	2	3	4	5	6	7	8
Variable	PPID	PID						
Type	I	I						
Default	none	optional						

VARIABLE	DESCRIPTION
FILENAME	File name of OBJ file to be included
PPID	Parent part ID. The OBJ geometry will follow the motion of the rigid part with ID PPID.
PID	Optional part ID to identify this OBJ file in d3plot and ISPHFOR outputs. An ID will be automatically generated if this parameter is left blank.

Remarks:

When this keyword is included in the input deck, DCOMP = 5 is automatically set for *DATABASE_EXTENT_BINARY.

*DEFINE_SPH_MESH_SURFACE

Purpose: Generate and place SPH elements on the surface of triangular shell elements.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	TYPE	SPHPID	SPHXID	NSID	SPACE	IOUT	
Type	I	I	I	I	I	F	I	
Default	none	none	Rem 1	Rem 1	0	none	0	

VARIABLE	DESCRIPTION
SID	Part or part set ID for the region of the mesh upon which the SPH elements will be placed
TYPE	SID type: EQ.0: part set ID EQ.1: part ID
SPHPID	Part ID for generated SPH elements
SPHXID	Section ID for generated SPH elements
NSID	If defined, this card creates a node set with ID NSID (see *SET_NODE) for the nodes generated by this card.
SPACE	Maximum space between SPH elements
IOUT	Keyword file output: EQ.0: no output (default) EQ.1: output generated nodes, SPH elements and node set to a keyword file with SPH_surface_ prefix.

Remarks:

1. **SPHPID and SPHXID.** Part ID and/or section ID will be generated by this card if they are not provided in the input.

*DEFINE_SPH_TO_SPH_COUPLING

Purpose: Define a penalty-based, node-to-node contact for particles of SPH parts. Note that this contact type is an alternative to inter-part particle interaction by "particle approximation;" see the field CONT in *CONTROL_SPH and the INTERACTION option of *SECTION_SPH.

Card Sets: Each set consists of a Card 1 and may include an additional Card 2. Unless the card following Card 1 contains an "&" in its first column, the optional card is not read. Provide as many sets as necessary. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SIDA	SIDB	SATYP	SBTYP	IBOXA	IBOXB	PFACT	SRAD
Type	I	I	I	I	I	I	F	F
Default	none	none	none	none	none	none	1.0	1.0

Optional. The keyword reader identifies this card by an "&" in the first column.

Card 2	1	2	3	4	5	6	7	8
Variable	DFACT	ISOFT						
Type	F	I						
Default	0.0	0						

VARIABLE	DESCRIPTION
SIDA	Part or part set ID for one set of particles in the contact
SIDB	Part or part set ID for the other set of particles in the contact
SATYP	SIDA part type: EQ.0: Part set ID EQ.1: Part ID

VARIABLE	DESCRIPTION
SBTYP	SIDB part type: EQ.0: Part set ID EQ.1: Part ID
IBOXA	Box ID for the A parts; see Remark 1.
IBOXB	Box ID for the B parts; see Remark 1.
PFACT	Penalty scale factor; see Remark 2.
SRAD	Scale factor for nodes to nodes contact criteria; see Remark 3.
DFACT	Penalty scale factor for contact damping coefficient; see Remark 4.
ISOFT	Soft constraint option: EQ.0: Penalty formulation (default) EQ.1: Soft constraint formulation The soft constraint may be necessary if the material constants of the parts in contact have a wide variation in the elastic bulk moduli. In the soft constraint option, the interface stiffness is based on the nodal mass and the global time step size.

Remarks:

1. **Contact Particles.** IBOXA and IBOXB are used to define the box IDs for the A parts and the B parts, respectively. Only the particles inside the boxes are defined for the node to node contacts.

2. **Impact Velocity.** For High Velocity Impact problems, a smaller value ranging from 0.01 to 10^{-4} for the PFACT field is recommended. A value ranging from 0.1 to 1 is recommended for low velocity contact between two SPH parts.

3. **Contact Detection.** Contact between two SPH particles from different parts is detected when the distance of two SPH particles I and J is less than SRAD $\times \left(h_I + h_J\right)/2.0$. If SRAD < 0, the contact distance is based on the nodal volumes instead of the smoothing lengths: SRAD $\times \left(\sqrt[3]{V_I} + \sqrt[3]{V_J}\right)/2.0$.

4. **DFACT.** The default value, DFACT = 0.0, is recommended. For DFACT > 0.0, interaction between SPH parts includes a viscous effect, providing some stickiness similar to the particle approximation invoked when CONT = 0 in *CON-

TROL_SPH. At present, no recommendation can be given for a value of DFACT other than the value should be less than 1.0.

*DEFINE_SPH_VICINITY_SENSOR

Purpose: Measure the mass of specified SPH particles in the vicinity of a surface. The list of all particles flagged as within the vicinity of the surface is exported along with time at which particle moved within the vicinity. See also the accompanying keyword *DATABASE_SPHVICINITY which controls the output frequency.

Card 1	1	2	3	4	5	6	7	8
Variable	PRTCLSID	SURFSID	PTYPE	STYPE	DIST			
Type	I	I	I	I	F			
Default	0	0	0	0	0.0			

VARIABLE	DESCRIPTION
PRTCLSID	Node set ID, node ID, part set ID or part ID specifying the checked SPH particles. PTYPE below indicates the ID type specified by PRTCLSID.
SURFSID	Part set ID or part ID defining the surface. STYPE below indicates the ID type specified by SURFSID.
PTYPE	PRTCLSID type: EQ.0: Node set EQ.1: Node EQ.2: Part set EQ.3: Part
STYPE	SURFID type: EQ.0: Part set EQ.1: Part
DIST	Distance criteria. Any particle closer than this distance to the surface is considered in the vicinity.

*DEFINE_SPOTWELD_FAILURE_{OPTION}

The available options are

<BLANK>

ADD

PID

Purpose: Define spot weld failure data for the failure criterion developed by Lee and Balur (2011). This card provides the failure data for OPT = 10 on *MAT_SPOTWELD. It is available for spot welds consisting of beam elements, solid elements, or solid assemblies.

*DEFINE_SPOTWELD_FAILURE requires that the weld nodes be tied to shell elements using tied constraint based contact options:

1. For beam element welds, only *CONTACT_SPOTWELD is valid.
2. For solid element welds or solid assembly welds, valid options are the following:

   *CONTACT_TIED_SURFACE_TO_SURFACE

   *CONTACT_SPOTWELD

   *CONTACT_TIED_SHELL_EDGE_TO_SURFACE

Other tied contact types cannot be used.

The ADD keyword option adds materials to a previously defined spot weld failure data set. The PID option changes the Card 3 input to use part set ID's rather than material ID's.

Card Summary:

Card 1. This card is required.

ID	TFLAG	DC1	DC2	DC3	DC4	EXN	EXS

Card 2. This card is included unless the ADD option is used.

NAVG	D_SN	D_SS	R_SULT	TSCALE			

Card 3a. This card is included if the PID option is used. Include one card for each pair of weld parts associated with the data set. The next keyword ("*") card terminates the keyword.

PID1	PID2	SN	SS				

Card 3b. This card is included if the PID option is *not* used. Include one card for each material associated with the data set. The next keyword ("*") card terminates the keyword.

MID	SN	SS					

Data Card 1. This card contains the data set's ID and the first 7 parameters. When the ADD option is active *leave the 7 parameters blank*.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TFLAG	DC1	DC2	DC3	DC4	EXN	EXS
Type	I	I	F	F	F	F	F	F
Default	none	0	1.183	0.002963	0.0458	0.1	2.0	2.0

VARIABLE	DESCRIPTION
ID	Identification number of data set, input as FVAL on *MAT_SPOTWELD
TFLAG	Thickness flag for nominal stress calculation EQ.0: Use minimum sheet thickness EQ.1: Use average sheet thickness EQ.2: Use maximum sheet thickness EQ.3: Use sum of sheet thicknesses
DC1	Dynamic coefficient, c_1
DC2	Dynamic coefficient, c_2
DC3	Dynamic coefficient, c_3
DC4	Dynamic coefficient, c_4

VARIABLE	DESCRIPTION
EXN	Exponent on the normal term, n_n
EXS	Exponent on the shear term, n_s

Data Card 2. This card contains 3 spot weld failure data parameters. *Do not include this card when the ADD option is active*

Card 2	1	2	3	4	5	6	7	8
Variable	NAVG	D_SN	D_SS	R_SULT	TSCALE			
Type	I	F	F	F	F			
Default	0	0.0	0.0	Rem 2	1.0			

VARIABLE	DESCRIPTION
NAVG	Number of points in the time average of the load rates. See Remark 4.
D_SN	Reference value of the static normal strength, $S_{n,\text{stat}}$. See Remark 2.
D_SS	Reference value of the static shear strength, $S_{s,\text{stat}}$. See Remark 2.
R_SULT	Reference ultimate strength. See Remark 2.
TSCALE	Scale factor for thickness used in nominal stress calculations

Material-Specific Strength Data Cards with PID option. Include one card for each pair of weld parts associated with the data set. The next keyword ("*") card terminates the keyword.

Card 3a	1	2	3	4	5	6	7	8
Variable	PID1	PID2	SN	SS				
Type	I	I	F	F				
Default	none	none	Rem 2	Rem 2				

VARIABLE	DESCRIPTION
PID1	Part ID of welded shell part
PID2	Part ID of part welded to PID1
SN	Static normal strength of material MID. $S_{n,\text{stat}}$. See Remark 2.
SS	Static shear strength of material MID, $S_{s,\text{stat}}$. See Remark 2.

Material-Specific Strength Data Cards without PID option. Include one card for each material associated with the data set. The next keyword ("*") card terminates the keyword.

Card 3b	1	2	3	4	5	6	7	8
Variable	MID	SN	SS					
Type	I	F	F					
Default	none	Rem 2	Rem 2					

VARIABLE	DESCRIPTION
MID	Material ID number of welded shell material
SN	Static normal strength of material MID. $S_{n,\text{stat}}$. See Remark 2.
SS	Static shear strength of material MID, $S_{s,\text{stat}}$. See Remark 2.

Remarks:

1. **Failure Model.** This stress based failure model, which was developed by Yung-Li Lee and Santosh Balur (2011) of FCA, compares nominal stress to dynamical strengths for the weld. The weld fails when the stresses are outside of the failure surface defined as

$$\left(\frac{s_n}{S_{n,\text{dyn}}}\right)^{n_n} + \left(\frac{s_s}{S_{s,\text{dyn}}}\right)^{n_s} = 1\,,$$

where s_n and s_s are nominal stresses in the normal and tangential directions, $S_{n,\text{dyn}}$ and $S_{s,\text{dyn}}$ are dynamical strengths in the normal and tangential directions, and n_n and n_s are the exponential factors EXN and EXS, respectively. The nominal stresses are defined as

$$s_n = \frac{P_n}{Dct}, \qquad s_s = \frac{P_s}{Dct},$$

where P_n and P_s are the loads carried by the weld in the normal and tangential directions, D is the weld diameter, c is scale factor TSCALE, and t is the thickness of the welded sheets calculated according to the value of TFLAG. The dynamical strength terms in the denominator are load-rate dependent and are derived from static strength:

$$S_{n,\text{dyn}} = S_{n,\text{stat}}\left[c_1 + c_2\left(\frac{\dot{P}_n}{c_4}\right) + c_3 \log\left(\frac{\dot{P}_n}{c_4}\right)\right]$$
$$S_{s,\text{dyn}} = S_{s,\text{stat}}\left[c_1 + c_2\left(\frac{\dot{P}_s}{c_4}\right) + c_3 \log\left(\frac{\dot{P}_s}{c_4}\right)\right]$$

where the constants c_1 to c_4 are the input in the fields DC1 to DC4, $\dot{P}_n$ and $\dot{P}_s$ are the load rates, and $S_{n,\text{stat}}$ and $S_{s,\text{stat}}$ are the static strengths of the welded sheet materials (see Remark 2).

2. **Static Strengths.** When two different materials are welded, the material having the smaller normal strength (SN) determines the static strengths used for the weld. Materials that do not have SN and SS values default to D_SN and D_SS from Card 2.

   If R_SULT is defined on Card 2 and the PID keyword option is not used, then D_SN and D_SS are interpreted to be reference values of the normal and shear static strength, and the SN field on Card 3 is interpreted as a material specific ultimate strength. These values are then used to calculate material specific strength values by

$$S_{n,\text{stat}} = S_{n,\text{ref}}\left(\frac{S_u}{S_{u,\text{ref}}}\right), \qquad S_{s,\text{stat}} = S_{s,\text{ref}}\left(\frac{S_u}{S_{u,\text{ref}}}\right)$$

   where $S_{n,\text{ref}}$, $S_{s,\text{ref}}$, and $S_{u,\text{ref}}$, are D_SN, D_SS, and R_SULT on Card 2, and S_u is SN on Card 3. The SS values are ignored.

   If the PID keyword option is used, then R_SULT is ignored, and SN and SS are static strength values.

3. **Default Values.** The default values for DC1 to DC4, and EXN and EXS are based on the work Chao, Wang, Miller and Zhu (2010). and Wang, Chao, Zhu, and Miller (2010). These parameters are unitless except for DC4 which has units of force per unit time. The default value of 0.1 has units of MN/sec.

4. **Load Rate.** The load rate, $\dot{P}$, can be time averaged to reduce the effect of high frequency oscillations on the dynamic weld strength. NAVG is the number of terms in the time average.

*DEFINE_SPOTWELD_FAILURE_RESULTANTS

Purpose: Define failure criteria between part pairs for predicting spot weld failure. This table is implemented for *solid* element spot welds, which are used with the tied, constraint based, contact option: *CONTACT_TIED_SURFACE_TO_SURFACE. *Note that other tied contact types cannot be used.* The input in this section continues until then next "*" card is encountered. Default values are used for any part ID pair that is not defined. Only one table can be defined. See *MAT_SPOTWELD where this option is used whenever *OPT* = 7.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	DSN	DSS	DLCIDSN	DLCIDSS			
Type	I	F	F	I	I			
Default	0	0.0	0.0	0	0			

Failure Cards. Provide as many as necessary. The next keyword ("*") card terminates the table definition.

Card 2…	1	2	3	4	5	6	7	8
Variable	PID_I	PID_J	SNIJ	SSIJ	LCIDSNIJ	LCIDSSIJ		
Type	I	I	F	F	I	I		
Default	none	none	0.0	0.0	0	0		

VARIABLE	DESCRIPTION
ID	Identification number. Only one table is allowed.
DSN	Default value of the normal static stress at failure.
DSS	Default value of the transverse static stress at failure.
DLCIDSN	Load curve ID defining a scale factor for the normal stress as a function of strain rate. This factor multiplies DSN to obtain the failure value at a given strain rate.

VARIABLE	DESCRIPTION
DLCIDSS	Load curve ID defining a scale factor for static shear stress as a function of strain rate. This factor multiplies DSS to obtain the failure value at a given strain rate.
PID_I	Part ID I
PID_J	Part ID J
SNIJ	The maximum axial stress at failure between parts I and J. The axial stress is computed from the solid element stress resultants, which are based on the nodal point forces of the solid element.
DSSIJ	The maximum shear stress at failure between parts I and J. The shear stress is computed from the solid element stress resultants, which are based on the nodal point forces of the solid element.
LCIDSNIJ	Load curve ID defining a scale factor for the normal stress as a function of strain rate. This factor multiplies SNIJ to obtain the failure value at a given strain rate.
LCIDSSIJ	Load curve ID defining a scale factor for static shear stress as a function of strain rate. This factor multiplies SSIJ to obtain the failure value at a given strain rate.

Remarks:

The stress based failure model, which was developed by *Toyota Motor Corporation,* is a function of the peak axial and transverse shear stresses. The entire weld fails if the stresses are outside of the failure surface defined by:

$$\left(\frac{\sigma_{rr}}{\sigma_{rr}^F}\right)^2 + \left(\frac{\tau}{\tau^F}\right)^2 - 1 = 0$$

where σ_{rr}^F and τ^F are specified in the above table by part ID pairs. LS-DYNA automatically identifies the part ID of the attached shell element for each node of the spot weld solid and checks for failure. If failure is detected the solid element is deleted from the calculation.

If the effects of strain rate are considered, then the failure criteria becomes:

$$\left[\frac{\sigma_{rr}}{f_{dsn}(\dot{\varepsilon}^p)\sigma_{rr}^F}\right]^2 + \left[\frac{\tau}{f_{dss}(\dot{\varepsilon}^p)\tau^F}\right]^2 - 1 = 0$$

*DEFINE_SPOTWELD_MULTISCALE

Purpose: Associate beam sets with multi-scale spot weld types for modeling spot weld failure via the multi-scale spot weld method.

Spot Weld/Beam Set Association Cards. Provide as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	TYPE	BSET	TYPE	BSET	TYPE	BSET	TYPE	BSET
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
TYPE	MULTISCALE spot weld type to use. See *INCLUDE_MULTI-SCALE_SPOTWELD.
BSET	Beam set which uses this multi-scale spot weld type for failure modeling.

Remarks:

See *INCLUDE_MULTISCALE_SPOTWELD for a detailed explanation of this capability.

*DEFINE_SPOTWELD_RUPTURE_PARAMETER

Purpose: Define a parameter by part ID for shell elements attached to spot weld *beam* elements using the constrained contact option: *CONTACT_SPOTWELD. *This table will not work with other contact types*. Only one table is permitted in the problem definition. Data, which is defined in this table, is used by the stress based spot weld failure model developed by *Toyota Motor Corporation*. See *MAT_SPOTWELD where this option is activated by setting the parameter OPT to a value of 9. This spot weld failure model is a development of *Toyota Motor Corporation*.

Card 1	1	2	3	4	5	6	7	8
Variable	PID							
Type	I							

Card 2	1	2	3	4	5	6	7	8
Variable	C11	C12	C13	N11	N12	N13		SIG_PF
Type	F	F	F	F	F	F		F

Card 3	1	2	3	4	5	6	7	8
Variable	C21	C22	C23	N2				SIG_NF
Type	F	F	F	F				F

Card 4	1	2	3	4	5	6	7	8
Variable	LCDPA	LCDPM	LCDPS	LCDNA	LCDNM	LCDNS		NSMT
Type	I	I	I	I	I	I		I
Default	0	0	0	0	0	0		0

VARIABLE	DESCRIPTION
PID	Part ID for the attached shell.
C11-N2	Parameters for model, see Remarks below.
SIG_PF	Nugget pull-out stress, σ_P
SIG_NF	Nugget fracture stress, σ_F
LCDPA	Curve ID defining dynamic scale factor of spot weld axial load rate for nugget pull-out mode.
LCDPM	Curve ID defining dynamic scale factor of spot weld moment load rate for nugget pull-out mode.
LCDPS	Curve ID defining dynamic scale factor of spot weld shear load rate for nugget pull-out mode.
LCDNA	Curve ID defining dynamic scale factor of spot weld axial load rate for nugget fracture mode.
LCDNM	Curve ID defining dynamic scale factor of spot weld moment load rate for nugget fracture mode.
LCDNS	Curve ID defining dynamic scale factor of spot weld shear load rate for nugget fracture mode.
NSMT	The number of time steps used for averaging the resultant rates for the dynamic scale factors.

Remarks:

This failure model incorporates two failure functions, one for nugget pull-out and the other for nugget fracture. The nugget pull-out failure function is

$$F_p = \frac{\mathrm{C11}\times\frac{A}{D^{\mathrm{N11}}} + \mathrm{C12}\times\frac{M}{D^{\mathrm{N12}}} + \mathrm{C13}\times\frac{S}{D^{\mathrm{N13}}}}{\sigma_P\left[1+\left(\frac{\dot{\varepsilon}^p}{C}\right)^{1/p}\right]},$$

where A, M, and S are the axial force, moment, and shear resultants respectively, D is the spot weld diameter, and the Cowper-Symonds coefficients are from the attached shell material model. If the Cowper-Symonds coefficients aren't specified, the term within the square brackets, [ ], is 1.0. The fracture failure function is

$$F_n = \frac{\sqrt{(\text{C21} \times A + \text{C22} \times M)^2 + 3(\text{C23} \times S)^2}}{D^{\text{N2}}\sigma_F \left[1 + \left(\frac{\dot{\varepsilon}^p}{C}\right)^{1/p}\right]} .$$

When the load curves for the rate effects are specified, the failure criteria are

$$F_p = \frac{\text{C11} \times f_{\text{dpa}}(\dot{A}) \times \frac{A}{D^{\text{N11}}} + \text{C12} \times f_{\text{dpa}}(\dot{M}) \times \frac{M}{D^{\text{N12}}} + \text{C13} \times f_{\text{dpa}}(\dot{S}) \times \frac{S}{D^{\text{N13}}}}{\sigma_P}$$

$$F_n = \frac{\sqrt{\left[\text{C21} \times f_{\text{dna}}(\dot{A}) \times A + \text{C22} \times f_{\text{dnm}}(\dot{M}) \times M\right]^2 + 3\left[\text{C23} \times f_{dns}(\dot{S}) \times S\right]^2}}{D^{\text{N2}}\sigma_F}$$

where f is the appropriate load curve scale factor. The scale factor for each term is set to 1.0 for when no load curve is specified. No extrapolation is performed if the rates fall outside of the range specified in the load curve to avoid negative scale factors. A negative load curve ID designates that the curve abscissa is the $\log_{10}$ of the resultant rate. This option is recommended when the curve data covers several orders of magnitude in the resultant rate. Note that the load curve dynamic scaling replaces the Cowper-Symonds model for rate effects.

Failure occurs when either of the failure functions is greater than 1.0.

*DEFINE_SPOTWELD_RUPTURE_STRESS

Purpose: Define a static stress rupture table by part ID for shell elements connected to spot weld *beam* elements using the constrained contact option: *CONTACT_SPOTWELD. *This table will not work with other contact types*. Only one table is permitted in the problem definition. Data, which is defined in this table, is used by the stress based spot weld failure model developed by *Toyota Motor Corporation*. See *MAT_SPOTWELD where this option is activated by setting the parameter *OPT* to a value of 6.

Part Cards. Define rupture stresses part by part. The next keyword ("*") card terminates this input.

Card	1	2	3	4	5	6	7	8
Variable	PID	SRSIG	SIGTAU	ALPHA				
Type	I	F	F	F				

VARIABLE	DESCRIPTION
PID	Part ID for the attached shell.
SRSIG	Axial (normal) rupture stress, σ_{rr}^F.
SRTAU	Transverse (shear) rupture stress, τ^F.
ALPHA	Scaling factor for the axial stress as defined by Toyota. The default value is 1.0.

Remarks:

The stress based failure model, which was developed by *Toyota Motor Corporation*, is a function of the peak axial and transverse shear stresses. The entire weld fails if the stresses are outside of the failure surface defined by:

$$\left(\frac{\sigma_{rr}}{\sigma_{rr}^F}\right)^2 + \left(\frac{\tau}{\tau^F}\right)^2 - 1 = 0$$

where σ_{rr}^F and τ^F are specified in the above table by part ID. LS-DYNA automatically identifies the part ID of the attached shell element for each node of the spot weld beam and independently checks each end for failure. If failure is detected in the end attached to the shell with the greatest plastic strain, the beam element is deleted from the calculation.

If the effects of strain rate are considered, then the failure criteria becomes:

$$\left[\frac{\sigma_{rr}}{\sigma_{rr}^F(\dot{\varepsilon}^p)}\right]^2 + \left[\frac{\tau}{\tau^F(\dot{\varepsilon}^p)}\right]^2 - 1 = 0$$

where $\sigma_{rr}^F(\dot{\varepsilon}^p)$ and $\tau^F(\dot{\varepsilon}^p)$ are found by using the Cowper and Symonds model which scales the static failure stresses:

$$\sigma_{rr}^F(\dot{\varepsilon}^p) = \sigma_{rr}^F\left[1 + \left(\frac{\dot{\varepsilon}^p}{C}\right)^{1/p}\right]$$

$$\tau^F(\dot{\varepsilon}^p) = \tau^F\left[1 + \left(\frac{\dot{\varepsilon}^p}{C}\right)^{1/p}\right]$$

where $\dot{\varepsilon}^p$is the average plastic strain rate which is integrated over the domain of the attached shell element, and the constants p and C are uniquely defined at each end of the beam element by the constitutive data of the attached shell. The constitutive model is described in the material section under keyword: *MAT_PIECEWISE_LINEAR_PLASTICITY.

The peak stresses are calculated from the resultants using simple beam theory.

$$\sigma_{rr} = \frac{N_{rr}}{A} + \frac{\sqrt{M_{rs}^2 + M_{rt}^2}}{\alpha Z} \quad \tau = \frac{M_{rr}}{2Z} + \frac{\sqrt{N_{rs}^2 + N_{rt}^2}}{A}$$

where the area and section modulus are given by:

$$A = \pi\frac{d^2}{4}$$

$$Z = \pi\frac{d^3}{32}$$

and d is the diameter of the spot weld beam.

*DEFINE_STAGED_CONSTRUCTION_PART_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Staged construction. This keyword offers a simple way to define parts that are removed (e.g., during excavation), added (e.g., new construction) and used temporarily (e.g., props) during the analysis. Available for solid, shell, thick shell, and beam element parts.

Part Cards. Provide as many as necessary. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	STGA	STGR					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
PID	Part ID (or Part Set ID for the SET keyword option)
STGA	Construction stage at which part is added. See Remark 1.
STGR	Construction stage at which part is removed. See Remark 1.

Remarks:

1. **Adding and Removing Stages.** Used with *DEFINE_CONSTRUCTION_-STAGES (defines the meaning of stages STGA and STGR) and *CONTROL_-STAGED_CONSTRUCTION. If STGA = 0, the part is present at the start of the analysis. If STGR = 0, the part is still present at the end of the analysis. Examples:

   a) Soil that is excavated would have STGA = 0 but STGR > 0

   b) New construction would have STGA > 0 and STGR = 0

c) Temporary works would have STGA > 0, STGR > STGA.

2. **Construction Models.** This is a convenience feature that reduces the amount of input data needed for many typical construction models. Internally, LS-DYNA automatically creates *LOAD_REMOVE_PART, *LOAD_GRAVITY_PART and *LOAD_STIFFEN_PART referencing the same PID and using the default gravity and pre-construction stiffness factors from *CONTROL_STAGED_CONSTRUCTION. If the same PID is also referenced in the input file by any of the three types of *LOAD cards mentioned above, the load curves entered on the *LOAD cards will override the STGA, STGR inputs on *DEFINE_STAGED_CONSTRUCTION_PART.

3. **Use of Ramp Time.** Ramp time ATR on *DEFINE_CONSTRUCTION_STAGES is intended to reduce dynamic effects that would occur if loading or stresses were changed suddenly. It applies to gravity loading during addition and removal of parts, i.e. *LOAD_GRAVITY_PART automatically gets ramped up to its full value during the first ATR of the stage when a part is added (STGA), and ramped down to zero during the first ATR of the stage when a part is removed (STGR). For the stiffness, strength and stresses, ATR applies during removal of a part but not during addition. Starting from R11, when a part is added, the stiffness jumps immediately to its full value at the start of STGA. This behavior is different from versions R10 and previous, where ATR was also applied to stiffness during part addition. The disadvantage of the R10 behavior was that significant deformations could occur before the part reached its full stiffness.

DEFINE_STOCHASTIC_ELEMENT_*OPTION

Options:

SOLID_VARIATION for solid elements

SHELL_VARIATION for shell elements

Purpose: Define the stochastic variation in the yield stress, damage/failure models, density, and elastic moduli for solid material models with the STOCHASTIC keyword option on an element basis. This keyword works currently with materials 10, 15, 24, 81, and 98. This option overrides values assigned by *DEFINE_STOCHASTIC_VARIATION.

Card 1	1	2	3	4	5	6	7	8
Variable	IDE	VARSY	VARF	VARRO	VARE			
Type	I	F	F	F	F			
Default	none	0.0	0.0	0.0	0.0			

VARIABLE	DESCRIPTION
IDE	Element ID
VARSY	The yield stress and its hardening function are scaled by 1.0 + VARSY.
VARF	The failure criterion is scaled by 1.0 + VARF.
VARRO	The density is scaled by 1.0 + VARRO. This is intended to be used with topology optimization. This option is not available for shell elements.
VARE	The elastic moduli are scaled by 1.0 + VARE. This is intended to be used with topology optimization.

*DEFINE_STOCHASTIC_VARIATION

Purpose: Define the stochastic variation in the yield stress and damage/failure models for material models with the STOCHASTIC keyword option. This keyword currently works with materials 10, 15, 24, 81, 98, 280, and the shell version of material 123. It is now also possible to vary failure strain in GISSMO with this keyword.

Card Summary:

Card 1. This card is required

ID_SV	PID	PID_TYP	ICOR	VAR_S	VAR_F	IRNG	

Card 2a. This card is included if and only if VAR_S = 0, 1, or 2.

R1	R2	R3					

Card 2b. This card is included if and only if VAR_S = 3 or 4.

LCID							

Card 3a. This card is included if and only if VAR_F = 0, 1, or 2.

R1	R2	R3					

Card 3b. This card is included if and only if VAR_S = 3 or 4.

LCID							

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	ID_SV	PID	PID_TYP	ICOR	VAR_S	VAR_F	IRNG	
Type	I	I	I	I	I	I	I	
Default	none	0	0	0	0	0	0	

VARIABLE	DESCRIPTION
ID_SV	Stochastic variation ID. A unique ID number must be used.

VARIABLE	DESCRIPTION
PID	*PART ID or *SET_PART ID.
PID_TYP	Flag for PID type. If PID and PID_TYP are both 0, then the properties defined here apply to all shell and solid parts using materials with the STOCHASTIC option. EQ.0: PID is a *PART ID. EQ.1: PID is a *SET_PART ID
ICOR	Correlation between the yield stress and failure strain scaling. EQ.0: Perfect correlation. EQ.1: No correlation. The yield stress and failure strain are independently scaled.
VAR_S	Variation type for scaling the yield stress (or tensile strength for material 280). EQ.0: The scale factor is 1.0 everywhere. EQ.1: The scale factor is a random number in the uniform random distribution in the interval defined by R1 and R2. EQ.2: The scale factor is a random number obeying the Gaussian distribution defined by R1, R2, and R3. EQ.3: The scale factor is defined by the probability distribution function defined by curve LCID. EQ.4: The scale factor is defined by the cumulative distribution function defined by curve LCID.
VAR_F	Variation type for scaling failure strain. EQ.0: The scale factor is 1.0 everywhere. EQ.1: The scale factor is random number in the uniform random distribution in the interval defined by R1 and R2. EQ.2: The scale factor is a random number obeying the Gaussian distribution defined by R1, R2, and R3. EQ.3: The scale factor is defined by the probability distribution function defined by curve LCID. EQ.4: The scale factor is defined by the cumulative distribution function defined by curve LCID.

VARIABLE	DESCRIPTION
IRNG	Flag for random number generation. EQ.0: Use deterministic (pseudo-) random number generator. The same input always leads to the same distribution. EQ.1: Use non-deterministic (true) random number generator. With the same input, a different distribution is achieved in each run.

Yield Stress Card for Built-in Distribution. Card 2 for VAR_S set to 0, 1, or 2.

Card 2a	1	2	3	4	5	6	7	8
Variable	R1	R2	R3

Yield Stress Card for Load Curve. Card 2 for VAR_S set to 3 or 4.

Card 2b	1	2	3	4	5	6	7	8
Variable	LCID							
Type	I							

Failure Strain Card for Built-in Distribution. Card 3 for VAR_F set to 0, 1, or 2.

Card 3a	1	2	3	4	5	6	7	8
Variable	R1	R2	R3					
Type	F	F	F					

Failure Strain Card for Load Curve. Card 3 for VAR_F set to 3 or 4.

Card 3b	1	2	3	4	5	6	7	8
Variable	LCID							
Type	I							

VARIABLE	DESCRIPTION
R1, R2, R3	Real values to define the stochastic distribution. See below.
LCID	Curve ID defining the stochastic distribution. See below.

Remarks:

Each integration point x_g in the parts specifed by PID is assigned the random scale factors R_S and R_F that are applied to the values calculated by the material model for the yield stress and failure strain.

$$\sigma_y = R_s(x_g)\sigma_y(\bar{\varepsilon}^p, \dots)$$
$$\bar{\varepsilon}^p_{\text{FAIL}} = R_F(x_g)\bar{\varepsilon}^p_{\text{FAIL}}(\dot{\varepsilon}, \bar{\varepsilon}^p, \dots)$$

The scale factors vary spatially over the model according to the chosen statistical distributions defined in this section and are independent of time. The scale factors may be completely correlated or uncorrelated with the default being completely correlated since the failure strain is generally reduced as the yield stress increases. The scale factors R_S and R_F may be stored as extra history variables as follows:

Material Model	History Variable # for R_S	History Variable # for R_F
10	5	6
15	7	8
24	6	7
81	6	7
98	7	8
123 (shells only)	6	7
280	13	n.a.
GISSMO	n.a.	ND + 20

The user is responsible for defining the distributions so that they are physically meaningful and are restricted to a realistic range. Since neither the yield stress nor the failure strain may be negative, for example, the minimum values of the distributions must always be greater than zero.

The probability that a particular value R will occur defines the *probability distribution function*, $P(R)$. Since a value must be chosen from the distribution, the integral from the minimum to the maximum value of R of the probability distribution function must be 1.0,

$$\int_{R_{\text{MIN}}}^{R_{\text{MAX}}} P(R)dR = 1.0 \ .$$

Another way to characterize a distribution is the *cumulative distribution function* $C(R)$ which defines the probability that a value will lie between R_{MIN} and R,

$$C(R) = \int_{R_{\text{MIN}}}^{R} P(\hat{R})d\hat{R}.$$

By definition $C(R_{\text{MIN}}) = 0$ and $C(R_{\text{MAX}}) = 1$. An inverse cumulative probability function D gives the number for a cumulative probability of $C(R)$,

$$D\big(C(R)\big) = R.$$

A random variable satisfying the probability distribution function $P(R)$ can be generated from a sequence of uniformly distributed numbers, $\hat{R}_I$, for $I = 1, N$, using the inverse cumulative distribution function D as

$$R_I = D(\hat{R}_I).$$

The scale factors for the yield stress and the failure strain may be generated using the same value of $\hat{R}_I$ for both (ICOR = 0) or by using independent values each one (ICOR = 1). If the same values are used, there is perfect correlation, and the failure strain scale factor becomes an implicit value of yield stress scale factor.

VAR = 0. No Scaling.

The corresponding yield stress or failure strain is not scaled.

VAR = 1. Scaling from Uniform Distribution

A uniform distribution is specified by setting VAR = 1. The input variable R1 is interpreted as R_{MIN} and R2 as R_{MAX}. If R1 = R2, then the yield stress or failure strain will be scaled by R1.

When using the uniform random distribution, the probability of a particular value is given by

$$P(R) = \frac{1}{R_{\text{MAX}} - R_{\text{MIN}}}$$

and the cumulative probability function is given by

$$C(R) = \frac{R - R_{\text{MIN}}}{R_{\text{MAX}} - R_{\text{MIN}}}.$$

VAR = 2. Gaussian Distribution

The Gaussian distribution, VAR = 2, is smoothly varying with a peak at μ and 68 percent of the values occurring within the interval of one standard deviation σ, $[\mu - \sigma, \mu + \sigma]$. The input parameter R1 is interpreted as the mean, μ,, while R2 is interpreted as the standard deviation, σ. There is a finite probability that the values of R will be outside of the range that are physically meaningful in the scaling process, and R3 which is interpreted as δ restricts the range of R to $[\mu - \delta, \mu + \delta]$ The resulting truncated Gaussian distribution is rescaled such that,

$$D(\mu + \delta) = 1 \, .$$

VAR = 3 or 4. Distribution from a Load Curve

The user may directly specify the probability distribution function or the cumulative probability distribution function with *DEFINE_CURVE by setting VAR = 3 or VAR = 4, respectively, and then specifying the required curve ID on the next data card.

Stochastic variations may be used simultaneously with the heat affected zone (HAZ) options in LS-DYNA (see *DEFINE_HAZ_PROPERTIES). The effect of the scale factors from stochastic variation and HAZ options are multiplied together to scale the yield stress and failure strain,

$$\begin{aligned} \sigma_y &= R_S(x_g) R_S^{\mathrm{HAZ}} \sigma_y(\bar{\varepsilon}^p, \dots) \\ \bar{\varepsilon}^p_{\mathrm{FAIL}} &= R_F(x_g) R_F^{\mathrm{HAZ}} \bar{\varepsilon}^p_{\mathrm{FAIL}}(\dot{\varepsilon}, \bar{\varepsilon}^p, \dots). \end{aligned}$$

*DEFINE_STOCHASTIC_VARIATION_PROPERTIES

Purpose: Define the stochastic variation in predefined material model history variables. The predefined history variables to which the stochastic variation can be applied are listed in the documentation of the material model. It is an extension of *DEFINE_STOCHASTIC_VARIATION to more material models and additional material properties.

This keyword currently works with materials 10, 15, 24, 81, 98, and 213 as well the shell version of material 123.

Card Summary:

Card 1. This card is required.

ID_SV	MTYPE	PID	PID_TYP	IRNG	NUMV	NUM_BEG	

Card 2a. This card is included if and only if VARTYP = 0, 1, or 2 (built-in distributions). For each predefined history variable, include a combination of Cards 2a and 2b in the order of the history variables.

VARTYP	CORLGRP	R1	R2	R3			

Card 2b. This card is included if and only if VARTYP = 3 or 4 (distributions defined by curves). For each predefined history variable, include a combination of Cards 2a and 2b in the order of the history variables.

VARTYP	CORLGRP	LCID					

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	ID_SV	MTYPE	PID	PID_TYP	IRNG	NUMV	NUM_BEG	
Type	I	I	I	I	I	I	I	
Default	none	none	0	0	0	0	0	

VARIABLE	DESCRIPTION
ID_SV	Stochastic variation ID. A unique ID number must be used.

VARIABLE	DESCRIPTION
MTYPE	Material type. The available types are 10, 15, 24, 81, 98, and 213. This variation only works for this material.
PID	*PART ID or *SET_PART ID.
PID_TYP	Flag for PID type. If PID and PID_TYP are both 0, then the properties defined here apply to all shell and solid parts using the materials defined in the *OPTION* string. EQ.0: PID is a *PART ID. EQ.1: PID is a *SET_PART ID.
IRNG	Flag for random number generation. EQ.0: Use deterministic (pseudo-) random number generator. The same input always leads to the same distribution. EQ.1: Use non-deterministic (true) random number generator. With the same input, a different distribution is achieved in each run.
NUMV	Number of variations for a user material
NUM_BEG	The location of the first variation in the history variables for a user material. The remaining variations are added sequentially.

Card for Built-in Distributions. Card 2 for VARTYP set to 0, 1, or 2.

Card 2a	1	2	3	4	5	6	7	8
Variable	VARTYP	CORLGRP	R1	R2	R3			
Type	I	I	F	F	F			

Card for Distributions Defined by a Curve. Card 2 for VARTYP set to 3 or 4.

Card 2b	1	2	3	4	5	6	7	8
Variable	VARTYP	CORLGRP	LCID					
Type	I	I	I					

VARIABLE	DESCRIPTION
VARTYP	Variation type for scaling the material property: EQ.0: The scale factor is 1.0 everywhere. EQ.1: The scale factor is a random number in the uniform random distribution in the interval defined by R1 and R2. EQ.2: The scale factor is a random number obeying the Gaussian distribution defined by R1, R2, and R3. EQ.3: The scale factor is defined by the probability distribution function defined by curve LCID. EQ.4: The scale factor is defined by the cumulative distribution function defined by curve LCID.
CORLGRP	Correlation group number. If CORLGRP is 0, then the random number for the distribution is uncorrelated with all the other distributions. The same random number is used for evaluating all the distributions having the same positive integer value for CORLGRP.
R1, R2, R3	Real values to define the stochastic distribution. See Remark 6.
LCID	Curve ID defining the stochastic distribution. See Remark 6.

Remarks:

1. **Physically Meaningful Distributions.** The user is responsible for defining the distributions so that they are physically meaningful and are restricted to a realistic range. A certain history variable may not be negative, for example, so the minimum values of the distributions must always be greater than zero.

2. **Compatibility.** This implementation is compatible with *DEFINE_STOCHASTIC_VARIATION for materials 10, 15, 24, 81, 98, and the shell version of material 123 in that it scales the yield stress and the failure strain. This implementation also supports stochastic variations with user materials but does not support GISSMO. The results of the two implementations will not be identical because the generality of the correlation groups results in the random number generator being called in a different order.

3. **Correlation Group Number.** The correlation group number allows the user to selectively correlate different history variables for a given material model. For a material model that is scaling five history variables with the group numbers being 0, 0, 1, 2, 2, each of the first two variables will be uncorrelated with the other

four, the third variable is also uncorrelated with the rest, while the last two are perfectly correlated with each other but not with any others.

4. **Number of Variations.** If more variations are defined in the input than are permitted by the material model, the excess will be ignored. If fewer variations are defined, the unspecified variations will be set to 1.0.

5. **Distribution Functions.** The probability that a particular value R will occur defines the *probability distribution function*, $P(R)$. Since a value must be chosen from the distribution, the integral from the minimum to the maximum value of R of the probability distribution function must be 1.0,

$$\int_{R_{\text{MIN}}}^{R_{\text{MAX}}} P(R)dR = 1.0 \ .$$

Another way to characterize a distribution is the *cumulative distribution function*, $C(R)$, which defines the probability that a value will lie between R_{MIN} and R,

$$C(R) = \int_{R_{\text{MIN}}}^{R} P(\hat{R})d\hat{R} \ .$$

By definition $C(R_{\text{MIN}}) = 0$ and $C(R_{\text{MAX}}) = 1$. An inverse cumulative probability function D gives the number for a cumulative probability of $C(R)$,

$$D\big(C(R)\big) = R \ .$$

A random variable satisfying the probability distribution function $P(R)$ can be generated from a sequence of uniformly distributed numbers, $\hat{R}_I$, for $I = 1, \ldots, N$, using the inverse cumulative distribution function D as

$$R_I = D(\hat{R}_I).$$

6. **VARTYP.** The applied distribution and input fields for Card 2 depends on VARTYP. Descriptions of each distribution follows.

   a) *No Scaling (VARTYP = 0).* The distribution value is 1.0.

   b) *Scaling from Uniform Distribution (VARTYP = 1).* A uniform distribution is specified by setting VAR = 1. The input variable R1 is interpreted as R_{MIN} and R2 as R_{MAX}. If R1 = R2, then the material property will be scaled by R1.

      When using the uniform random distribution, the probability of a particular value is given by

$$P(R) = \frac{1}{R_{\text{MAX}} - R_{\text{MIN}}} \ ,$$

      and the cumulative probability function is given by

$$C(R) = \frac{R - R_{\text{MIN}}}{R_{\text{MAX}} - R_{\text{MIN}}} \ .$$

c) *Gaussian Distribution (VARTYP = 2).* The Gaussian distribution, VAR = 2, is smoothly varying with a peak at μ and 63 percent of the values occurring within the interval of one standard deviation σ, $[\mu - \sigma, \mu + \sigma]$. The input parameter R1 is interpreted as the mean, μ,, while R2 is interpreted as the standard deviation, σ. There is a finite probability that the values of R will be outside of the range that are physically meaningful in the scaling process, and R3 which is interpreted as δ restricts the range of R to $[\mu - \delta, \mu + \delta]$. The resulting truncated Gaussian distribution is rescaled such that,

$$D(\mu + \delta) = 1 \ .$$

d) *Distribution from a Load Curve (VARTYP = 3 or 4).* The user may directly specify the probability distribution function or the cumulative probability distribution function with *DEFINE_CURVE by setting VAR = 3 or VAR = 4, respectively, and then specifying the required curve ID.

7. **Heat Affected Zone.** Stochastic variations may be used simultaneously with the heat affected zone (HAZ) options in LS-DYNA (see *DEFINE_HAZ_PROPERTIES). The effect of the scale factors from stochastic variation and HAZ options are multiplied together to scale the predefined history variables.

*DEFINE_TABLE

Purpose: To interpolate from point data a continuously indexed family of nonintersecting curves. The family of curves, $\mathcal{F}$, consists of x-y curves, $f_s(x)$, indexed by a parameter, s.

$$\mathcal{F} = \{f_s(x) | \forall s \in [s_{\min}, s_{\max}]\}.$$

The interpolation is built up by sampling functions in $\mathcal{F}$ at discrete parameter values, s_i,

$$f_{s_i}(x) \in \mathcal{F}.$$

The points, s_i, are input to LS-DYNA on the data cards for the *DEFINE_TABLE keyword. LS-DYNA requires that they be ordered from least to greatest. The curves, $f_{s_i}(x)$, must be defined as lists of (x, y) pairs in a collection of *DEFINE_CURVE sections that directly follow the *DEFINE_TABLE section. Each *DEFINE_CURVE section is paired to its corresponding s_i value by list position (and not load curve ID, for that see *DEFINE_TABLE_2D).

Card 1	1	2	3	4	5	6	7	8
Variable	TBID	SFA	OFFA					
Type	I	F	F					
Default	none	1.	0.					

Points Cards. Place one point per card. The values must be in ascending order. Input is terminated when a "*DEFINE_CURVE" keyword card is found.

Card 2	1	2	3	4	5	6	7	8
Variable	VALUE							
Type	F							
Default	0.0							

Include one ***DEFINE_CURVE** input section here for each point defined above. The i^{th} *DEFINE_CURVE card contains the curve at the i^{th} *DEFINE_TABLE value.

VARIABLE	DESCRIPTION
TBID	Table ID. Tables and Load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably.
SFA	Scale factor for VALUE.
OFFA	Offset for VALUE, see explanation below.
VALUE	Load curve will be defined corresponding to this value, e.g., this value could be a strain rate, see purpose above.

Motivation:

This capability was implemented with strain-rate dependent stress-strain relations in mind. To define such a function, the first step is to tabulate stress-strain curves at known strain-rate values. Then, the list of strain-rates is written in ascending order to the data cards following *DEFINE_TABLE. Following *DEFINE_TABLE, the tabulated stress-strain curves must be input to LS-DYNA as a set of *DEFINE_CURVE sections ordered so that the i^{th} curve corresponds to the i^{th} strain-rate point. This section is structured as:

***DEFINE_TABLE**
strain-rate point 1
strain-rate point 2
⋮
strain-rate point n
***DEFINE_CURVE**
[stress-strain curve at strain-rate 1]
***DEFINE_CURVE**
[stress-strain curve at strain-rate 2]
⋮
***DEFINE_CURVE**
[stress-strain curve at strain-rate n]

Details, Features and Limitations:

1. All the curves in a table must start from the same abscissa value and end at the same abscissa value. This limitation is necessary to avoid slow indirect addressing in the inner loops used in the constitutive model stress evaluation. Curves must not intersect except at the origin and end points.

2. Each curve may have unique spacing and an arbitrary number of points in its definition.

3. All the curves in a table must share the same value of LCINT.

4. In most applications, curves can only be extrapolated in one direction, that is, to the right of the last data point. An example would be curves representing effective stress vs. effective plastic strain. For cases when extrapolation is only to the right, the curves comprising a table are allowed to intersect *only* at their starting point but the curves *and their extrapolations* must not intersect elsewhere.

   For other applications in which the curves are extrapolated in both directions, the curves and their extrapolations are not allowed to intersect except at the origin (0,0). An example would be curves representing force vs. change in gage length where negative values are compressive and positive values are tensile.

5. Load curve IDs defined for the table may be referenced elsewhere in the input.

6. No keyword commands may come between *DEFINE_TABLE and the *DEFINE_CURVE commands that feed the table. The set of *DEFINE_CURVE commands must not be interrupted by any other keyword. This coupling between *DEFINE_TABLE and subsequent *DEFINE_CURVE commands is an exception to the general order-independence of the keyword format.

7. VALUE is scaled in the same manner as in *DEFINE_CURVE, i.e.,

$$\text{Scaled value} = \text{SFA} \times (\text{Defined value} + \text{OFFA}).$$

8. Unless stated otherwise in the description of a keyword command that references a table, there is no extrapolation beyond the range of VALUEs defined for the table. For example, if the table VALUE represents strain rate and the calculated strain rate exceeds the last/highest VALUE given by the table, the stress-strain curve corresponding to the last/highest table VALUE will be used.

*DEFINE_TABLE_2D

Purpose: Define a table. Unlike the *DEFINE_TABLE keyword above, a curve ID is specified for each value defined in the table. This allows the same curve ID to be referenced by multiple tables, and the curves may be defined anywhere in the input file. Other than these differences from *DEFINE_TABLE, the general rules given in the remarks of *DEFINE_TABLE still apply.

Card 1	1	2	3	4	5	6	7	8
Variable	TBID	SFA	OFFA					
Type	I	F	F					
Default	none	1.	0.					

Points Cards. Place one point per card. The values must be in ascending order. Input is terminated when the next keyword card is found.

Card 2	1	2	3	4
Variable	VALUE	CURVE ID		
Type	F	I		
Default	0.0	none		

VARIABLE	DESCRIPTION
TBID	Table ID. Tables and Load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably.
SFA	Scale factor for VALUE.
OFFA	Offset for VALUE; see remarks for *DEFINE_TABLE.
VALUE	Load curve will be defined corresponding to this value. The value could be, for example, a strain rate.
CURVEID	Load curve ID. See Remark 1.

Remarks:

1. **Curve IDs.** Though generally of no concern to the user, curve CURVEID is automatically duplicated during initialization and the duplicate curve is automatically assigned a unique curve ID. The generated curve IDs used by the table are revealed in d3hsp. It is generally only necessary to know the generated curve IDs when interpreting warning messages about those curves.

*DEFINE_TABLE_3D

Purpose: Define a three dimensional table. For each value defined below, a table ID is specified. For example, in a thermally dependent material model, the value given below could correspond to temperature for a table ID defining effective stress versus strain curves for a set of strain rate values. Each table ID can be referenced by multiple three dimensional tables, and the tables may be defined anywhere in the input.

Card 1	1	2	3	4	5	6	7	8
Variable	TBID	SFA	OFFA					
Type	I	F	F					
Default	none	1.	0.					

Points Cards. Place one point per card. The values must be in ascending order. Input is terminated when the next keyword card is found.

Card 2	1	2	3	4
Variable	VALUE	TABLE ID		
Type	F	I		
Default	0.0	none		

VARIABLE	DESCRIPTION
TBID	Table ID. Tables and load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably.
SFA	Scale factor for VALUE.
OFFA	Offset for VALUE, see explanation below.
VALUE	Load curve will be defined corresponding to this value, e.g., this value could be a strain rate for example.
TABLEID	Table ID.

Remarks:

1. **Scaling.** VALUE is scaled in the same manner as in *DEFINE_CURVE, that is,

$$\text{Scaled value} = \text{SFA} \times (\text{Defined value} + \text{OFFA}).$$

2. **Extrapolation.** Unless stated otherwise in the description of a keyword command that references a table, there is no extrapolation beyond the range of VALUEs defined for the table. For example, if the table VALUE represents strain rate and the calculated strain rate exceeds the last/highest VALUE given by the table, the stress-strain curve corresponding to the last/highest table VALUE will be used

*DEFINE_TABLE_*{X}*D

Available options for *X* are 4, 5, 6, 7, 8, or 9.

Purpose: Define an *X*-dimensional table. For each value defined below, a table ID of one lower dimension is specified. This keyword works in the same way as *DEFINE_TABLE_3D, but with a higher dimensionality (current maximum would be X = 9).

Card 1	1	2	3	4	5	6	7	8
Variable	TBID	SFA	OFFA					
Type	I	F	F					
Default	none	1.	0.					

Points Cards. Place one point per card. The values must be in ascending order. Input is terminated when the next keyword card is found.

Card 2	1	2	3	4
Variable	VALUE	TABLE ID		
Type	F	I		
Default	0.0	none		

VARIABLE	DESCRIPTION
TBID	Table ID. Tables and load curves may not share common IDs. LS-DYNA allows load curve IDs and table IDs to be used interchangeably.
SFA	Scale factor for VALUE
OFFA	Offset for VALUE; see explanation below.
VALUE	Value which corresponds to a $X-1$ dimension with ID TABLEID
TABLEID	Table ID of table with one dimension smaller

Remarks:

1. **Scaling.** VALUE is scaled in the same manner as in *DEFINE_CURVE, that is,

$$\text{Scaled value} = \text{SFA} \times (\text{Defined value} + \text{OFFA}).$$

2. **Extrapolation.** Unless stated otherwise in the description of a keyword command that references a table, there is no extrapolation beyond the range of values defined for the table. For example, if the table VALUE represents strain rate and the calculated strain rate exceeds the last/highest VALUE given by the table, the stress-strain curve corresponding to the last/highest table VALUE will be used.

3. **Example.** The following input shows the possible definition of stress-strain curves for *MAT_251 with 3 points each for two values of history variable #7 (80 and 200), two values for history variable #6 (20 and 400), and two strain rates (0 and 100) using a TABLE_4D:

*DEFINE_TABLE_COMPACT

Purpose: Define a multi-dimensional table, meaning a functional dependence on several variables. Each ordinate value (for example, stress) can depend on several abscissa values (such as strain, strain rate, history variables, …).

Card Summary:

Card 1. This card is required.

TBID	NVAR	LCINT	MATHIS	INEXETC	ISCALE		

Card 2. This card is included if MATHIS = 1.

	HIS1	HIS2	HIS3	HIS4	HIS5	HIS6	HIS7

Card 2.1. This card is included if MATHIS = 1 and NVAR > 7.

	HIS8	HIS9					

Card 3. This card is included if INEXETC = 1.

	IXE1	IXE2	IXE3	IXE4	IXE5	IXE6	IXE7

Card 3.1. This card is included if INEXETC = 1 and NVAR > 7.

	IXE8	IX89					

Card 4. This card is included if ISCALE = 1.

SF0	SFA1	SFA2	SFA3	SFA4	SFA5	SFA6	SFA7

Card 4.1. This card is included if ISCALE = 1 and NVAR > 7.

	SFA8	SFA9					

Card 5. Include one of this card for each ordinate value if NVAR ≤ 7 or a set of this card and Card 4.1 for each ordinate value if NVAR > 7. This input ends with the next keyword (“*”) card.

01	A1.1	A1.2	A1.3	A1.4	A1.5	A1.6	A1.7

Card 5.1. Include this in a set of this card with Card 4 if NVAR > 7 for each ordinate value. This input ends with the next keyword (“*”) card,

	A1.8	A1.9					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	TBID	NVAR	LCINT	MATHIS	INEXETC	ISCALE		
Type	I	I	I	I	I	I		
Default	none	none	0	0	0	0		

VARIABLE	DESCRIPTION
TBID	Table ID. Tables and load curves may not share common IDs. LS-DYNA allows load curve IDs and table IDs to be used interchangeably.
NVAR	Number of variables (dimension of the table). Current maximum is 9.
LCINT	Number of discretization points. EQ.0: Value of LCINT from *CONTROL_SOLUTION will be used.
MATHIS	Material history flag. Option to identify the abscissa variables as a specified history variable number(s) (see Remarks 3 and 6). Additional Card 2 (and possibly Card 2.1) is read if this option is active. EQ.0: Off EQ.1: On
INEXETC	Extra curve settings flag. Option to assign settings about curve discretization, extrapolation and interpolation for each abscissa variable. Additional Card 3 (and possibly Card 3.1) is read if this option is active. EQ.0: Off EQ.1: On
ISCALE	Variable scaling flag. Option to scale ordinate and abscissa values. Additional Card 4 (and possibly Card 4.1) is read if this option is active. EQ.0: Off

VARIABLE	DESCRIPTION
	EQ.1: On

Material History Card. Additional card for MATHIS = 1 only.

Card 2	1	2	3	4	5	6	7	8
Variable		HIS1	HIS2	HIS3	HIS4	HIS5	HIS6	HIS7
Type		I	I	I	I	I	I	I

Optional Material History Card. Include up to 2 additional values if MATHIS = 1 and NVAR > 7.

Card 2.1	1	2	3	4	5	6	7	8
Variable		HIS8	HIS9					
Type		I	I					

VARIABLE	DESCRIPTION
HIS1, HIS2, …	History variable numbers which indicate that variable X is HISX. For instance, setting HIS2 = 6 indicates that variable 2 is history variable 6 for the material. A value of 0 indicates that the abscissa variable is not a history variable. See Remarks 3 and 6.

Extra Settings Card. Additional card for INEXETC = 1 only.

Card 3	1	2	3	4	5	6	7	8
Variable		IXE1	IXE2	IXE3	IXE4	IXE5	IXE6	IXE7
Type		I	I	I	I	I	I	I

Optional Extra Settings Card. Include up to 2 additional values if INEXETC = 1 and NVAR > 7.

Card 3.1	1	2	3	4	5	6	7	8
Variable		IXE8	IXE9					
Type		I	I					

VARIABLE	DESCRIPTION
IXE1, IXE2, …	Extra settings assigned to abscissa values. See Remark 3. IXE is interpreted digit-wise, namely as, $\text{IXE} = [MLK] = K + 10 \times L + 100 \times M$. with the following interpretations: K.EQ.0: Discretized curve using LCINT is used. K.EQ.1: Original curve as defined in this keyword is used. L.EQ.0: Extrapolation at lower and upper end is used. L.EQ.1: No extrapolation is used, meaning the first and last values are kept constant. M.EQ.0: Linear interpolation between data points is used. M.EQ.1: Logarithmic interpolation between data points is used.

Variable Scaling Card. Additional card for ISCALE = 1 only.

Card 4	1	2	3	4	5	6	7	8
Variable	SF0	SFA1	SFA2	SFA3	SFA4	SFA5	SFA6	SFA7
Type	F	F	F	F	F	F	F	F

Optional Variable Scaling Card. Include up to 2 additional values if ISCALE = 1 and NVAR > 7.

Card 4.1	1	2	3	4	5	6	7	8
Variable		SFA8	SFA9					
Type		F	F					

VARIABLE	DESCRIPTION
SFO	Scale factor for ordinate value. Default set to 1.0.
SFA1, SFA2, …	Scale factors for abscissa values. Defaults set to 1.0.

Point Cards. Place one ordinate value with NVAR abscissa values per card. If NVAR > 7, include sets of Card 5 and Card 5.1 for each ordinate value. The values must be placed in a special ascending order; see Remarks. Input ends with the next keyword ("*") card.

Card 5	1	2	3	4	5	6	7	8
Variable	01	A1.1	A1.2	A1.3	A1.4	A1.5	A1.6	A1.7
Type	F	F	F	F	F	F	F	F

Optional Point Cards. Include this card if NVAR > 7 in a set with Card 5 for the same ordinate value to define up to 2 additional abscissa values.

Card 5.1	1	2	3	4	5	6	7	8
Variable		A1.8	A1.9					
Type		F	F					

VARIABLE	DESCRIPTION
O1, O2, …	Ordinate (function) values. See Remarks 2, 4 and 5.
A1.X, A2.X, …	Abscissa values of variable X. See Remarks 2, 4 and 5.

Remarks:

1. **Internal Conversion.** The input from this keyword is internally converted into a *DEFINE_TABLE_{X}D with dimension X = NVAR. Corresponding sub-tables and curves will automatically be created, and all rules/properties described in *DEFINE_CURVE / *DEFINE_TABLE hold.

2. **Input Syntax.** The abscissa values of the first variable (second column) should increase first, while values in the following columns are kept constant. Then, values of variable 2 should increase next while the remaining variables to the right are kept constant. Next, the same for variable 3, and so on.

3. **Support Material Models for Material History and Extra Settings.** The options MATHIS and INEXETC are currently supported for *MAT_024 with VP = 3 and *MAT_ADD_DAMAGE_DIEM (or *MAT_ADD_EROSION with IDAM < 0).

4. **Basic Example.** The following input shows the possible definition of stress-strain curves for *MAT_251 with 3 points each for two different values of history variable #7 (80 and 200), two values for history variable #6 (20 and 400), and two strain rates (0 and 100), as an alternative to *DEFINE_TABLE_4D (see remarks there for comparison):

```
*DEFINE_TABLE_COMPACT
$     tbid    numvar     lcint
     10000         4
$    value      var1      var2      var3      var4
$      sig       eps      rate     his#6     his#7
     360.0       0.0       0.0      20.0      80.0
     570.0       0.3       0.0      20.0      80.0
     780.0       1.0       0.0      20.0      80.0
     470.0       0.0     100.0      20.0      80.0
     680.0       0.3     100.0      20.0      80.0
     860.0       1.0     100.0      20.0      80.0
     180.0       0.0       0.0     400.0      80.0
     285.0       0.3       0.0     400.0      80.0
     390.0       1.0       0.0     400.0      80.0
     235.0       0.0     100.0     400.0      80.0
     340.0       0.3     100.0     400.0      80.0
     430.0       1.0     100.0     400.0      80.0
     540.0       0.0       0.0      20.0     200.0
     855.0       0.3       0.0      20.0     200.0
    1170.0       1.0       0.0      20.0     200.0
     705.0       0.0     100.0      20.0     200.0
    1020.0       0.3     100.0      20.0     200.0
    1290.0       1.0     100.0      20.0     200.0
     270.0       0.0       0.0     400.0     200.0
     427.5       0.3       0.0     400.0     200.0
     585.0       1.0       0.0     400.0     200.0
     352.5       0.0     100.0     400.0     200.0
     510.0       0.3     100.0     400.0     200.0
```

5. **Empty Columns.** It is possible to leave individual columns without defined values. For instance, if history variable #6 were to be left out in the above example, the table would reduce to:

```
*DEFINE_TABLE_COMPACT
$     tbid    numvar     lcint
     10000         4
$    value      var1      var2      var3      var4
```

```
$       sig       eps      rate     his#6     his#7
     360.0       0.0       0.0                80.0
     570.0       0.3       0.0                80.0
     780.0       1.0       0.0                80.0
     470.0       0.0     100.0                80.0
     680.0       0.3     100.0                80.0
     860.0       1.0     100.0                80.0
     540.0       0.0       0.0               200.0
     855.0       0.3       0.0               200.0
    1170.0       1.0       0.0               200.0
     705.0       0.0     100.0               200.0
    1020.0       0.3     100.0               200.0
    1290.0       1.0     100.0               200.0
```

6. **MATHIS Example.** MATHIS = 1 causes the reading of one to two additional cards depending on NVAR which indicate which history variable a given abscissa variable is. Usually there is a fixed order to the history variables used in this table, but MATHIS = 1 gives you more freedom when assigning the variables to the table. In the following example, variable 2 is history variable #1, variable 3 is history variable #6, variable 4 is history variable #7, variable 5 is history variable #8, and variable 6 is history variable #9.

```
*DEFINE_TABLE_COMPACT
$     tbid    numvar     lcint    mathis   inexetc
     10000         6       201         1         1
$              his1      his2      his3      his4      his5      his6
                  0         1         6         7         8         9
$              ixe1      ixe2      ixe3      ixe4      ixe5      ixe6
                  0       111        10        10        10        10
$    value      var1      var2      var3      var4      var5      var6
$      sig       eps     his#1     his#6     his#7     his#8     his#9
     360.0       0.0       0.0      20.0      80.0       0.0       1.0
     570.0       0.3       0.0      20.0      80.0       0.0       1.0
     780.0       1.0       0.0      20.0      80.0       0.0       1.0
                                      ⋮
```

*DEFINE_TABLE_MATRIX

Purpose: This is an alternative input format for *DEFINE_TABLE that allows for reading data from an unformatted text file containing a matrix with data separated by comma delimiters. The purpose is to use data saved directly from excel sheets without having to convert it to keyword syntax.

Card 1	1	2	3	4	5	6	7	8
Variable	TBID	FILENAME						
Type	I	A70						

Card 2	1	2	3	4	5	6	7	8
Variable	NROW	NCOL	SROW	SCOL	SVAL	OROW	OCOL	OVAL
Type	I	I	F	F	F	F	F	F
Default	none	none	1.	1.	1.	0.	0.	0.

VARIABLE	DESCRIPTION
TBID	Table ID. Tables and Load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably.
FILENAME	Name of file containing table data (stored as a matrix).
NROW	Number of rows in the matrix, same as number of rows in the file FILENAME. A negative value of NROW switches the interpretation of rows and columns in the read matrix, see Remarks 1 and 2.
NCOL	Number of columns in the matrix, same as number of data entries per row in the file FILENAME
SROW	Scale factor for row data, see Remark 2.
SCOL	Scale factor for column data, see Remark 2.
SVAL	Scale factor for matrix values, see Remark 2.

VARIABLE	DESCRIPTION
OROW	Offset for row data, see Remark 2.
OCOL	Offset for column data, see Remark 2.
OVAL	Offset for matrix values, see Remark 2.

Remarks:

1. **Example.** The use of this keyword allows for inputting a table in form of a matrix from a file, exemplified here by a 4 × 5 matrix.

	C1	C2	C3	C4
R1	V11	V12	V13	V14
R2	V21	V22	V23	V24
R3	V31	V32	V33	V34
⋮	⋮	⋮	⋮	⋮

The unformatted file representing this matrix would contain the following data

```
,C1,C2,C3,C4
R1,V11,V12,V13,V14
R2,V21,V22,V23,V24
R3,V31,V32,V33,V34
```

Note that the first entry in the matrix is a dummy and delimited by an initial comma in the file. The keyword card for this matrix is: (TBID = 1000 and the filename is file.txt)

```
*DEFINE_TABLE_MATRIX
1000,file.txt
4,5
```

This is equivalent to using:

```
*DEFINE_TABLE
1000
C1
C2
C3
C4
*DEFINE_CURVE
1001
R1,V11
R2,V21
R3,V31
*DEFINE_CURVE
```

```
1002
R1,V12
R2,V22
R3,V32
*DEFINE_CURVE
1003
R1,V13
R2,V23
R3,V33
*DEFINE_CURVE
1004
R1,V14
R2,V24
R3,V34
```

2. **Scaling, Offsets, and Transposition.** All entries in the matrix can be scaled and offset following the convention for other tables and curves:

$$\text{Scaled Value} = \text{S[ROW/COL]} \times (\text{Value} + \text{O[ROW/COL]})$$

Finally, the matrix can be transposed by setting NROW to a negative value. In the example above (Remark 1) this would mean that

```
*DEFINE_TABLE_MATRIX
1000,file.txt
-4,5
```

is equivalent to using:

```
*DEFINE_TABLE
1000
R1
R2
R3
*DEFINE_CURVE
1001
C1,V11
C2,V12
C3,V13
C4,V14
*DEFINE_CURVE
1002
C1,V21
C2,V22
C3,V23
C4,V24
*DEFINE_CURVE
1003
C1,V31
C2,V32
```

```
C3,V33
C4,V34
```

In this case, any scaling applies to the matrix entries before transposing the data, i.e., for row entries the scaled value is

$$\text{Scaled Value} = \text{SROW} \times (R + \text{OROW}),$$

and for column entries

$$\text{Scaled Value} = \text{SCOL} \times (C + \text{OCOL})$$

regardless the sign of NROW.

*DEFINE_TARGET_BOUNDARY

Purpose: This keyword is used to define the desired boundary of a formed part. This boundary provides the criteria used during blank size development. The definitions associated with this keyword are used, exclusively, by the *INTERFACE_BLANKSIZE_DEVELOPMENT feature.

Point Cards. Include one card for each point in the curve. These points are interpolated to form a closed curve. This input is terminated with *END.

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	X		Y		Z					
Type	E16.0		E16.0		E16.0					
Default	none		none		none					

VARIABLE	DESCRIPTION
X, Y, Z	Location coordinates of a target node.

Remarks:

1. **INTERFACE_BLANKSIZE_DEVELOPMENT.** The keyword file specified on the second data card for the *INTERFACE_BLANKSIZE_DEVELOPMENT keyword must contain a *DEFINE_TARGET_BOUNDARY keyword.

2. **Example.** A partial keyword input is shown below. Note that the input is in a 3E16.0 FORTRAN format. Also note that the first and last curve points coincide.

```
*KEYWORD
*DEFINE_TARGET_BOUNDARY
    -1.83355e+02    -5.94068e+02    -1.58639e+02
    -1.80736e+02    -5.94071e+02    -1.58196e+02
    -1.78126e+02    -5.94098e+02    -1.57813e+02
    -1.75546e+02    -5.94096e+02    -1.57433e+02
    -1.72888e+02    -5.94117e+02    -1.57026e+02
           ⋮               ⋮               ⋮
    -1.83355e+02    -5.94068e+02    -1.58639e+02
*END
```

3. **IGES to Keyword Format.** Typically, these boundary nodes are obtained from the boundary curves for a final (trimmed) piece or from a draw blank edge at a certain distance outside of the draw beads. LS-PrePost 4.1 can generate the

points for this keyword from IGES data. To use IGES data select *Curve → Convert→ Method (To Keyword) → Select *DEFINE_TARGET_BOUNDARY*; pick the curves; and then select *To Key*. To output in keyword format, choose *File → Save as → Save Keyword As*, and select "Output Version" as "V971_R7".

Revisions:

This feature is available in LS-DYNA R6 Revision 74560 and later releases.

*DEFINE_TRACER_PARTICLES_2D

Purpose: Define tracer particles that follow the deformation of a material. This is useful for visualizing the deformation of a part that is being adapted in a metal forming operation. Nodes used as tracer particles should only be used for visualization and not associated with anything in the model that may alter the response of the model, e.g., they should not be used in any elements except those with null materials.

Card 1	1	2	3	4	5	6	7	8
Variable	NSET	PSET						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
NSET	The node set ID for the nodes used as tracer particles.
PSET	Optional part set ID. If this part set is specified, only tracer particles in these parts are updated and the others are stationary. If this part set is not specified, all tracer particles are updated.

*DEFINE_TRANSFORMATION

Purpose: Define a transformation for the *INCLUDE_TRANSFORM keyword option. The *DEFINE_TRANSFORMATION command must be defined before the *INCLUDE_-TRANSFORM command can be used.

Card 1	1	2	3	4	5	6	7	8
Variable	TRANID							
Type	I							
Default	none							

Transformation Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	OPTION	A1	A2	A3	A4	A5	A6	A7
Type	A	F	F	F	F	F	F	F

Matrix Card 1. Cards 3 and 4 are only included when OPTION = MATRIX.

Card 3	1	2	3	4	5	6	7	8
Variable	M11	M12	M13	M14	M21	M22	M23	M24
Type	F	F	F	F	F	F	F	F

Matrix Card 2. Cards 3 and 4 are only included when OPTION = MATRIX.

Card 4	1	2	3	4	5	6	7	8
Variable	M31	M32	M33	M34	M41	M42	M43	M44
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
TRANID	Transform ID
OPTION	For the available options, see the table below.
A1-A7	Parameters. See Table 17-58 below for the available options.

OPTION	PARAMETERS	FUNCTION
MIRROR	a1, a2, a3, a4, a5, a6, a7	Reflect about a mirror plane defined to contain the point (a1, a2, a3) having its normal pointing from point (a1, a2, a3) toward (a4, a5, a6). Setting a7 = 1 reflects the coordinate system as well, that this, the mirrored coordinate system uses the left-hand-rule to determine the local z-axis.
MATRIX	M*ij* in Cards 3 & 4	Direct input of a 4x4 space transformation matrix. A node with coordinates (x, y, z) will be transformed according to $(x, y, z, 1)M$. In most cases M14 = M24 = M34 = 0 and M44 = 1.0. The matrix can be equivalent to other options. For example, TRANSL is equivalent to M41 = a1, M42 = a2 and M43 = a3, and SCALE is the same as M11 = a1, M22 = a2 and M33 = a3.
POINT	a1,a2,a3,a4	Define a point with ID, a1, with the initial coordinates a2, a3, and a4.
POS6P	a1, a2, a3, a4, a5, a6	Positioning by 6 points. Affine transformation (rotation and translation, no scaling) given by three start points a1, a2, and a3 and three target points a4, a5, and a6. The six POINTs must be defined before they are referenced. Only 1 POS6P option is permitted within a *DEFINE_TRANSFORMATION definition.
POS6N	a1, a2, a3, a4, a5, a6	Positioning by 6 nodes. Affine transformation (rotation and translation, no scaling) given by three start nodes a1, a2, and a3 and three target nodes a4, a5, and a6. The

OPTION	PARAMETERS	FUNCTION
		six nodes must be defined before they are referenced. Only 1 POS6N option is permitted within a *DEFINE_TRANSFORMATION definition.
ROTATE	a1, a2, a3, a4, a5, a6, a7	Rotate through an angle (deg), a7, about a line with direction cosines a1, a2, and a3 passing through the point with coordinates a4, a5, and a6. If a4 through a7 are zero, then a1 and a2 are the ID's of two POINTs and a3 defines the rotation angle. The axis of rotation is defined by a vector going from point with ID a1 to point with ID a2.
ROTATE3NA	a1, a2, a3, a4	Rotate through an angle (deg), a4. The axis of rotation is defined by a vector going from the node with ID a1 to the node with ID a2 and passing through the node with ID a3 (a3 could be the same as a1 or a2). The three nodes must be defined before they are referenced. Only 1 ROTATE3NA option is permitted within a *DEFINE_TRANSFORMATION definition.
SCALE	a1, a2, a3	Scale the global x, y, and z coordinates of a point by a1, a2, and a3, respectively. If zero, a default of unity is set.
TRANSL	a1, a2, a3	Translate the x, y, and z coordinates of a point by a1, a2, and a3, respectively.
TRANSL2ND	a1, a2, a3	Translate by distance a3. The direction is defined by a vector going from node with ID a1 to node with ID a2. The two nodes must be defined before they are referenced. If a3 is set to zero, then the distance between nodes a1 and a2 is used directly for the translation. Only 1 TRANSL2ND option is permitted within a *DEFINE_TRANSFORMATION definition.

Table 17-58. List of allowed transformations.

Each option represents a transformation matrix. When more than one option is used, the transformation matrix defined by MIRROR, SCALE, ROTATE, ROTATE3NA, TRANSL, or TRANSL2ND is applied to the previously defined existing matrix to form the new global transformation matrix. Therefore the ordering of the MIRROR, SCALE, ROTATE, ROTATE3NA, TRANSL, and TRANSL2ND commands is important. We generally recommend first scaling, then rotating, and finally translating the model. When used together with *INCLUDE_TRANSFORM, we advise defining the 6 nodes referred to by POS6N and the *DEFINE_TRANSFORMATION in the same file.

The POINT option in ROTATE provides a means of defining rotations about axes defined by the previous transformations. The coordinates of the two POINTs are transformed by all the transformations up to the transformation where they are referenced. The POINTs must be defined before they are referenced, and their identification numbers are local to each *DEFINE_TRANSFORMATION. The coordinates of a POINT are transformed using all the transformations before it is referenced, not just the transformations between its definition and its reference. To put it another way, while the ordering of the transformations is important, the ordering between the POINTs and the transformations is not important.

> **NOTE:** When *DEFINE_TRANSFORMATION is called from within the target of an *INCLUDE_TRANSFORM keyword, the result will involve stacked transformations.

In the following example, the *DEFINE_TRANSFORMATION command is used 3 times to input the same dummy model and position it as follows:

1. Transformation ID 1000 imports the dummy model (dummy.k) and rotates it 45 degrees about z-axis at the point (0.0,0.0,0.0). Transformation ID 1001 performs the same transformation using the POINT option.

2. Transformation ID 2000 imports the same dummy model (dummy.k) and translates 1000 units in the x direction.

3. Transformation ID 3000 imports the same dummy model (dummy.k) and translates 2000 units in the x direction. For each *DEFINE_TRANSFORMATION, the commands TRANSL, SCALE, and ROTATE are available. The transformations are applied in the order in which they are defined in the file. For instance, transformation ID 1000 in this example would translate, scale and then rotate the model. *INCLUDE_TRANSFORM uses a transformation ID defined by a *DEFINE_TRANSFORMATION command to import a model and perform the associated transformations. It also allows the user upon importing the model to apply offsets to the various entity IDs and perform unit conversion of the imported model.

```

*DEFINE_TRIM_SEED_POINT_COORDINATES

Purpose: The keyword facilitates blank trimming during a stamping line die simulation. It allows for the trimming process and inputs to be defined independent of the previous process simulation results and is applicable to shell, solid and laminate.

Card 1	1	2	3	4	5	6	7	8
Variable	NSEED	X1	Y1	Z1	X2	Y2	Z2	
Type	I	F	F	F	F	F	F	
Default	none	0.0	0.0	0.0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
NSEED	Number of seed points. Maximum value of "2" is allowed.
X1, Y1, Z1	Location coordinates of seed point 1.
X2, Y2, Z2	Location coordinates of seed point 2.

Remarks:

1. **Associated Keywords.** This keyword is used in conjunction with keywords *ELEMENT_TRIM and *DEFINE_CURVE_TRIM, where variables NSEED1 and NSEED2 should be left as blank. For detailed usage, refer to **Seed Node Definition** section in *DEFINE_CURVE_TRIM.

2. **Number of Seed Points.** Variable NSEED is set to the number of seed points desired. For example, in a double attached drawn panel trimming, NSEED would equal to 2.

3. **Example Input Deck.** A partial keyword inputs for a single drawn panel trimming is listed below.

```
*INCLUDE_TRIM
drawn.dynain
*ELEMENT_TRIM         1
*DEFINE_CURVE_TRIM_NEW
$#    TCID    TCTYPE      TFLG      TDIR     TCTOL      TOLN     NSEED
         1         2                11     0.250
trimlines.iges
*DEFINE_TRIM_SEED_POINT_COORDINATES
$    NSEED        X1        Y1         Z1        X2        Y2        Z2
         1    -271.4     89.13   1125.679
*DEFINE_VECTOR
```

```
11,0.0,0.0,0.0,0.0,0.0,10.0
```

Typically, seed point coordinates can be selected from the stationary post in punch home position.

4. **Revision Information.** This feature is available in LS-DYNA R4 Revision 53048 and later releases.

*DEFINE_VECTOR

Purpose: Define a vector by defining the coordinates of two points.

Card	1	2	3	4	5	6	7	8
Variable	VID	XT	YT	ZT	XH	YH	ZH	CID
Type	I	F	F	F	F	F	F	I
Default	0	0.0	0.0	0.0	0.0	0.0	0.0	global

VARIABLE	DESCRIPTION
VID	Vector ID
XT	*X*-coordinate of tail of vector
YT	*Y*-coordinate of tail of vector
ZT	*Z*-coordinate of tail of vector
XH	*X*-coordinate of head of vector
YH	*Y*-coordinate of head of vector
ZH	*Z*-coordinate of head of vector
CID	Coordinate system ID to define vector in local coordinate system. All coordinates, XT, YT, ZT, XH, YH, and ZH are in respect to CID. EQ.0: global (default).

Remarks:

1. **Numerical Inaccuracies.** The coordinates should differ by a certain margin to avoid numerical inaccuracies.

*DEFINE_VECTOR_NODES

Purpose: Define a vector with two nodal points.

Card	1	2	3	4	5	6	7	8
Variable	VID	NODET	NODEH					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
VID	Vector ID
NODET	Nodal point to define tail of vector
NODEH	Nodal point to define head of vector

EXAMPLES

The following examples demonstrate the input for these options:

*DEFINE_BOX

*DEFINE_COORDINATE_NODES,

*DEFINE_COORDINATE_SYSTEM,

*DEFINE_COORDINATE_VECTOR

*DEFINE_CURVE

*DEFINE_SD_ORIENTATION

*DEFINE_VECTOR commands.

*DEFORMABLE_TO_RIGID

The cards in this section are defined in alphabetical order and are as follows:

*DEFORMABLE_TO_RIGID

*DEFORMABLE_TO_RIGID_AUTOMATIC

*DEFORMABLE_TO_RIGID_INERTIA

If one of these cards is defined, then any deformable part defined in the model may be switched to rigid during the calculation. Parts that are defined as rigid (*MAT_RIGID) in the input are permanently rigid and cannot be changed to deformable.

Deformable parts may be switched to rigid at the start of the calculation by specifying them on the *DEFORMABLE_TO_RIGID card.

Part switching may be specified on a restart (see RESTART section of this manual) or it may be performed automatically by use of the *DEFORMABLE_TO_RIGID_AUTOMATIC cards.

The *DEFORMABLE_TO_RIGID_INERTIA cards allow inertial properties to be defined for deformable parts that are to be swapped to rigid at a later stage.

It is not possible to perform part material switching on a restart if it was not flagged in the initial analysis. The reason for this is that extra memory needs to be set up internally to allow the switching to take place. If part switching is to take place on a restart, but no parts are to be switched at the start of the calculation, no inertia properties for switching and no automatic switching sets are to be defined, then just define one *DEFORMABLE_TO_RIGID card without further input.

*DEFORMABLE_TO_RIGID

Purpose: Define parts for which the material will be switched to rigid at the start of the calculation.

Card	1	2	3	4	5	6	7	8
Variable	PID	LRB	PTYPE					
Type	I	I	A					
Default	none	0	PART					

VARIABLE	DESCRIPTION
PID	Part ID for the part that will be switched to a rigid material; also see *PART.
LRB	Part ID of the lead rigid body to which the part is merged. If zero, the part becomes either an independent or lead rigid body.
PTYPE	Type of PID: EQ."PART": PID is a part ID. EQ."PSET": PID is a part set ID. All parts included in part set PID will be switched to rigid at the start of the calculation.

*DEFORMABLE_TO_RIGID_AUTOMATIC

Purpose: Define a set of parts to be switched to rigid or to deformable at some stage during the calculation.

Card Summary:

Card 1. This card is required

SWSET	CODE	TIME1	TIME2	TIME3	ENTNO	RELSW	PAIRED

Card 2. This card is required.

NRBF	NCSF	RWF	DTMAX	D2R	R2D	OFFSET	

Card 3. Include D2R of this card.

PID	LRB	PTYPE					

Card 4. Include R2D of this card.

PID	PTYPE						

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	SWSET	CODE	TIME1	TIME2	TIME3	ENTNO	RELSW	PAIRED
Type	I	I	F	F	F	I	I	I
Default	none	0	0.	10^{20}	0.	0.	0	0
Remark		1				1, 2		3

VARIABLE	DESCRIPTION
SWSET	Set number for this automatic switch set. Must be unique.
CODE	Activation switch code. Defines the test to activate the automatic material switch of the part: EQ.0: Switch takes place at time 1.

VARIABLE	DESCRIPTION
	EQ.1: Switch takes place between time 1 and time 2 if rigid wall force (specified below) is zero. EQ.2: Switch takes place between time 1 and time 2 if contact surface force (specified below) is zero. EQ.3: Switch takes place between time 1 and time 2 if rigid wall force (specified below) is nonzero. EQ.4: Switch takes place between time 1 and time 2 if contact surface force (specified below) is nonzero. EQ.5: Switch is controlled by *SENSOR_CONTROL with TYPE = DEF2RIG; see *SENSOR_CONTROL. When CODE = 5, inputs of column 3 to column 8, TIME1 to PAIRED, are ignored.
TIME1	Switch will not take place before this time
TIME2	Switch will not take place after this time: EQ.0.0: Time 2 set to 10^{20}
TIME3	Delay period. After this part switch has taken place, another automatic switch will not take place for the duration of the delay period. If set to zero, a part switch may take place immediately after this switch.
ENTNO	Rigid wall / contact surface number for switch codes 1, 2, 3, 4
RELSW	Related switch set. The related switch set is another automatic switch set paired to this one so the switches can be activated more than once. EQ.0: No related switch set
PAIRED	Specify how the related switch sets are paired (if there are paired switches): EQ.0: SWSET is not paired to another switch set. EQ.1: SWSET is paired with switch set RELSW and is the first switch set to be activated. EQ.-1: SWSET is paired with switch set RELSW and is the second switch to be activated.

Card 2	1	2	3	4	5	6	7	8
Variable	NRBF	NCSF	RWF	DTMAX	D2R	R2D	OFFSET	
Type	I	I	I	F	I	I	F	
Default	0	0	0	0.	0	0	0.	
Remark	4	4	4					

VARIABLE	DESCRIPTION
NRBF	Nodal rigid body flag. For all values of NRBF, nodal rigid bodies defined using *CONSTRAINED_NODAL_RIGID_BODY and *CONSTRAINED_GENERALIZED_WELD_OPTION, which share any nodes with a rigid body created by deformable-to-rigid switching, are merged with the latter to form a single rigid body. Other actions dependent upon the value of NRBF are: EQ.0: No further action EQ.1: Delete all remaining nodal rigid bodies, that is, delete those nodal rigid bodies that do not share any nodes with a rigid body created by deformable-to-rigid switching. EQ.2: Activate nodal rigid bodies.
NCSF	Nodal constraint set flag. If nodal constraint / spot weld definitions are active in the deformable bodies that are switched to rigid, then the definitions should be deleted to avoid instabilities. EQ.0: No change EQ.1: Delete EQ.2: Activate
RWF	Flag to delete or activate rigid walls: EQ.0: No change EQ.1: Delete EQ.2: Activate
DTMAX	Maximum permitted time step size after switch

VARIABLE	DESCRIPTION
D2R	Number of deformable parts to be switched to rigid plus number of rigid parts for which new merged (lead/constrained) rigid body combinations will be defined. EQ.0: No parts defined
R2D	Number of rigid parts to be switched to deformable. EQ.0: No parts defined
OFFSET	Optional contact thickness for switch to deformable. For contact, its value should be set to a value greater than the contact thickness offsets to ensure the switching occurs prior to impact. This option applies if and only if CODE is set to 3 or 4. For CODE = 3 all rigid wall options are implemented. For CODE = 4, the implementation works for the contact type CONTACT_AUTOMATIC when the options: ONE_WAY_SURFACE_TO_SURFACE, NODES_TO_-SURFACE, and SURFACE_TO_SURFACE are invoked.

Deformable to Rigid Cards. D2R additional cards with one for each part.

Card 3	1	2	3	4	5	6	7	8
Variable	PID	LRB	PTYPE					
Type	I	I	A					
Default	none	0	PART					

VARIABLE	DESCRIPTION
PID	Part ID of the part which is switched to a rigid material. When PID is merged to another rigid body by the LRB field, this part is allowed to be rigid before the switch.
LRB	Part ID of the lead rigid body to which part PID is merged. If zero, part PID becomes either an independent or lead rigid body.
PTYPE	Type of PID: EQ.PART: PID is a part ID. EQ.PSET: PID is a part set ID.

Rigid to Deformable Cards. R2D additional cards with one for each part.

Card 4	1	2	3	4	5	6	7	8
Variable	PID	PTYPE						
Type	I	A						
Default	none	PART						

VARIABLE	DESCRIPTION
PID	Part ID of the part which is switched to a deformable material
PTYPE	Type of PID: EQ.PART: PID is a part ID. EQ.PSET: PID is a part set ID.

Remarks:

1. **Allowed Contact Types.** Only surface to surface and node to surface contacts can be used to activate an automatic part switch.

2. **Rigid Wall Numbering.** Rigid wall numbers are the order in which they are defined in the deck. The first rigid wall and the first contact surface encountered in the input deck will have an entity number of 1. The contact surface ID is that as defined on the *CONTACT_…_ID card.

3. **Paired Switches.** Switch sets may be paired together to allow a pair of switches to be activated more than once. Each pair of switches should use consistent values for CODE, meaning 1 & 3 or 2 & 4. Within each pair of switches, the related switch, RELSW, should be set to the ID of the other switch in the pair. The first switch (PAIRED = 1) will be activated before the second switch (PAIRED = -1). Pairing allows multiple switches to take place as for example when contact is made and lost several times during an analysis.

```
$  Define a pair of related switches that will be activated by force/no force on
$  Contact 3.  To start with, switch set 20 will be activated (PAIRED = 1),
$  swapping the PARTS to RIGID. When the contact force is non-zero, switch set
$  10 will be activated, swapping the PARTS to DEFORMABLE.  If the contact force
$  returns to zero, switch set 20 will be activated again, making the PARTS
$  RIGID.

```

4. **Delete Switch.** If the delete switch is activated, *all* corresponding constraints are deactivated regardless of their relationship to a switched part. By default, constraints which are directly associated with a switched part are deactivated/activated as necessary.

*DEFORMABLE_TO_RIGID_INERTIA

Purpose: Inertial properties can be defined for the new rigid bodies that are created when the deformable parts are switched. These can only be defined in the initial input if they are needed in a later restart. Unless these properties are defined, LS-DYNA will recompute the new rigid body properties from the finite element mesh. The latter requires an accurate mesh description. *When rigid bodies are merged to a lead rigid body, the inertial properties specified for the lead rigid body apply to all members of the merged set.*

Card 1	1	2	3	4	5	6	7	8
Variable	PID

*ELEMENT

The element cards in this section are defined in alphabetical order:

*ELEMENT_BEAM

*ELEMENT_BEAM_PULLEY

*ELEMENT_BEAM_SOURCE

*ELEMENT_BEARING

*ELEMENT_BLANKING

*ELEMENT_DIRECT_MATRIX_INPUT

*ELEMENT_DISCRETE

*ELEMENT_DISCRETE_SPHERE

*ELEMENT_GENERALIZED_SHELL

*ELEMENT_GENERALIZED_SOLID

*ELEMENT_INERTIA

*ELEMENT_INTERPOLATION_SHELL

*ELEMENT_INTERPOLATION_SOLID

*ELEMENT_LANCING

*ELEMENT_MASS

*ELEMENT_MASS_MATRIX

*ELEMENT_MASS_PART

*ELEMENT_PLOTEL

*ELEMENT_SEATBELT

*ELEMENT_SEATBELT_ACCELEROMETER

*ELEMENT_SEATBELT_PRETENSIONER

*ELEMENT_SEATBELT_RETRACTOR

*ELEMENT_SEATBELT_SENSOR

*ELEMENT_SEATBELT_SLIPRING

*ELEMENT_SHELL

*ELEMENT_SHELL_NURBS_PATCH

*ELEMENT_SHELL_SOURCE_SINK

*ELEMENT_SOLID

*ELEMENT_SOLID_NURBS_PATCH

*ELEMENT_SOLID_PERI

*ELEMENT_SPH

*ELEMENT_TRIM

*ELEMENT_TSHELL

The ordering of the element cards in the input file is completely arbitrary. An arbitrary number of element blocks can be defined preceded by a keyword control card.

***ELEMENT_BEAM**_{OPTION}_{OPTION}

Available options include:

<BLANK>

THICKNESS, SCALAR, SCALR or SECTION

PID

OFFSET

ORIENTATION

WARPAGE

ELBOW (*beta*)

Purpose: Define two node elements including 3D beams, trusses, 2D axisymmetric shells, and 2D plane strain beam elements. The type of the element and its formulation is specified through the part ID (see *PART) and the section ID (see *SECTION_BEAM).

Two alternative methods are available for defining the cross sectional property data. The THICKNESS and SECTION options are provided for the user to override the *SECTION_BEAM data which is taken as the default if the THICKNESS or SECTION option is not used. The SECTION option applies only to resultant beams (ELFORM = 2 on *SECTION_BEAM). End release conditions are imposed using constraint equations, and caution must be used with this option as discussed in Remark 2.

The SCALAR and SCALR options apply only to material model type 146, *MAT_1DOF_GENERALIZED_SPRING.

The PID option is used by the type 9 spot weld element only and is ignored for all other beam types. When the PID option is active, you provide two part IDs that are tied by the spot weld element in an additional card. If the PID option is inactive for the type 9 element, the nodal points of the spot weld are located to the two nearest reference surface segments. In either case, *CONTACT_SPOTWELD must be defined with the spot weld beam part as the tracked surface and the shell parts (including parts PID1 and PID2) as the reference surface. The surface of each segment should project to the other and in the most typical case the node defining the weld, assuming only one node is used, should lie in the middle; however, this is not a requirement. Note that with the spot weld elements only one node is needed to define the weld, and two nodes are optional.

The OFFSET option is not available for discrete beam elements or spotweld beam elements. Neither the OFFSET option nor the ORIENTATION option is available for truss elements or 2D beam element forms 7 or 8.

The ELBOW option is a 3-node beam element with quadratic interpolation that is tailored for the piping industry. It includes 12 degrees of freedom, including 6 ovalization degrees of freedom for describing the ovalization, per node. That is a total of 36 DOFs for each element. An internal pressure can also be given that tries to stiffen the pipe. The pressure, if activated accordingly, can also contribute to the elongation of the pipe. The control node must be given, but it is only used for initially straight elbow elements. For curved elements the curvature center is used as the control node. See *SECTION_BEAM for more information about the physical properties such as pressure and output options.

Card Summary:

Card 1. This card is required,

EID	PID	N1	N2	N3	RT1	RR1	RT2	RR2	LOCAL

Card 2. This card is included if the THICKNESS keyword option is used.

PARM1	PARM2	PARM3	PARM4	PARM5

Card 3. This card is included if the SECTION keyword option is used.

STYPE	D1	D2	D3	D4	D5	D6	

Card 4. This card is included if the SCALAR keyword option is used.

VOL	INER	CID	DOFN1	DOFN2

Card 5. This card is included if the SCALR keyword option is used.

VOL	INER	CID1	CID2	DOFNS

Card 6. This card is included if the PID keyword option is used.

PID1	PID2								

Card 7. This card is included if the OFFSET keyword option is used.

WX1	WY1	WZ1	WX2	WY2	WZ2		

Card 8. This card is included if the ORIENTATION keyword option is used.

VX	VY	VZ					

Card 9. This card is included if the WARPAGE keyword option is used.

SN1	SN2						

Card 10. This card is included if the ELBOW keyword option is used.

MN							

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	EID	PID	N1	N2	N3	RT1	RR1	RT2	RR2	LOCAL
Type	I	I	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	0	0	0	0	2
Remarks					1	2	2	2	2	

VARIABLE	DESCRIPTION
EID	Element ID. A unique ID is generally required, that is, EID must be different from the element IDs also defined under *ELEMENT_DISCRETE and *ELEMENT_SEATBELT. If the field BEAM is set to 1 on the keyword input for *DATABASE_BINARY_D3PLOT, the null beams used for visualization are not created for the latter two types, and the IDs used for the discrete elements and the seatbelt elements can be identical to those defined here.
PID	Part ID; see *PART.
N1	Nodal point (end) 1
N2	Nodal point (end) 2. This node is optional for the spot weld, beam type 9, since if it not defined it will be created automatically and given a non-conflicting nodal point ID. Nodes N1 and N2 are automatically positioned for the spot weld beam element. For the zero length discrete beam elements where one end is attached to ground, set N2 = -N1. For this case, a fully constrained nodal point will be created with a unique ID for node N2.

VARIABLE	DESCRIPTION
N3	Nodal point 3 for orientation. The third node, N3, is optional for beam types 3, 6, 7, and 8; if the cross-section is circular, it is optional for beam types 1 and 9. The third node is used for the discrete beam, type 6, if and only if SCOOR is set to 2.0 in the *SECTION_BEAM input, but even in this case it is optional. An orientation vector can be defined directly by using the option, ORIENTATION. For this case N3 can be defined as zero.
RT1, RT2	Release conditions for translations at nodes N1 and N2, respectively: EQ.0: No translational degrees-of-freedom are released. EQ.1: x-translational degree-of-freedom EQ.2: y-translational degree-of-freedom EQ.3: z-translational degree-of-freedom EQ.4: x and y-translational degrees-of-freedom EQ.5: y and z-translational degrees-of-freedom EQ.6: z and x-translational degrees-of-freedom EQ.7: x, y, and z-translational degrees-of-freedom (3DOF) This option does not apply to the spot weld, beam type 9.
RR1, RR2	Release conditions for rotations at nodes N1 and N2, respectively: EQ.0: No rotational degrees-of-freedom are released. EQ.1: x-rotational degree-of-freedom EQ.2: y-rotational degree-of-freedom EQ.3: z-rotational degree-of-freedom EQ.4: x and y-rotational degrees-of-freedom EQ.5: y and z-rotational degrees-of-freedom EQ.6: z and x-rotational degrees-of-freedom EQ.7: x, y, and z-rotational degrees-of-freedom (3DOF) This option does not apply to the spot weld, beam type 9.
LOCAL	Coordinate system option for release conditions: EQ.1: Global coordinate system EQ.2: Local coordinate system (default)

Thickness Card. Additional card required for THICKNESS keyword option.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	PARM1		PARM2		PARM3		PARM4		PARM5

EQ.SECTION_22: Hat-Shape 2

D1-D6	Input parameters for section option using STYPE above.

Scalar card. Additional card for SCALAR keyword option.

Card 4	1	2	3	4	5	6	7	8	9	10
Variable	VOL		INER		CID		DOFN1		DOFN2	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
VOL	Volume of discrete beam and scalar (MAT_146) beam. If the mass density of the material model for the discrete beam is set to unity, the magnitude of the lumped mass can be defined here instead. This lumped mass is partitioned to the two nodes of the beam element. The translational time step size for the type 6 beam is dependent on the volume, mass density, and the translational stiffness values, so it is important to define this parameter. Defining the volume is also essential for mass scaling if the type 6 beam controls the time step size.
INER	Mass moment of inertia for the six degree of freedom discrete beam and scalar (MAT_146) beam. This lumped inertia is partitioned to the two nodes of the beam element. The rotational time step size for the type 6 beam is dependent on the lumped inertia and the rotational stiffness values, so it is important to define this parameter if the rotational springs are active. Defining the rotational inertia is also essential for mass scaling if the type 6 beam rotational stiffness controls the time step size.
CID	Coordinate system ID for orientation, material type 146; see *DEFINE_COORDINATE_SYSTEM. If CID = 0, a default coordinate system is defined in the global system.
DOFN1	Active degree-of-freedom at node 1, a number between 1 to 6 where 1, 2, and 3 are the x, y, and z-translations and 4, 5, and 6 are the x, y, and z-rotations. This degree-of-freedom acts in the local system given by CID above. This input applies to material model type 146.
DOFN2	Active degree-of-freedom at node 2, a number between 1 to 6 as described in DOF1 above. This degree-of-freedom acts in the local system given by CID above. This input applies to material model type 146.

Scalar Card (alternative). Additional card for SCALR keyword option.

Card 5	1	2	3	4	5	6	7	8	9	10
Variable	VOL		INER		CID1		CID2		DOFNS	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
VOL	Volume of discrete beam and scalar (MAT_146) beam. If the mass density of the material model for the discrete beam is set to unity, the magnitude of the lumped mass can be defined here instead. This lumped mass is partitioned to the two nodes of the beam element. The translational time step size for the type 6 beam is dependent on the volume, mass density, and the translational stiffness values, so it is important to define this parameter. Defining the volume is also essential for mass scaling if the type 6 beam controls the time step size.
INER	Mass moment of inertia for the six degree of freedom discrete beam and scalar (MAT_146) beam. This lumped inertia is partitioned to the two nodes of the beam element. The rotational time step size for the type 6 beam is dependent on the lumped inertia and the rotational stiffness values, so it is important to define this parameter if the rotational springs are active. Defining the rotational inertia is also essential for mass scaling if the type 6 beam rotational stiffness controls the time step size.
CID1	Coordinate system ID at node 1 for orientation for material type 146; see *DEFINE_COORDINATE_SYSTEM. If CID1 = 0, a default coordinate system is defined in the global system.
CID2	Coordinate system ID at node 2 for orientation for material type 146; see *DEFINE_COORDINATE_SYSTEM. If CID2 = 0, a default coordinate system is defined in the global system.
DOFNS	Active degrees-of-freedom at node 1 and node 2. A two-digit number, the first for node 1 and the second for node 2, between 11 and 66 is expected where 1, 2, and 3 are the x, y, and z-translations and 4, 5, and 6 are the x, y, and z-rotations. These degrees-of-freedom acts in the local system given by CID1 and CID2 above. This input applies to material model type 146. For example, if DOFNS = 12, node 1 has an x-translation and node 2 has a y-translation.

Spot Weld Part Card. Additional card for PID keyword option.

Card 6	1	2	3	4	5	6	7	8	9	10
Variable	PID1	PID2								
Type	I	I								

VARIABLE	DESCRIPTION
PID1	Optional part ID for spot weld element type 9
PID2	Optional part ID for spot weld element type 9

Offset Card. Additional card for OFFSET keyword option.

Card 7	1	2	3	4	5	6	7	8
Variable	WX1	WY1	WZ1	WX2	WY2	WZ2		
Type	F	F	F	F	F	F		
Default	0.0	0.0	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
WX1 - WZ1	Offset vector at nodal point N1. See Remark 7.
WX2 - WZ2	Offset vector at nodal point N2. See Remark 7.

Orientation Card. Additional card for ORIENTATION keyword option.

Card 8	1	2	3	4	5	6	7	8
Variable	VX	VY	VZ					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
VX, VY, VZ	Coordinates of an orientation vector relative to node N1. In this case, the orientation vector points to a virtual third node, so the field N3 should be left undefined.

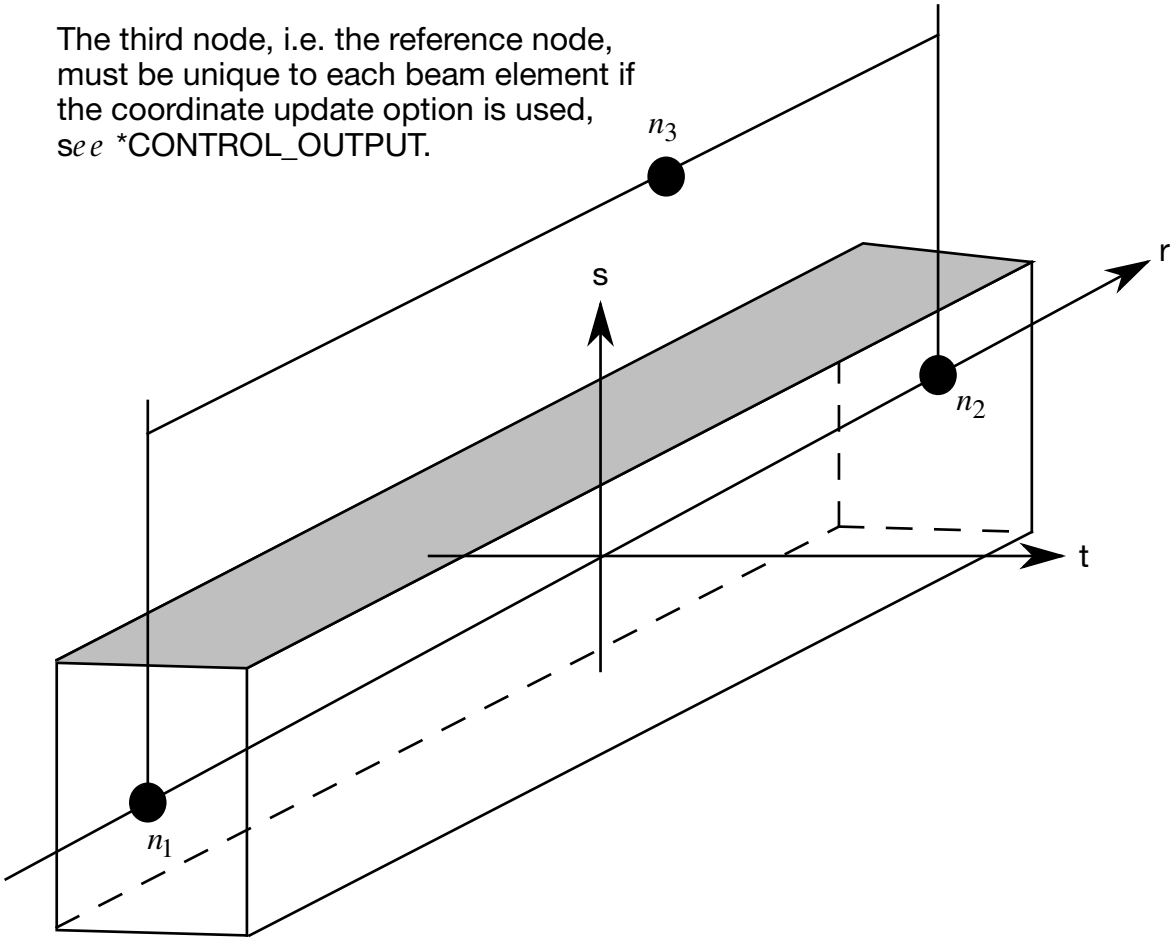

Figure 19-1. LS-DYNA beam elements. Node n_3 determines the initial orientation of the cross section.

Warpage Card. Additional card for WARPAGE keyword option.

Card 9	1	2	3	4	5	6	7	8
Variable	SN1	SN2						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
SN1	Scalar nodal point (end) 1. This node is required.
SN2	Scalar nodal point (end) 2. This node is required.

Elbow Card. Additional card for ELBOW keyword option.

Card 10	1	2	3	4	5	6	7	8
Variable	MN							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
MN	Middle node for the ELBOW element. See Remark 8.

Remarks:

1. **Beam Orientation.** A plane through N_1, N_2, and N_3 defines the orientation of the principal *r-s* plane of the beam; see Figure 19-1.

2. **Release Conditions.** The option to specify release conditions applies to all three-dimensional beam elements. The released degrees-of-freedom can be either global, or local relative to the local beam coordinate system as shown in Figure 19-1. A local coordinate system is stored for each node of the beam element and the orientation of the local coordinate systems rotates with the node. To properly track the response, the nodal points with a released resultant are automatically replaced with new nodes to accommodate the added degrees-of-freedom. Then constraint equations are used to join the nodal points together with the proper release conditions imposed.

   > Nodal points which belong to beam elements that have release conditions applied cannot be subjected to other constraints, such as applied displacement/velocity/acceleration boundary conditions, nodal rigid bodies, nodal constraint sets, or any of the constraint type contact definitions.

   Force type loading conditions and penalty based contact algorithms may be used with this option.

   Please note that specification of translational release conditions may lead to non-physical constraints, but this should not be a problem if the displacements are infinitesimal.

3. **Beam Properties.** If the THICKNESS option is not used, or if THICKNESS is used but essential PARMx values are not provided, beam properties are taken from *SECTION_BEAM.

4. **Discrete Beam Elements.** In the case of the THICKNESS option for type 6, discrete beam elements, PARM1 through PARM5 replace the first five fields on Card 2 of *SECTION_BEAM. Cables are a subset of type 6 beams. PARM1 is for non-cable discrete beams and is optional for cables, PARM2 and PARM3 apply only to non-cable discrete beams, and PARM4 and PARM5 apply only to cables.

5. **PARM5.** In the THICKNESS option, PARM5 applies only to beam types 2, 6 (cables only), and 9.

6. **Stress Resultants.** The stress resultants are output in local coordinate system for the beam. Stress information is optional and is also output in the local system for the beam.

7. **Offsets.** Beam offsets are sometimes necessary for correctly modeling beams that act compositely with other elements such as shells or other beams. When the OFFSET option is specified, global X, Y, and Z components of two offset vectors are given, one vector for each of the two beam nodes. The offset vector extends from the beam node (N1 or N2) to the reference axis of the beam. The beam reference axis lies at the origin of the local s and t-axes. For beam formulations 1 and 11, this origin is halfway between the outermost surfaces of the beam cross-section. Note that for cross-sections that are not doubly symmetric, such as a T-section, the reference axis does not pass through the centroid of the cross-section. For beam formulation 2, the origin is at the centroid of the cross-section.

8. **Elbow.** The Elbow beam is defined with 4 nodes; see Figure 19-2. Nodes n_1 and n_2 are the end nodes, and node n_3 is the middle node. It is custom to set n_3 at the midpoint of the beam. Node n_4 is an orientation node that should be at the curvature center of the beam. If a straight beam is defined initially, the orientation node must be defined and should be on the convex side of the beam. If a curved beam is defined initially, the orientation node is automatically calculated as the center of the beam curvature. However, an orientation node is still required at the input.

The extra nodes that include the ovalization degree of freedom are written to the messag file during initialization. These extra nodes have 3 DOFs each. That means that there are 2 extra nodes for each physical node. For example, it can look something like this:

```
ELBOW BEAM:            1
n1-n3-n2:              1      3      2
ovalization nodes:     5      7      6
                       8     10      9
```

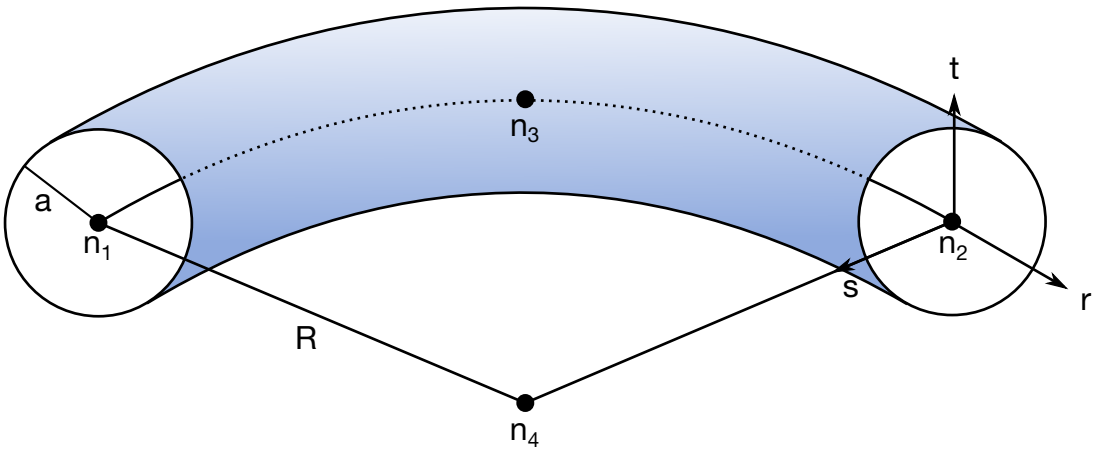

Figure 19-2. LS-DYNA Elbow element. Node n_4 is the control node and is given as the beam center of curvature.

And it means that node 1 has the ovalization extra nodes 5 and 8. The first line of ovalization nodes includes the c_1, c_2 and c_3 parameters, and the second line includes the d_1, d_2 and d_3 parameters. That means that node 5 includes c_1, c_2 and c_3, and node 8 includes d_1, d_2 and d_3 for beam node 1. All ovalization dofs can be written to the ASCII file "elbwov" if the correct print flag IOVPR is set to 1 on *SECTION_BEAM. These extra nodes can be constrained as usual nodes. For example, for a cantilever beam that is mounted at node 1, the nodes 1, 5 and 8 should be constrained. The ovalization is approximated with the following trigonometric function:

$$w(r,\theta) = \sum_{k=1}^{3} \sum_{m=1}^{3} h_k(r)\left(c_m^k \cos 2m\theta + d_m^k \sin 2m\theta\right), \qquad -1 \le r \le 1, 0 \le \theta < 2\pi$$

where h_k is the interpolation function at the physical node k.

The Elbow beam only supports tubular cross sections and the pipe outer radius, a, should be smaller than the pipe bend radius, R. That is $a/R \ll 1$. Moreover, the ELBOW beams have 4 stresses: axial *rr*-, shear *rs*-, shear *rt*- and loop-stresses. The loop stress is written at each integration point and can be visualized in LS-PrePost with the user fringe plot file "elbwlp.k". NOTE that the loop-stress is not written to d3plot as default! The NEIPB flag on *DATABASE_EXTENT_BINARY must be set to enable d3plot support.

Right now there is only basic support from the material library. The following materials are currently supported for the ELBOW beam (if requested more materials might be added in the future):

*MAT_ELASTIC (MAT_001)

*MAT_PLASTIC_KINEMATIC (MAT_003)

*MAT_ELASTIC_PLASTIC_THERMAL (MAT_004)

*MAT_VISCOELASTIC (MAT_006)

*MAT_PIECEWISE_LINEAR_PLASTICITY (MAT_024)

*MAT_DAMAGE_3 (MAT_153, explicit only)

*MAT_CONCRETE_BEAM (MAT_195)

*ELEMENT_BEAM_PULLEY

Purpose: Define pulley for beam elements. This feature is implemented for truss beam elements (*SECTION_BEAM, ELFORM = 3) using materials *MAT_001 and *MAT_156 or discrete beam elements (ELFORM = 6) using *MAT_CABLE_DISCRETE_BEAM.

Card 1	1	2	3	4	5	6	7	8
Variable	PUID	BID1	BID2	PNID	FD	FS	LMIN	DC
Type	I	I	I	I	F	F	F	F
Default	none	0	0	0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
PUID	Pulley ID. A unique number has to be used.
BID1	Truss beam element 1 ID.
BID2	Truss beam element 2 ID.
PNID	Pulley node, NID.
FD	Coulomb dynamic friction coefficient.
FS	Optional Coulomb static friction coefficient.
LMIN	Minimum length, see notes below.
DC	Optional decay constant to allow smooth transition between the static and dynamic friction coefficient, i.e., $\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\times\lvert v_{\text{rel}}\rvert}$

Remarks:

Elements 1 and 2 should share a node which is coincident with the pulley node. The pulley node should not be on any beam elements.

Pulleys allow continuous sliding of a truss beam element through a sharp change of angle. Two elements (1 & 2 in Figure 19-23 of *ELEMENT_SEATBELT_SLIPRING) meet at the pulley. Node *B* in the beam material remains attached to the pulley node, but beam material (in the form of unstretched length) is passed from element 1 to element 2 to

achieve slip. The amount of slip at each time step is calculated from the ratio of forces in elements 1 and 2. The ratio of forces is determined by the relative angle between elements 1 and 2 and the coefficient of friction, FD. The tension in the beams are taken as T_1 and T_2, where T_2 is on the high tension side and T_1 is the force on the low tension side. Thus, if T_2 is sufficiently close to T_1, no slip occurs; otherwise, slip is just sufficient to reduce the ratio T_2/T_1 to $e^{FC\times\theta}$, where θ is the wrap angle; see Figures 19-24 of *ELEMENT_SEATBELT_SLIPRING. The out-of-balance force at node B is reacted on the pulley node; the motion of node B follows that of pulley node.

If, due to slip through the pulley, the unstretched length of an element becomes less than the minimum length LMIN, the beam is remeshed locally: the short element passes through the pulley and reappears on the other side (see Figure 19-23). The new unstretched length of e_1 is 1.1 × minimum length. The force and strain in e_2 and e_3 are unchanged; while the force and strain in e_1 are now equal to those in e_2. Subsequent slip will pass material from e_3 to e_1. This process can continue with several elements passing in turn through the pulley.

To define a pulley, the user identifies the two beam elements which meet at the pulley, the friction coefficient, and the pulley node. If BID1 and BID2 are defined as 0 (zero), adjacent beam elements are automatically detected. The two elements must have a common node coincident with the pulley node. No attempt should be made to restrain or constrain the common node for its motion will automatically be constrained to follow the pulley node. Typically, the pulley node is part of a structure and, therefore, beam elements should not be connected to this node directly, but any other feature can be attached, including rigid bodies.

*DATABASE_PLLYOUT can be used to write a time history output database pllyout for the pulley which records beam IDs, slip, slip rate, resultant force, and wrap angle.

*ELEMENT_BEAM_SOURCE

Purpose: Define a nodal source for beam elements. This feature is implemented *only* for truss beam elements (*SECTION_BEAM, ELFORM = 3) with material *MAT_001, for discrete beam elements (ELFORM = 6) with material *MAT_071 or for Belytschko-Schwer resultant beam elements (ELFORM = 2) using material *MAT_001 or *MAT_028.

Card 1	1	2	3	4	5	6	7	8
Variable	BSID	BSNID	BSEID	NELE	LFED	FPULL	LMIN	
Type	I	I	I	I	F	F	F	
Default	none	none	none	0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
BSID	Beam Source ID. A unique number has to be used.
BSNID	Source node ID.
BSEID	Source element ID.
NELE	Number of elements to be pulled out.
LFED	Beam element fed length (typical element initial length).
FPULL	Pull-out force. GT.0: Constant value, LT.0: Load curve ID = |FPULL| which defines pull-out force as a function of time. Either *DEFINE_FUNCTION or *DEFINE_ CURVE_FUNCTION (with argument TIME) can be used.
LMIN	Minimum beam element length, see notes below. One to two tenth of the fed length LFED is usually a good choice.

Remarks:

The source node BSNID can be defined by itself or it can be part of another structure. It is free to move in space during the simulation process. Initially, the source node should have the same coordinates as one of the source element (BSEID) nodes, but not having

the same ID. If the pre-defined pull-out force FPULL is exceeded in the element next to the source, beam material gets drawn out by increasing the length of the beam without increasing its axial force (equivalent to ideal plastic flow at a given yield force). If more than the pre-defined length LFED is drawn out, a new beam element is generated. A new beam element has an initial undeformed length of 1.1 × LMIN. The maximum number of elements, NELE, times the fed length, LFED, defines the maximum cable length that can be pulled out from the source node.

***ELEMENT_BEARING**_OPTION

The available option is:

TITLE

Purpose: Define a bearing between two nodes. See Carney, Howard, Miller, and Benson [2014] for a description of this model.

Title Card. Additional card for title keyword option.

Title	1	2	3	4	5	6	7	8

Preloading Card.

Card 5	1	2	3	4	5	6	7	8
Variable	IPFLAG	XTRAN	YTRAN	ZTRAN	XROT	YROT		
Type	I	F	F	F	F	F		
Default	00	0.0	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
ID	Bearing ID
ITYPE	Bearing type: EQ.1: Ball bearing EQ.2: Roller bearing
N1	Node on the centerline of the shaft (the shaft rotates)

VARIABLE	DESCRIPTION
CID1	Coordinate system ID orienting the shaft. The local *z*-axis defines the axis of rotation. See Remark 2.
N2	Node on the centerline of the bearing (the bearing does not rotate). It should initially coincide with N1.
CID2	Coordinate system ID orienting the bearing. The local *z*-axis defines the axis of rotation. See Remark 2.
NB	Number of balls or rollers
EBALL	Young's modulus for balls or rollers
PRBALL	Poisson's ratio for balls or rollers
ERACE	Young's modulus for races
PRRACE	Poisson's ratio for races
STRESL	Value of the bearing stress that causes LS-DYNA to print a warning message when it has been reached. If it is 0.0, then no message is printed. See Remark 1.
D	Diameter of balls or rollers
DI	Bore inner diameter
DO	Bore outer diameter
DM	Pitch diameter. If DM is not specified, it is calculated as the average of DI and DO.
A0	Initial contact angle in degrees
BI	Inner groove radius to ball diameter ratio for ball bearings and the roller length for roller bearings
BO	Outer race groove radius to ball diameter ratio. Unused for roller bearings.
PD	Total radial clearance between the ball bearings and races when no load is applied
IPFLAG	Preload flag (see Remark 3): EQ.0: No preload

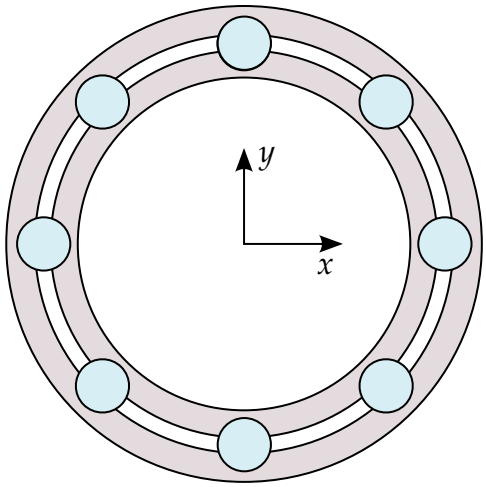

Figure 19-3. Schematic indicating the bearing's local coordinate system determined internally by LS-DYNA. LS-DYNA applies the preload in this coordinate system. The bearing rotates about the local z-axis determined with the right-hand rule.

VARIABLE	DESCRIPTION
	EQ.1: Displacement preload specified
	EQ.2: Force preload specified
XTRAN	Displacement or force preload in the local x-direction (see Remark 3)
YTRAN	Displacement or force preload in the local y-direction (see Remark 3)
ZTRAN	Displacement or force preload in the local z-direction (see Remark 3)
XROT	Angle (in radians) or moment preload in local x-direction (see Remark 3)
YROT	Angle (in radians) or moment preload in local y-direction (see Remark 3)

Remarks:

1. **Exceeding stress limit parameter.** If the bearing stress limit parameter, STRESL, is exceeded, LS-DYNA writes to the messag and d3hsp files. The element's behavior does not change when this value is surpassed.

2. **Local coordinate systems.** The coordinate systems, CID1 and CID2, must initially be aligned. Define these coordinate systems with *DEFINE_COORDINATE_NODES using FLAG = 1 because their orientations need to be updated.

3. **Preload coordinate system.** When LS-DYNA applies the preload, it applies values input on Card 5 exactly in the internally determined local, bearing coordinate system shown in Figure 19-3. In other words, LS-DYNA does not transform the values from the coordinate system into this system. LS-DYNA orients this local coordinate system such that the bearing rotates about the local z-direction and matches the system manufacturers use. Note that this bearing coordinate is not exactly the same as the coordinate system input with CID2. However, it will be very similar to CID2.

4. **Simulation precision.** We strongly suggest using double precision for solution stability.

5. **Bearing damping.** A realistic level of bearing damping (which can be included using *ELEMENT_DISCRETE and *MAT_DAMPER_VISCOUS) may be needed for solution stability.

6. **Bearing forces.** Bearing forces can be output in the brngout file, using *DATABASE_BEARING. This output includes the effects of the preload.

*ELEMENT_BLANKING

Purpose: Define a part set to be used by keyword *DEFINE_FORMING_BLANKMESH to generate a mesh on a sheet blank for metal forming simulations.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PSID	Part set ID. See *SET_PART.

Revisions:

This feature is available in LS-DYNA R5 Revision 59165 or later releases.

***ELEMENT_DIRECT_MATRIX_INPUT**_{OPTION}_

Available options include:

<BLANK>

BINARY

Purpose: Define an element consisting of mass, damping, stiffness, and inertia matrices in a specified file which follows the format used in the direct matrix input, DMIG, of NASTRAN. The supported format is the type 6 symmetric matrix in real double precision. LS-DYNA supports both the standard and the extended precision formats. The binary format from *CONTROL_IMPLICIT_MODES or *CONTROL_IMPLICIT_STATIC_CONDENSATION is another input option. The mass and stiffness matrices are required. The inertia matrix is required when using *LOAD_BODY_OPTION to correctly compute the action of a prescribed base acceleration on the superelement, otherwise the inertia matrix is unused. The damping matrix is optional. The combination of these matrices is referred to as a superelement. Three input cards are required for each superelement.

The degrees-of-freedom for this superelement may consist of generalized coordinates as well as nodal point quantities. Degrees-of-freedom, defined using *NODE input, are called attachment nodes. Only attachment nodes are included in the output to the ASCII and binary databases.

The matrices for a given superelement can be of different order. However, the explicit integration scheme requires the inversion of the union of the element mass matrix and nodal masses associated with attachment nodes. Any degree of freedom included in the other (stiffness, damping, inertia) matrices but without nonzero columns in the combined mass matrix will be viewed as massless and constrained not to move. After deleting zero rows and columns, the combined mass matrix is required to be positive definite.

The inertia matrix is required to have 3 columns which corresponds to the 3 global coordinates. It is used to compute the forces acting on the superelement by multiplying the inertia matrix times the gravitational acceleration specified using *LOAD_BODY_OPTION.

There is no assumption made on the order of the matrices nor the sparse matrix structure of the element matrices, except that they are symmetric and the combined mass matrix is invertible as described above.

Multiple elements may be input using *ELEMENT_DIRECT_MATRIX_INPUT. They may share attachment nodes with other direct matrix input elements. Only *BOUNDARY_PRESCRIBED_MOTION and global constraints imposed using *NODE or *BOUNDARY_SPC on attachment nodes can be applied in explicit applications. Implicit applications can have additional constraints on attachment nodes.

Damping is included via the damping matrix; see the variable DAMP. That damping matrix may be computed by including *DAMPING_GLOBAL or *DAMPING_PART_-MASS when constructing the elemental matrices; see SE_DAMP in *CONTROL_IMPLIC-IT_MODES.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	IFRMT

Type	A80							

Card 3	1	2	3	4	5	6	7	8
Variable	MASS	DAMP	STIF	INERT				
Type	A10	A10	A10	A10				

VARIABLE	DESCRIPTION
EID	Super element ID.
IFRMT	Format: EQ.0: standard format NE.0: extended precision format
FILENAME	Name of file that has the element matrices.
MASS	Name of mass matrix in the file defined by FILENAME. This filename should be no more than eight characters to be compatible with NASTRAN.

VARIABLE	DESCRIPTION
DAMP	Name of damping matrix in the file defined by FILENAME. This filename should be no more than eight characters to be compatible with NASTRAN.
STIF	Name of stiffness matrix in the file defined by FILENAME. This filename should be no more than eight characters to be compatible with NASTRAN.
INERT	Name of inertia matrix in the file defined by FILENAME. This filename should be no more than eight characters to be compatible with NASTRAN. This file must be present when *LOAD_BODY is used to put gravitational forces on the model.

*ELEMENT_DISCRETE_{OPTION}

Available options include:

<BLANK>

LCO

Purpose: Define a discrete (spring or damper) element between two nodes or a node and ground.

An option, LCO, is available for using a load curve(s) to initialize the offset to avoid the excitation of numerical noise that can sometimes result with an instantaneous imposition of the offset. This can be done using a single curve at the start of the calculation or two curves where the second is used during dynamic relaxation prior to beginning the transient part. In the latter case, the first curve would simply specify the offset as constant during time. If the LCO option is active, a second card is read.

Beam type 6, see *ELEMENT_BEAM and SECTION_BEAM, may be used as an alternative to *ELEMENT_DISCRETE and *SECTION_DISCRETE, and is recommended if the discrete element's line of action is not node N1 to N2, i.e., if VID ≠ 0.

> **NOTE:** The discrete elements enter into the time step calculations. Care must be taken to ensure that the nodal masses connected by the springs and dampers are defined and unrealistically high stiffness and damping values must be avoided. **All rotations are in radians**.

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	EID	PID	N1	N2	VID	S		PF	OFFSET	
Type	I	I	I	I	I	F		I	F	
Default	none	none	none	none	0	1.0		0	0.0	

Offset Load Curve Card. Additional card for LCO keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	LCID	LCIDDR						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
EID	Element ID. A unique number is required. Since null beams are created for visualization, this element ID should not be identical to element ID's defined for *ELEMENT_BEAM and *ELEMENT_SEATBELT.
PID	Part ID, see *PART.
N1	Nodal point 1.
N2	Nodal point 2. If zero, the spring/damper connects node N1 to ground.
VID	Orientation option. The orientation option should be used cautiously since forces, which are generated as the nodal points displace, are not orthogonal to rigid body rotation unless the nodes are coincident. The type 6, 3D beam element, is recommended when orientation is required with the absolute value of the parameter SCOOR set to 2 or 3, since this option avoids rotational constraints. EQ.0: the spring/damper acts along the axis from node N1 to N2, NE.0: the spring/damper acts along the axis defined by the orientation vector, VID defined in the *DEFINE_SD_ORIENTATION section.
S	Scale factor on forces.
PF	Print flag: EQ.0: forces are printed in DEFORC file, EQ.1: forces are not printed DEFORC file.

VARIABLE	DESCRIPTION
OFFSET	Initial offset. The initial offset is a displacement or rotation at time zero. For example, a positive offset on a translational spring will lead to a tensile force being developed at time zero. Ignore this input if LCID is defined below.
LCID	Load curve ID defining the initial OFFSET as a function of time. Positive offsets correspond to tensile forces, and, likewise negative offsets result in compressive forces.
LCIDDR	Load curve ID defining OFFSET as a function of time during the dynamic relaxation phase.

*ELEMENT_DISCRETE_SPHERE_{OPTION}

Available options include:

<BLANK>

VOLUME

Purpose: Define a discrete spherical element for discrete element method (DEM) calculations. Currently, LS-DYNA's implementation of the DEM supports only spherical particles, as discrete element spheres (DES). Each DES consists of a single node with its mass, mass moment of inertia, and radius defined by the input below. Initial coordinates and velocities are specified using the nodal data. The element ID corresponds to the ID of the node. The discrete spherical elements are visualized in LS-PrePost using the same options as the SPH elements.

Please note, the DES part requires *PART, *SECTION, and *MAT keywords. The element type and formulation values in *SECTION are ignored. DEM retrieves the bulk modulus from the *MAT input for coupling stiffness and time step size evaluation, and density from the *MAT input if VOLUME is used to calculate the proper mass. *MAT_ELASTIC and *MAT_RIGID are most commonly used, but other material models are also permissible.

Card Summary:

Card 1a. This card is included if and only if the keyword option is unused.

NID	PID	MASS	INERTIA	RADIUS			NID2

Card 1b. This card is included if and only if the VOLUME keyword option is used.

NID	PID	VOLUME	INERTIA	RADIUS			NID2

Data Card Definitions:

Card 1a	1	2	3	4	5	6	7	8
Variable	NID	PID	MASS	INERTIA	RADIUS			NID2
Type	I	I	F	F	F			I
Default	none	none	none	none	none			0

VARIABLE	DESCRIPTION
NID	DES Node ID.
PID	DES Part ID, see *PART.
MASS	mass
INERTIA	Mass moment of inertia.
RADIUS	Particle radius. The particle radius is used for defining contact between particles.
NID2	More than one element with the same PID, MASS, INERTIA, and RADIUS can be defined by setting this field without requiring additional cards. If set, NID2 is a node ID that must have a value greater than NID. Then, DES are defined for each node with an ID between NID and NID2 (including NID and NID2). If 0 or left blank, then only a DES for NID is specified.

Card 1b	1	2	3	4	5	6	7	8
Variable	NID	PID	VOLUME	INERTIA	RADIUS			NID2
Type	I	I	F	F	F			I
Default	none	none	none	none	none			0

VARIABLE	DESCRIPTION
NID	DES Node ID.
PID	DES Part ID, see *PART.
VOLUME	Volume. The mass is calculated from material density, $M = \text{VOLUME} \times \rho_{\text{mat}}$.
INERTIA	Inertia per unit density. The actual inertia is calculated from material density, $I = \text{INERTIA} \times \rho_{\text{mat}}$.
RADIUS	Particle radius. The particle radius is used for defining contact between particles.

VARIABLE	DESCRIPTION
NID2	More than one element with the same PID, VOLUME, INERTIA, and RADIUS can be defined by setting this field without requiring additional cards. If set, NID2 is a node ID that must have a value greater than NID. Then, DES are defined for each node with an ID between NID and NID2 (including NID and NID2). If 0 or left blank, then only a DES for NID is specified.

*ELEMENT_GENERALIZED_SHELL

Purpose: Define a general 3D shell element with an arbitrary number of nodes. The formulation of this element is specified in *DEFINE_ELEMENT_GENERALIZED_-SHELL, which is specified through the part ID (see *PART) and the section ID (see *SECTION_SHELL). For an illustration of this referencing, see Figure 19-4. This generalized shell implementation allows for rapid prototyping of new shell element formulations without requiring further coding.

The element formulation used in *SECTION_SHELL needs to be greater or equal than 1000.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	PID	NMNP					
Type	I	I	I					
Default	none	none	none					

Connectivity Cards. Define the connectivity of the element by specifying NMNP-nodes (up to eight nodes per card). Include as many cards as needed. For example, for NMNP = 10, the deck should include two additional cards.

Card 2	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	N5	N6	N7	N8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
EID	Element ID. Chose a unique number with respect to other elements.
PID	Part ID, see *PART.
NMNP	Number of nodes to define this element.
N_i	Nodal point *i* (defined via *NODE) to define connectivity of this element.

Remarks:

1. **Interpolation Shell Elements.** For post-processing and the treatment of contact boundary conditions, the use of interpolation shell elements (see *ELEMENT_-INTERPOLATION_SHELL and *CONSTRAINED_NODE_INTERPOLATION) is necessary.

2. **Connectivity.** The definition of the connectivity of the element is basically arbitrary, but it has to correlate with the definition of the element formulation in *DEFINE_ELEMENT_GENERALIZED_SHELL.

Card 3	1	2	3	4	5	6	7	8
Variable	X-OFF	Y-OFF	Z-OFF					
Type	F	F	F					
Default	0.	0.	0.					

VARIABLE	DESCRIPTION
EID	Element ID. A unique number must be used.
NID	Node ID. Node to which the mass and inertia is assigned.
CSID	Coordinate system ID EQ.0: Components of the inertia tensor are input with orientation in the global coordinate system. GE.1: Principal moments of inertias are input with orientation of the principal axes defined by coordinate system CSID. See *DEFINE_COORDINATE_*OPTION*. See Remark 2.
IXX	*xx* component of inertia tensor
IXY	*xy* component of inertia tensor
IXZ	*xz* component of inertia tensor
IYY	*yy* component of inertia tensor
IYZ	*yz* component of inertia tensor
IZZ	*zz* component of inertia tensor
MASS	Lumped mass (optional)
X-OFF	*x*-offset from nodal point
Y-OFF	*y*-offset from nodal point
Z-OFF	*z*-offset from nodal point

Remarks:

1. **Inertia and Mass Contribution.** The inertia and mass specified by this keyword is added to the inertia and mass contributed by the elements.

2. **Principal Moments of Inertia.** If CSID is defined, then IXY, IXZ and IYZ are set to zero. Because its inverse is required, the nodal inertia tensor must be positive definite, meaning its determinant must be greater than zero. This check is done after the nodal inertia is added to the defined inertia tensor.

3. **Inertia Tensor for Deformable Bodies.** Nodes of deformable bodies do not support a full inertia tensor. For these bodies, only one value is needed. Specified off-diagonal terms will be ignored. If there is variation among terms on the

diagonal, the largest value will be used. Therefore, an easy way to input inertia for a deformable body node is to define only IXX.

*ELEMENT_INTERPOLATION_SHELL

Purpose: With the definition of interpolation shells, the stresses and other solution variables can be interpolated from the generalized shell elements (see *ELEMENT_GENERALIZED_SHELL and *DEFINE_ELEMENT_GENERALIZED_SHELL) permitting the solution to be visualized using standard 4-node shell elements with one integration point (one value of each solution variable per interpolation shell). The definition of the interpolation shells is based on interpolation nodes (see *CONSTRAINED_NODE_INTERPOLATION). The connections between these various keywords are illustrated in Figure 19-6.

Card 1	1	2	3	4	5	6	7	8
Variable	EIDS	EIDGS	NGP					
Type	I	I	I					
Default	none	none	none					

Weighting Factor Cards. These cards set the weighting factors used for interpolating the solution onto the center of *this* interpolation shell. Set one weight for each of the NGP integration points. Each card can accommodate 4 points; define as many cards as necessary. For example, if NGP = 10, three cards are required.

Card 2	1	2	3	4	5	6	7	8
Variable	IP1	W1	IP2	W2	IP3	W3	IP4	W4
Type	I	F	I	F	I	F	I	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
EIDS	Element ID of the interpolation shell. This needs to coincide with a proper definition of a 4-node shell element (*ELEMENT_SHELL) using interpolation nodes (*CONSTRAINED_NODE_INTERPOLATION).
EIDGS	Element ID of the master element defined in *ELEMENT_GENERALIZED_SHELL.

VARIABLE	DESCRIPTION
NGP	Number of in-plane integration points of the master element.
IP_i	Integration point number (1 to NGP) in the order they were defined in *DEFINE_ELEMENT_GENERALIZED_SHELL.
W_i	Interpolation weight of integration point i.

Remarks:

1. **Interpolation.** For each interpolation shell element, one single value (v_{IS}) of a solution variable is interpolated based on values at the integration points (v_i) of the master element (*ELEMENT_GENERALIZED_SHELL) and the appropriate weighting factors (w_i). The interpolation is computed as follows:

$$v_{IS} = \sum_{i=1}^{NGP} w_i v_i \ .$$

2. **Element Formulation.** To use *ELEMENT_INTERPOLATION_SHELL, ELFORM = 98 must be used in *SECTION_SHELL.

Figure 19-6. Example for *ELEMENT_INTERPOLATION_SHELL.

*ELEMENT_INTERPOLATION_SOLID

Purpose: With the definition of interpolation solids, the stresses and other solution variables can be interpolated from the generalized solid elements (see *ELEMENT_GENERALIZED_SOLID and *DEFINE_ELEMENT_GENERALIZED_SOLID) permitting the solution to be visualized using standard 8-noded solid elements with one integration point (one value of each solution variable per interpolation solid). The definition of the interpolation solids is based on interpolation nodes (see *CONSTRAINED_NODE_INTERPOLATION). The connection between these various keywords are illustrated in Figure 19-7.

Card 1	1	2	3	4	5	6	7	8
Variable	EIDS	EIDGS	NGP					
Type	I	I	I					
Default	none	none	none					

Weighting Factor Cards. These cards set the weighting factors used for interpolating the solution onto the center of *this* interpolation solid. Set one weight for each of the element's NGP integration points. Each card can accommodate 4 points; define as many cards as necessary. As an example, for NGP = 10 three cards are required.

```

Figure 19-7. Example for *ELEMENT INTERPOLATION SOLID.

*ELEMENT_LANCING

Purpose: This feature models a lancing process during a metal forming process by trimming along a curve. Two types of lancing, instant and progressive, are supported. This keyword is used together with *DEFINE_CURVE_TRIM_3D, and only applies to shell elements. The lanced scraps can be removed (trimming) during or after lancing when used in conjunction with *DEFINE_LANCE_SEED_POINT_COORDINATES; see Trimming remarks below.

The element lancing feature is supported in LS-PrePost 4.3, under Application → Metal-Forming → Easy Setup.

For each trim include an additional card. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	IDPT	IDCV	IREFINE	SMIN	AT	ENDT	NTIMES	CIVD
Type	I	I	I	F	F	F	I	I
Default	none	none	1	none	none	↓	↓	↓

VARIABLE	DESCRIPTION
IDPT	A flag to indicate if a part to be lanced is a part or a part set. GT.0: IDPT is the PID of a part to be lanced; see *PART. LT.0: The absolute value is the part set ID as in *SET_PART_-LIST. This option allows the lancing to be performed across a tailor-welded line.
IDCV	A trim curve ID (the variable TCID in *DEFINE_CURVE_TRIM_-3D) defining a lancing route (see Remarks). XYZ format (TC-TYPE = 1) has always been supported; however, IGES format (TC-TYPE = 2) is not supported until Revision 110246.
IREFINE	Set IREFINE = 1 to refine elements along lancing route until no adapted nodes exist in the neighborhood. This feature results in a more robust lancing in the form of improved lancing boundary. Available starting in Revision 107708. Values greater than "1" are not allowed. See Figure 19-16 for an example of the mesh refinement.

VARIABLE	DESCRIPTION
SMIN	Minimum element characteristic length to be refined to (to be supported in the future). Currently, one level of refinement will be automatically done.
AT	Activation time for lancing operation. This variable needs to be defined for both instant and progressive lancing types (see Remarks). If CIVD is defined, AT becomes the distance from the punch home position.
ENDT	Lancing end time (for progressive lancing only). If CIVD is defined, ENDT becomes the distance from the punch home position. Do not define for instant lancing.
NTIMES	A progressive lancing operation is evenly divided into NTIMES segments between AT and ENDT; within each segment lancing is done instantly. Do not define for instant lancing.
CIVD	The load curve ID (LCID) to define the kinematics (time vs. velocity) of the tool, with VAD = 0; see *DEFINE_CURVE. When this variable is used, AT and ENDT will become the distances from the punch bottom position, unless the variables DT and BT are defined in *BOUNDARY_PRESCRIBED_MOTION_RIGID. See an example with CIVD.

Remarks:

Lancing the blank during forming at strategic locations under controlled conditions alleviates thinning and necking of sheet metal panels. Typically, the blank is lanced in the last few millimeters before the punch reaches its home position. Being an unstable process, lancing is not favored by all stampers; nevertheless, many users have devised processes which would be impossible without lancing.

The benefits of lancing are illustrated in Figure 19-8. In this figure two closed-loop holes are instantly lanced each along the C-pillar top (window opening area) and bottom (window regulator area) to improve the formability at those two corners. The right panel of Figure 19-8 is lanced and suffers less thinning compared to the no-lancing case, which is shown in the left-panel. This keyword offers two types of lancing operations:

1. **Instant lancing.** Instant lancing cuts the sheet metal once along the defined curve at a time specified in the AT field.

2. **Progressive lancing.** The cut is spatially divided into NTIMES sub-lances traveling along the curve in the direction of definition. See Figure 19-11. Progressive

lancing starts at AT and ends at ENDT thereby achieving a gradual and even release along the curve.

Modeling Guidelines:

Some modeling guidelines and limitations are listed below:

1. Both closed-loop (Figure 19-9) and open-loop (Figure 19-10) lancing curves are supported. A lancing curve may not cross another lancing curve or itself.

2. Since progressive lancing starts from the beginning of the curve and proceeds towards the end, the direction of the curve needs to be defined to match the direction of the physical cut (Figure 19-11). The direction can be set using LS-PrePost. The menu option GeoTol→ Measure with the Edge box checked can be used to show the direction of the curve. If the direction is not as desired, GeoTol → Rever can be used to reverse the direction.

3. The effect of NTIMES can be seen in Figure 19-12. Compared with NTIMES of 6, setting NTIMES to a value of 20 results in a smoother lancing boundary and less stress concentration along the separated route.

4. Although the IGES format curve is supported by the keyword *DEFINE_CURVE_TRIM_3D, curves defined with the keyword and used for lancing must be specified using only the XYZ format (TCTYPE = 1 or 0) for revisions prior to Revision 110246. The manual entry in the keyword manual for the *INTERFACE_BLANKSIZE_DEVELOPMENT keyword outlines a procedure for converting an IGES file into the required XYZ format. Note the IGES format support for lancing is enabled starting in Revision 110246.

5. The first two points as well as the last two points of any progressive lancing curve must be separated so that LS-DYNA can correctly determine the direction of the curve.

6. The lancing curve needs to be much longer than the element sizes in the lancing area.

7. To prevent mesh distortion at the end of the lancing route ENDT must be defined to be less than the simulation completion time (slightly less is sufficient).

8. Lancing can be in any direction. The direction is determined by *DEFINE_CURVE_TRIM_3D.

9. Tailor-welded blanks are supported; however, the lancing route should not cross the laser line, as currently only one part can be defined with one lancing curve.

10. Both *PARAMETER and *PARAMETER_EXPRESSION are supported for AT and ENDT as of Revision 92335. This makes it possible for users to input distance from punch home as onset of the lancing. Refer to Figure 19-14, where a punch's velocity profile is shown, the lancing activation time AT, is calculated based on the distance to home, "dhome" (the shaded area), punch travel velocity "vdraw", and total simulation time "ENDTIME". The variable CIVD implemented in Rev 110173 removes the need for the calculation of AT from punch distance to home.

11. Mesh adaptivity (*CONTROL_ADAPTIVE and the parameter "ADPOPT" under *PART) must be turned on during lancing.

12. All trim curves used to define lancing routes (*DEFINE_CURVE_TRIM_3D) must be placed after all other curves in the input deck. Furthermore, no curves defined by *DEFINE_CURVE_TRIM_3D that are not used for lancing should be present anywhere in the input deck. Note this restriction is removed starting in Revision 110316.

13. Only *DEFINE_CURVE_TRIM_3D is supported. If defined curve is far away from the blank, it will be projected onto the blank.

14. This keyword is input order sensitive: *DEFINE_CURVE_TRIM_3D must be placed after *ELEMENT_LANCING.

Application example:

A partial deck implementing instant lancing is listed below. A blank having a PID of 8 is being lanced along curves #119 and #202 instantly at 0.05 and 0.051 seconds, respectively.

```

```

A partial keyword deck implementing two progressive lances is listed below. Both lances travel along paths starting at the same coordinate value. A sheet blank having a part ID of 9 is progressively lanced along both curves (IDCV = 1 and 2) as defined by *DEFINE_-CURVE_TRIM_3D. Both lancing operations commence at 0.05 seconds and finish at 0.053 seconds with 20 cuts along each curve in opposite directions. The lancing results are shown in Figure 19-13. Note that the termination time is 53.875 seconds, which is slightly larger than the ENDT.

```

Trimming after lancing:

As shown in Figure 19-15 and the following partial keyword file, the lanced scraps can be removed (trimming) after a lancing simulation. An extra keyword, *DEFINE_-LANCE_SEED_POINT_COORDINATES is needed to define the portion that would remain after the lancing and trimming. It should be obvious that the lancing curve defined by *DEFINE_CURVE_TRIM_3D must form a closed loop. The following example will trim a part ID 9 with a fully enclosed lancing curve #1, at time = 0.049 seconds. Since the termination time is 0.0525 seconds, the scrap will be deleted (trimmed off) before the simulation ends. The scrap, enclosed by the curve, is located outside of the seed node, defined by *DEFINE_LANCE_SEED_POINT_COORDINATES (starting in Revision 107262).

This feature also makes it possible to combine the trimming process with a forming simulation, saving a trimming step in a line-die process simulation by skipping writing out a formed dynain file and reading in the same file for the trimming simulation.

Lance-trimming with a part set, IGES curve, a seed node and CIVD:

The following partial keyword input shows instant lance-trimming across the weld line of a tailor-welded blank using the part set ID "blksid" 100, which consists of PIDs 1 and 9. The part set ID used for *ELEMENT_LANCING input is "idpt", which is set as the negative of blksid (-100). The lance-trimming curve ID 1117 is defined using the file lance4.iges in IGES format (TCTYPE = 2). The defined variable CIVD refers to the load curve ID 1115 under *DEFINE_CURVE, which is the kinematic curve for the upper die. The lancing starts at 15.5 mm (AT = 15.5) away from upper die bottom position. A lance seed coordinate (-382.0, -17.0, 76.0) is defined using the keyword *DEFINE_LANCE_-SEED_POINT_COORDINATES, resulting in the lanced scrap piece being removed after lancing.

Revision information:

This feature is available starting in Revision 83562 for SMP and in Revision 94383 for MPP, in explicit dynamic calculation only. Later revisions incorporate various improvements. The list below provides revision information:

15. Revision 92335: support of *PARAMETER and *PARAMETER_EXPRESSION.

16. Revision 94383: MPP support of lancing is available.

17. Revision 107708: support IREFINE = 1.

18. Revision 107262: lancing with trimming is supported.

19. Revision 110173: CIVD is supported, and AT and ENDT become distances from punch home if CIVD is activated.

20. Revision 110177: support negative IDPT for part set ID, enabling lancing across the laser welded line.

21. Revision 110246: lancing curve definition in IGES format is supported.

***ELEMENT_MASS**_*{OPTION}*

Available options include:

<BLANK>

NODE_SET

Purpose: Define a lumped mass element assigned to a nodal point or equally distributed to the nodes of a node set. The nodal point can belong to either a deformable or rigid body.

Card	1	2	3	4	5	6	7	8	9	10
Variable	EID	ID	MASS		PID					
Type	I	I	F		I					
Default	none	none	0.		0					

VARIABLE	DESCRIPTION
EID	Element ID. A unique number is recommended. The nodes in a node set share the same element ID.
ID	Node ID or node set ID if the NODE_SET option is active. This is the node or node set to which the mass is assigned.
MASS	Mass value. When the NODE_SET option is active, the mass is equally distributed to all nodes in a node set.
PID	Part ID. This input is optional.

Remarks:

1. **Kinetic Energy Output.** Kinetic energy of lumped mass elements is output as kinetic energy of part 0 in matsum (*DATABASE_MATSUM) if IERODE is set to 1 on *CONTROL_OUTPUT.

*ELEMENT_MASS_MATRIX_{OPTION}

Available options include:

<BLANK>

NODE_SET

Purpose: Define a 6 × 6 symmetric nodal mass matrix assigned to a nodal point or each node within a node set. A node may not be included in more than one *ELEMENT_MASS_MATRIX(_NODE_SET) command. The nodal point can only belong to a deformable body. This keyword cannot be applied to nodes that belong to rigid bodies.

Type	F	F	F	F	F	F	F	
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
EID	Element ID. A unique number is recommended. The nodes in a node set share the same element ID.
ID	Node ID or node set ID if the NODE_SET option is active. This is the node or node set to which the mass is assigned.
CID	Local coordinate ID which defines the orientation of the mass matrix
M*ij*	The ij^{th} term of the symmetric mass matrix. The lower triangular part of the matrix is defined.

*ELEMENT_MASS_PART_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Define additional non-structural mass to be distributed by an area (shell) / volume (solid) or mass weighted distribution to all nodes of a given part, or part set, ID. As an option, the total mass can be defined and the additional non-structural mass is computed. This option applies to all part IDs defined by shell, tshell and solid elements.

Card	1	2	3	4	5	6	7	8	9	10
Variable	ID	ADDMASS		FINMASS		LCID		MWD		
Type	I	F		F		I		I		
Default	none	0.		0.		0		0		

VARIABLE	DESCRIPTION
ID	Part or part set ID if the SET option is active. A unique number must be used.
ADDMASS	Added translational mass to be distributed to the nodes of the part ID or part set ID. Set to zero if FINMASS is nonzero. Since the additional mass is not included in the time step calculation of the elements in the PID or SID, ADDMASS must be greater than zero if FINMASS is zero. Multiple applications of mass using the SET option are treated by the additional masses being summed. For multiple mass applications to the same PID (<BLANK> option), only the last definition is used.
FINMASS	Final translational mass of the part ID or part set ID. The total mass of the PID or SID is computed and subtracted from the final mass of the part or part set to obtain the added translational mass, which must exceed zero. Set FINMASS to zero if ADDMASS is nonzero. FINMASS is available in the R3 release of version 971.

VARIABLE	DESCRIPTION
LCID	Optional load curve ID to scale the added mass at time = 0. This curve defines the scale factor as a function versus time. The curve must start at unity at $t = 0$. This option applies to deformable bodies only.
MWD	Optional flag for mass-weighted distribution, valid for SET option only: EQ.0: non-structural mass is distributed by area (shell) / volume (solid) weighted distribution, EQ.1: non-structural mass is distributed by mass weighted, area × density × thickness (shell) / volume × density (solid), distribution. Mixed uses with MWD for the same part should be avoided.

*ELEMENT_PLOTEL

Purpose: Define a null beam element for visualization.

Card	1	2	3	4	5	6	7	8	9	10
Variable	EID	N1	N2							
Type	I	I	I							
Default	none	none	none							

VARIABLE	DESCRIPTION
EID	Element ID. A unique number must be used.
N1	Nodal point (end) 1.
N2	Nodal point (end) 2.

Remarks:

1. **Part ID.** Part ID, 10000000, is assigned to PLOTEL elements.
2. **Beam Element IDs.** PLOTEL element IDs must be unique with respect to other beam elements.

*ELEMENT_SEATBELT

Purpose: Define a seat belt element.

Card	1	2	3	4	5	6	7	8	9	10
Variable	EID	PID	N1	N2	SBRID	SLEN		N3	N4	
Type	I	I	I	I	I	F		I	I	
Default	none	none	none	none	Rem 2	0.0		0	0	

VARIABLE	DESCRIPTION
EID	Element ID. A unique number is required. Since null beams are created for visualization, this element ID should not be identical to element IDs defined for *ELEMENT_BEAM and *ELEMENT_DISCRETE.
PID	Part ID
N1	Node 1 ID
N2	Node 2 ID
SBRID	Retractor ID, see *ELEMENT_SEATBELT_RETRACTOR.
SLEN	Initial slack length. See Remarks 1 and 3.
N3	Optional node 3 ID. When N3 > 0 and N4 > 0, the element becomes a shell seat belt element. The thickness of the shell seatbelt is defined in *SECTION_SHELL, not in *SECTION_SEATBELT. The shell-type seatbelt must be of a rectangular shape as shown in Figure 19-17 and contained in a logically regular mesh. See Remark 4.
N4	Node 4 ID, which is required if and only if N3 is defined.

Remarks:

1. **Unstretched Length.** The unstretched length, l, of the belt is given as

$$l = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2} + \text{SLEN} \ ,$$

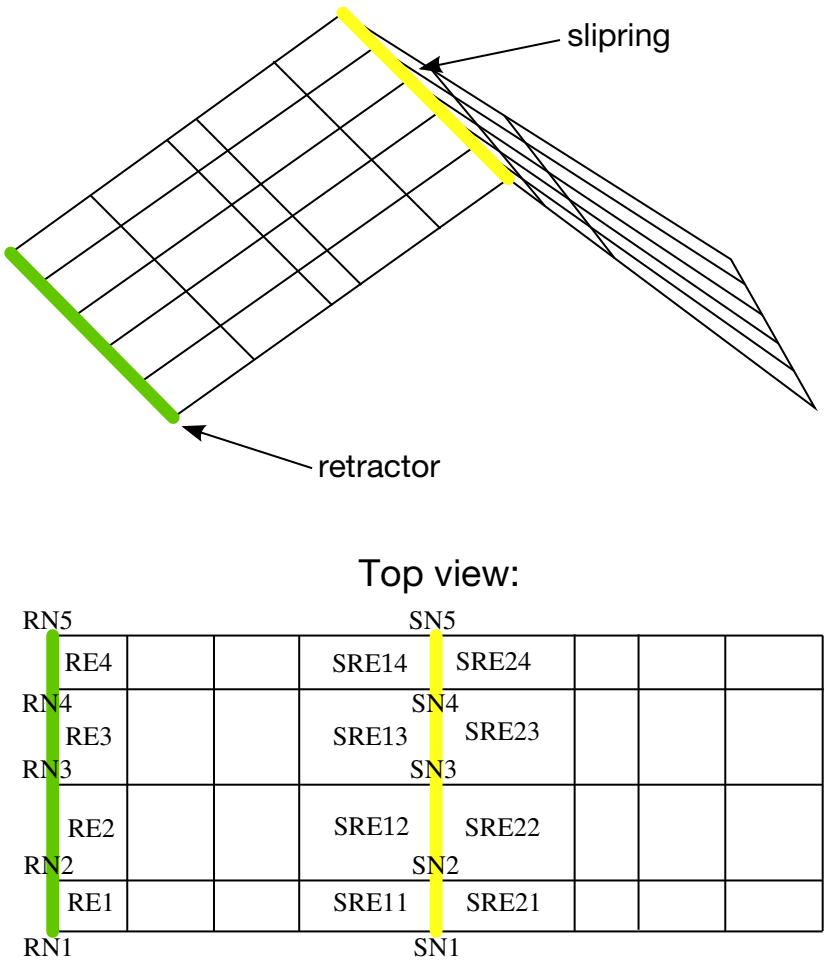

Figure 19-17. Definition of seatbelt shell elements. The ordering of the nodes and elements are important for seatbelt shells. See the input descriptions for SECTION_SHELL, ELEMENT_SEATBELT_RETRACTOR and ELEMENT_-SEATBELT_SLIPRING.

where (x_1, y_1, z_1) and (x_2, y_2, z_2) are the positions of the nodes defining the seatbelt element and SLEN is the slack length. All seatbelt elements *must* have an unstretched length *greater than* LMIN, where LMIN is a minimum length field defined on *MAT_SEATBELT. *However, when a seatbelt element is either initially connected to a slipring or is a mouth element for a retractor (see *ELEMENT_SEATBELT_SLIPRING and *ELEMENT_SEATBELT_RETRACTOR), l must be greater than 1.6 × LMIN. Also, if a seatbelt element has the potential of going through a slipring or retractor at some time during the simulation, it must have an unstretched length of at least 1.1 × LMIN.*

2. **Retractor.** The retractor ID should be defined only if the element is initially *inside* a retractor, see *ELEMENT_SEATBELT_RETRACTOR.

3. **Forces.** Belt elements are single degree of freedom elements connecting two nodes. When the strain in an element is positive (that is, the current length is

greater than the unstretched length), a tension force is calculated from the material characteristics and is applied along the current axis of the element to oppose further stretching.

4. **Shell Elements.** Seatbelt shell elements are included as a feature as of version 971 and must be used with caution. The seatbelt shells distribute the loading on the surface of the dummy more realistically than the two node belt elements. For the seatbelt shells to work with sliprings and retractors it is necessary to use a logically regular mesh of quadrilateral elements. *A seatbelt defined by a part ID must not be disjoint.*

5. **Material ID.** 1D and 2D seatbelt elements may not share the same material ID.

*ELEMENT_SEATBELT_ACCELEROMETER

Purpose: This keyword command defines an accelerometer. Contrary to the keyword name, an accelerometer need not be associated with a seat belt. The accelerometer is fixed to a rigid body containing the three nodes defined below. An accelerometer will exhibit considerably less numerical noise than a deformable node, thereby reporting more meaningful data to the user. Whenever computed accelerations are compared to experimental data, or whenever computed accelerations are compared between different runs, this feature is essential.

Card	1	2	3	4	5	6	7	8
Variable	SBACID	NID1	NID2	NID3	IGRAV	INTOPT	MASS	
Type	I	I	I	I	I	I	F	
Default	none	none	none	none	0	0	0.	

VARIABLE	DESCRIPTION
SBACID	Accelerometer ID. A unique number must be used.
NID1	Node 1 ID
NID2	Node 2 ID
NID3	Node 3 ID
IGRAV	Gravitational accelerations due to body force loads: EQ.-6: z and x components removed from acceleration output EQ.-5: y and z components removed from acceleration output EQ.-4: x and y components removed from acceleration output EQ.-3: z component removed from acceleration output EQ.-2: y component removed from acceleration output EQ.-1: x component removed from acceleration output EQ.0: all components included in acceleration output EQ.1: all components removed from acceleration output

VARIABLE	DESCRIPTION
	GT.1: IGRAV is a curve ID defining the gravitation-flag versus time. The ordinate values, representing the gravitation-flag, can be -6, -5, -4, -3, -2, -1, 0 or 1, as described above. For example, a curve with 4 data points of (0.,1), (10.,1), (10.000001,0), (200.,0) sets the gravitation flag to be 1 when time ≤ 10, and 0 when time > 10. In other words, all components of gravitational accelerations are removed when time ≤ 10., and then included when time > 10.0.
INTOPT	Integration option. If the accelerometer undergoes rigid body translation without rotation, this option has no effect; however, if rotation occurs, INTOPT affects how translational velocities (and displacements) are calculated. Note that the acceleration values written to the nodout file are unaffected by INTOPT. EQ.0: velocities are integrated from the global accelerations and transformed into the local system of the accelerometer. EQ.1: velocities are integrated directly from the local accelerations of the accelerometer.
MASS	Optional added mass for accelerometer. This mass is equally distributed to nodal points NID1, NID2, and NID3. This option avoids the need to use the *ELEMENT_MASS keyword input if additional mass is required.

Remarks:

The presence of the accelerometer means that the accelerations and velocities of node 1 will be output to **all** output files in local instead of global coordinates.

The local coordinate system is defined by the three nodes as follows:

1. local **x** from node 1 to node 2,
2. local **z** perpendicular to the plane containing nodes 1, 2, and 3 ($\mathbf{z} = \mathbf{x} \times \mathbf{a}$), where **a** is from node 1 to node 3,
3. local $\mathbf{y} = \mathbf{z} \times \mathbf{x}$.

The three nodes should all be part of the same rigid body. The local axis then rotates with the body.

*ELEMENT_SEATBELT_PRETENSIONER

Purpose: Define seat belt pretensioner. A combination with sensors and retractors is also possible.

Card 1	1	2	3	4	5	6	7	8
Variable	SBPRID	SBPRTY	SBSID1	SBSID2	SBSID3	SBSID4		
Type	I	I	I	I	I	I		
Default	none	none	0	0	0	0		

Card 2	1	2	3	4	5	6	7	8
Variable	SBRID	TIME	PTLCID	LMTFRC				
Type	I	F	I	F				
Default	0	0.0	0	0				

VARIABLE	DESCRIPTION
SBPRID	Pretensioner ID. A unique number has to be used.
SBPRTY	Pretensioner type (see Activation): EQ.1: Pyrotechnic retractor with force limits (see Type 1), EQ.2: Pre-loaded spring becomes active (see Types 2 and 3), EQ.3: Lock spring removed (see Types 2 and 3), EQ.4: Force as a function of time retractor (see Type 4). EQ.5: Pyrotechnic retractor (older implementation of type 1) but with optional force limiter, LMTFRC (see Type 1 and Type 5). EQ.6: Combination of types 4 and 5 as described in Type 6 below. EQ.7: Independent pretensioner/retractor (see Type 7).

VARIABLE	DESCRIPTION
	EQ.8: Energy as a function of time retractor pretensioner with optional force limiter, LMTFRC (see Type 8). EQ.9: Energy as a function of time buckle or anchor pretensioner (see Type 9).
SBSID1	Sensor 1, see *ELEMENT_SEATBELT_SENSOR. See Activation.
SBSID2	Sensor 2, see *ELEMENT_SEATBELT_SENSOR.
SBSID3	Sensor 3, see *ELEMENT_SEATBELT_SENSOR.
SBSID4	Sensor 4, see *ELEMENT_SEATBELT_SENSOR.
SBRID	Retractor number (SBPRTY = 1, 4, 5, 6, 7 or 8) or spring element number (SBPRTY = 2, 3 or 9).
TIME	Time between sensor triggering and pretensioner acting.
PTLCID	Load curve for pretensioner (Time after activation, Pull-in) (SBPRTY = 1, 4, 5, 6, 7, 8 or 9).
LMTFRC	Optional limiting force for retractor types 5 and 8. If zero, this option is ignored. See Type 5 and Type 8.

Activation:

To activate the pretensioner, the following sequence of events must occur:

1. Any one of up to four sensors must be triggered.
2. Then a user-defined time delay occurs.
3. Then the pretensioner acts.

At least one sensor should be defined.

Pretensioners allow modeling of seven types of active devices which tighten the belt during the initial stages of a crash. Types 1 and 5 implement a pyrotechnic device which spins the spool of a retractor, causing the belt to be reeled in. The user defines a pull-in as a function of time curve which applies once the pretensioner activates. Types 2 and 3 implement preloaded springs or torsion bars which move the buckle when released.

Types 2 and 3:

The pretensioner is associated with any type of spring element including rotational. Note that the preloaded spring, locking spring, and any restraints on the motion of the associated nodes are defined in the normal way; the action of the pretensioner is merely to cancel the force in one spring until (or after) it fires. With the second type, the force in the spring element is canceled out until the pretensioner is activated. In this case the spring in question is normally a stiff, linear spring which acts as a locking mechanism, preventing motion of the seat belt buckle relative to the vehicle. A preloaded spring is defined in parallel with the locking spring. This type avoids the problem of the buckle being free to "drift" before the pretensioner is activated. Types 4, 6, and 7, force types, are described below.

Type 1:

The older implementation of the type 1 pretensioner (essentially available as type 5, but type 5 restricts the force value) requires a load curve that tabulates the pull-in of the pretensioner as a function of time. This pretensioner type interacts with the retractor, forcing it to pull in by the amount of belt indicated. It works well, and does exactly what it says it will do, but it can be difficult to use because it has no regard for the forces being exerted on the belt. If a pull-in of 20 mm is specified at a particular time, then 20 mm of belt will be pulled in, even if this results in unrealistic forces in the seatbelt. Furthermore, there was no explicit way to turn this pretensioner off. Once defined, it overrode the retractor completely, and the amount of belt passing into or out of the retractor depended solely on the load curve specified.

The behavior of the type 1 pretensioner was changed due to user feedback regarding these shortcomings. Each retractor has a loading (and optional unloading) curve that describes the force on the belt element as a function of the amount of belt that has been pulled out of the retractor since the retractor locked. The current type 1 pretensioner acts as a shift on this retractor load curve. An example will make this clear. Suppose at a particular time that 5 mm of belt material has left the retractor. The retractor will respond with a force corresponding to 5 mm pull-out on its loading curve. But suppose this retractor has a type 1 pretensioner defined, and at this instant of time the pretensioner specifies a pull-in of 20 mm. The retractor will then respond with a force that corresponds to (5mm + 20mm) on its loading curve. This results in a much larger force. The effect can be that belt material will be pulled in, but unlike with the older implementation, there is no guarantee. The benefit of this implementation is that the force as a function of pull-in load curve for the retractor is followed and no unrealistic forces are generated. Still, it may be difficult to produce realistic models using this option, so other pretensioners have been added.

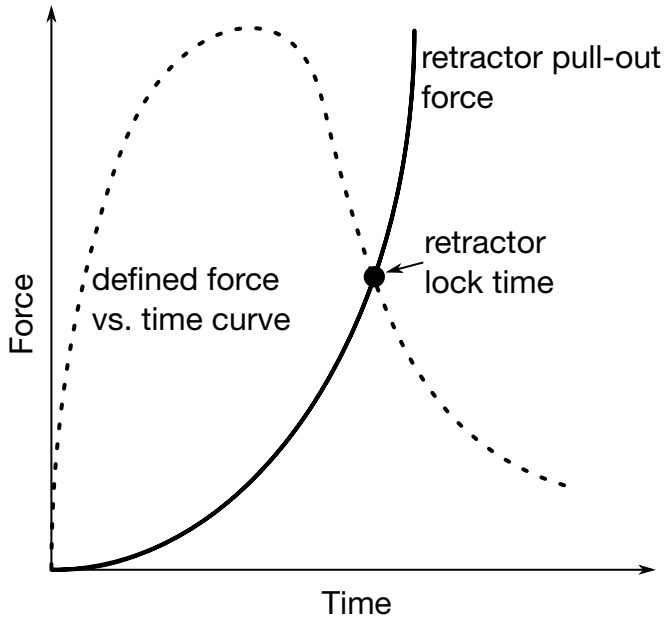

Figure 19-18. Force as a function of time for the pretensioner. At the intersection, the retractor locks.

Type 4:

The type 4 pretensioner requires a force as a function of time curve (see Figure 19-18). At each time step, the retractor computes the desired force without regard to the pretensioner. If the resulting force is less than that specified by the pretensioner load curve, then the pretensioner value is used instead. As time goes on, the pretensioner load curve should drop below the forces generated by the retractor, and the pretensioner is then essentially inactive. This provides for good control of the actual forces, so no unrealistic values are generated. The actual direction and amount of belt movement is unspecified, and will depend on the other forces being exerted on the belt. This is suitable when the force the pretensioner exerts over time is known.

Type 5:

The type 5 pretensioner is essentially the same as the old type 1 pretensioner, but with the addition of a force limiting value. The pull-in is given as a function of time, and the belt is drawn into the retractor exactly as desired. However, if at any point the forces generated in the belt exceed the pretensioner force limit, then the pretensioner is deactivated and the retractor takes over. In order to prevent a large discontinuity in the force at this point, the loading curve for the retractor is shifted (in the abscissa) by the amount required to put the current (pull-out,force) on the load curve. For example, suppose the current force is 1000, and the current pull-out is -10 (10 mm of belt has been *pulled in* by the pretensioner). If the retractor would normally generate a force of 1000 after 25 mm of belt had been *pulled out*, then the load curve is shifted to the left by 35 and remains that

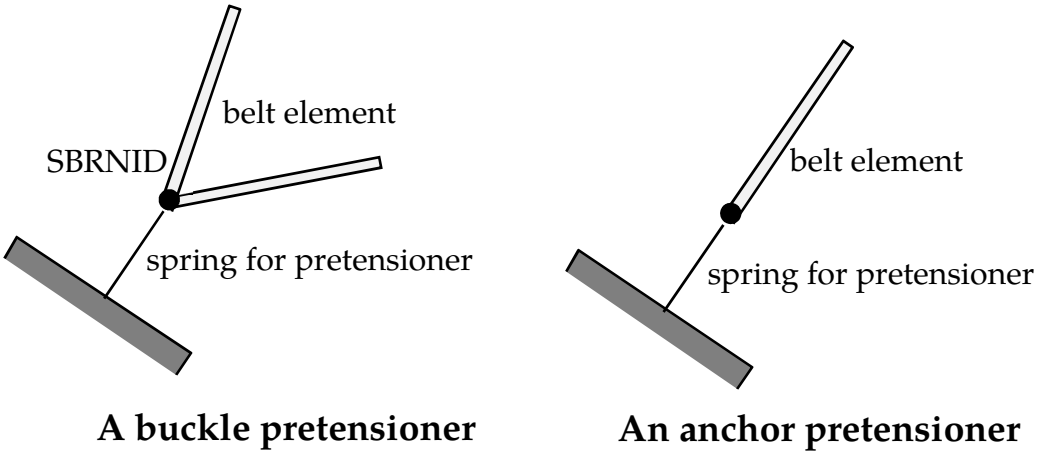

Figure 19-19. Schematics of different kinds of pretensioners.

way for the duration of the calculation. So that at the current pull-in of 10, it will generate the force normally associated with a pull-out of 25. If the belt reaches a pull-out of 5, the force will be as if it were pulled out 40 (5 + the shift of 35), and so on. This option is included for those who liked the general behavior of the old type 1 pretensioner but has the added feature of the force limit to prevent unrealistic behavior.

Note that the retractor will be locked if either of the following two conditions are met:

- The current time exceeds the maximum abscissa of PTLCID, or
- LMTFRC is reached.

Type 6:

The type 6 pretensioner is a variation of the type 4 pretensioner, with features of the type 5 pretensioner. A force as a function of time curve is input and the pretensioner force is computed each cycle. The retractor linked to this pretensioner should specify a positive value for pull, which is the distance the belt pulls out before it locks. As the pretensioner pulls the belt into the retractor, the amount of pull-in is tracked. As the pretensioner force decreases and drops below the belt tension, belt will begin to move back out of the retractor. Once pull amount of belt has moved out of the retractor (relative to the maximum pull in encountered), the retractor will lock. At this time, the pretensioner is disabled, and the retractor force curve is shifted to match the current belt tension. This shifting is done just like the type 5 pretensioner. It is important that a positive value of pull be specified to prevent premature retractor locking which could occur due to small outward belt movements generated by noise in the simulation.

Type 7:

The type 7 pretensioner is a simple combination of retractor and pretensioner. It is similar to the type 6 pretensioner except for the following changes:

1. when the retractor locks, the pretensioner is *not* disabled – it continues to exert force according to the force as a function of time curve until the end of the simulation. (The force as a function of time curve should probably drop to 0 at some time.)

2. The retractor load curve is not shifted – the retractor begins to exert force according to the force as a function of pull-out curve. These two forces are added together and applied to the belt. Thus, the pretensioner and retractor are essentially independent.

Type 8:

The type 8 pretensioner is a variation of the type 5 pretensioner. The pretension energy, instead of pull-in for type 5, is given as a function of time. This enables users to use a single pretensioner curve, PTLCID, for various sizes of dummies. The energy could be yielded from the baseline test or simulation by

$$E(t) = \int_0^t f dp \ ,$$

where f is the force of the mouth element of the retractor and dp is the incremental pull-in.

Note that the retractor will be locked if either of the following two conditions are met:

- The current time exceeds the maximum abscissa of PTLCID, or
- LMTFRC is reached.

Type 9:

The type 9 pretensioner is designed for a pretension-energy based buckle or anchor pretensioner. The pretensioner is modeled as a spring element, SBRID. One end of the spring element is attached to the vehicle. For a buckle pretensioner, the other end of SBRID is the slip ring node, SBRNID, of a slip ring representing the buckle. For an anchor pretensioner, SBRID shares the other end with a belt element; see Figure 19-19.

*ELEMENT_SEATBELT_RETRACTOR

Purpose: Define seat belt retractor. See Remark 4 below for seatbelt shell elements.

Card 1	1	2	3	4	5	6	7	8

SBID	Seat belt element ID
SID1	Sensor ID 1
SID2	Sensor ID 2
SID3	Sensor ID 3
SID4	Sensor ID 4

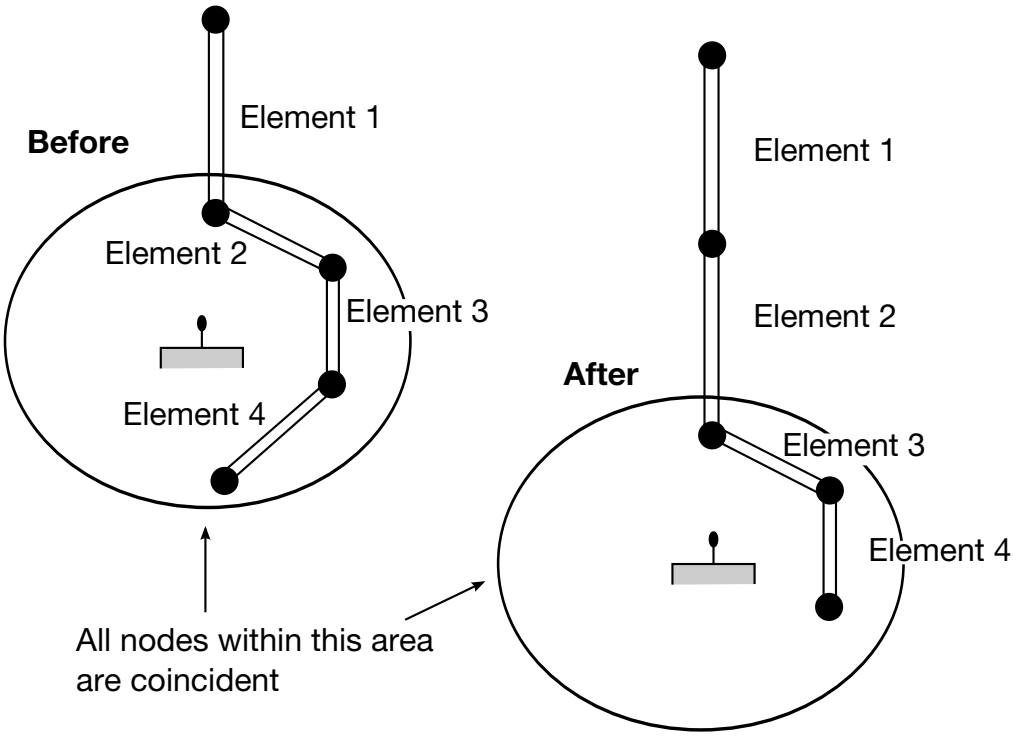

Figure 19-20. Elements in a retractor.

VARIABLE	DESCRIPTION
DSID	Retractor deactivation sensor
TDEL	Time delay after sensor triggers
PULL	Amount of pull-out between time delay ending and retractor locking, a length value.
LLCID	Load curve for loading (Pull-out, Force); see Figure 19-20.
ULCID	Load curve for unloading (Pull-out, Force); see Figure 19-20.
LFED	Fed length

Remarks:

1. **Defining a Retractor.** To define a retractor, the user enters the retractor node and the 'mouth' element (into which belt material will be fed), which is shown as e1 in Figure 19-20. Up to 4 sensors which can trigger unlocking, a time delay, a payout delay (optional), load and unload curve numbers, and the fed length are also defined. An optional deactivation sensor, DSID, can be used to deactivate the retractor. Once deactivated, no further payin or payout will be allowed. The retractor node is typically part of the vehicle structure; belt elements should

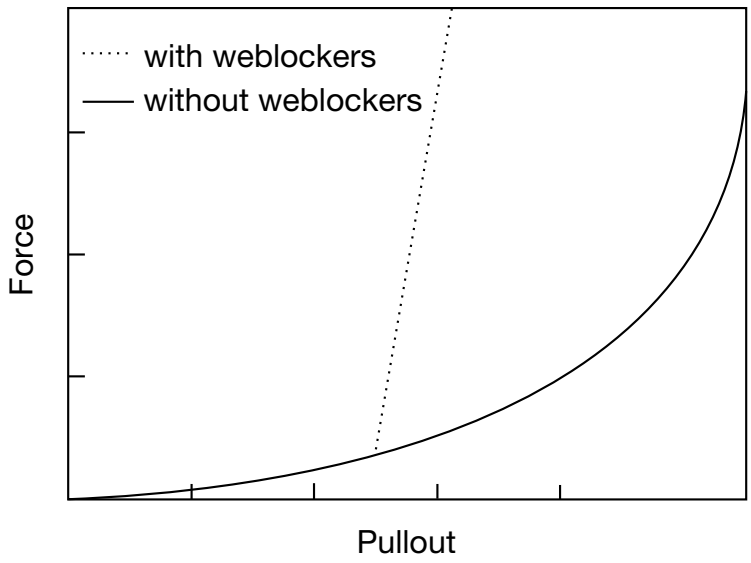

Figure 19-21. Retractor force pull characteristics.

not be connected to this node directly, but any other feature can be attached including rigid bodies. The mouth element should have a node coincident with the retractor but should not be inside the retractor. The unstretched length of the mouth element during initialization *must be at least* 1.6 × LMIN where LMIN is a field defined in *MAT_SEATBELT. Also, any other element that might become a mouth element *must have an unstretched length of at least* 1.1 × LMIN. The unstretched length, l, of a seatbelt element is

$$l = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2} + \text{SLEN} \ ,$$

where (x_1, y_1, z_1) and (x_2, y_2, z_2) are the locations of the two nodes defining the seatbelt element and SLEN is the slack length (see *ELEMENT_SEATBELT). The fed length, LFED, would typically be set either to a typical element initial length, for the distance between painted marks on a real belt for comparisons with high speed film. *The fed length should be at least three times the minimum length, LMIN.*

If there are elements initially inside the retractor (e2, e3 and e4 in Figure 19-20), they should not be referred to on the retractor input, but the retractor should be identified on the element input for these elements. Their nodes should all be coincident with the retractor node and should not be restrained or constrained. Initial slack will automatically be set to 1.1 × minimum length for these elements; this overrides any user-defined value.

Weblockers can be included within the retractor representation simply by entering a 'locking up' characteristic in the force pullout curve, see Figure 19-21. The final section can be very steep (but must have a finite slope).

2. **Multiple Belt Elements.** If desired, belt elements may be defined which are initially inside the retractor. These will emerge as belt material is paid out and

may return into the retractor if sufficient material is reeled in during unloading. For example, elements e2, e3 and e4 in Figure 19-20 are initially inside the retractor, which is paying out material into element e1. When the retractor has fed L_{crit} into e1, where

$$L_{crit} = \text{LFED} - 1.1 \times \text{LMIN}$$

in which LMIN is the minimum length defined on the belt material input (see *MAT_SEATBELT) and LFED is the fed length, element e2 emerges with an unstretched length of 1.1 × minimum length; the unstretched length of element e1 is reduced by the same amount. The force and strain in e1 are unchanged; in e2, they are set equal to those in e1. The retractor now pays out material into e2.

If no elements are inside the retractor, e2 can continue to extend as more material is fed into it.

As the retractor pulls in the belt (for example, during initial tightening), if the unstretched length of the mouth element becomes less than the minimum length, the element is taken into the retractor.

3. **Retractor Node and Belt Elements.** The retractor node should not be on any belt elements. The element defined should have one node coincident with the retractor node but should not be inside the retractor.

4. **Shell-Type Seatbelt.** When SBRNID < 0, this retractor is for shell-type seatbelt, -SBRNID is the *SET_NODE containing RN1, RN2, …RN5. SBID is then a *SET_SHELL_LIST. Note that the numbering of –SBRNID and SBID must be consistent in the direction of numbering. For example, if *SET_NODE for SBRNID has nodes of (RN1, RN2, RN3, RN4, RN5), then *SET_SHELL_LIST for SBID should have elem. of (RE1, RE2, RE3, RE4). See Figure 19-17.

5. **Sensor Definitions.** At least one sensor should be defined.

6. **Loading Curve.** The first point of the load curve should be $(0, T_{min})$. T_{min} is the minimum tension. All subsequent tension values should be greater than T_{min}.

7. **Unloading Curve.** The unloading curve should start at zero tension and increase monotonically (i.e., no segments of negative or zero slope).

8. **Retractor Characteristics and Loading.** Retractors allow belt material to be paid out into a belt element. Retractors operate in one of two regimes: unlocked when the belt material is paid out, or reeled in under constant tension and locked when a user defined force-pullout relationship applies.

   The retractor is initially unlocked, and the following sequence of events must occur for it to become locked:

a) Any one of up to four sensors must be triggered. (The sensors are described below.)

b) Then a user-defined time delay occurs.

c) Then a user-defined length of belt must be paid out (optional).

d) Then the retractor locks and once locked, it remains locked.

In the unlocked regime, the retractor attempts to apply a constant tension to the belt. This feature allows an initial tightening of the belt and takes up any slack whenever it occurs. The tension value is taken from the first point on the force-pullout load curve. The maximum rate of pull out or pull in is given by $0.01 \times$ fed length per time step. Because of this, the constant tension value is not always achieved.

In the locked regime, a user-defined curve describes the relationship between the force in the attached element and the amount of belt material paid out. If the tension in the belt subsequently relaxes, a different user-defined curve applies for unloading. The unloading curve is followed until the minimum tension is reached.

The curves are defined in terms of initial length of belt. For example, if a belt is marked at 10 mm intervals and then wound onto a retractor, and the force required to make each mark emerge from the (locked) retractor is recorded, the curves used for input would be as follows:

0 mm	Minimum tension (should be > zero)
10 mm	Force to emergence of first mark
20 mm	Force to emergence of second mark
⋮	

Pyrotechnic pretensions may be defined which cause the retractor to pull in the belt at a predetermined rate. This overrides the retractor force-pullout relationship from the moment when the pretensioner activates.

9. **Locking and Pretensioners.** In an event when only retractors are used in the model, be aware that the pull-out is measured from the point when the retractor is locked. If the belt has been pulled IN since the retractor was locked, then minimum force will be seen in the retractor until the system pays out enough belt to get back to the point when locked.

If the behavior described in the above note undesirable, then the type 6 pretensioner model is recommended for the seat belt system. A constant force as a

function of time load curve with a force equal to minimum tension will be defined, with a small PULL value on the retractor. With this set up, the pretensioner will be active until the belt pulls all the way in, but as soon as the belt starts to move back out, the pretensioner will get disabled and the retractor will take over.

*ELEMENT_SEATBELT_SENSOR

Purpose: Define seat belt sensor. Five types are possible; see Remark 3.

Card Summary:

Card 1. This card is required.

SBSID	SBSTYP	SBSFL					

Card 2a. This card is included if and only if SBSTYP = 1.

NID	DOF	ACC	ATIME				

Card 2b. This card is included if and only if SBSTYP = 2.

SBRID	PULRAT	PULTIM					

Card 2c. This card is included if and only if SBSTYP = 3.

TIME							

Card 2d. This card is included if and only if SBSTYP = 4.

NID1	NID2	DMX	DMN	NID1			

Card 2e. This card is included if and only if SBSTYP = 5.

SBRID	PAYMX	PAYMN					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SBSID	SBSTYP	SBSFL					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
SBSID	Sensor ID. A unique number must be used.

VARIABLE	DESCRIPTION
SBSTYP	Sensor type: EQ.1: acceleration of node EQ.2: retractor pull-out rate EQ.3: time EQ.4: distance between nodes EQ.5: retractor pull-out
SBSFL	Sensor flag: EQ.0: sensor is not active during dynamic relaxation EQ.1: sensor can be triggered during dynamic relaxation

Additional card for SBSTYP = 1.

Card 2a	1	2	3	4	5	6	7	8
Variable	NID	DOF	ACC	ATIME				
Type	I	I	F	F				
Default	none	none	0.0	0.0				

VARIABLE	DESCRIPTION
NID	Node ID of sensor. See Remark 1.
DOF	Degree of freedom: EQ.1: x EQ.2: y EQ.3: z
ACC	Activating acceleration
ATIME	Time over which acceleration must be exceeded

Additional card for SBSTYP = 2.

Card 2b	1	2	3	4	5	6	7	8
Variable	SBRID	PULRAT	PULTIM					
Type	I	F	F					
Default	0	0.0	0.0					

VARIABLE	DESCRIPTION
SBRID	Retractor ID; see *ELEMENT_SEATBELT_RETRACTOR.
PULRAT	Rate of pull-out (length/time units)
PULTIM	Time over which rate of pull-out must be exceeded

Additional card for SBSTYP = 3.

Card 2c	1	2	3	4	5	6	7	8
Variable	TIME							
Type	F							
Default	0.0							

VARIABLE	DESCRIPTION
TIME	Time at which sensor triggers

Additional card for SBSTYP = 4.

Card 2d	1	2	3	4	5	6	7	8
Variable	NID1	NID2	DMX	DMN				
Type	I	I	F	F				
Default	0	0	0.0	0.0				
Remarks			2	2				

VARIABLE	DESCRIPTION
NID1	Node 1 ID
NID2	Node 2 ID
DMX	Maximum distance
DMN	Minimum distance

Additional card for SBSTYP = 5.

Card 2e	1	2	3	4	5	6	7	8
Variable	SBRID	PULMX	PULMN					
Type	I	F	F					
Default	0	10^{16}	-10^{16}					

VARIABLE	DESCRIPTION
SBRID	Retractor ID; see *ELEMENT_SEATBELT_RETRACTOR.
PULMX	Maximum pull-out
PULMN	Minimum pull-out

Remarks:

1. **Node ID for Acceleration of Node Sensor.** Node should not be on rigid body, velocity boundary condition, or other 'imposed motion' feature.

2. **Distance Sensor.** Sensor triggers when the distance between the two nodes is $d \geq d_{\max}$ or $d \leq d_{\min}$.

3. **Sensor Types.** Sensors are used to trigger locking of retractors and to activate pretensioners. Four types of sensors are available which trigger according to the following criteria:

   Type 1: When the magnitude of x-, y-, or z-acceleration of a given node has remained above a given level continuously for a given time, the sensor triggers. This does not work with nodes on rigid bodies.

   Type 2: When the rate of belt payout from a given retractor has remained above a given level continuously for a given time, the sensor triggers.

   Type 3: The sensor triggers at a given time.

   Type 4: The sensor triggers when the distance between two nodes exceeds a given maximum or becomes less than a given minimum. This type of sensor is intended for use with an explicit mass/spring representation of the sensor mechanism.

   Type 5: The sensor triggers when the retractor's payout is out of the range specified by PULMX and PULMN.

   By default, the sensors are inactive during dynamic relaxation. This allows initial tightening of the belt and positioning of the occupant on the seat without locking the retractor or firing any pretensioners. However, a flag can be set in the sensor input to make the sensors active during the dynamic relaxation phase.

*ELEMENT_SEATBELT_SLIPRING

Purpose: Define seat belt slip ring.

Card 1	1	2	3	4	5	6	7	8
Variable	SBSRID	SBID1	SBID2	FC	SBRNID	LTIME	FCS	ONID
Type	I	I	I	F	I	F	F	I
Default	0	0	0	0.0	0	10^{20}	0.0	0

Optional Card.

Card 2	1	2	3	4	5	6	7	8
Variable	K	FUNCID	DIRECT	DC		LCNFFD	LCNFFS	
Type	F	I	I	F		I	I	
Default	0.0	0	0	0.0		0	0	

VARIABLE	DESCRIPTION
SBSRID	Slip ring ID. A unique number has to be used. See Remark 4 below for the treatment of slip rings for shell belt elements.
SBID1	Seat belt element 1 ID
SBID2	Seat belt element 2 ID
FC	Coulomb dynamic friction coefficient. If less than zero, |FC| refers to a curve which defines the dynamic friction coefficient as a function of time.
SBRNID	Slip ring node, NID
LTIME	Slip ring lockup time. After this time no material is moved from one side of the slip ring to the other. This option is not active during dynamic relaxation.

VARIABLE	DESCRIPTION
FCS	Optional Coulomb static friction coefficient. If less than zero, |FCS| refers to a curve which defines the static friction coefficient as a function of time.
ONID	Optional orientation node ID used to define the skew angle, α (see Figures 19-22 and 19-25). If ONID is undefined, the skew angle is assumed to be 0.0.
K	Optional coefficient for determining the Coulomb friction coefficient related to the skew angle, α (see Figure 19-25). See Remark 5.
FUNCID	Function ID to determine friction coefficient.
DIRECT	Direction of belt movement. To disable the belt slip behavior imposed by DIRECT, see the Remark "Seatbelt Slip Ring" under *SENSOR_CONTROL. EQ.0: If the belt can move along both directions. EQ.12: If the belt is only allowed to slip along the direction from SBID1 to SBID2. EQ.21: If the belt is only allowed to slip along the direction from SBID2 to SBID1.
DC	Optional decay constant to allow a smooth transition between the static and dynamic friction coefficients, that is, $\mu_c = \text{FC} + (\text{FCS} - \text{FC})e^{-\text{DC}\times\lvert v_{\text{rel}}\rvert}$
LCNFFD	Optional curve for normal-force-dependent Coulomb dynamic friction coefficient. When defined, the dynamic friction coefficient becomes $\text{FC} + f_{\text{LCNFFD}}(F_n)$, where $f_{\text{LCNFFD}}(F_n)$ is the function value of LCNFFD at contact force, F_n. The normal direction is defined as the average of the directions along the length of the seatbelt elements SBID1 and SBID2. The normal (or contact) force, F_n, is the sum of the projection of the tension forces on these elements, T_1 and T_2, onto the normal direction.
LCNFFS	Optional curve for normal-force-dependent Coulomb static friction coefficient. When defined, the static friction coefficient becomes $\text{FCS} + f_{\text{LCNFFS}}(F_n)$, where $f_{\text{LCNFFS}}(F_n)$ is the function value of LCNFFS at contact force, F_n.

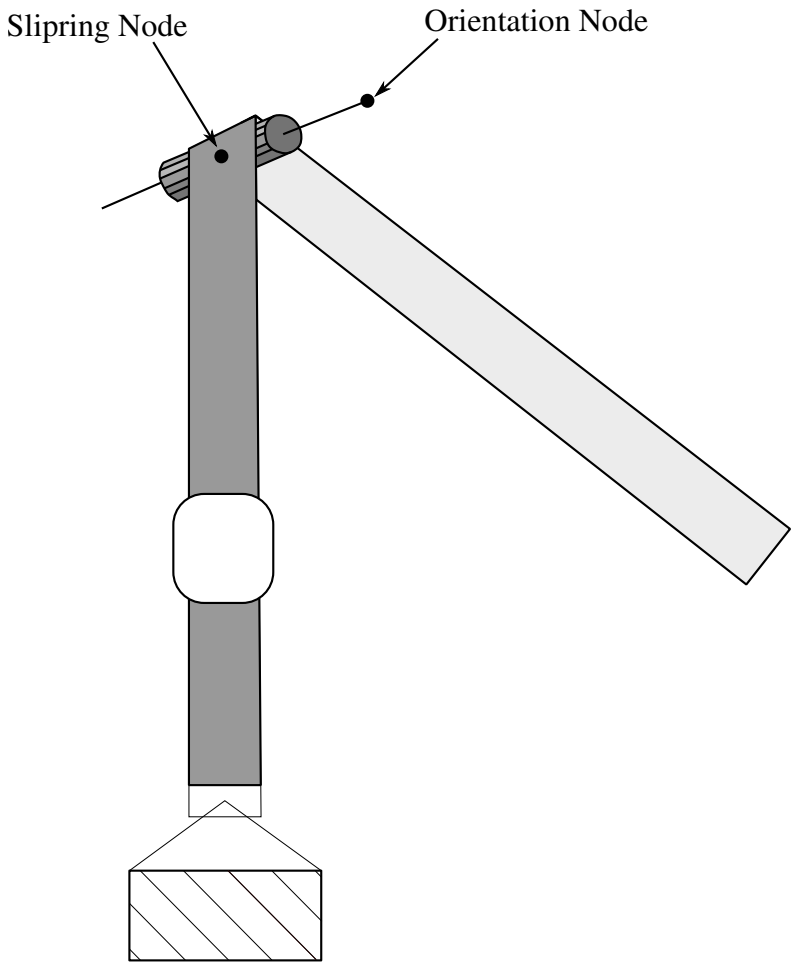

Figure 19-22. Orientation node.

Remarks:

1. **Slip Ring Model.** Slip rings allow continuous sliding of a belt through a sharp change of angle. To define a slip ring, the user identifies the two belt elements which meet at the slip ring (such as Elements 1 and 2 shown in Figure 19-23), the friction coefficient, and the slip ring node. The two elements must have a common node coincident with the slip ring node and should not be referenced by any other slip ring definition. No attempt should be made to restrain or constrain the common node because its motion will automatically be constrained to follow the slip ring node. Typically, the slip ring node is part of the vehicle body structure; therefore, belt elements should not be connected to this node directly, but any other feature can be attached, including rigid bodies.

   As shown in Figure 19-23, during slip Node B in the belt material remains attached to the slip ring node, but belt material (in the form of unstretched length) is passed from Element 1 to Element 2 to achieve slip. The amount of slip at each time step is calculated from the ratio of forces in Elements 1 and 2. The ratio of

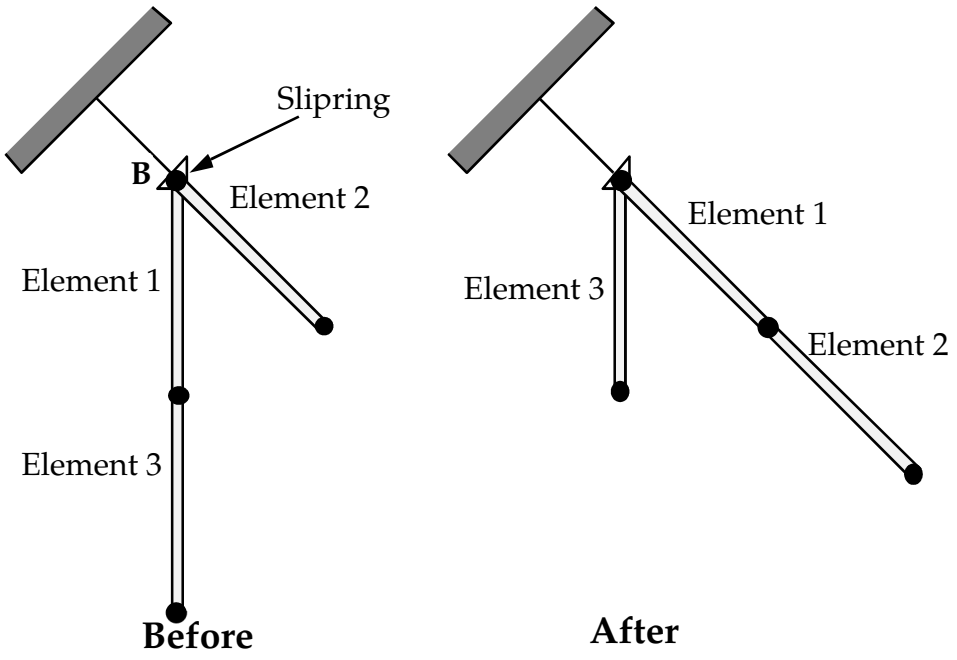

Figure 19-23. Elements passing through slipring.

forces is determined by the relative angle between the elements and the coefficient of friction, FC. The tension in the belts are T_1 and T_2, where T_2 is on the high tension side and T_1 is the force on the low tension side. Thus, if T_2 is sufficiently close to T_1, no slip occurs; otherwise, slip is just sufficient to reduce the ratio T_2/T_1 to $e^{\mathrm{FC}\times\theta}$, where θ is the wrap angle; see Figures 19-22 and 19-24. No slip occurs if both elements are slack. The out-of-balance force at Node B is reacted on the slip ring node; the motion of node B follows that of slip ring node.

2. **Elements Connected to Sliprings.** The unstretched length of a seatbelt element connected to a slipring during initialization *must be at least* 1.6 × LMIN where LMIN is a field defined in *MAT_SEATBELT. The unstretched length, l, of a seatbelt element is

$$l = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2} + \mathrm{SLEN} \ ,$$

where (x_1, y_1, z_1) and (x_2, y_2, z_2) are the locations of the two nodes defining the seatbelt element and SLEN is the slack length (see *ELEMENT_SEATBELT). Any other element that may interact with the slipring *must have an unstretched length of at least* 1.1 × LMIN.

3. **Local Remeshing.** If, due to slip through the slip ring, the unstretched length of an element becomes less than the minimum length (as entered on the belt material card), the belt is remeshed locally: the short element passes through the slip ring and reappears on the other side (see Figure 19-23). The new unstretched length of element 1 is 1.1 × minimum length. Force and strain in elements 2 and 3 are unchanged; force and strain in element 1 are now equal to

those in element 2. Subsequent slip will pass material from element 3 to element 1. This process can continue with several elements passing in turn through the slip ring.

4. **Shell Elements.** When SBRNID < 0, this slip ring is for shell-type seatbelt; -SBRNID is the *SET_NODE containing SN1, SN2, …SN5. SBID1 and SBID2 are then *SET_SHELL_LIST. Note that the numbering of -SBRNID, SBID1 and SBID2 has to be consistent in the direction of numbering. For example, if *SET_-NODE for SBRNID has nodes (SN1, SN2, SN3, SN4, SN5) then *SET_SHELL_-LIST for SBID1 should have elements (SRE11, SRE12, SRE13, SRE14) and *SET_-SHELL_LIST for SBID2 should have elements (SRE21, SRE22, SRE23, SRE24). See Figure 19-22.

5. **Coulomb Friction.** If K is undefined, the limiting force ratio is taken as $e^{\mathrm{FC}\times\theta}$. If K is defined, the maximum force ratio is computed as

$$e^{\mathrm{FC}\times\theta(1+\mathrm{K}\times\alpha^2)},$$

where α is the angle shown in Figure 19-25. The function is defined using the *DEFINE_FUNCTION keyword input. This function is a function of three variables, and the ratio is given by evaluating

$$\frac{T_2}{T_1} = \mathrm{FUNC}(\mathrm{FCT}, \theta, \alpha),$$

where FCT is the instantaneous friction coefficient at time t, that is, it has the value of FC if the belt has moved in the last time-step and the value of FCS if the belt has been stationary. For example, the default behavior can be obtained using the function definition (assuming FCT has a value of 0.025 and the function ID is 1):

```
*DEFINE_FUNCTION
    1,
f(fct,theta,alpha) = exp(0.025*theta)
```

Behavior like the default option can be obtained with (K = 0.1):

```
*DEFINE_FUNCTION
    1,
f(fct,theta,alpha) = exp(0.025*theta*(1.+0.1*alpha*alpha))
```

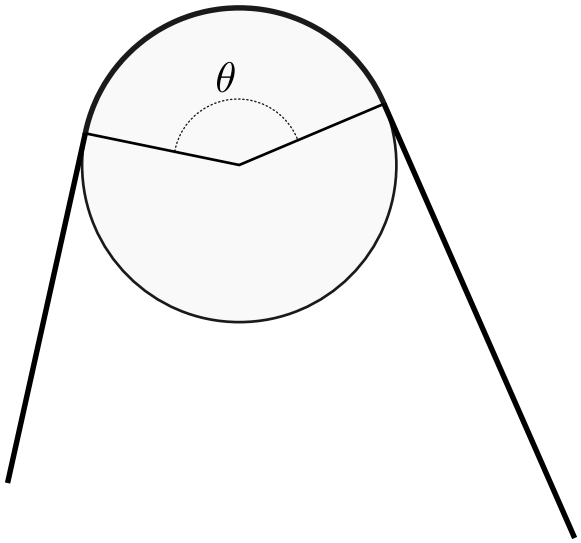

Figure 19-24. Front view showing wrap angle.

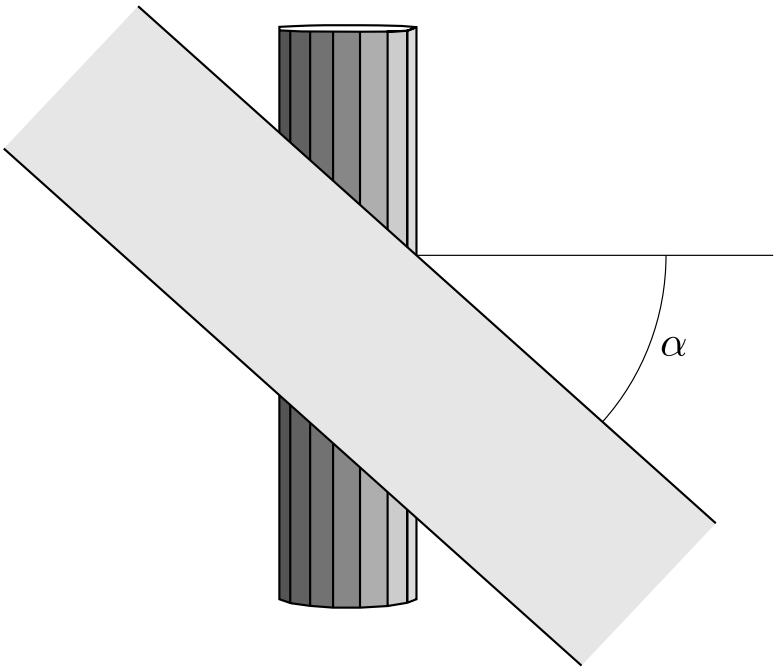

Figure 19-25. Top view shows orientation of belt relative to axis.

***ELEMENT_SHELL**_{OPTION}

Available options include:

<BLANK>

THICKNESS

BETA or MCID

OFFSET

DOF

COMPOSITE

COMPOSITE_LONG

SHL4_TO_SHL8

Stacking of options, e.g., THICKNESS_OFFSET, is allowed in some cases. When combining options in this manner, check d3hsp to confirm that all the options are acknowledged.

Purpose: Define three, four, six, and eight node elements including 3D shells, membranes, 2D plane stress, plane strain, and axisymmetric solids. The type of the element and its formulation is specified through the part ID (see *PART) and the section ID (see *SECTION_SHELL). Also, the thickness of each element can be specified when applicable on the element cards or else a default thickness value is used from the section definition.

For orthotropic and anisotropic materials, a local material angle (variable BETA) can be defined which is cumulative with the integration point angles specified in *SECTION_SHELL, *PART_COMPOSITE, *ELEMENT_SHELL_COMPOSITE, or *ELEMENT_SHELL_COMPOSITE_LONG. Alternatively, the material coordinate system can be defined as the projection of a local coordinate system, MCID, onto the shell.

An offset option, OFFSET, is available for moving the shell reference surface from the nodal points that define the shell.

The COMPOSITE or COMPOSITE_LONG option allows an arbitrary number of integration points across the thickness of shells sharing the same part ID. This is independent of thickness defined in *SECTION_SHELL. To maintain a direct association of through-thickness integration point numbers with physical plies in the case where the number of plies varies from element to element, see Remark 12.

The option, SHL4_TO_SHL8, converts 3 node triangular and 4 node quadrilateral shell elements to 6 node triangular and 8 node quadrilateral quadratic shell elements, respectively, by the addition of mid-side nodal points. See Remark 9 below.

For the shell formulation that uses additional nodal degrees-of-freedom, the option DOF is available to connect the nodes of the shell to corresponding scalar nodes. Four scalar nodes are required for element type 25 to model the thickness changes that require 2 additional degrees-of-freedom per shell node. Defining these nodes is optional; if left undefined, they will be automatically created.

COMPOSITE Cards. Additional set of cards for the COMPOSITE keyword option. Values of material ID, thickness, and material angle for each through-thickness integration point of a composite shell are defined using these cards (up to two integration points per card), and these values overrule values specified elsewhere. The integration point data should be given sequentially starting with the bottommost integration point. The total number of integration points is determined by the number of entries on these cards. The thickness of each shell is the summation of the integration point thicknesses. Define as many cards as needed to define all the through-thickness integration points. The fourth field must be zero or blank to be interpreted as a Card 6.

N5 - N8	Mid-side nodes for eight node shell
THIC1	Shell thickness at node 1
THIC2	Shell thickness at node 2
THIC3	Shell thickness at node 3
THIC4	Shell thickness at node 4
BETA	Orthotropic material base offset angle (see Remarks 5 and 6 below). The angle is given in degrees. If blank, the default is set to zero.
MCID	Material coordinate system ID. The **a**-axis of the base (or element-level) material coordinate system is the projection of the x-axis of coordinate system MCID onto the surface of the shell element. The **c**-axis of the material coordinate system aligns with the shell normal. The **b**-axis is taken as $\mathbf{b} = \mathbf{c} \times \mathbf{a}$. Each layer in the element can have a unique material orientation by defining a rotation angle for each layer as described in Remark 5.
THIC5	Shell thickness at node 5
THIC6	Shell thickness at node 6
THIC7	Shell thickness at node 7
THIC8	Shell thickness at node 8
OFFSET	The offset distance from the plane of the nodal points to the reference surface of the shell in the direction of the normal vector to the shell.
NS1	Scalar node 1, parameter NDOF on the *NODE_SCALAR is normally set to 2. If the thickness is constrained, set NDOF = 0.
NS2	Scalar node 2
NS3	Scalar node 3
NS4	Scalar node 4
MID*i*	Material ID of integration point *i*, see *MAT_… Section.

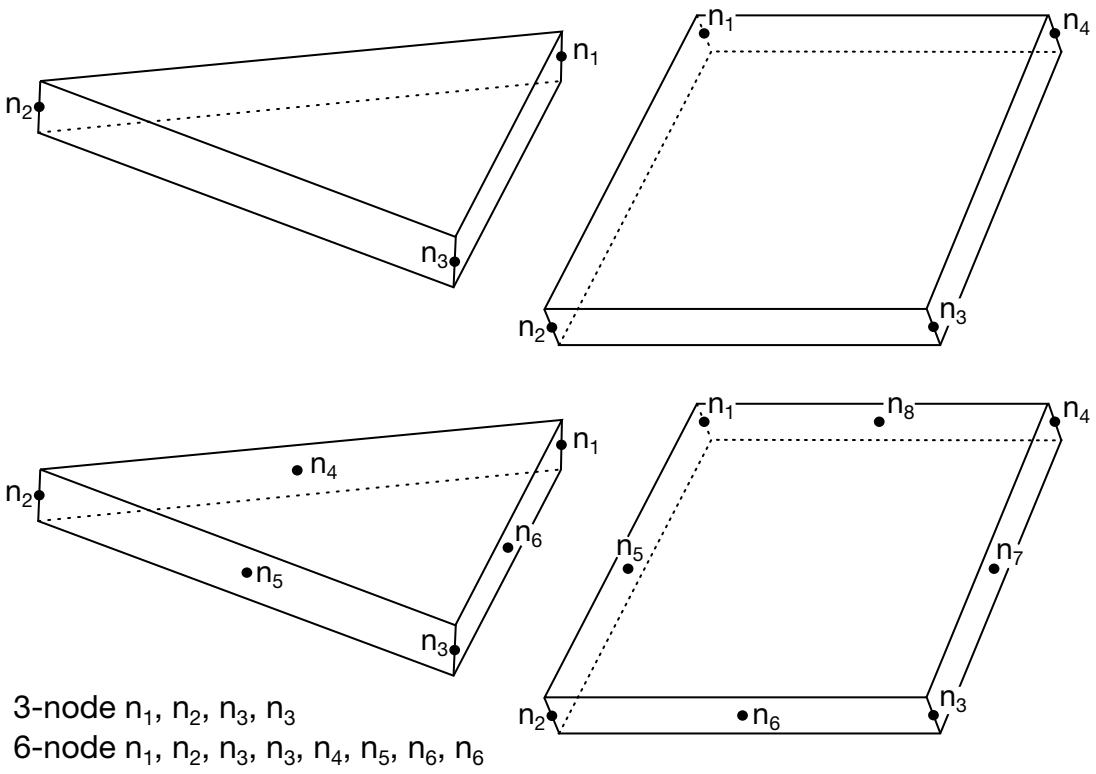

Figure 19-26. LS-DYNA shell elements. Counterclockwise node numbering determines the top surface.

VARIABLE	DESCRIPTION
THICK*i*	Thickness of integration point *i*.
B*i*	Material angle of integration point *i*.
PLYID*i*	Ply ID for integration point *i* (for post-processing purposes).

Remarks:

1. **Default Thickness.** Default values in place of zero shell thicknesses are taken from the cross-section property definition of the PID; see *SECTION_SHELL.

2. **Ordering.** Counterclockwise node numbering determines the top surface, see Figure 19-26

3. **Coordinate Systems.** Stresses and strain output in the binary databases are given in the global coordinate system, whereas stress resultants are output in the local coordinate system for the shell element.

4. **Convexity.** Interior angles must be less than 180 degrees.

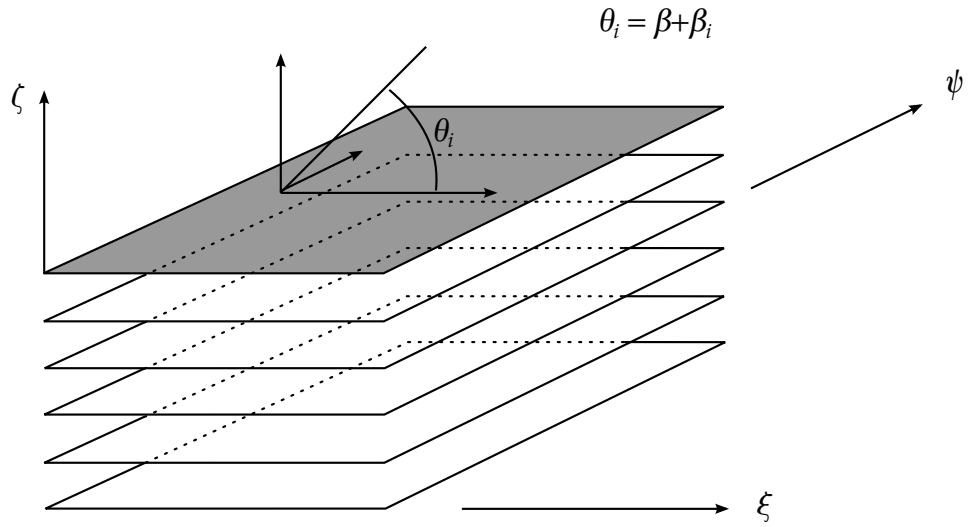

Figure 19-27. A multi-layer laminate can be defined. The angle β_i is defined for the i^{th} lamina (integration point), see *SECTION_SHELL.

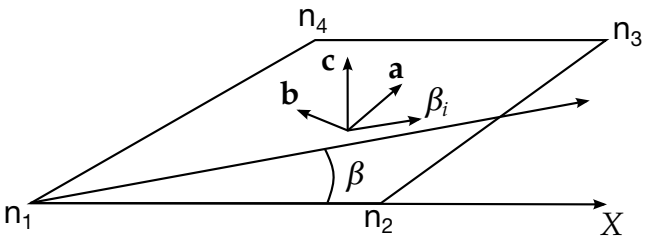

Figure 19-28. Orientation of material directions (shown relative to the 1-2 side as when AOPT = 0 in *MAT).

5. **Material Orientation.** To allow the orientation of orthotropic and anisotropic materials to be defined for each shell element, a BETA angle can be defined. This BETA angle is used with the AOPT parameter and associated data on the *MAT card to determine an element reference direction for the element. The AOPT data defines a coordinate system and the BETA angle defines a subsequent rotation about the element normal to determine the element reference system. For composite modeling, each layer in the element can have a unique material direction by defining an additional rotation angle for the layer, using either the ICOMP and B*i* parameters on *SECTION_SHELL or the B*i* parameter on *PART_COMPOSITE. The material direction for layer *i* is then determined by a rotation angle, θ_i as shown in Figures 19-27 and 19-28.

6. **Activation of the BETA Field and Its Interpretation.** To activate the BETA field, either the BETA or THICKNESS keyword option must be used. There is a difference in how a zero value or empty field is interpreted. When the BETA keyword option is used, a zero value or empty BETA field will override the BETA on *MAT. However, when the THICKNESS keyword option is used, a zero value or empty BETA field will not override the BETA value on *MAT.

Therefore, to input BETA = 0, the BETA keyword option is recommended. If a THIC value is omitted or input as zero, the thickness will default to the value on the *SECTION_SHELL card. If mid-side nodes are defined (N5 - N8), then a second line of thickness values will be read. This line may be left blank, but cannot be omitted.

7. **Offset for the Reference Surface.** The parameter OFFSET gives the offset from the nodal points of the shell to the reference surface. This option applies to most shell formulations excluding two-dimensional elements, membrane elements, and quadratic shell elements. Except for Mortar contacts, the reference surface offset given by OFFSET is not taken into account in the contact subroutines unless CNTCO is set to 1 in *CONTROL_SHELL. For Mortar contacts the OFFSET determines the location of the contact surface.

8. **Scalar Nodes.** The scalar nodes specified on the optional card refer to the scalar nodes defined by the user to hold additional degrees of freedom for shells with this capability. Scalar nodes are used with shell element type 25 and 26.

9. **Automatic Order Increase.** The option, SHL4_TO_SHL8, converts 3 node triangular and 4 node quadrilateral shell elements to 6 node triangular and 8 node quadrilateral quadratic shell elements, respectively, by the addition of mid-side nodal points. The user node ID's for these generated nodes are offset after the largest user node ID defined in the input file. When defining the *SECTION_SHELL keyword, the element type must be specified as either 23 or 24 corresponding to quadratic quadrilateral and triangular shells, respectively.

10. **Cohesive Elements.** Cohesive elements (ELFORM = 29, 46 or 47 on *SECTION_SHELL) may be defined with zero depth to connect surfaces with no gap between them, but must have nodes 1 and 2 on one surface and nodes 3 and 4 on the other.

11. **Contact Thickness when using *ELEMENT_SHELL_THICKNESS in MPP.** When using MPP, THEORY = 1 in *CONTROL_SHELL has special meaning when dealing with non-uniform-thickness shells, that is, it serves to set the nodal contact thickness equal to the average of the nodal thicknesses from the shells sharing that node. Thus when a contact surface is comprised of non-uniform-thickness shells, THEORY = 1 is recommended; the actual shell formulation can be set using ELFORM in *SECTION_SHELL. (This remark does not apply to segment based (SOFT=2) contact wherein each contact segment is considered to be of uniform thickness.)

12. **Assignment of Zero Thickness to Integration Points.** The ability to assign zero- thickness integration points in the stacking sequence allows the number of integration points to remain constant even as the number of physical plies varies from element to element and eases post-processing since a particular integration point corresponds to a physical ply. Such a capability is important when one or

more of the physical plies are not continuous across a part. To represent a missing ply in *ELEMENT_SHELL_COMPOSITE, set THICK*i* to 0.0 for the corresponding integration point and additionally, either set MID = -1 or, if the LONG option is used, set PLYID to any nonzero value

When postprocessing the results using LS-PrePost version 4.5, read both the keyword deck and d3plot database into the code and then select Option → N/A gray fringe. Then, when viewing fringe plots for a particular integration point (FriComp → IPt → intpt#), the element will be grayed out if the selected integration point is missing (or has zero thickness) in that element.

13. **PID with COMPOSITE keyword option.** When using the COMPOSITE keyword option, the PID on Card 1 must reference a *PART card that does not also use the COMPOSITE keyword option.

*ELEMENT_SHELL_NURBS_PATCH_{OPTION1}_{OPTION2}

Available options for *OPTION1* include:

<BLANK>

TRIMMED

Available options for *OPTION2* include:

<BLANK>

TITLE

Purpose: Define a NURBS surface patch using two univariate knot vectors, a rectangular grid of control points, and optionally a set of control weights. The two knot vectors define the necessary shape functions and parameterize the surface by virtue of the tensor product scheme.

The *r*- and *s*-direction knot vectors have lengths of NPR+PR+1 and NPS+PS+1, respectively. NPR and NPS are the number of control points in each direction while PR and PS define the polynomial degree in each direction. The control grid consists of NPR × NPS control points. A control weight may be defined for each control point. There is no limit on the size of a NURBS surface patch.

The total number of necessary data cards depends on the parameters given in Cards 1 and 2, that is,

$$\#\ \text{of cards} = 2 + \left\lceil \frac{\text{NPR} + \text{PR} + 1}{8} \right\rceil + \left\lceil \frac{\text{NPS} + \text{PS} + 1}{8} \right\rceil + (\text{WFL} + 1) \times \text{NPS} \times \left\lceil \frac{\text{NPR}}{8} \right\rceil ,$$

where $\lceil x \rceil = \text{ceil}(x)$. The flag WFL (see Card 2 below) indicates whether the control weights are user-defined. An example NURBS surface and the partial keyword deck using this keyword is given in Figures 19-29 and 19-30, respectively.

A NURBS surface patch may be trimmed using the TRIMMED option. This requires the definition of additional trimming loop(s) which can be defined using Cards E and F. Note that optional cards used to define trimming loops are not counted in the above expression. See Remark 6.

A description of the NURBS surface patch may be provided using the option TITLE which is also written to the d3hsp file.

Card Summary:

Card Title. This card is included if and only if the TITLE keyword option is used.

TITLE

Card 1. This card is required.

Data Cards:

Title Card. Additional card for the TITLE keyword option.

Card Title	1	2	3	4	5	6	7	8
Variable	TITLE							
Type	A80							

VARIABLE	DESCRIPTION
TITLE	Description of the NURBS patch surface

Card 1	1	2	3	4	5	6	7	8
Variable	NPID	PID	NPR	PR	NPS	PS		
Type	I	I	I	I	I	I		
Default	none	none	None	none	none	none		

VARIABLE	DESCRIPTION
NPID	NURBS surface element / patch ID. A unique number must be chosen.
PID	PART ID. See *PART.
NPR	Number of control points in the local *r*-direction.
PR	Polynomial degree of the basis function in the local *r*-direction.
NPS	Number of control points in the local *s*-direction.
PS	Polynomial degree of the basis function in the local *s*-direction.

Card 2	1	2	3	4	5	6	7	8
Variable	WFL	ELFORM	INT	NISR	NISS	IMASS		IDFNE
Type	I	I	I	F	F	I		I
Default	0	0	0	PR	PS	0		0

VARIABLE	DESCRIPTION
WFL	Flag for user defined control weights: EQ.0: Control weights are assumed to be uniform and positive; that is, the surface is a B-spline surface. No optional Cards D is allowed. EQ.1: Control weights are defined using optional Cards D.
ELFORM	Shell formulation to be used (see Remark 3): EQ.0: Reissner-Mindlin with fibers at the control points EQ.1: Kirchhoff-Love with fibers at the control points (not recommended) EQ.2: Kirchhoff-Love with fibers at the integration points EQ.3: Reissner-Mindlin with fibers at the integration points EQ.-4/4: Combination of FORM = 0 and FORM = 1. See Remark 4.
INT	In-plane numerical integration rule: EQ.0: Uniformly reduced Gauss integration. NIP = PR × PS. EQ.1: Full Gauss integration. NIP = (PR + 1) × (PS + 1). EQ.2: Reduced, patch-wise integration rule for C^1-continuous quadratic NURBS surfaces.

VARIABLE	DESCRIPTION
NISR	Number or average edge length of automatically created interpolation shell elements per each knot span in the *r*-direction. See Remark 5 and Figure 19-30. GT.0: NINT(NISR) is the number of interpolation elements in the *r*-direction LT.0: |NISR| is the average edge length of the interpolation elements in the *r*-direction.
NISS	Number or average edge length of automatically created interpolation shell elements per each knot span in the *s*-direction. See Remark 5 and Figure 19-30. GT.0: NINT(NISS) is the number of interpolation elements in the *s*-direction LT.0: |NISS| is the average edge length of the interpolation elements in the *s*-direction
IMASS	Mass matrix lumping scheme: EQ.0: Row sum. EQ.1: Diagonal weighting.
IDFNE	Element ID of first NURBS-Element within this NURBS-Patch definition.

Knot Vector Cards (for *r*-direction). The knot vector in *r*-direction with length NPR + PR + 1 is given below requiring a total of ceil[(NPR + PR + 1)/8] cards.

Cards A	1	2	3	4	5	6	7	8
Variable	RK1	RK2	RK3	RK4	RK5	RK6	RK7	RK8
Type	F	F	F	F	F	F	F	F
Default	none	none	None	none	none	none	none	none

VARIABLE	DESCRIPTION
RK*m*	Values of the univariate knot vector in *r*-direction

Knot Vector Cards (for *s*-direction). The knot vector in *s*-direction with length NPS + PS + 1 is given below requiring a total of ceil[(NPS + PS + 1)/8] cards.

Cards B	1	2	3	4	5	6	7	8
Variable	SK1	SK2	SK3	SK4	SK5	SK6	SK7	SK8
Type	F	F	F	F	F	F	F	F
Default	none	none	None	none	none	none	none	none

VARIABLE	DESCRIPTION
SK*n*	Values of the univariate knot vector in *s*-direction

Connectivity Cards. The connectivity of the control grid is a two dimensional table of NPS rows and NPR columns. This data fills the NPS sets (one set for each row) of NPR points tightly packed into ceil(NPR/8) connectivity cards, for a total of NPS × ceil(NPR/8) cards.

Cards C	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	N5	N6	N7	N8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
N*k*	Control point IDs, defined via *NODE, to define the control grid
	LT.0: Control point with rotational DOFs for FORM = 4 /-4; see Remark 4.

Control Weight Cards (Optional). Additional cards are used to set a weight for each control point if WFL = 1 on Card 2. These cards have an ordering identical to the connectivity cards (Cards C).

Cards D	1	2	3	4	5	6	7	8
Variable	W1	W2	W3	W4	W5	W6	W7	W8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
W*k*	Control weights of the surface patch

Trimming Loop Title Card.

Cards E	1	2	3	4	5	6	7	8
Variable	TITLE							
Type	A80							
Default	trimming loop							

Trimming Loop Connectivity Cards. Define a trimming loop. See Remark 6.

Cards F	1	2	3	4	5	6	7	8
Variable	C1	C2	C3	C4	C5	C6	C7	C8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
TITLE	Title of the trimming loop
C*l*	Trimming curve ID pointing to a curve defined using *DEFINE_-NURBS_CURVE. A unique number has to be chosen.

Remarks:

1. **Shell Thickness.** The thickness of the shell is defined in *SECTION_SHELL and referenced via *PART.

2. **Element Formulation.** ELFORM = 201 must be used in *SECTION_SHELL.

3. **Thin Shell Formulation.** For thin IGA shells we do not recommend using FORM = 1. Instead we recommend using FORM = 2.

4. **Rotational Degrees of Freedom.** FORM = 4 allows the mixture of control points with and without rotational DOFs. This might be useful at the boundaries of NURBS patches where the continuity usually drops to C^0 and rotational DOFs are necessary. To indicate control points with rotational DOFs (6 DOFs/control point), the node number of the corresponding control point has to be set as the negative node ID in the connectivity Cards C. Positive node IDs indicate control points without rotational DOFs (3 DOFs/control point).

   If FORM = -4 is used, the control points at the patch boundary are automatically treated with rotational DOFs without the need to specify them explicitly in the connectivity cards (Cards C). This might be sufficient in many cases.

5. **Interpolation Elements.** The post-processing and the treatment of contact boundary conditions are presently dealt with interpolation elements, defined via interpolation nodes. These nodes and elements are automatically created, see Figure 19-30, where NISR and NISS indicate the number or average length of interpolation elements to be created per NURBS-element in the r- and s-directions, respectively.

6. **Trimming Loops.** Trimmed NURBS surface elements / patches can be analyzed by defining trimming loops. A trimming loop is formed by a set of NURBS curves defined in the surface parametric coordinate system. Each trimming curve is defined using the *DEFINE_NURBS_CURVE keyword.

   Trimming loops may be given a distinct title on Cards E and the connectivity of trimming curves defining a loop is stored on Cards F. The end and starting points of two consecutive curves *must* coincide. If the loop is defined by a single curve, the starting and end points of the curve *must* match. Furthermore, the orientation of the trimming loop is essential to define the trimmed surface. Travelling along the trimming loop, the surface on the right-hand side of the loop will be trimmed. There is no limitation on either the number of trimming curves forming a loop or the number of loops used to trim a NURBS surface element/patch.

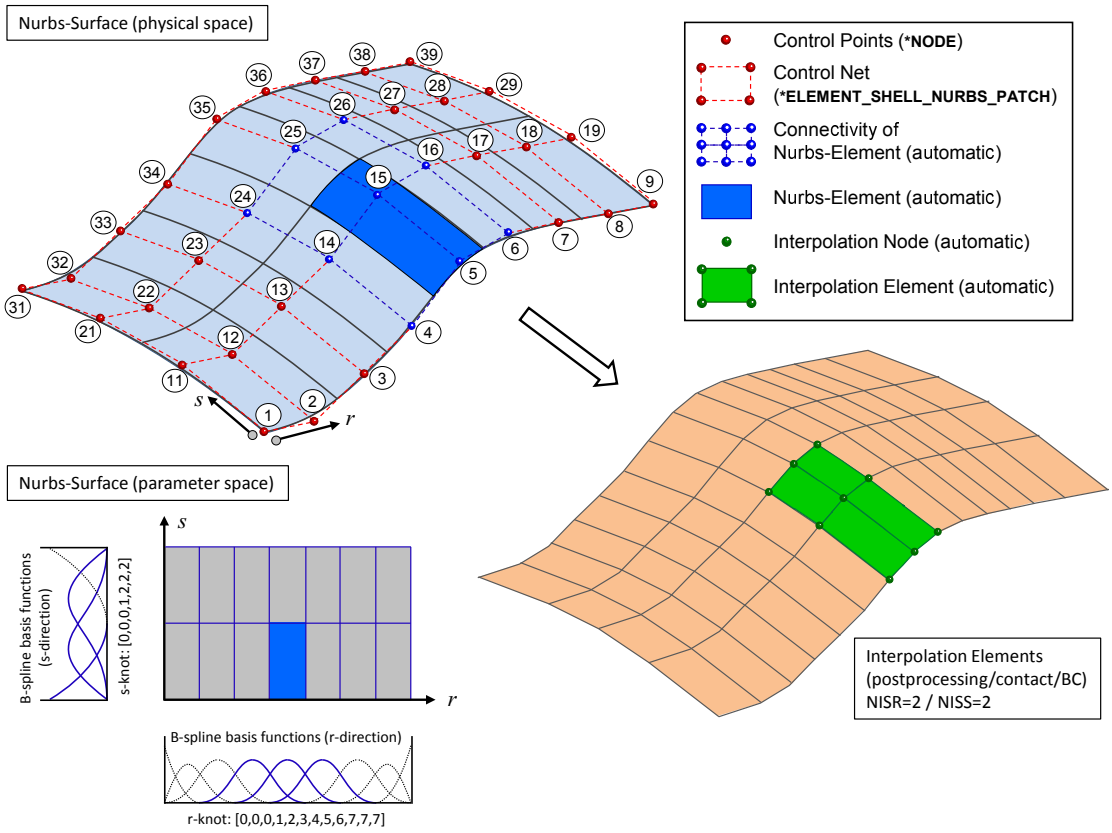

Figure 19-29. An example biquadratic NURBS surface patch and its interpolation mesh.

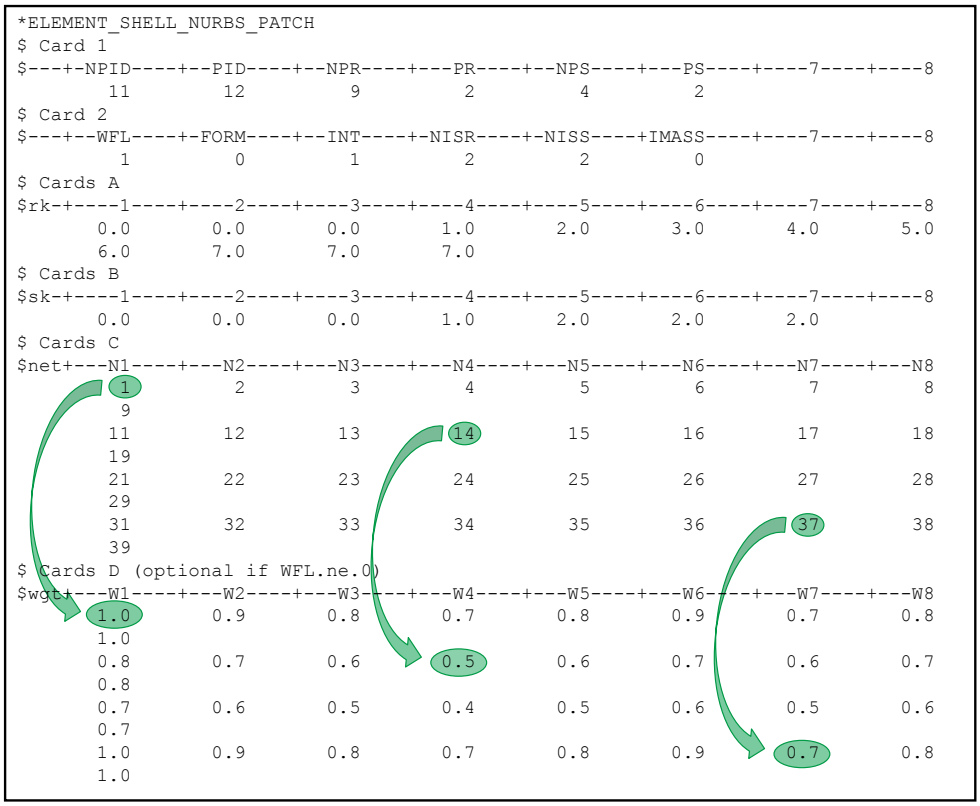

Figure 19-30. Excerpt of the *ELEMENT_SHELL_NURBS_PATCH keyword defining the biquadratic NURBS surface patch in Figure 19-29.

*ELEMENT_SHELL_SOURCE_SINK

Purpose: Define a strip of shell elements of a single part ID to simulate a continuous forming operation. This option requires logical regular meshing of rectangular elements, which implies that the number of nodal points across the strip is constant along the length. Elements are created at the source and disappear at the sink. The advantage of this approach is that it is not necessary to define an enormous number of elements to simulate a continuous forming operation. Currently, only one source-sink definition is allowed. The boundary conditions at the source are discrete nodal point forces to keep the work piece in tension. At the sink, displacement boundary conditions are applied.

Card	1	2	3	4	5	6	7	8
Variable	NSSR	NSSK	PID					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
NSSR	Node set at source. Provide an ordered set of nodes between corner nodes, which include the corner nodes.
NSSK	Node set at sink. Provide an ordered set of nodes between corner nodes, which include the corner nodes.
PID	Part ID of work piece.

P21

P40

T15

T20

Stacking of options, such as ORTHO_DOF, is allowed in some cases. When combining options in this manner, check d3hsp to confirm that all options are acknowledged.

Purpose: Define three-dimensional solid elements. The type of solid element and its formulation is specified through the part ID (see *PART) and the section ID (see *SECTION_SOLID_*OPTION*). Also, a local coordinate system for orthotropic and anisotropic materials can be defined by using the ORTHO option. If extra degrees of freedom are needed, the DOF option should be used. The option TET4TOTET10 converts 4 node tetrahedrons to 10 node tetrahedrons, and H8TOH20/H8TOH27 converts 8-node hexahedrons to 20-node/27-node hexahedrons. The option H8TOH64 converts elements with linear basis functions to elements with cubic basis functions. See Remark 1.

Card Summary:

Card Sets. Include as many of the following sets of cards matching the keyword options as desired. This input ends with the next keyword ("*") card.

Card 1. This card is required.

EID	PID						

Card 2. This card is required.

N1	N2	N3	N4	N5	N6	N7	N8	N9	N10

Card 3. Include as many of this card as needed to specify the nodes of the 15-node tetrahedron, 20-node tetrahedron and hexahedron, 21-node and 40 node pentahedron, and the 27-node and 64-node hexahedron.

VARIABLE	DESCRIPTION
NS1	Scalar node 1. See Remark 7.
NS2	Scalar node 2
⋮	⋮
NS8	Scalar node 8

Remarks:

1. **Automatic Node Generation**. The option TET4TOTET10 automatically converts 4 node tetrahedral solids to 10 node quadratic tetrahedral solids. Additional mid-side nodes are created which are shared by all tetrahedral elements that contain the edge. The user node ID's for these generated nodes are offset after the largest user node ID defined in the input file. When defining the *SECTION_SOLID keyword, the element type must be specified as either 16 or 17 which are the 10-noded tetrahedrons in LS-DYNA. Mid-side nodes created as a result of TET4TOTET10 will not be automatically added to node sets that include the nodes of the original tetrahedron. So, for example, if the tetrahedrons are to have an initial velocity, velocity initialization by part ID or part set ID using *INITIAL_VELOCITY_GENERATION is necessary as opposed to velocity initialization by node set ID using *INITIAL_VELOCITY. The option H8TOH20/H8TOH27 provides the same functionality for converting 8-node to 20-node/27-node elements. The option H8TOH64 converts 8-node to 64-node hexahedra, 4-nodel to 20-node tetraheda, and 6-node to 40-node pentahedra. Mid-side nodes and face nodes created as a result of H8TOH20/H8TO27/H8TO64 will automatically be added to node sets that include the nodes of the original hexahedron.

2. **Node Numbering.** Four, six, and eight node elements are shown in Figure 19-31 where the ordering of the nodal points is shown. 27-node elements are shown

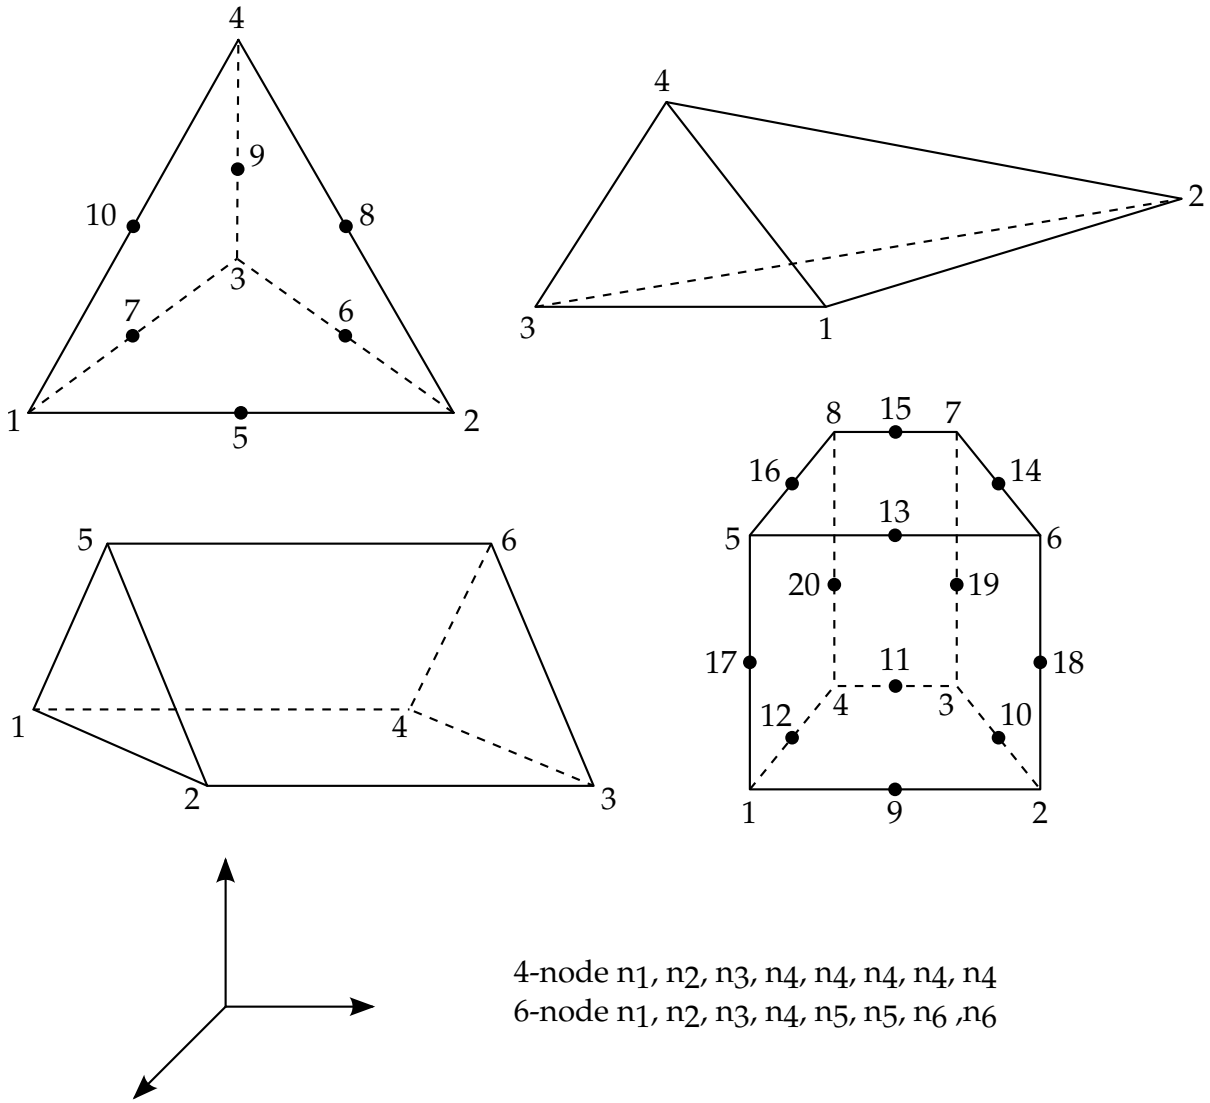

Figure 19-31. Four, six, eight, ten, and twenty node solid elements. For the hexahedral and pentahedral shapes, nodes 1-4 are on the bottom surface.

in Figure 19-32. This ordering must be followed or code termination with occur during the initialization phase with a negative volume message. The input of nodes on the element cards for the tetrahedral and pentahedral elements is given by:

4-noded tetrahedron	N1, N2, N3, N4, N4, N4, N4, N4, 0, 0
6-noded pentahedron	N1, N2, N3, N4, N5, N5, N6, N6, 0, 0

To visualize the node numbering for higher order elements, that is, options H27, H64, P21, P40, T15, and T20, see hexahedron 27, hexahedron 64, pentahedron 21, pentahedron 40, tetrahedron 15, and tetrahedron 20.

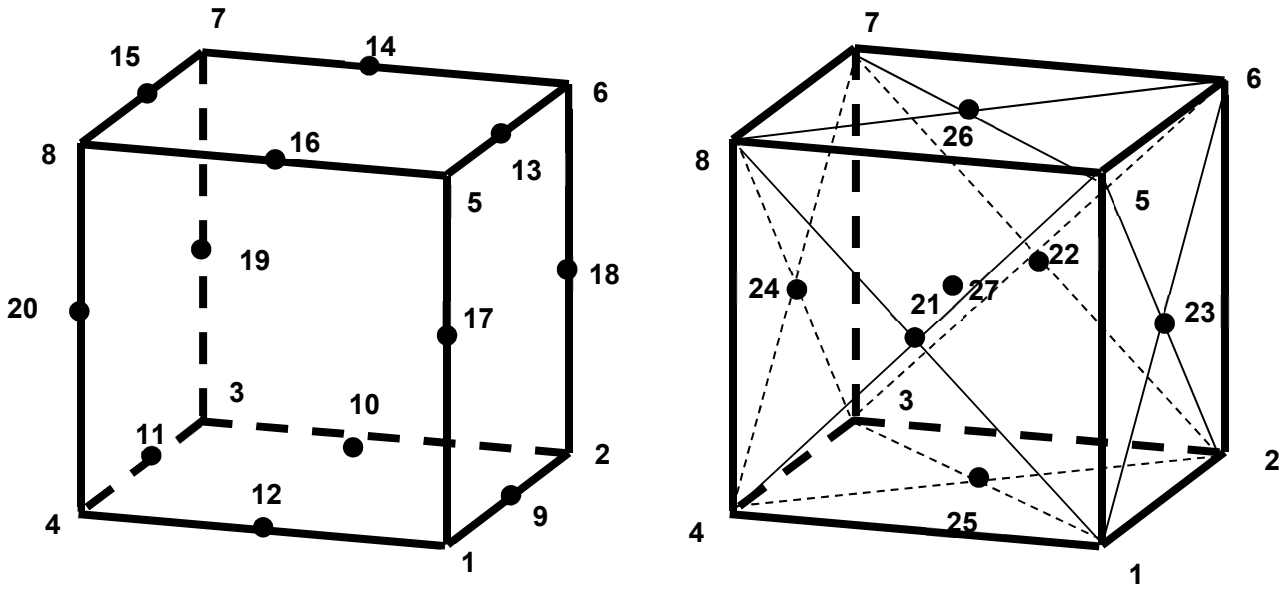

Figure 19-32. 27-node solid element.

3. **Degenerate Solids.** If hexahedrons are mixed with tetrahedrons and pentahedrons in the input under the same part ID, *degenerate* tetrahedrons and pentahedrons are used. One problem with degenerate elements is related to an uneven mass distribution (node 4 of the tetrahedron has five times the mass of nodes 1-3) which can make these elements somewhat unstable with the default time step size. By using the control flag under the keyword, *CONTROL_SOLID, automatic sorting can be invoked to treat the degenerate elements as type 10 and type 15 tetrahedral and pentahedral elements, respectively. The elements with cubic basis functions do not support degeneration.

4. **Obsolete Card Format.** For elements with 4-8 nodes the cards in the format of LS-DYNA versions 940-970 are still supported. The older format does not include Card 2.

Obsolete Element Solid Card.

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	EID	PID	N1	N2	N3	N4	N5	N6	N7	N8
Type	I	I	I	I	I	I	I	I	I	I

5. **Local Directions.** For the orthotropic and anisotropic material models the local directions may be defined on the second card following the element connectivity definition. The local directions are then computed from the two vectors such that (see Figure 19-33):

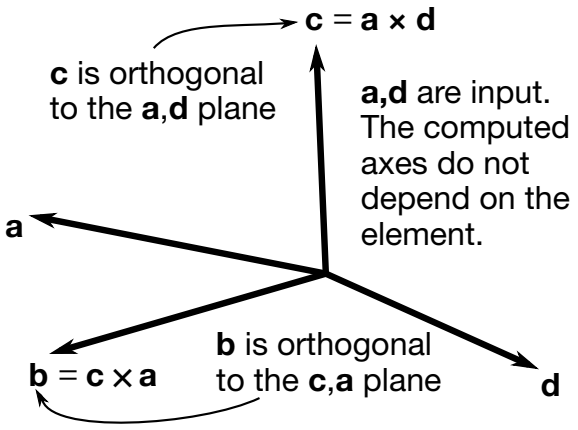

Figure 19-33. Two vectors **a** and **d** are defined and the triad is computed and stored.

$$\mathbf{c} = \mathbf{a} \times \mathbf{d} \text{ and } \mathbf{b} = \mathbf{c} \times \mathbf{a}.$$

These vectors are internally normalized within LS-DYNA. In this case, (**a**, **b**, **c**) are not calculated from AOPT and associated parameters for this element. If the material model uses AOPT = 3, the *a* and *b*-axes will be rotated about the *c*-axis by the angle BETA specified on the material card.

If vector **d** is input as a zero length vector, then A1 is interpreted as an offset rotation angle BETA in degrees. BETA describes a rotation about the **c**-axis of the **a**-**b**-**c** coordinate system that is found through AOPT and associated parameters on the *MAT input. Note that the axes may be switched before or after the application of BETA depending on the value of MACF in the material keyword input.. This BETA angle applies to all values of AOPT, and it overrides the BETA angle on the *MAT card in the case of AOPT = 3.

6. **Stress Output Coordinates.** Stress output for solid elements is in the global coordinate system by default.

7. **Optional "Scalar" Nodes.** The scalar nodes specified on Card 6 refer to extra nodes used by certain features (usually user defined) to store additional degrees of freedom.

*ELEMENT_SOLID_NURBS_PATCH

Purpose: Define a NURBS-block element (patch) based on a cuboid grid of control points. This grid consists of NPR*NPS*NPT control points, where NPR, NPS and NPT are the number of control points in local *r*-, *s*- and *t*-directions, respectively. The necessary shape functions are defined through three knot-vectors:

1. Knot-Vector in *r*-direction with length NPR + PR + 1
2. Knot-Vector in *s*-direction with length NPS + PS + 1
3. Knot-Vector in *t*-direction with length NPT + PT + 1

There is no limit on the size of the underlying grid to define a NURBS-block element, so the total number of necessary cards depends on the parameters given in the first two cards and is given by

$$\#\ \text{of cards} = 2 + \left\lceil \frac{\text{NPR} + \text{PR} + 1}{8} \right\rceil + \left\lceil \frac{\text{NPS} + \text{PS} + 1}{8} \right\rceil + \left\lceil \frac{\text{NPT} + \text{PT} + 1}{8} \right\rceil + \text{NPT} \times \text{NPS} \times \left\lceil \frac{\text{NPR}}{8} \right\rceil$$

where $\lceil x \rceil = \text{ceil}(x)$. (NOTE: the last term in the sum is doubled if WFL = 1, indicating that the weights are user-specified).

Card Summary:

Card 1. This card is required.

NPID	PID	NPR	PR	NPS	PS	NPT	PT

Card 2. This card is required.

WFL	NISR	NISS	NIST	IMASS	IINT		IDFNE

Card 3. Include ceil[(NPR +PR + 1)/8] of this card to define the knot vector in the local *r*-direction.

RK1	RK2	RK3	RK4	RK5	RK6	RK7	RK8

Card 4. Include ceil[(NPS +PS + 1)/8] of this card to define the knot vector in the local *s*-direction.

SK1	SK2	SK3	SK4	SK5	SK6	SK7	SK8

Card 5. Include ceil[(NPT+PT + 1)/8] of this card to define the knot vector in the local *t*-direction.

TK1	TK2	TK3	TK4	TK5	TK6	TK7	TK8

Card 6. The connectivity of the control grid is a two-dimensional table of NPT × NPS rows and NPR columns. This data fills NPT × NPS sets (one set for each row) of NPR points tightly packed into ceil(NPR/8) Connectivity Cards, for a total of NPT × NPS × ceil(NPR/8) cards.

N1	N2	N3	N4	N5	N6	N7	N8

Card 7. Additional card for WFL ≠ 0. Set a weight for each control point. These cards have an ordering identical to the Connectivity Cards (Card 6).

W1	W2	W3	W4	W5	W6	W7	W8

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	NPID	PID	NPR	PR	NPS	PS	NPT	PT
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
NPID	NURBS-Patch Element ID. A unique number has to be chosen
PID	Part ID, see *PART.
NPR	Number of control points in local *r*-direction.
PR	Order of polynomial of univariate NURBS basis functions in local *r*-direction.
NPS	Number of control points in local *s*-direction.
PS	Order of polynomial of univariate NURBS basis functions in local *s*-direction.

VARIABLE	DESCRIPTION
NPT	Number of control points in local *t*-direction.
PT	Order of polynomial of univariate NURBS basis functions in local *t*-direction.

Card 2	1	2	3	4	5	6	7	8
Variable	WFL	NISR	NISS	NIST	IMASS	IINT		IDFNE
Type	I	I	I	I	I	I		I
Default	0	PR	PS	PT	0	0		0

VARIABLE	DESCRIPTION
WFL	Flag for weighting factors of the control points EQ.0: all weights at the control points are set to 1.0 (B-spline basis) and no optional Card 7 sets are allowed NE.0: the weights at the control points are defined with optional Card 7 which must be defined after sets of Card 6.
NISR	Number of (automatically created) Interpolation Solid elements in local *r*-direction per created NURBS-element for visualization (post-processing) and contact.
NISS	Number of (automatically created) Interpolation Solid elements in local *s*-direction per created NURBS-element for visualization (post-processing) and contact.
NIST	Number of (automatically created) Interpolation Solid elements in local *t*-direction per created NURBS-element for visualization (postprocessing) and contact.
IMASS	Option for lumping of mass matrix: EQ.0: row sum EQ.1: diagonal weighting.
IINT	Numerical integration rule:

VARIABLE	DESCRIPTION
	EQ.0: uniformly reduced Gauss integration. NIP = PR × PS × PT.
	EQ.1: full Gauss integration. NIP = (PR+1) × (PS+1) × (PT+1).
	EQ.2: reduced, patch-wise integration rule for C1-continuous quadratic NURBS surfaces.
	EQ.3: non-uniformly reduced Gauss integration. Full integration on the boundary elements and reduced integration on the interior elements.
IDFNE	Element ID of first NURBS-Element within this NURBS-Patch definition.

Knot Vector Cards (for *r*-direction). The knot-vector in local *r*-direction with length NPR +PR + 1 is given below (up to eight values per card) requiring a total of ceil[(NPR +PR + 1)/8] cards.

Card 3	1	2	3	4	5	6	7	8
Variable	RK1	RK2	RK3	RK4	RK5	RK6	RK7	RK8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

Knot Vector Cards (for *s*-direction). The knot-vector in local *s*-direction with length NPS +PS + 1 is given below (up to eight values per card) requiring a total of ceil[(NPS +PS + 1)/8] cards.

Card 4	1	2	3	4	5	6	7	8
Variable	SK1	SK2	SK3	SK4	SK5	SK6	SK7	SK8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

Knot Vector Cards (for *t*-direction). The knot-vector in local *t*-direction with length NPT +PT + 1 is given below (up to eight values per card) requiring a total of ceil[(NPT+PT + 1)/8] cards.

Card 5	1	2	3	4	5	6	7	8
Variable	TK1	TK2	TK3	TK4	TK5	TK6	TK7	TK8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
RK*i*	Values of the univariate knot vector in local *r*-direction
SK*i*	Values of the univariate knot vector in local *s*-direction
TK*i*	Values of the univariate knot vector in local *t*-direction

Connectivity Cards. The connectivity of the control grid is a two-dimensional table of NPT × NPS rows and NPR columns. This data fills NPT × NPS sets (one *set* for each row) of NPR points tightly packed into ceil(NPR/8) Connectivity Cards, for a total of NPT × NPS × ceil(NPR/8) cards.

Card 6	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	N5	N6	N7	N8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
N*i*	Control points *i* (defined via *NODE) to define the control grid

Weight Cards. Additional card for WFL ≠ 0. Set a weight for each control point. These cards have an ordering identical to the Connectivity Cards (Card 6).

Card 7	1	2	3	4	5	6	7	8
Variable	W1	W2	W3	W4	W5	W6	W7	W8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
W*i*	Weighting factors of control point *i*

Remarks:

1. **ELFORM.** ELFORM = 201 has to be used in *SECTION_SOLID.

2. **Interpolation Elements.** The post-processing and the treatment of contact boundary conditions are presently dealt with using interpolation elements, defined via interpolation nodes. These nodes and elements are automatically created, where NISR, NISS and NIST indicate the number of interpolation elements to be created per NURBS-element in the local *r*-, *s*- and *t*-direction, respectively.

Example:

```

*ELEMENT_SOLID_PERI

Purpose: Define the connectivity of four node surface elements for Peridynamics laminate parts.

Include this card for each element. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	PID	N1	N2	N3	N4		
Type	I	I	I	I	I	I		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
EID	Element ID. A unique number must be chosen.
PID	Part ID
N*i*	Nodal point *i*

Remarks:

1. **Discretizing the Laminate.** To discretize a laminate, first, construct a layer of 3D surface mesh with 4 node elements, such as shell elements, according to the geometric shape of the laminate. Then, copy this layer of mesh and move it to the middle surface of a lamina. Continue copying and moving the layer of mesh until each lamina has one layer of mesh. See Figure 19-34.

2. **Coincident Nodes.** To represent in-plane material split, Peridynamics laminate elements must not share nodes. As a result, shared corners will have coincident nodes, one for each element. In other words, the total number of nodes is 4 × the total number of Peridynamics laminate elements.

3. **MPP.** We recommend for computational efficiency decomposing the model for MPP such that corresponding elements in each layer are on the same processor. To ensure this decomposition, we suggest specifying box regions that have the lumped grouping in the pfile (see Appendix O) around the corresponding elements. Figure 19-34 illustrates this decomposition for four processors.

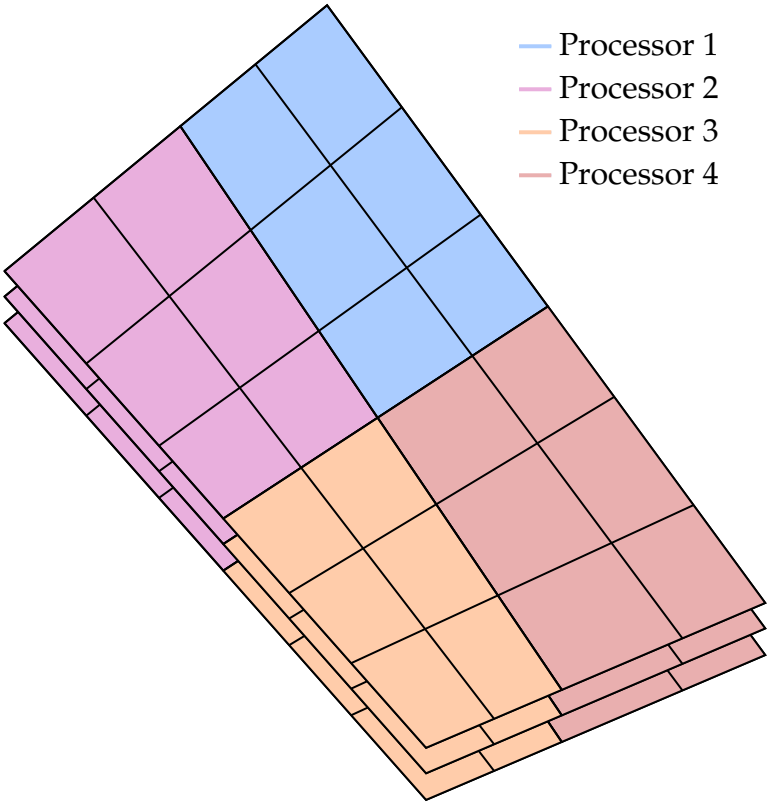

Figure 19-34. Simple example of the mesh for a three layer laminate. Each color represents an example decomposition of the mesh for MPP.

*ELEMENT_SPH_{OPTION}

Available options include:

<BLANK>

VOLUME

Purpose: Define a lumped mass element assigned to a nodal point.

If the VOLUME option is used, the field for MASS is treated as particle volume. It has the same effect as giving a negative number in the MASS field.

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	NID	PID	MASS		NEND					
Type	I	I	F		I					
Default	none	none	0.		0					

VARIABLE	DESCRIPTION
NID	Node ID and Element ID are the same for the SPH option.
PID	Part ID to which this node (element) belongs
MASS	Mass/volume (see Remark 1): GT.0.0: Mass value LT.0.0: Volume. The absolute value will be used as volume. The density, ρ, will be retrieved from the material card defined in PID. SPH element mass is calculated by $\lvert\text{MASS}\rvert \times \rho$.
NEND	Optional input: GT.0: *ELEMENT_SPH cards are generated between NID to NEND using current PID and MASS data.

Remarks:

1. **Axisymmetric SPH.** Axisymmetric SPH (IDIM = -2 in *CONTROL_SPH) is defined on the global XY-plane with the Y-axis as the axis of rotation. An

axisymmetric SPH element has a mass of ρA, where ρ is its density and A is the area of the SPH element. A can be approximated by the area of its corresponding axisymmetric shell element (see Figure 19-35). The mass printout in the d3hsp file is the mass per radian, that is, $\rho A x_i$. See Figure 19-36.

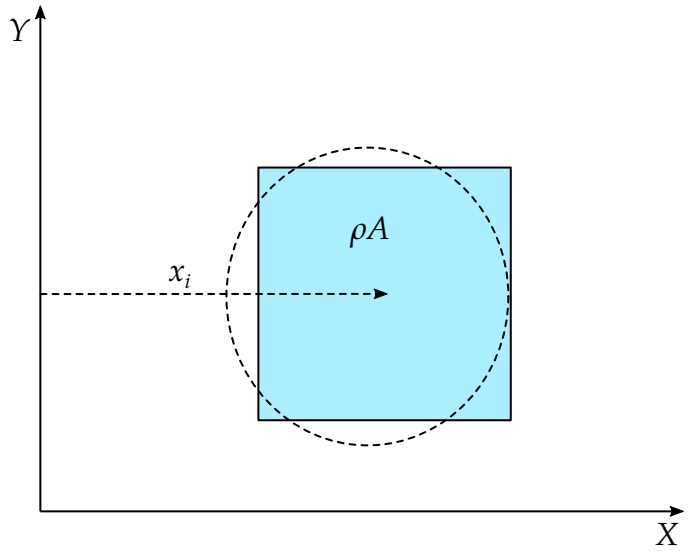

Figure 19-35. Schematic of axisymmetric SPH cross section

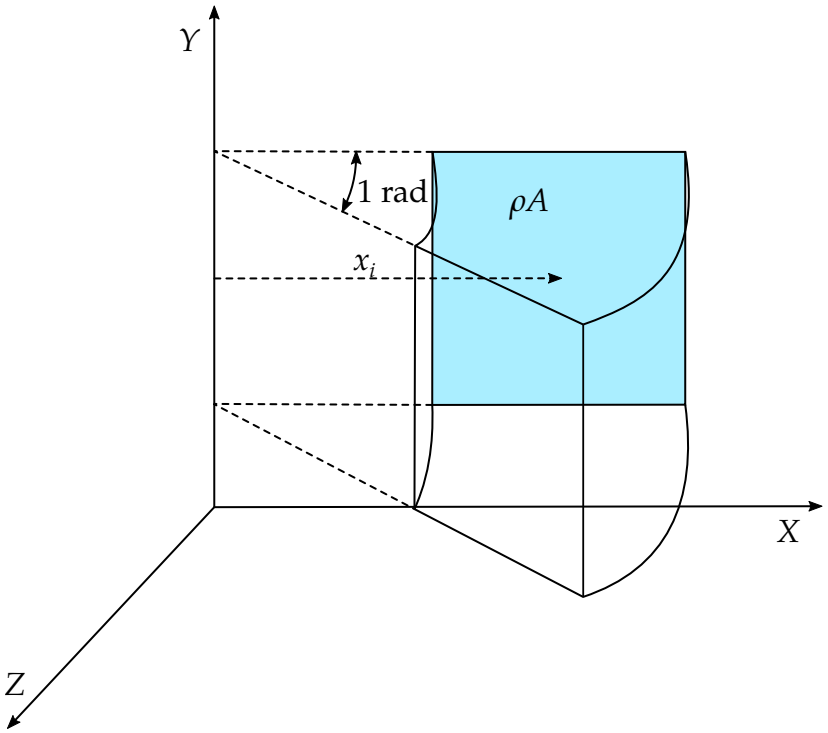

Figure 19-36. Mass printout in d3hsp

*ELEMENT_TRIM

NOTE: This keyword was replaced by *CONTROL_FORMING_TRIMMING starting in Revision 87566.

*ELEMENT_TSHELL_{OPTION}

Available options include:

<BLANK>

BETA

COMPOSITE

Purpose: Define an eight node thick shell element which is available with either fully reduced or selectively reduced integration rules. Thick shell formulations 1, 2, and 6 are plane stress elements that can be used as an alternative to the 4 node shell elements in cases where an 8-node element is desired. Thick shell formulations 3, 5 and 7 are layered solids with 3D stress updates. Formulation 5, 6, and 7 are based on an enhanced strain. The number of through-thickness integration points is specified by the user.

For orthotropic and anisotropic materials, a local material angle (variable BETA) can be defined which is cumulative with the integration point angles specified in *SECTION_-TSHELL or *PART_COMPOSITE_TSHELL.

The COMPOSITE option for *ELEMENT_TSHELL allows a unique stack of integration points for each element sharing the same part ID, and is available only when combined with *PART. The COMPOSITE option is not available in combination with *PART_COMPOSITE_TSHELL. To maintain a direct association of through-thickness integration point numbers with physical plies in the case where the number of plies varies from element to element, see Remark 5.

Card Summary:

Card 1. This card is required.

EID	PID	N1	N2	N3	N4	N5	N6	N7	N8

Card 2a. This card is included if the BETA keyword option is used.

			BETA

Card 2b. This card is included if the COMPOSITE keyword option is used.

MID1	THICK1	B1		MID2	THICK2	B2	

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	EID	PID	N1	N2	N3	N4	N5	N6	N7	N8
Type	I	I	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none	none	none
Remarks			1							

VARIABLE	DESCRIPTION
EID	Element ID. Unique numbers have to be used.
PID	Part ID, see *PART.
N*i*	Node *i*

Beta Card. Additional card for the BETA keyword option.

Card 2a	1	2	3	4	5	6	7	8	9	10
Variable									BETA	
Type									F	
Default									0.	
Remarks									4	

VARIABLE	DESCRIPTION
BETA	Orthotropic material base offset angle (see Remark 4). The angle is given in degrees. If blank, the default is set to zero.

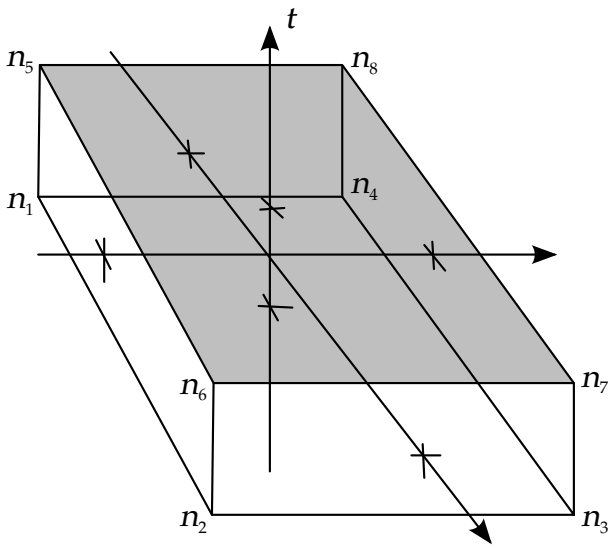

Figure 19-37. 8-node Thick Shell Element.

Composite Cards. Additional card for the COMPOSITE keyword option. Values of material ID, thickness, and material angle for each through-thickness integration point of a composite shell are defined using these cards, and these values override values specified elsewhere. The integration point data should be given sequentially starting with the bottommost integration point. The total number of integration points is determined by the number of entries on these cards. The total thickness is the distance between the top and bottom surface as determined by the element connectivity, so the THICK*i* values are scaled to fit the element. Define as many cards as needed to define all the through-thickness integration points. The fourth field must be zero or blank to be interpreted as a Card 2b.

Card 2b	1	2	3	4	5	6	7	8
Variable	MID1	THICK1	B1		MID2	THICK2	B2	
Type	I	F	F		I	F	F	

VARIABLE	DESCRIPTION
MID*i*	Material ID of integration point *i*, see the *MAT_… cards.
THICK*i*	Thickness of integration point *i*
B*i*	Material angle of integration point *i*

Remarks:

1. **Orientation.** Extreme care must be used in defining the connectivity to ensure proper orientation of the through-thickness direction. For a hexahedron, nodes n_1 to n_4 define the lower surface, and nodes n_5 to n_8 define the upper surface. For a pentahedron, nodes n_1, n_2, n_3 form the lower triangular surface and the eight variables N1 to N8 should be defined using nodes n_1, n_2, n_3, n_3, n_4, n_5, n_6, n_6, respectively. Note that node n_3 and node n_6 are each repeated.

2. **Integration.** Element formulations 1 and 5 (see *SECTION_TSHELL), use one point integration and the integration points then lie along the t-axis as shown in Figure 19-37. Element formulations 2 and 3 use two by two selective reduced integration in each layer.

3. **Stress Output.** The stresses for thick shell elements are output in the global coordinate system.

4. **Local Coordinate System.** To allow the orientation of orthotropic and anisotropic materials to be defined for each thick shell element, a beta angle can be defined. This beta angle is used with the AOPT parameter and associated data on the *MAT card to determine an element reference direction for the element.

   The AOPT data defines a coordinate system and the BETA angle defines a subsequent rotation about the element normal to determine the element reference system. For composite modeling, each layer in the element can have a unique material direction by defining an additional rotation angle for the layer, using either the ICOMP and Bi fields on *SECTION_TSHELL or the Bi parameter on *PART_COMPOSITE_TSHELL. The material direction for layer i is then determined by a rotation angle, θ_i.

5. **Assignment of Zero Thickness to Integration Points.** The ability to assign zero- thickness integration points in the stacking sequence allows the number of integration points to remain constant even as the number of physical plies varies from element to element and eases post-processing since a particular integration point corresponds to a physical ply. Such a capability is important when one or more of the physical plies are not continuous across a part. To represent a missing ply in *ELEMENT_TSHELL_COMPOSITE, set THICKi to 0.0 for the corresponding integration point and additionally, set MID to -1.

   When post-processing the results using LS-PrePost version 4.5, read both the keyword deck and d3plot database into the code and then select Option→N/A gray fringe. Then, when viewing fringe plots for a particular integration point (FriComp→IPt →intpt#), the element will be grayed out if the selected integration point is missing (or has zero thickness) in that element.

6. **PID with COMPOSITE keyword option.** When using the COMPOSITE keyword option, the PID on Card 1 must reference a *PART card that does not also use the COMPOSITE keyword option.

*END

The *END command is optional and signals the conclusion of a keyword input file. Data in a keyword file beyond a *END command are not read by LS-DYNA.

*EOS

Please see LS-DYNA Keyword User's Manual, Volume II (Material Models).

*FATIGUE

The keyword *FATIGUE provides a way of defining and solving fatigue and durability analysis problems. The keyword cards in this section are defined in alphabetical order:

FATIGUE_*{OPTION}

*FATIGUE_FAILURE

*FATIGUE_LOADSTEP

*FATIGUE_MEAN_STRESS_CORRECTION

*FATIGUE_MULTIAXIAL

*FATIGUE_SUMMATION

*FATIGUE_{OPTION}

Available options include:

<BLANK>

D3PLOT

ELOUT

Purpose: Perform fatigue analysis on parts or structures to get cumulative damage ratio and expected fatigue life. See Remark 3.

Card Summary:

Card 1. This card is only required when the keyword option is unused (<BLANK>).

PID	PTYPE						

Card 2. This card is only required when keyword option is unused (<BLANK>).

DT							

Card 3. This card is required.

STRSN	INDEX	RESTRT	TEXPOS	DMGMIN			

Card 3a. This card is only read when RESTART = 1. It is optional.

FILENAME

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PID	PTYPE						
Type	I	I						
Default	none	0						

Card 2	1	2	3	4	5	6	7	8
Variable	DT							
Type	F							
Default	none							

Card 3	1	2	3	4	5	6	7	8
Variable	STRSN	INDEX	RESTRT	TEXPOS				
Type	I	I	I	F				
Default	0	0	0	0.0				

Stress/Strain Binary Database Card. Card 3a is only read if RESTART = 1. It is optional.

Card 3a	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

VARIABLE	DESCRIPTION
PID	Part ID, part set ID, or element (solid, shell, beam, thick shell) set ID. EQ.0: fatigue analysis is performed on the whole structure.
PTYPE	Type of PID: EQ.0: part (default) EQ.1: part set EQ.2: SET_SOLID EQ.3: SET_BEAM

VARIABLE	DESCRIPTION
	EQ.4: SET_SHELL EQ.5: SET_TSHELL
DT	Time step for saving the stress/strain data in transient analysis
STRSN	Type of fatigue analysis variable: EQ.0: stress (default) EQ.1: strain
INDEX	Stress/strain index for performing fatigue analysis: EQ.0: von Mises stress/strain EQ.1: maximum principal stress/strain EQ.2: maximum shear stress/strain
RESTRT	Restart options. This flag is used to save an LS-DYNA transient analysis if the binary database for stress/strain time history data has been created in previous runs. See Remark 4. EQ.0: initial run EQ.1: restart with existing stress/strain binary database
TEXPOS	Exposure time. If this is 0, the exposure time is the same as ENDTIM in *CONTROL_TERMINATION.
DMGMIN	Minimum fatigue damage ratio for parts undergoing fatigue analysis: EQ.0: no change on computed fatigue damage ratio LT.0: for each part, the minimum fatigue damage ratio dumped to D3FTG is |DMGMIN| × the computed nonzero minimum fatigue damage ratio computed on the current part. GT.0: for each part, the minimum fatigue damage ratio dumped to D3FTG is DMGMIN.
FILENAME	Path and name of existing stress/strain binary database (such as d3plot or binout)

Remarks:

1. **D3PLOT.** When D3PLOT is used, the stress/strain data are provided by the D3PLOT database.

2. **ELOUT.** When ELOUT is used, the stress/strain data are provided by the ELOUT database. The keyword *DATABASE_ELOUT must be included to define time step for writing the stress/strain data. In addition, BINARY must be set to 2 in *DATABASE_ELOUT so that the data is written to a binary database binout. The keyword(s) *DATABASE_HISTORY_*OPTION* with the element type specified in the option must be included to define the elements where the stress/strain data are needed, and the fatigue analysis is requested.

3. **Current Restrictions.** Currently, the fatigue analysis is performed based on the D3PLOT or ELOUT database. Thus, the option D3PLOT or ELOUT is always needed.

4. **Restarts.** When RESTRT = 1, LS-DYNA reads the existing binary database (by default, d3plot if the option D3PLOT is used, or binout if the option ELOUT is used) to obtain the stress/strain time history data for the fatigue analysis. This binary database should be in the same directory as the current run. Otherwise, the path and name of the binary database should be defined by Card 3a. When running a restart with the ELOUT keyword option, *DATABASE_ELOUT must be removed from the input deck to avoid overwriting the original ELOUT database (which is saved in binout).

5. **Exposure Time.** The exposure time is ENDTIM in *CONTROL_TERMINATION, unless it is defined by a nonzero TEXPOS in Card 3. The exposure time is needed for computing the expected fatigue life, which is given as "exposure time" / "cumulative damage ratio". The expected fatigue life is only computed for the case without initial fatigue damage ratio. This is because for the case with initial fatigue damage ratio (see *INITIAL_FATIGUE_DAMAGE_RATIO), the cumulative damage ratio includes the damage ratio from preceding loads. For structures subjected to long term periodic fatigue loading, the computation can be run for this small fraction of the exposure time using a small ENDTIM in *CONTROL_TERMINATION (if the stress / strain response in this period is a good representation for the whole exposure time). The computed cumulative damage ratio is scaled accordingly to provide the cumulative damage ratio for the whole exposure time.

6. **Minimum Damage Ratio.** The minimum damage ratio dumped to d3ftg can be defined and adjusted by DMGMIN. For some parts, some elements may have 0 damage ratio from computation if they are rigid bodies or they have minimum stress (e.g. the stress is lower than the fatigue limit on the SN curve). The 0 damage ratio may cause a mathematical problem if you want to calculate the fatigue life of the element, or take log scale on the damage ratio for better visualization

of the fatigue damage distribution. DMGMIN can define a nonzero minimum damage ratio for the parts undergoing fatigue analysis to avoid this problem.

7. **Results.** The results (fatigue life, cumulative damage ratio, etc.) are saved in binary plot database d3ftg.

*FATIGUE_FAILURE

Purpose: Determine the treatment of elements that failed due to fatigue in subsequent analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	IFAILURE	DRATIO						
Type	I	F						
Default	0	1.0						

VARIABLE	DESCRIPTION
IFAILURE	Treatment of elements failed due to fatigue: EQ.0: keep the elements in the model. EQ.1: delete the elements from the model.
DRATIO	Threshold value of cumulative damage ratio for an element to be considered failed

Remarks:

1. **Cumulative Damage Ratio.** This keyword controls the treatment of elements which fail during fatigue loading. Usually an element fails if the cumulative damage ratio is ≥ 1. For shell elements and thick shell elements, it is assumed that the elements fail if the cumulative damage ratio from one of the integration points through thickness is ≥ 1. For added safety, a smaller DRATIO may be used, such as DRATIO = 0.5.

2. **Deleted Elements.** If IFAILURE = 1, all the elements with cumulative damage ratio ≥ DRATIO, will be deleted from the model. They will not participate in subsequent computations.

3. **Applicability.** This keyword is only applicable to time domain fatigue analysis.

*FATIGUE_LOADSTEP

Purpose: Define load steps for fatigue analysis.

Load Step Card. This card may be repeated if multiple load steps are present.

Card 1	1	2	3	4	5	6	7	8
Variable	TSTART	TEND	TEXPOS					
Type	F	F	F					
Default	none	none	0.0					

VARIABLE	DESCRIPTION
TSTART	Start time of current load step
TEND	End time of current load step
TEXPOS	Exposure time of current load step EQ.0.0: set to TEND – TSTART (default).

Remarks:

1. **Fatigue Calculation and Exposure Time.** This keyword is applicable to time domain fatigue analysis. For each fatigue load step, LS-DYNA performs a fatigue calculation only for the stress / strain history extracted between TSTART and TEND. The calculated cumulative damage ratio is multiplied by a scale factor (= TEXPOS / (TEND – TSTART)) to provide a cumulative damage ratio for the real load step (for exposure time of TEXPOS). It is assumed that the stress / strain cycles between TSTART and TEND are a good representative of the stress / strain response for the whole exposure time TEXPOS. TEXPOS defined in this Card overrides the same variable defined in Card 3 in the keyword *FATIGUE_*{OPTION}*.

2. **Multiple Load Steps.** Card 1 can be repeated if there are multiple fatigue load steps. The cumulative damage ratios from each load step are summed up to provide the final cumulative damage ratio to be saved in the binary plot database d3ftg. If initial fatigue damage ratios are defined (by the keyword *INITIAL_FATIGUE_DAMAGE_RATIO), they are also added to the final cumulative damage ratio.

*FATIGUE_MEAN_STRESS_CORRECTION

Purpose: Define mean stress correction method for fatigue analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	METHOD							
Type	I							
Default	0							

Card 2	1	2	3	4	5	6	7	8

Default	none	none						

VARIABLE	DESCRIPTION
METHOD	Mean stress correction method: EQ.0: Goodman equation EQ.1: Soderberg equation EQ.2: Gerber equation EQ.3: Goodman tension only EQ.4: Gerber tension only EQ.5: Morrow equation (for correction on SN curve) EQ.11: Morrow equation (for correction on EN curve) EQ.12: Smith-Watson-Topper equation
MID	Material ID for which the current mean stress correction method is applied.

VARIABLE	DESCRIPTION
SIGMA	Ultimate tensile strength, σ_u, to be used in the Goodman equation (METHOD = 0, 3) or the Gerber equation (METHOD = 2, 4), yield strength, σ_y, to be used in the Soderberg equation (METHOD = 1), or true fracture strength, σ_f, to be used in the Morrow equation (METHOD = 5)

Remarks:

1. **Fatigue Analysis Types.** This keyword can be applied in both time domain and frequency domain fatigue analysis. The method options 0, 1, 2, 3, and 4 are used for stress-based fatigue analysis; the method options 11 and 12 are used for strain-based fatigue analysis.

2. **Multiple Material Models.** Card 2 can be repeated if there are multiple material models in the input deck and they have different SIGMA values.

*FATIGUE_MULTIAXIAL

Purpose: Define criterion for multiaxial fatigue analysis. Many mechanical components experience multiaxial cyclic loadings during their service life. Compared with the uniaxial fatigue problem, the multiaxial fatigue problem is more complex due to the complex stress / strain states and loading histories. Fatigue cracks initiate and grow on certain critical planes in the material.

Card 1	1	2	3	4	5	6	7	8
Variable	MAXIAL	NPLANE						
Type	I	I						
Default	0	18						

VARIABLE	DESCRIPTION
MAXIAL	Multiaxial fatigue analysis criterion: EQ.0: Fatigue analysis using equivalent stress or strain index (defined by INDEX in *FATIGUE) EQ.1: Fatigue analysis on multiple planes EQ.2: Fatigue analysis on critical plane which is determined by the highest 1st principal stress or strain
NPLANE	Number of planes for fatigue analysis (for MAXIAL = 1 only)

Remarks:

1. **Multiaxial Fatigue Models.** Several criteria have been implemented in LS-DYNA to run multiaxial fatigue problems.

   a) With MAXIAL = 0, the multiaxial fatigue problem can be simplified to uniaxial fatigue problem using an equivalent scalar stress or strain index, such as Von-Mises stress / strain and maximum principal stress / strain. The equivalent scalar stress or strain index is defined by INDEX in *FATIGUE.

   b) With MAXIAL = 1, fatigue analysis can be performed on multiple predefined planes. The highest fatigue damage value from the planes is taken as the fatigue damage value on that element. The number of planes is defined by NPLANE, with the default value of 18. The inclination angles of the

planes range from 0 to NPLANE × $\delta\theta$ where $\delta\theta = 180°/\text{NPLANE}$. This criterion is only valid for shell elements with plane stress condition (and this is true for shell elements on the surface of the structure components).

c) With MAXIAL = 2, fatigue analysis can be performed on a critical plane. LS-DYNA goes through whole time history of stress / strain states and computes the principal stress / strain at each time point. At the time point which gives the highest 1st principal stress / strain, orientation of the principal plane is computed, and this defines the critical plane for fatigue damage computation for the whole time history.

*FATIGUE_SUMMATION

Purpose: Cause LS-DYNA to read in existing fatigue databases defined by *INITIAL_-FATIGUE_DAMAGE_RATIO and sum up the damage ratio results from them to obtain the final cumulative damage ratio. The final cumulative damage ratio results are dumped to a new d3ftg database if BINARY in *DATABASE_FREQUENCY_BINARY_D3FTG is set to 1.

*FREQUENCY_DOMAIN

Purpose: The keyword *FREQUENCY_DOMAIN provides a way of defining and solving frequency domain vibration and acoustic problems. The keyword cards in this section are defined in alphabetical order:

*FREQUENCY_DOMAIN_ACCELERATION_UNIT

FREQUENCY_DOMAIN_ACOUSTIC_BEM_*{OPTION}

*FREQUENCY_DOMAIN_ACOUSTIC_DIRECTIVITY

*FREQUENCY_DOMAIN_ACOUSTIC_FEM

FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT_*{OPTION}

*FREQUENCY_DOMAIN_ACOUSTIC_INCIDENT_WAVE

*FREQUENCY_DOMAIN_ACOUSTIC_SOUND_SPEED

*FREQUENCY_DOMAIN_FRF

FREQUENCY_DOMAIN_LOCAL_*{OPTION}

FREQUENCY_DOMAIN_MODE_*{OPTION}

*FREQUENCY_DOMAIN_PATH

FREQUENCY_DOMAIN_RANDOM_VIBRATION_*{OPTION}

*FREQUENCY_DOMAIN_RESPONSE_SPECTRUM

*FREQUENCY_DOMAIN_SEA_CONNECTION

*FREQUENCY_DOMAIN_SEA_INPUT

*FREQUENCY_DOMAIN_SEA_SUBSYSTEM

*FREQUENCY_DOMAIN_SSD

*FREQUENCY_DOMAIN_ACCELERATION_UNIT

Purpose: LS-DYNA's default behavior is to *assume* that accelerations are derived:

$$[\text{acceleration unit}] = \frac{[\text{length unit}]}{[\text{time unit}]^2}.$$

This card extends LS-DYNA to support *other* units for acceleration.

Card 1	1	2						
Variable	UNIT	UMLT						
Type	I	F						

VARIABLE	DESCRIPTION
UNIT	Flag for acceleration unit conversion: EQ.0: use [length unit]/[time unit]^2 as unit of acceleration. EQ.1: use g as unit for acceleration, and SI units (Newton, kg, meter, second, etc.) elsewhere. EQ.2: use g as unit for acceleration, and Engineering units (lbf, lbf × second^2/inch, inch, second, etc.) elsewhere. EQ.3: use g as unit for acceleration, and units (kN, kg, mm, ms, GPa, etc.) elsewhere. EQ.4: use g as unit for acceleration, and units (Newton, ton, mm, second, MPa, etc.) elsewhere. EQ.-1: use g as unit for acceleration and provide the multiplier for converting g to [length unit]/[time unit]^2.
UMLT	Multiplier for converting g to [length unit]/[time unit]^2 (used only for UNIT = -1).

Remarks:

LS-DYNA uses consistent units. With *consistent units* acceleration is defined using:

$$[\text{acceleration unit}] = \frac{[\text{length unit}]}{[\text{time unit}]^2}.$$

However, it is the convention of many industries to use g (gravitational acceleration on the Earth's surface) as the base unit for acceleration. Usually, data from vibration tests,

both random and sine sweep, are expressed in systems for which *g* is the unit of acceleration. With this keyword, LS-DYNA supports such conventions. Internally, LS-DYNA implements this keyword by converting the input deck into consistent units, and then proceeding with the calculation as usual. However, results are output in the unit system specified with this keyword.

*FREQUENCY_DOMAIN_ACOUSTIC_BEM_{OPTION1}_{OPTION2}

Available options include:

<BLANK>

ATV

MATV

HALF_SPACE

PANEL_CONTRIBUTION

POWER (see Remark 18)

Purpose: Activate the boundary element method in frequency domain for acoustic problems. This keyword is ignored unless the BEM=**filename** option is included in the LS-DYNA command line.

Card Summary:

Card 1. This card is required.

RO	C	FMIN	FMAX	NFREQ	DTOUT	TSTART	PREF

Card 2. This card is required.

NSIDEXT	TYPEXT	NSIDINT	TYPINT	FFTWIN	TRSLT	IPFILE	IUNITS

Card 2.1. This card is included if FFTWIN = 5.

T_HOLD	DECAY						

Card 3. This card is required.

METHOD	MAXIT	TOLITR	NDD	TOLLR	TOLFCT	IBDIM	NPG

Card 4. This card is required.

	NBC	RESTRT	IEDGE	NOEL	NFRUP	VELOUT	DBA

Card 4.1. Include NBC of this card.

SSID	SSTYPE	NORM	BEMTYP	LC1	LC2		

Card 5. Include if the PANEL_CONTRIBUTION keyword option is used.

NSIDPC							

Card 6. This card is included if the HALF_SPACE keyword option is used.

PID							

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	RO	C	FMIN	FMAX	NFREQ	DTOUT	TSTART	PREF
Type	F	F	F	F	I	F	F	F
Default	none	none	none	none	0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
RO	Fluid density
C	Sound speed of the fluid: GT.0: Real constant sound speed LT.0: |C| is the load curve ID, which defines the frequency dependent complex sound speed. See *FREQUENCY_DOMAIN_ACOUSTIC_SOUND_SPEED.
FMIN	Minimum value of output frequencies
FMAX	Maximum value of output frequencies
NFREQ	Number of output frequencies
DTOUT	Time interval between writing velocity or acceleration, and pressure at boundary elements in the binary file, to be proceeded at the end of LS-DYNA simulation.
TSTART	Start time for recording velocity or acceleration in LS-DYNA simulation. See Remark 1.

VARIABLE	DESCRIPTION
PREF	Reference pressure to be used to output pressure in dB, in the file Press_dB. If PREF = 0.0, the Press_dB file will not be generated. A file called Press_Pa is generated and contains the pressure at the output nodes (see Card 2). See Remark 2.

Card 2	1	2	3	4	5	6	7	8
Variable	NSIDEXT	TYPEXT	NSIDINT	TYPINT	FFTWIN	TRSLT	IPFILE	IUNITS
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
NSIDEXT	Node ID, node set ID, or segment set ID of output exterior field points.
TYPEXT	Output exterior field point type: EQ.0: Node ID EQ.1: Node set ID EQ.2: Segment set ID
NSIDINT	Node ID, node set ID, or segment set ID of output interior field points.
TYPINT	Output interior field point type: EQ.0: Node ID EQ.1: Node set ID EQ.2: Segment set ID
FFTWIN	FFT windows (Default = 0). See Remark 3. EQ.0: Rectangular window EQ.1: Hanning window EQ.2: Hamming window EQ.3: Blackman window

VARIABLE	DESCRIPTION
	EQ.4: Raised cosine window
	EQ.5: Exponential window
	EQ.6: Triangular window
	EQ.7: Kaiser window
TRSLT	Request time domain results (see Remark 4):
	EQ.0: No time domain results are requested.
	EQ.1: Time domain results are requested (Press_Pa_t gives absolute value pressure as a function of time).
	EQ.2: Time domain results are requested (Press_Pa_t gives real value pressure as a function of time).
IPFILE	Flag for output files (default = 0):
	EQ.0: Press_Pa (magnitude of pressure as a function of frequency), Press_dB (sound pressure level or SPL as a function of frequency) and bepres (ASCII database file for LS-Prepost) are provided.
	EQ.1: Press_Pa_real (the real part of the pressure as a function of frequency) and Press_Pa_imag (the imaginary part of the pressure as a function of frequency) are provided, in addition to Press_Pa, Press_dB and bepres.
	EQ.10: Files for IPFILE = 0 and fringe files for acoustic pressure.
	EQ.11: Files for IPFILE = 1 and fringe files for acoustic pressure.
	EQ.20: Files for IPFILE = 0 and fringe files for sound pressure level.
	EQ.21: Files for IPFILE = 1 and fringe files for sound pressure level.
	EQ.31: Files for IPFILE = 1 and fringe files for acoustic pressure (real part).
	EQ.41: Files for IPFILE = 1 and fringe files for acoustic pressure (imaginary part).
IUNITS	Flag for unit changes (see Remark 5):
	EQ.0: Do not apply unit change.
	EQ.1: MKS units are used, no change needed.

VARIABLE	DESCRIPTION
	EQ.2: Units: lbf × s^2/in, inch, s, lbf, psi, etc. are used, changed to MKS in BEM Acoustic computation.
	EQ.3: Units: kg, mm, ms, kN, GPa, etc. are used, changed to MKS in BEM acoustic computation.
	EQ.4: Units: ton, mm, s, N, MPa, etc. are used, changed to MKS in BEM acoustic computation.

Exponential FFT Window. Additional card for FFTWIN = 5.

Card 2.1	1	2	3	4	5	6	7	8
Variable	T_HOLD	DECAY						
Type	F	F						
Default	0.0	0.02						

VARIABLE	DESCRIPTION
T_HOLD	Hold-off period before the exponential window. The length of the hold-off period should coincide with the pre-trigger time to reduce the effects of noise in the captured time domain data. It is only used when FFTWIN = 5.
DECAY	Decay ratio at the end of capture duration. For example, if the DECAY = 0.02, it means that the vibration is forced to decay to 2% of its amplitude within the capture duration. This field is only used when FFTWIN = 5.

Card 3	1	2	3	4	5	6	7	8
Variable	METHOD	MAXIT	TOLITR	NDD	TOLLR	TOLFCT	IBDIM	NPG
Type	I	I	F	I	F	F	I	I
Default	0	100	10^{-4}	1	10^{-6}	10^{-6}	200	2

VARIABLE	DESCRIPTION
METHOD	Method used in acoustic analysis: EQ.0: Rayleigh method (very fast). See Remark 6. EQ.1: Kirchhoff method coupled to FEM for acoustics (*MAT_ACOUSTIC). See Remark 6. EQ.2: Variational Indirect BEM EQ.3: Collocation BEM EQ.4: Collocation BEM with Burton-Miller formulation for exterior problems (no irregular frequency phenomenon) EQ.211: Variational Indirect BEM with Fast Matrix Assembly. See Remark 7.
MAXIT	Maximum number of iterations for iterative solver (default = 100) if METHOD ≥ 2.
TOLITR	Tolerance for the iterative solver. The default value is 10^{-4}.
NDD	Number of domain decompositions, used for memory saving. For large problems, the boundary mesh is decomposed into NDD domains for less memory allocation. This option is only used if METHOD ≥ 2. See Remark 8.
TOLLR	Tolerance for low rank approximation of dense matrix (default = 10^{-6}).
TOLFCT	Tolerance in factorization of the low rank matrix (default = 10^{-6}).
IBDIM	Inner iteration limit in GMRES iterative solver (default = 1000).
NPG	Number of Gauss integration points (default = 2).

Card 4	1	2	3	4	5	6	7	8
Variable		NBC	RESTRT	IEDGE	NOEL	NFRUP	VELOUT	DBA
Type		I	I	I	I	I	I	I
Default		1	0	0	0	0	0	0
Remark			9	10	11	12		

VARIABLE	DESCRIPTION
NBC	Number of boundary condition cards (default = 1). See Card 4.1.
RESTRT	This flag is used to save an LS-DYNA analysis if the binary output file in the (bem=**filename**) option has not been changed (default = 0).

EQ.0: LS-DYNA time domain analysis is processed and generates a new binary file.

EQ.1: LS-DYNA time domain analysis is not processed. The binary files from previous run are used. The files include the binary output file filename and the binary file bin_velfreq, which saves the boundary velocity from FFT.

EQ.2: LS-DYNA restarts from d3dump file by using "R=" command line parameter. This is useful when the last run was interrupted by sense switches such as "sw1".

EQ.3: LS-DYNA reads in user provided velocity history saved in an ASCII file, bevel.

EQ.-3: LS-DYNA reads in user provided velocity spectrum saved in an ASCII file, bevelf.

EQ.4: Run acoustic computation on a boundary element mesh with velocity information given with a denser finite element mesh in last run. This option requires both "bem = filename" and "lbem = filename2" in the command line, where filename2 is the name of the binary file generated in the last run with denser mesh.

EQ.5: LS-DYNA time domain analysis is not processed. The binary file filename from previous run is used. An FFT is

VARIABLE	DESCRIPTION
	performed to get the new frequency domain boundary velocity and the results are saved in bin_velfreq.
IEDGE	Free edge and multi-connection constraints option (default = 0): EQ.0: Free edge and multi-connection constraints not considered. EQ.1: Free edge and multi-connection constraints considered. EQ.2: Only free edge constraints are considered. EQ.3: Only multi-connection constraints are considered.
NOEL	Location where normal velocity or acceleration is taken (default = 0): EQ.0: Elements or segments EQ.1: Nodes
NFRUP	Preconditioner update option: EQ.0: Updated at every frequency. GE.1: Updated for every NFRUP frequencies.
VELOUT	Flag for writing out nodal or elemental velocity data: EQ.0: Do not write out velocity data. EQ.1: Write out time domain velocity data (in x, y and z directions). EQ.2: Write out frequency domain velocity data (in normal direction).
DBA	Flag for writing out weighted SPL files with different weighting options: EQ.0: Do not write out weighted SPL files. EQ.1: Write out Press_dB(A) by using A-weighting. EQ.2: Write out Press_dB(B) by using B-weighting. EQ.3: Write out Press_dB(C) by using C-weighting. EQ.4: Write out Press_dB(D) by using D-weighting.

Boundary Condition Cards. The deck must include NBC cards in this format: one for each boundary condition.

Card 4.1	1	2	3	4	5	6	7	8
Variable	SSID	SSTYPE	NORM	BEMTYP	LC1	LC2		
Type	I	I	I	I	I	I		
Default	0	0	0	0	0	0		

VARIABLE	DESCRIPTION
SSID	Part, part set ID, or segment set ID of boundary elements (see Remark 13)
SSTYPE	Boundary element type: EQ.0: Part set ID EQ.1: Part ID EQ.2: Segment set ID
NORM	NORM should be set such that the normal vectors point away from the fluid. EQ.0: Normal vectors are not inverted (default). EQ.1: Normal vectors are inverted.
BEMTYP	Type of input boundary values in BEM analysis. EQ.0: Boundary velocity will be processed in BEM analysis. EQ.1: Boundary acceleration will be processed in BEM analysis. EQ.2: Pressure is prescribed, and the real and imaginary parts are given by LC1 and LC2. EQ.3: Normal velocity is prescribed, and the real and imaginary parts are given by LC1 and LC2. EQ.4: Impedance is prescribed, and the real and imaginary parts are given by LC1 and LC2. EQ.5: Acoustic absorption coefficient is given by LC1. EQ.6: Symmetry condition (or rigid wall) is prescribed.

VARIABLE	DESCRIPTION
	LT.0: Normal velocity (only real part) is prescribed through amplitude as a function of frequency load curve with curve ID |BEMTYP|.
LC1	Load curve ID for defining the real part of pressure, the real part of normal velocity, the real part of impedance, or the real acoustic absorption coefficient. See BEMTYP = 2, 3, 4, and 5, respectively.
LC2	Load curve ID for defining imaginary part of pressure, normal velocity, or impedance. See BEMTYP = 2, 3, and 4, respectively.

Panel Contribution Card. Additional for PANEL_CONTRIBUTION keyword option.

Card 5	1	2	3	4	5	6	7	8
Variable	NSIDPC							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
NSIDPC	Node set ID for the field points where panel contributions to SPL (Sound Pressure Level) are requested. See Remark 14.

Half Space Card. Additional card for HALF_SPACE keyword option.

Card 6	1	2	3	4	5	6	7	8
Variable	PID							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
PID	Plane ID for defining the half-space problem; see keyword *DEFINE_PLANE.

Remarks:

1. **TSTART Field.** TSTART indicates the time at which velocity or acceleration and pressure are stored in the binary file.

2. **PREF Field.** This reference pressure is required for the computation of the pressure in dB. Usually, in International Unit System the reference pressure is 20 μPa.

3. **FFT Windowing.** Velocity or acceleration (pressure) is provided by LS-DYNA analysis. They are written in a binary file (bem=**filename**). The boundary element method is processed after the LS-DYNA analysis. An FFT algorithm is used to transform time domain data into frequency domain in order to use the boundary element method for acoustics. To overcome the FFT leakage problem due to the truncation of the temporal response, several windows are proposed. Windowing is used to have a periodic velocity, acceleration and pressure in order to use the FFT.

4. **TRSLT Field.** If time domain results are requested, FMIN is changed to 0.0 in the code.

5. **IUNITS Field.** Units are automatically converted into kg, m, s, N, and Pa so that the reference pressure will not be too small. For example, it may be as low as $20. \times 10^{-15}$ GPa if one uses the units kg, mm, ms, kN, and GPa, and this may result in truncation error in the computation, especially in single precision version.

6. **Rayleigh and Kirchhoff Methods.** The Rayleigh method (METHOD = 0) is an approximation suitable only for external radiation problems. It is very fast since there is no linear system to solve. The Kirchhoff method (METHOD = 1) involves coupling the BEM and FEM for acoustics (*MAT_ACOUSTIC) with a non-reflecting boundary condition; see *BOUNDARY_NON_REFLECTING. In this case, at least one fluid layer with a non-reflecting boundary condition is merged with the vibrating structure. This additional fluid is given in *MAT_ACOUSTIC by the same density and sound speed as used in this keyword. When used appropriately, both methods provide a good approximation to a full BEM calculation for external problems.

7. **Variational Indirect BEM with Fast Matrix Assembly Method.** The Variational Indirect BEM with fast matrix assembly method (METHOD = 211) uses Skeletonized Interpolation to speed up matrix assembly. It is up to 5 times faster than METHOD = 2 for large problems.

8. **NDD Field.** The BEM formulation for large and medium size problems (more than 2000 boundary elements) is memory and time consuming. In this case, LS-DYNA may be run using the memory option. To save memory, domain decomposition can be used.

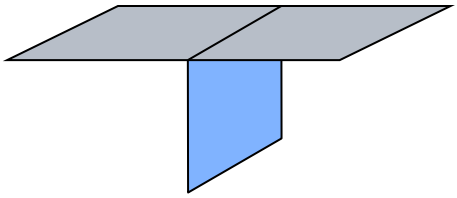

Figure 23-1. T-intersection in the Boundary Element Mesh

9. **RESTRT Field.** The binary file generated by a previous run can be used for the next run by using the restart option. With the restart option the BEM calculation uses the binary file generated from a previous calculation. In this case, the frequency range can be changed. However, the time parameters should not be modified between calculations.

10. **IEDGE Field.** This field only applies to METHOD = 2, the Variational Indirect BEM.

11. **OEL Field.** This field specifies whether the element or nodal velocity (or acceleration) is taken from FEM computation. NOEL should be 0 if Kirchhoff method (METHOD = 1) is used since elemental pressure is processed in FEM. NOEL should be 0 if Burton-Miller collocation method (METHOD = 4) is used since a constant strength element formulation is adopted. In other cases, it is strongly recommended to use element velocity or acceleration (NOEL = 0) if a T-intersection appears in the boundary element mesh. See Figure 23-1.

12. **NFRUP Field.** The preconditioner is obtained with the factorization of the influence coefficient matrix. To conserve CPU time, it can be retained for several frequencies. By default (NFRUP = 0), the preconditioner is updated for every frequency. Note that in MPP version, the preconditioner is updated every NFRUP frequencies on each processor.

13. **Boundary Condition Cards.** Card 4.1 can be defined if the boundary elements are composed of several panels. It can be defined multiple times if more than 2 panels are used. Each Card 4.1 defines one panel.

14. **NSIDPC Field.** The field points where the panel contribution analysis is requested must be one of the field points for acoustic computation (it must be included in the nodes specified by the NSIDEXT or NSIDINT). The panels are defined by Cards 4 and 4.1.

15. **Element Sizing.** To obtain accurate results, the element size should not be greater than 1/6 of the wave length λ ($\lambda = c/f$ where c is the wave speed and f is the frequency).

16. **Acoustic Transfer Vector.** The Acoustic Transfer Vector can be obtained by including the option ATV in the keyword. It calculates acoustic pressure (and

sound pressure level) at field points due to unit normal velocity of each surface node. ATV is dependent on structure model, properties of acoustic fluid as well as location of field points. When ATV option is included, the structure does not need any external excitation, and the curve IDs LC1 and LC2 are ignored. A binary plot database d3atv can be obtained by setting BINARY = 1 in *DATABASE_FREQUENCY_BINARY_D3ATV.

17. **Modal Acoustic Transfer Vector.** The Modal Acoustic Transfer Vector (MATV) is calculated when the MATV keyword option is included. The MATV option requires that the implicit eigenvalue solver be used, which is activated by keywords *CONTROL_IMPLICIT_GENERAL, and *CONTROL_IMPLICIT_EIGENVALUE. It calculates acoustic pressure (and sound pressure level) at field points due to vibration in the form of eigenmodes. For each excitation frequency f, LS-DYNA generates the pseudo-velocity boundary condition $2\pi i f\{\phi\}_j$, where $i = \sqrt{-1}$ is the imaginary unit and runs acoustic computation for each field point, based on the psedo-velocity boundary conditions, to get the MATV matrices. The MATV matrices are saved in binary file bin_bepressure for future use. Like ATV, MATV is also only dependent on structure model, properties of acoustic fluids as well as the location of field points.

18. **Power Option.** With the POWER keyword option, acoustic radiated power can be computed with the Rayleigh and Kirchhoff methods.

19. **Output Files.** The result files: Press_Pa, Press_dB, Press_Pa_real, Press_Pa_imag, Press_Pa_t and Press_dB_t have an xy-plot format that LS-PrePost can read and plot.

*FREQUENCY_DOMAIN_ACOUSTIC_DIRECTIVITY

Purpose: Define field point circles for acoustic directivity plot.

Include as many of this card as needed (see Remark 1). This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	CENTER	R	NP	NORM	ANGLE	X	Y	Z
Type	I	F	I	I	F	F	F	F
Default	none	none	none	none	0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
CENTER	Flag for defining the center point for the circle: EQ.1: Mass center of the original structure EQ.2: Geometry center of the original structure EQ.3: Defined by input variables X, Y, and Z
R	Radius of the circle
NP	Number of points on the circle
NORM	Norm direction of the circle. EQ.1: *x*-direction EQ.2: *y*-direction EQ.3: *z*-direction
ANGLE	Angle for the first point on the circle
X	*x*-coordinate of the center
Y	*y*-coordinate of the center
Z	*z*-coordinate of the center

Remarks:

1. **Multiple Directivity Plot.** Card 1 can be repeated if multiple acoustic directivity plot is desired.

2. **Results.** ASCII files Press_Pa_directivity_n and Press_dB_directivity_n are output. Press_Pa_directivity_n provides a list of acoustic pressures (magnitude) for each angle on the n^{th} circle for a series of frequencies. Press_dB_directivity_n provides a list of SPLs (or decibels) for each angle on the n^{th} circle for a series of frequencies. The frequencies are defined by FMIN, FMAX and NFREQ in the keyword *FREQUENCY_DOMAIN_ACOUSTIC_BEM.

*FREQUENCY_DOMAIN_ACOUSTIC_FEM_{OPTION}

Available options include:

<BLANK>

EIGENVALUE

MODAL

Purpose: Define an interior acoustic problem and solve the problem with a frequency domain finite element method. When the EIGENVALUE option is used, LS-DYNA computes eigenvalues and eigenvectors of the acoustic system. When the MODAL option is used, LS-DYNA uses a modal superposition method to solve the acoustic problem (see Remark 9).

Card Summary:

Card MDL. LS-DYNA only reads this card for the MODAL keyword option. It is optional and may be omitted. LS-DYNA assumes that the input contains this card if no data is in the fifth column.

MDMIN	MDMAX	FNMIN	FNMAX				

Card 1. This card is required.

RO	C	FMIN	FMAX	NFREQ	DTOUT	TSTART	PREF

Card 2. This card is required.

	FFTWIN	MTXDMP	RESTRT				

Card 3. This card is required.

PID	PTYP						

Card 4. This card can be repeated if multiple boundary conditions are present. For the EIGENVALUE keyword option, this card is optional.

SID	STYP	VAD	DOF	LCID1	LCID2	SF	VID

Card 5. Include this card only if the keyword option is *not* EIGENVALUE.

NID	NTYP	IPFILE	DBA				

Data Card Definitions:

MODAL Card. LS-DYNA only reads this optional card for the MODAL keyword option. LS-DYNA assumes that the input contains this card if the fifth column has no data. See Remark 9.

Card MDL	1	2	3	4	5	6	7	8
Variable	MDMIN	MDMAX	FNMIN	FNMAX				
Type	I	I	F	F				
Default	1	optional	0.0	optional				

VARIABLE	DESCRIPTION
MDMIN	First mode in modal superposition method (optional)
MDMAX	Last mode in modal superposition method (optional)
FNMIN	Minimum natural frequency in modal superposition method (optional)
FNMAX	Maximum natural frequency in modal superposition method (optional)

Card 1	1	2	3	4	5	6	7	8
Variable	RO	C	FMIN	FMAX	NFREQ	DTOUT	TSTART	PREF
Type	F	F	F	F	I	F	F	F
Default	Rem 2	none	none	none	0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
RO	Fluid density
C	Sound speed of the fluid. GT.0: Real constant sound speed. LT.0: |C| is the load curve ID, which defines the frequency-

VARIABLE	DESCRIPTION
	dependent complex sound speed. See *FREQUENCY_-DOMAIN_ACOUSTIC_SOUND_SPEED.
FMIN	Minimum value of output frequencies.
FMAX	Maximum value of output frequencies.
NFREQ	Number of output frequencies.
DTOUT	Time step for writing velocity or acceleration in the binary file.
TSTART	Start time for recording velocity or acceleration in transient analysis.
PREF	Reference pressure for converting the acoustic pressure to dB. See Remark 3.

Card 2	1	2	3	4	5	6	7	8
Variable		FFTWIN	MTXDMP	RESTRT				
Type		I	I	I				
Default		0	0	0				

VARIABLE	DESCRIPTION
FFTWIN	FFT windows (Default = 0): EQ.0: Rectangular window. EQ.1: Hanning window. EQ.2: Hamming window. EQ.3: Blackman window. EQ.4: Raised cosine window.
MTXDMP	Acoustic stiffness and mass matrices dumping (when using the option EIGENVALUE): EQ.0: No dumping. EQ.1: Dumping globally assembled acoustic stiffness and mass

VARIABLE	DESCRIPTION
	matrices in Harwell-Boeing sparse matrix format.
RESTRT	This flag is used to save an LS-DYNA time domain analysis if the binary output file (bin_femac) has not been changed (Default = 0): EQ.0: LS-DYNA time domain analysis is processed and generates a new binary file (bin_femac) which saves the boundary velocity history data. EQ.1: LS-DYNA time domain analysis is not processed. The binary file bin_femac from the last run is used.

Card 3	1	2	3	4	5	6	7	8
Variable	PID	PTYP						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
PID	Part ID or part set ID to define the acoustic domain.
PTYP	Set type: EQ.0: Part; see *PART. EQ.1: Part set; see *SET_PART.

Boundary Condition Definition Card. It can be repeated if multiple boundary conditions are present. This card is optional when option EIGENVALUE is present.

Card 4	1	2	3	4	5	6	7	8
Variable	SID	STYP	VAD	DOF	LCID1	LCID2	SF	VID
Type	I	I	I	I	I	I	F	I
Default	none	0	0	none	0	0	1.0	0

VARIABLE	DESCRIPTION
SID	Part ID, part set ID, segment set ID, or node set ID to define where the vibration boundary condition is.
STYP	Set type: EQ.0: Part; see *PART. EQ.1: Part set; see *SET_PART. EQ.2: Segment set; see *SET_SEGMENT. EQ.3: Node set; see *SET_NODE.
VAD	Boundary condition flag: EQ.0: Velocity by steady state dynamics (SSD). EQ.1: Velocity by transient analysis. EQ.2: Opening (zero pressure). EQ.11: Velocity by LCID1 (amplitude) and LCID2 (phase). EQ.12: Velocity by LCID1 (real) and LCID2 (imaginary). EQ.21: Acceleration by LCID1 (amplitude) and LCID2 (phase). EQ.22: Acceleration by LCID1 (real) and LCID2 (imaginary). EQ.31: Displacement by LCID1 (amplitude) and LCID2 (phase). EQ.32: Displacement by LCID1 (real) and LCID2 (imaginary). EQ.41: Impedance by LCID1 (amplitude) and LCID2 (phase). EQ.42: Impedance by LCID1 (real) and LCID2 (imaginary). EQ.51: Pressure by LCID1 (amplitude) and LCID2 (phase). EQ.52: Pressure by LCID1 (real) and LCID2 (imaginary).
DOF	Applicable degrees-of-freedom: EQ.0: Determined by steady state dynamics. EQ.1: x-translational degree-of-freedom, EQ.2: y-translational degree-of-freedom, EQ.3: z-translational degree-of-freedom, EQ.4: Translational motion in direction given by VID, EQ.5: Normal direction of the element or segment.

VARIABLE	DESCRIPTION
LCID1	Load curve ID to describe the amplitude (or real part) of velocity; see *DEFINE_CURVE.
LCID2	Load curve ID to describe the phase (or imaginary part) of velocity; see *DEFINE_CURVE.
SF	Load curve scale factor.
VID	Vector ID for DOF values of 4.

Field Points Definition Card. Not used when option EIGENVALUE is present.

Card 5	1	2	3	4	5	6	7	8
Variable	NID	NTYP	IPFILE	DBA				
Type	I	I	I	I				
Default	none	0	0	0				

VARIABLE	DESCRIPTION
NID	Node ID, node set ID, or segment set ID for acoustic result output
NTYP	Set type: EQ.0: Node; see *NODE. EQ.1: Node set; see *SET_NODE.
IPFILE	Flag for output files (default = 0): EQ.0: Press_Pa (magnitude of pressure as function of frequency), Press_dB (sound pressure level or SPL as a function of frequency) are provided. EQ.1: Press_Pa_real (real part of pressure as a function of frequency) and Press_Pa_imag (imaginary part of pressure as a function of frequency) are provided, in addition to Press_Pa, Press_dB.
DBA	Flag for writing out weighted SPL files with different weighting options. EQ.0: No writing out weighted SPL files.

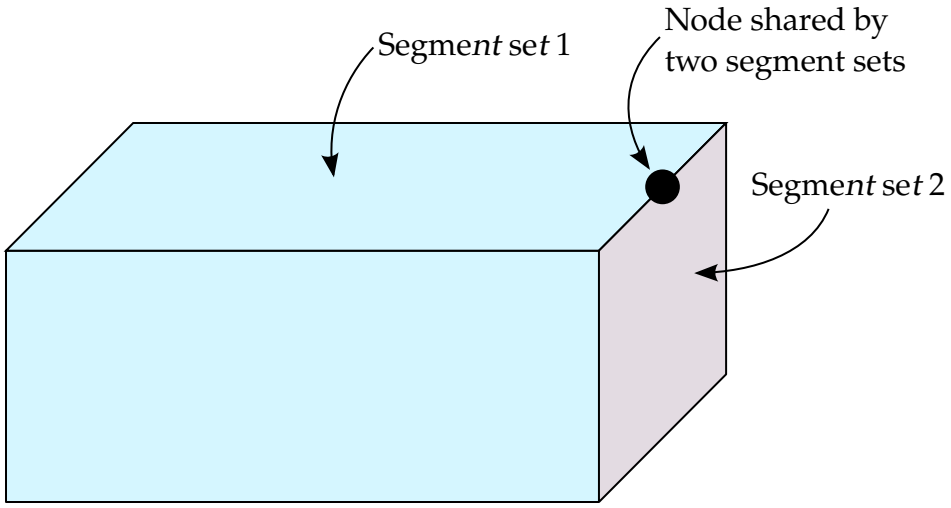

Figure 23-2. Nodes with Multiple Boundary Conditions.

VARIABLE	DESCRIPTION
	EQ.1: Write out Press_dB(A) by using A-weighting.
	EQ.2: Write out Press_dB(B) by using B-weighting.
	EQ.3: Write out Press_dB(C) by using C-weighting.
	EQ.4: Write out Press_dB(D) by using D-weighting.

Remarks:

1. **Acoustic problem.** This command solves the interior acoustic problems which is governed by Helmholtz equation $\nabla^2 p + k^2 p = 0$ with the boundary condition $\partial p/\partial n = -i\omega\rho v_n$, where p is the acoustic pressure; $k = \omega/c$ is the wave number; ω is the round frequency; c is the acoustic wave speed (sound speed); $i = \sqrt{-1}$ is the imaginary unit; ρ is the mass density; and v_n is the normal velocity. This command solves the acoustic problem in the frequency domain.

2. **Mass density.** If mass density RO is not given, the mass density of PID (the part which defines the acoustic domain), will be used

3. **Reference pressure.** PREF is the reference pressure to convert the acoustic pressure to dB $L_p = 10 \log_{10}(p^2/p_{\text{ref}}^2)$. Note that generally $p_{\text{ref}} = 20\ \mu$Pa for air.

4. **Material models for acoustic domain.** If the boundary velocity is obtained from steady state dynamics (VAD = 0) using the keyword *FREQUENCY_DOMAIN_SSD, the part (PID) which defines the acoustic domain should use material model *MAT_ELASTIC_FLUID which enables implicit eigenvalue analysis. If the boundary excitation is given by load curves LCID1 and LCID2 (VAD > 0), the part (PID) which defines the acoustic domain can use any material model

that is compatible with 8-node hexahedron, 6-node pentahedron, or 4-node tetrahedron elements since only the mesh of the PID will be used in the computation. For example, *MAT_ACOUSTIC or *MAT_ELASTIC_FLUID can be used.

5. **Steady state dynamics.** If VAD = 0, the boundary excitation is given as velocity obtained from steady state dynamics. The other parameters in Card 3 (DOF, LCID1, LCID2, SF and VID) are ignored.

6. **Multiple boundary condition definitions.** If a node's vibration boundary condition is defined multiple times, only the last definition is considered. This happens usually when a node is on an edge, is shared by two or more parts, part sets, node sets, or segment sets, and a different vibration condition is defined on each of the node or segment sets. See Figure 23-2.

7. **Output files.** Results including acoustic pressure and SPL are given in d3acs binary files, which can be accessed by LS-PrePost. Nodal pressure and SPL values for nodes specified by NID and NTYP are given in ASCII file Press_Pa and Press_dB, which can be accessed by LS-PrePost. Press_Pa gives magnitude of the pressure. Press_dB gives the SPL in terms of dB.

8. **Frequencies and steady state dynamics.** If the boundary velocity condition is given by Steady State Dynamics (VAD = 0), the range and number of frequencies (FMIN, FMAX and NFREQ) should be compatible with the corresponding parameters in Card 1 of the keyword *FREQUENCY_DOMAIN_SSD.

9. **Modal acoustics.** When keyword option MODAL is used, LS-DYNA computes the acoustic pressure response by a modal superposition method. An acoustic eigenvalue analysis problem (*FREQUENCY_DOMAIN_ACOUSTIC_FEM_EIGENVALUE) must be solved first and the binary database d3eigv_ac must be present in the same directory to run modal acoustics. Card MDL is optional, and it defines the eigenmodes to be used in modal superposition if present. Otherwise, all the acoustic eigenmodes saved in d3eigv_ac will be used.

FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT_*OPTION

Available options include:

CUBE

NODE_SET

PART

PART_SET

PLATE

SPHERE

Purpose: Define field points for the acoustic pressure computation by the BEM acoustic solver and save the results to D3ACP binary database. The field points can be defined using existing structure components if option PART, PART_SET or NODE_SET is used. The field points can be created by LS-DYNA if option SPHERE, PLATE, or CUBE is used. SPHERE, PLATE, and CUBE are only available for SMP while PART, PART_SET, and NODE_SET are available for both MPP and SMP.

Card Summary:

Card 1a. This card is included if the keyword option is NODE_SET, PART, or PART_-SET.

PID/SID							

Card 1b. This card is included if the keyword option is SPHERE.

CENTER	R	DENSITY	X	Y	Z	HALF1	HALF2

Card 1c. This card is included if the keyword option is PLATE.

NORM	LEN_X	LEN_Y	X	Y	Z	NELM_X	NELM_Y

Card 1d.1. This card is included if the keyword option is CUBE.

LEN_X	LEN_Y	LEN_Z	X	Y	Z		

Card 1d.2. This card is included if the keyword option is CUBE.

NELM_X	NELM_Y	NELM_Z					

Data Card Definitions:

PART, PART_SET, and NODE_SET Card.

Card 1a	1	2	3	4	5	6	7	8
Variable	PID/SID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PID/SID	Part ID, part set ID, or node set ID

SPHERE Card.

Card 1b	1	2	3	4	5	6	7	8
Variable	CENTER	R	DENSITY	X	Y	Z	HALF1	HALF2
Type	I	F	I	F	F	F	I	I
Default	1	none	none	none	none	none	0	0

VARIABLE	DESCRIPTION
CENTER	Flag for defining the center point for the sphere: EQ.1: Mass center of the original structure EQ.2: Geometry center of the original structure EQ.3: Defined by (x,y,z)
R	Radius of the sphere.
DENSITY	Parameter to define how coarse or dense the created sphere mesh is. It is a number between 3 and 39, where "3" gives you 24 elements while "39" gives you 8664 elements.
X	x-coordinate of the center

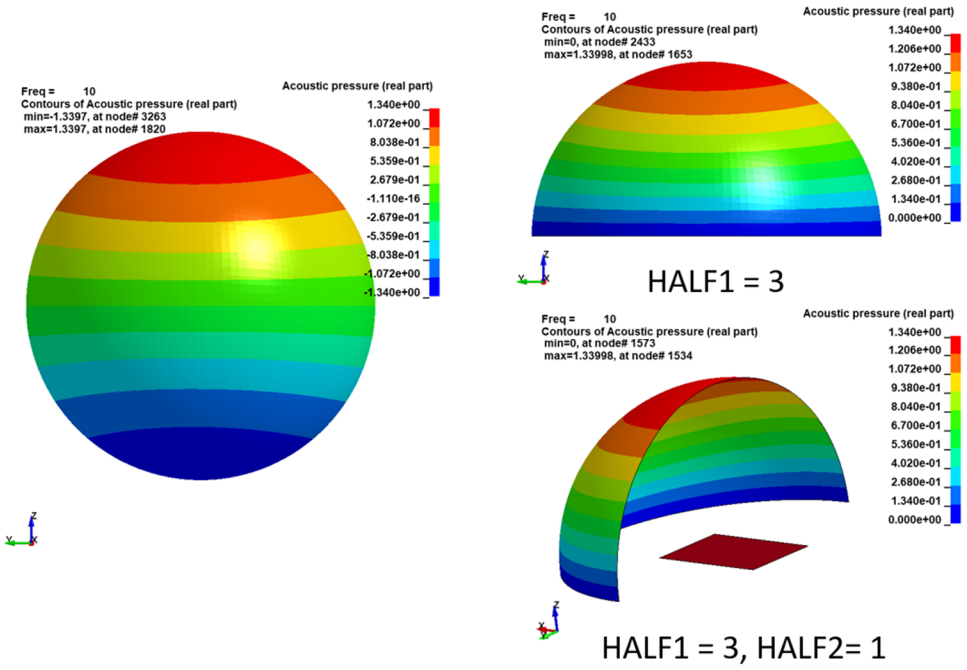

Figure 23-3. Defining a half or quarter sphere

VARIABLE	DESCRIPTION
Y	y-coordinate of the center
Z	z-coordinate of the center
HALF1	Create a half sphere by trimming the defined sphere (see Remark 3 and Figure 23-3). Note that (x_0, y_0, z_0) below is the center of the sphere. EQ.0: A full sphere is created, no trimming EQ.1: Keep $x \geq x_0$ EQ.-1: Keep $x \leq x_0$ EQ.2: Keep $y \geq y_0$ EQ.-2: Keep $y \leq y_0$ EQ.3: Keep $z \geq z_0$ EQ.-3: Keep $z \leq z_0$
HALF2	Create a quarter sphere by trimming the half sphere defined with HALF1 (see Remark 3 and Figure 23-3): EQ.0: No second trimming

VARIABLE	DESCRIPTION
	EQ.1: Keep $x \geq x_0$
	EQ.-1: Keep $x \leq x_0$
	EQ.2: Keep $y \geq y_0$
	EQ.-2: Keep $y \leq y_0$
	EQ.3: Keep $z \geq z_0$
	EQ.-3: Keep $z \leq z_0$

Plate Card.

Card 1c	1	2	3	4	5	6	7	8
Variable	NORM	LEN_X	LEN_Y	X	Y	Z	NELM_X	NELM_Y
Type	I	F	F	F	F	F	I	I
Default	1	none	none	none	none	none	10	10

VARIABLE	DESCRIPTION
NORM	Norm direction of the plate. EQ.1: x-direction EQ.2: y-direction EQ.3: z-direction
LEN_X	Length of longer side of the plate
LEN_Y	Length of shorter side of the plate
X	x-coordinate of the center
Y	y-coordinate of the center
Z	z-coordinate of the center
NELM_X	Number of elements on longer side of the plate
NELM_Y	Number of elements on shorter side of the plate

Cube Card 1.

Card 1d.1	1	2	3	4	5	6	7	8
Variable	LEN_X	LEN_Y	LEN_Z	X	Y	Z		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
LEN_X	Length of *x*-side of the cube
LEN_Y	Length of *y*-side of the cube
LEN_Z	Length of *z*-side of the cube
X	*x*-coordinate of the corner of the cube with smallest nodal coordinates
Y	*y*-coordinate of the corner of the cube with smallest nodal coordinates
Z	*z*-coordinate of the corner of the cube with smallest nodal coordinates

Cube Card 2.

Card 1d.2	1	2	3	4	5	6	7	8
Variable	NELM_X	NELM_Y	NELM_Z					
Type	I	I	I					
Default	10	10	10					

VARIABLE	DESCRIPTION
NELM_X	Number of elements on *x*-side of the cube
NELM_Y	Number of elements on *y*-side of the cube

VARIABLE	DESCRIPTION
NELM_Z	Number of elements on *z*-side of the cube

Remarks:

1. **LS-PrePost.** The acoustic pressure results at those field points are saved in D3ACP binary database and are accessible by LS-PrePost. With the FCOMP tool in LS-PrePost, the fringe plot of the results (real part acoustic pressure, imaginary part acoustic pressure, magnitude of acoustic pressure and Sound Pressure Level) can be generated.

2. **Field Points.** The field points defined by this keyword are separate from the field points defined in Card 2 of *FREQUENCY_DOMAIN_ACOUSTIC_BEM. The acoustic pressure results for the latter are only saved in ASCII database Press_Pa, Press_dB, etc. (in a tabular format that can be plotted in LS-PrePost by using the XYPlot tool).

3. **Half or Quarter Sphere.** The parameters HALF1 and HALF2 change a full sphere to a half sphere or a quarter sphere. See Figure 23-3 for illustration.

*FREQUENCY_DOMAIN_ACOUSTIC_INCIDENT_WAVE

Purpose: Define incident sound wave for acoustic scattering problems.

Wave Definition Cards. This card may be repeated to define multiple incident waves. Include as many cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	TYPE	MAG	XC	YC	ZC			
Type	I	F	F	F	F			
Default	1	none	none	none	none			

VARIABLE	DESCRIPTION
TYPE	Type of incident sound wave: EQ.1: plane wave. EQ.2: spherical wave.
MAG	Magnitude of the incident sound wave: GT.0: constant magnitude. LT.0: |MAG| is a curve ID, which defines the frequency dependent magnitude. See *DEFINE_CURVE.
XC, YC, ZC	Direction cosines for the plane wave (TYPE = 1) or coordinates of the point source for the spherical wave (TYPE = 2).

Remarks:

1. **Plane Waves.** For plane waves, the incident wave is defined as

$$p(x,y,z) = Ae^{-ik(\alpha x+\beta y+\gamma z)} \ ,$$

where A is the magnitude of the incident wave and α, β, and γ are the direction cosines along the incident direction. $i = \sqrt{-1}$ is the imaginary unit and $k = \omega/c$ is the wave number. ω is the round frequency and c is the sound speed.

2. **Spherical Waves.** For spherical waves, the incident wave is defined as

$$p(r) = A\frac{e^{-ikr}}{r} \ ,$$

where A is the magnitude of the incident wave and r is the distance measured from the position of the point source.

*FREQUENCY_DOMAIN_ACOUSTIC_SOUND_SPEED

Purpose: Define frequency dependent complex sound speed to be used in frequency domain finite element method or boundary element method acoustic analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	ID							
Type	I							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	LCID1	LCID2						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
ID	Complex sound speed ID.
LCID1	Curve ID for real part of frequency dependent complex sound speed.
LCID2	Curve ID for imaginary part of frequency dependent complex sound speed.

Remarks:

1. **Acoustic Mediums and Damping.** The sound speed in an acoustic medium is usually defined as a constant real value. But it can also be defined as a complex value which is dependent on frequency, to introduce damping in the system.

2. **Using Complex Sound Speed.** To use the frequency dependent complex sound speed defined here, set the sound speed C = -ID in *FREQUENCY_DO-

MAIN_ACOUSTIC_FEM or *FREQUENCY_DOMAIN_ACOUSTIC_BEM keywords.

*FREQUENCY_DOMAIN_FRF

Purpose: This keyword computes frequency response functions due to nodal excitations.

> NOTE: Natural frequencies and mode shapes are needed for computing the frequency response functions. Thus, keyword *CONTROL_IMPLICIT_EIGENVALUE *must* be included in input. See Remark 1.

Card 1	1	2	3	4	5	6	7	8
Variable	N1	N1TYP	DOF1	VAD1	VID1	FNMAX	MDMIN	MDMAX

Type	I	I	I	I	I	I		
Default	none	0	none	2	0	0		

Card 4	1	2	3	4	5	6	7	8
Variable	FMIN	FMAX	NFREQ	FSPACE	LCFREQ	RESTRT	OUTPUT	
Type	F	F	I	I	I	I	I	
Default	none	none	2	0	none	0	0	

VARIABLE	DESCRIPTION
N1	Node / Node set / Segment set ID for excitation input. When VAD1, the excitation type, is set to 0, 1 or 2 (base velocity, base acceleration, or base displacement, respectively), this field is ignored. In this case, the excitation is applied through node(s) that are under constraints, that is, the node(s) defined in *BOUNDARY_SPC_NODE or *BOUNDARY_SPC_SET.
N1TYP	Type of N1: EQ.0: Node ID, EQ.1: Node set ID, EQ.2: Segment set ID. When VAD1, the excitation type, is set to 1, which is acceleration, this field is ignored.
DOF1	Applicable degrees-of-freedom for excitation input (ignored if VAD1 = 4): EQ.0: Translational movement in direction given by vector VID1, EQ.1: *x*-translational degree-of-freedom, or *x*-rotational degree-of-freedom (for torque excitation, VAD1 = 8) EQ.2: *y*-translational degree-of-freedom, or *y*-rotational degree-of-freedom (for torque excitation, VAD1 = 8), EQ.3: *z*-translational degree-of-freedom, or *z*-rotational degree-of-freedom (for torque excitation, VAD1 = 8).
VAD1	Excitation input type: EQ.0: Base velocity, EQ.1: Base acceleration,

VARIABLE	DESCRIPTION
	EQ.2: Base displacement, EQ.3: Nodal force, EQ.4: Pressure, EQ.5: Enforced velocity by large mass method, EQ.6: Enforced acceleration by large mass method, EQ.7: Enforced displacement by large mass method. EQ.8: Torque, EQ.9: Base angular velocity, EQ.10: Base angular acceleration, EQ.11: Base angular displacement
VID1	Vector ID for DOF1 = 0 for excitation input, see *DEFINE_VECTOR.
FNMAX	Optional maximum natural frequency employed in FRF computation. See Remark 3.
MDMIN	The first mode employed in FRF computation (optional). See Remarks 3 and 4.
MDMAX	The last mode employed in FRF computation (optional). It should be set as a positive integer in a restart run (RESTRT = 1 or 3) based on the number of eigenmodes available in the existing d3eigv database. See Remarks 3 and 4.
DAMPF	Modal damping coefficient, ζ. See Remark 5.
LCDAM	Load Curve ID defining mode dependent modal damping coefficient, ζ. See Remark 5.
LCTYP	Type of load curve defining modal damping coefficient: EQ.0: Abscissa value defines frequency, EQ.1: Abscissa value defines mode number. See Remark 5.
DMPMAS	Mass proportional damping constant, α, in Rayleigh damping. See Remark 5.
DMPSTF	Stiffness proportional damping constant, β, in Rayleigh damping. See Remark 5.

VARIABLE	DESCRIPTION
N2	Node / Node set / Segment set ID for response output.
N2TYP	Type of N2: EQ.0: Node ID, EQ.1: Node set ID, EQ.2: Segment set ID.
DOF2	Applicable degrees-of-freedom for response output: EQ.0: direction given by vector VID2, EQ.1: x-translational degree-of-freedom, EQ.2: y-translational degree-of-freedom, EQ.3: z-translational degree-of-freedom, EQ.4: x-rotational degree-of-freedom, EQ.5: y-rotational degree-of-freedom, EQ.6: z-rotational degree-of-freedom, EQ.7: x, y and z-translational degrees-of-freedom, EQ.8: x, y and z-rotational degrees-of-freedom.
VAD2	Response output type: EQ.0: Velocity, EQ.1: Acceleration, EQ.2: Displacement, EQ.3: Nodal force (see Remark 8).
VID2	Vector ID for DOF2 = 0 for response direction; see *DEFINE_VECTOR.
RELATV	FLAG for displacement, velocity and acceleration results: EQ.0: Absolute values are requested, EQ.1: Relative values are requested (for VAD1 = 0, 1, 2 only).
FMIN	Minimum frequency for FRF output (cycles/time). See Remark 6.
FMAX	Maximum frequency for FRF output (cycles/time). See Remark 6.
NFREQ	Number of frequencies for FRF output. See Remark 6.

VARIABLE	DESCRIPTION
FSPACE	Frequency spacing option for FRF output: EQ.0: Linear, EQ.1: Logarithmic, EQ.2: Biased. See Remark 6.
LCFREQ	Load Curve ID defining the frequencies for FRF output. See Remark 6.
RESTRT	Restart option: EQ.0: Initial run, EQ.1: Restart with d3eigv family files, EQ.2: Restart with dumpfrf, EQ.3: Restart with d3eigv family files and dumpfrf. See Remark 7.
OUTPUT	Output option: EQ.0: Write amplitude and phase angle pairs, EQ.1: Write real and imaginary pairs.

Remarks:

1. **Frequency Response Functions.** The FRF (frequency response functions) can be given as Displacement/Force (called Admittance, Compliance, or Receptance), Velocity/Force (called Mobility), Acceleration/Force (called Accelerance, Inertance), etc.

2. **Enforced Motion.** The excitation input can be given as enforced motion (VAD1 = 5, 6, 7). Large mass method is used for this type of excitation input. The user need to attach a large mass to the nodes where the enforced motion is applied by using the keyword *ELEMENT_MASS_*{OPTION}*, and report the large mass per node (MPN) in the keyword *CONTROL_FREQUENCY_DOMAIN. For more details, please refer to *CONTROL_FREQUENCY_DOMAIN.

3. **Maximum Frequency.** FNMAX decides how many natural vibration modes are adopted in FRF computation. LS-DYNA uses only modes with lower or equal frequency than FNMAX in FRF computation. If FNMAX is not given, the number of modes for the FRF computation is the same as the number of modes,

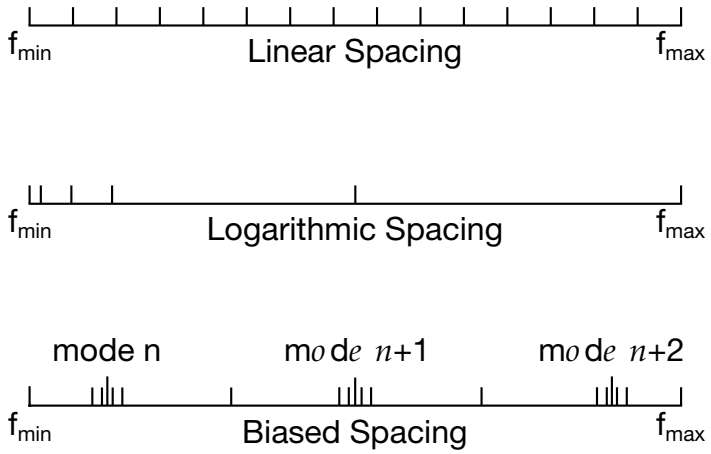

Figure 23-4. Spacing options of the frequency points.

NEIG, from the *CONTROL_IMPLICIT_EIGENVALUE keyword card, unless MDMIN and MDMAX are prescribed (see Remark 5).

4. **Maximum/Minimum Mode.** MDMIN and MDMAX decide which mode(s) are adopted in FRF computation. This option is useful for calculating the contribution from a single mode (MDMIN = MDMAX) or several modes (MDMIN < MDMAX). If only MDMIN is given, LS-DYNA uses the single mode (MDMIN) to compute FRF. In a restart run based on existing eigenmode database d3eigv (RESTRT = 1 or 3), MDMAX should be a positive integer which is equal to or less than the number of eigenmodes available in d3eigv.

5. **Damping.** Damping can be prescribed in several ways:

   a) To use a constant modal damping coefficient ζ for all the modes, define DAMPF only. LCDMP, LCTYP, DMPMAS and DMPSTF are ignored.

   b) To use mode dependent modal damping, define a load curve (*DEFINE_CURVE) and specify that if the abscissa value defines the frequency or mode number by LCTYP. DMPMAS and DMPSTF are ignored.

   c) To use Rayleigh damping, define DMPMAS (α) and DMPSTF (β) and keep DAMPF as 0.0, and keep LCDMP, LCTYP as 0. The damping matrix in Rayleigh damping is defined as $\mathbf{C} = \alpha\mathbf{M} + \beta\mathbf{K}$, where, $\mathbf{C}$, $\mathbf{M}$ and $\mathbf{K}$ are the damping, mass and stiffness matrices respectively.

6. **Frequency Points.** There are two methods to define the frequencies.

   a) The first method is to define FMIN, FMAX, NFREQ and FSPACE. FMIN and FMAX specify the frequency range of interest and NFREQ specifies the number of frequencies at which results are required. FSPACE specifies the type of frequency spacing (linear, logarithmic or biased) to be used.

These frequency points for which results are required can be spaced equally along the frequency axis (on a linear or logarithmic scale). Or they can be biased toward the eigenfrequencies (the frequency points are placed closer together at eigenfrequencies in the frequency range) so that the detailed definition of the response close to resonance frequencies can be obtained. See Figure 23-4.

b) The second method is to use a load curve (LCFREQ) to define the frequencies of interest.

7. **RESTRT Field.** To save time in subsequent runs, the modal analysis stored in the d3eigv file during the first run can be reused by setting RESTRT = 1.

RESTRT = 2 or 3 is used when the user wants to add extra vibration modes to the FRF computation. After the initial FRF computation, the number of vibration modes may not be enough. For example, in the initial computation, the only vibration modes used may be up to 500 Hz. However, vibration modes at higher frequencies are needed, so just computing the extra modes (frequencies above 500 Hz) and adding the contribution from these extra modes to the previous FRF results is more efficient.

For RESTRT = 2, LS-DYNA runs a new modal analysis, reads in the previous FRF results (stored in the binary dump file dumpfrf), and adds the contribution from the new modes. For RESTRT = 3, LS-DYNA reads in d3eigv family files generated elsewhere, reads in dumpfrf, and adds the contribution from the new modes.

8. **Nodal Force Response Output.** For nodal force response (VAD2 = 3), the same nodes (or node set) need to be defined in *DATABASE_NODAL_FORCE_GROUP. In addition, the MSTRES field for the *CONTROL_IMPLICIT_EIGENVALUE keyword must be set to 1.

***FREQUENCY_DOMAIN_LOCAL**_*OPTION1_{OPTION2}*

Available options for *OPTION1* include:

NODE_SET

PART

PART_SET

For *OPTION2* the available option is:

<BLANK>

EXCLUDE

Purpose: Define local nodes and parts to be included in frequency domain analysis (random vibration, response spectrum analysis and SSD). When the keyword OPTION2 EXCLUDE is used, the nodes and parts defined in this keyword are excluded from participating in the frequency domain analysis. Without this keyword, the frequency domain analysis is always performed on the whole model.

Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
ID*n*	Node set ID or Part ID or Part set ID *n*.

Remarks:

This keyword defines the nodes/parts to be included in frequency domain analysis (random vibration analysis, response spectrum analysis and SSD). The nodes/parts not defined here will be skipped in the analysis (in result databases, the response for those nodes/parts is marked as 0). With this keyword, significant CPU cost saving can be obtained if the user wants only response on a fraction of the nodes/parts of the model. With the option EXCLUDE, this keyword can be used to remove some nodes/parts from the analysis. Without using this keyword, the frequency domain analysis is always performed on the whole model.

***FREQUENCY_DOMAIN_MODE**_*OPTION1*_*{OPTION2}*

Available options for *OPTION1* include:

LIST

GENERATE

SET

LOAD_PROJECTION

MODAL_COEFFICIENT

For *OPTION2* the available option is:

<BLANK>

EXCLUDE

Purpose: Define vibration modes to be used in modal superposition, modal acceleration or modal combination procedures for mode-based frequency domain analysis (such as frequency response functions, steady state dynamics, random vibration analysis and response spectrum analysis). When the keyword OPTION2 EXCLUDE is used, the modes defined in this keyword are excluded from participating in the modal superposition, modal acceleration, or modal combination procedures.

Card Summary:

Card 1a. This card is included if and only if OPTION1 is LIST. Include as many cards as necessary. This input ends at the next keyword ("*") card.

MID1	MID2	MID3	MID4	MID5	MID6	MID7	MID8

Card 1b. This card is included if and only if OPTION1 is GENERATE. Include as many cards as necessary. This input ends at the next keyword ("*") card.

M1BEG	M1END	M2BEG	M2END	M3BEG	M3END	M4BEG	M4END

Card 1c. This card is included if and only if OPTION1 is SET.

SID							

Card 1d. This card is included if and only if OPTION1 is LOAD_PROJECTION.

NMSORT	DSKIP						

Card 1e. This card is included if and only if OPTION1 is MODAL_COEFFICIENT.

DSKIP							

Data Cards:

Mode ID Cards. For LIST keyword option, list the mode IDs. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
MID*n*	Mode ID *n*.

Mode Block Cards. For GENERATE keyword option specify ranges of modes. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1b	1	2	3	4	5	6	7	8
Variable	M1BEG	M1END	M2BEG	M2END	M3BEG	M3END	M4BEG	M4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
M*n*BEG	First mode ID in block *n*.
M*n*END	Last mode ID in block *n*. All mode ID's between and including M*n*BEG and M*n*END are added to the list.

Mode Set Card. For SET keyword option specify a mode set. Include only one card.

Card 1c	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							

VARIABLE	DESCRIPTION
SID	Mode set identification (see *SET_MODE).

Load Projection Card. For LOAD_PROJECTION keyword option specify the number of modes to be retained, which have the largest load projection ratios, or specify a threshold load projection ratio for mode truncation.

Card 1d	1	2	3	4	5	6	7	8
Variable	NMSORT	DSKIP						
Type	I	F						

VARIABLE	DESCRIPTION
NMSORT	Number of modes to be retained which have the largest load projection ratios.
DSKIP	The threshold load projection ratio. All modes with load projection ratio less than this value will be skipped.

Modal Coefficient Ratio Card. For MODAL_COEFFICIENT keyword option, specify a threshold modal coefficient ratio (over the largest modal coefficient) for mode truncation.

Card 1e	1	2	3	4	5	6	7	8
Variable	DSKIP							
Type	F							

VARIABLE	DESCRIPTION
DSKIP	The threshold modal coefficient ratio. All modes with the ratio of its modal coefficient over the largest modal coefficient less than this value will be skipped.

Remarks:

1. **Excluding Modes.** This keyword can be used to remove the modes that add a much smaller contribution to the total structural response than the other modes from the modal superposition, modal acceleration or modal combination procedures of the mode-based frequency domain analysis.

2. **Overriding Mode Lists.** The mode list defined by this keyword overrides the modes specified by MDMIN, MDMAX (or FNMIX, FNMAX) in the keywords *FREQUENCY_DOMAIN_FRF, *FREQUENCY_DOMAIN_SSD, etc.

*FREQUENCY_DOMAIN_PATH_{OPTION}

Available options include:

<BLANK>

NOJOBID

PARTITION

Purpose: Specify the path and file name of binary databases, such as d3eigv, containing mode information for restarting frequency domain analyses such as FRF, SSD, Random vibration, and Response spectrum analysis.

The PARTITION option supports assigning different binary databases to different frequency ranges. Specifically, each frequency range can be associated with different eigenmodes and modal shape vectors provided by the binary database. This option provides a model for materials that have frequency-dependent properties.

Partition Cards. Card 1 for the PARTITION keyword option. Include one card for each frequency range. This input ends at the next keyword ("*") card. See Remark 3.

Card 1	1	2	3	4	5	6	7	8
Variable	FBEG	FEND	FILENAME					
Type	F	F	C					
Default	none	none	none					

Filename Card. Card 1 format used with the keyword option left blank.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

VARIABLE	DESCRIPTION
FBEG	Beginning frequency for using this database

FEND	Ending frequency for using this database
FILENAME	Path to the database which contains modal information.

Remarks:

1. **Binary File Location.** If the binary database files are in the runtime directory, this card is not needed for the case *without* partitioning.

2. **NOJOBID Option.** When the option NOJOBID is active, LS-DYNA will not add a prefix to the FILENAME on card 1. Even if the user is running LS-DYNA with *CASE or has JOBID in the command line, LS-DYNA will not add a prefix when NOJOBID is active.

   To understand the intent of this feature recall that job ID numbers exist to ensure that filenames are unique so that output files are not overwritten for each calculation in some sequence. When the modal data is being read in as part of a restart calculation from some database already on disk, the default behavior is to replace FILENAME with FILENAME prefixed by the job ID. Consequently, without the NOJOBID option, reusing a single database across multiple modal analyses would involve either renaming or symbolically linking the existing file to the prefixed filename. The NOJOBID option circumvents this difficulty.

   This is useful when the user wants to run multiple load cases for a single frequency domain analysis (FRF, SSD, random vibration, response spectrum analysis), and would like to run each load case with the restart option, RESTRT = 1, in *FREQUENCY_DOMAIN_FRF, or *FREQUENCY_DOMAIN_RANDOM_VIBRATION, or *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM, etc., or RESTMD = 1 in *FREQUENCY_DOMAIN_SSD. In this case, with the option NOJOBID, a single eigenvector database, such as d3eigv, can be used for all the load cases.

3. **Frequency Partition.** When the option PARTITION is active, the binary database designated by FILENAME is used for the frequency range starting from (and including) FBEG and ending at (not including) FEND.

*FREQUENCY_DOMAIN_RANDOM_VIBRATION_{OPTION}

Available options include:

<BLANK>

FATIGUE

Purpose: Set random vibration control options. When the FATIGUE keyword option is used, compute fatigue life of structures or parts under random vibration (see Remark 2).

Card Summary:

Card 1. This card is required.

MDMIN	MDMAX	FNMIN	FNMAX	RESTRT			

Card 2. This card is required.

DAMPF	LCDAM	LCTYP	DMPMAS	DMPSTF	DMPTYP		

Card 3. This card is required.

VAFLAG	METHOD	UNIT	UMLT	VAPSD	VARMS	NAPSD	NCPSD

Card 3.1. This card is read if VAFLAG = 5, 6, or 7. It is optional.

PREF							

Card 4. This card is required.

LDTYP	IPANELU	IPANELV	TEMPER		LDFLAG	ICOARSE	TCOARSE

Card 5. Include NAPSD of this card.

SID	STYPE	DOF	LDPSD	LDVEL	LDFLW	LDSPN	CID

Card 6. Include NCPSD of this card.

LOAD_I	LOAD_J	LCTYP2	LDPSD1	LDPSD2			

Card 7. This card is included if the FATIGUE keyword option is used.

MFTG	NFTG	STRTYP	TEXPOS	STRSF	INFTG		

Card 7.1a. Include NFTG cards that are any combination of this card and Card 7.1b. This card is included when LCID > 0.

PID	LCID	PTYPE	LTYPE				SNLIMT

Card 7.1b. Include NFTG cards that are any combination of this card and Card 7.1a. This card is included when LCID < 0.

PID	LCID	PTYPE		A	B	STHRES	SNLIMT

Card 7.2. Include INFTG of this card when INFTG > 0.

FILENAME

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	MDMIN	MDMAX	FNMIN	FNMAX	RESTRT			
Type	I	I	F	F	I			
Default	1	optional	0.0	optional	0			

VARIABLE	DESCRIPTION
MDMIN	First mode in modal superposition method (optional)
MDMAX	Last mode in modal superposition method (optional)
FNMIN	Minimum natural frequency in modal superposition method (optional)
FNMAX	Maximum natural frequency in modal superposition method (optional)
RESTRT	Restart option (see Remark 4): EQ.0: A new modal analysis is performed. EQ.1: Restart with d3eigv. EQ.2: Sum up precomputed random vibration PSD and RMS results only.

Card 2	1	2	3	4	5	6	7	8
Variable	DAMPF	LCDAM	LCTYP	DMPMAS	DMPSTF	DMPTYP		
Type	F	I	I	F	F	I		
Default	0.0	0	0	0.0	0.0	0		

VARIABLE	DESCRIPTION
DAMPF	Modal damping coefficient, ζ.
LCDAM	Load Curve ID defining mode dependent modal damping coefficient ζ.
LCTYP	Type of load curve defining modal damping coefficient: EQ.0: Abscissa value defines frequency. EQ.1: Abscissa value defines mode number.
DMPMAS	Mass proportional damping constant α, in Rayleigh damping.
DMPSTF	Stiffness proportional damping constant β, in Rayleigh damping.
DMPTYP	Type of damping: EQ.0: Modal damping EQ.1: Broadband damping

Card 3	1	2	3	4	5	6	7	8
Variable	VAFLAG	METHOD	UNIT	UMLT	VAPSD	VARMS	NAPSD	NCPSD
Type	I	I	I	F	I	I	I	I
Default	none	0	none	↓	none	none	1	0

VARIABLE	DESCRIPTION
VAFLAG	Loading type: EQ.0: No random vibration analysis EQ.1: Base acceleration EQ.2: Random pressure EQ.3: Plane wave EQ.4: Shock wave EQ.5: Progressive wave EQ.6: Reverberant wave EQ.7: Turbulent boundary layer wave EQ.8: Nodal force EQ.9: Base velocity EQ.10: Base displacement EQ.11: Enforced acceleration by large mass method (see Remark 15) EQ.12: Enforced velocity by large mass method (see Remark 15) EQ.13: Enforced displacement by large mass method (see Remark 15)
METHOD	Method for modal response analysis (see Remark 6): EQ.0: Method set automatically by LS-DYNA (recommended) EQ.1: Modal superposition method EQ.2: Modal acceleration method EQ.3: Modal truncation augmentation method
UNIT	Flag for acceleration unit conversion (see Remark 7): EQ.0: Use [length unit]/[time unit]^2 as unit of acceleration. EQ.1: Use g as unit for acceleration and SI units (Newton, kg, meter, second, etc.) elsewhere. EQ.2: Use g as unit for acceleration and engineering units (lbf, lbf × second^2/inch, inch, second, etc.) elsewhere. EQ.3: Use g as unit for acceleration and units (kN, kg, mm, ms, GPa, etc.) elsewhere.

VARIABLE	DESCRIPTION
	EQ.4: Use g as unit for acceleration and units (Newton, ton, mm, second, MPa, etc.) elsewhere.
	EQ.-1: Use g as unit for acceleration and provide the multiplier for converting g to [length unit]/[time unit]^2.
UMLT	Multiplier for converting g to [length unit]/[time unit]^2 (used only for UNIT = -1).
VAPSD	Flag for PSD output: EQ.0: Absolute PSD output is requested. EQ.1: Relative PSD output is requested (used only for VAFLAG = 1).
VARMS	Flag for RMS output: EQ.0: Absolute RMS output is requested. EQ.1: Relative RMS output is requested (used only for VAFLAG = 1).
NAPSD	Number of auto PSD load definition. Card 5 is repeated NAPSD times; one for each auto PSD load definition. The default value is 1.
NCPSD	Number of cross PSD load definition. Card 6 is repeated NCPSD times; one for each cross PSD load definition. The default value is 0.

This card is read when VAFLAG = 5, 6, or 7. It is optional.

Card 3.1	1	2	3	4	5	6	7	8
Variable	PREF							
Type	I							
Default	2.e-5							

VARIABLE	DESCRIPTION
PREF	Reference pressure used to convert acoustic pressure to SPL (dB). This reference pressure is only needed if VAFLAG = 5, 6, or 7. For

VARIABLE	DESCRIPTION
	VAFLAG = 5, 6, or 7, if this Card 3.1 is not provided, LS-DYNA will use a default value 2.0 $\times 10^{-5}$ as the reference pressure.

Card 4	1	2	3	4	5	6	7	8
Variable	LDTYP	IPANELU	IPANELV	TEMPER		LDFLAG	ICOARSE	TCOARSE
Type	I	I	I	F		I	I	F
Default	0	0	0	0.0		0	0	0.1

VARIABLE	DESCRIPTION
LDTYP	Excitation load (LDPSD in Card 5) type: EQ.0: PSD EQ.1: SPL (for plane wave only) EQ.2: Time history load
IPANELU	Number of strips in *U*-direction (used only for VAFLAG = 5, 6, 7). See Remark 3.
IPANELV	Number of strips in *V*-direction (used only for VAFLAG = 5, 6, 7). See Remark 3.
TEMPER	Temperature
LDFLAG	Type of loading curves: EQ.0: Log-log interpolation (default) EQ.1: Semi-log interpolation EQ.2: Linear-linear interpolation
ICOARSE	Option for PSD curve coarsening: EQ.0: No coarsening; use original data (default). EQ.1: Coarsening by keeping only peaks and troughs EQ.2: Coarsening by removing intermediate points whose slope change percentage is less than prescribed tolerance (TCOARSE)

VARIABLE	DESCRIPTION
TCOARSE	Tolerance for slope change percentage for removing intermediate points from PSD curve (default is 0.1) for ICOARSE = 2

Auto PSD Cards. Include NAPSD cards of this format, one per excitation.

Card 5	1	2	3	4	5	6	7	8
Variable	SID	STYPE	DOF	LDPSD	LDVEL	LDFLW	LDSPN	CID/VID
Type	I	I	I	I	I	I	I	I
Default	↓	none	none	none	0	0	0	0

VARIABLE	DESCRIPTION
SID	GE.0: Set ID for the panel exposed to acoustic environment, or the nodes subjected to nodal force excitation, or nodal acceleration excitation. For VAFLAG = 1, base acceleration, leave this as blank LT.0: Used to define the cross-PSD. |SID| is the ID of the load cases.
STYPE	Flag specifying meaning of SID: EQ.0: Node EQ.1: Node set EQ.2: Segment set EQ.3: Part EQ.4: Part set LT.0: Used to define the cross-PSD. |STYPE| is the ID of the load cases.
DOF	Applicable degrees-of-freedom for nodal force excitation or base acceleration (DOF = 1, 2, and 3), or wave direction: EQ.0: Translational movement in direction given by vector VID EQ.1: x-translational degree-of-freedom EQ.2: y-translational degree-of-freedom

VARIABLE	DESCRIPTION
	EQ.3: *z*-translational degree-of-freedom
LDPSD	Load curve for PSD, SPL, or time history excitation
LDVEL	Load curve for phase velocity
LDFLW	Load curve for exponential decay for TBL in flow-wise direction
LDSPN	Load curve for exponential decay for TBL in span-wise direction
CID/VID	Coordinate system ID for defining wave direction, see *DEFINE_-COORDINATE_SYSTEM; or vector ID for defining load direction for nodal force or base excitation, see *DEFINE_VECTOR.

Cross PSD Cards. Include NCPSD cards of this format, one per excitation.

Card 6	1	2	3	4	5	6	7	8
Variable	LOAD_I	LOAD_J	LCTYP2	LDPSD1	LDPSD2			
Type	I	I	I	I	I			
Default	none	none	0	none	none			

VARIABLE	DESCRIPTION
LOAD_I	ID of load *i* for cross PSD
LOAD_J	ID of load *j* for cross PSD
LCTYP2	Type of load curves (LDPSD1 and LDPSD2) for defining cross PSD: EQ.0: LDPSD1 defines real part and LDPSD2 defines imaginary part. EQ.1: LDPSD1 defines magnitude and LDPSD2 defines phase angle (in degrees). EQ.2: LDPSD1 defines magnitude and LDPSD2 defines phase angle (in radians).
LDPSD1	Load curve for real part or magnitude of cross PSD
LDPSD2	Load curve for imaginary part or phase angle of cross PSD

Fatigue Card. Additional card for FATIGUE keyword option.

Card 7	1	2	3	4	5	6	7	8
Variable	MFTG	NFTG	STRTYP	TEXPOS	STRSF	INFTG		
Type	I	I	I	F	F	I		
Default	0	1	0	0.0	1.0	0		

VARIABLE	DESCRIPTION
MFTG	Method for random fatigue analysis: EQ.0: No fatigue analysis EQ.1: Steinberg's three-band method EQ.2: Dirlik method EQ.3: Narrow band method EQ.4: Wirsching method EQ.5: Chaudhury and Dover method EQ.6: Tunna method EQ.7: Hancock method EQ.8: Lalanne method.
NFTG	Field specifying the number of S - N curves to be defined: GE.0: Number of S - N curves defined by Cards 7.1a and 7.1b which are included in the required combination to get to "NFTG" number of cards, one for each S - N fatigue curve definition. The default value is 1. EQ.-999: S - N curves are defined through *MAT_ADD_FATIGUE.
STRTYP	Stress type of S - N curve in fatigue analysis: EQ.0: von-Mises stress EQ.1: Maximum principal stress (not implemented) EQ.2: Maximum shear stress (not implemented) EQ.-n: The n^{th} stress component

VARIABLE	DESCRIPTION
TEXPOS	Exposure time
STRSF	Stress scale factor to accommodate different ordinates in S - N curve (not used if NFTG = -999): EQ.1: Used if the ordinate in S - N curve is stress range (default) EQ.2: Used if the ordinate in S - N curve is stress amplitude
INFTG	Flag for including initial damage ratio (see Remark 5): EQ.0: No initial damage ratio, GT.0: Read existing d3ftg files to get initial damage ratio. When INFTG > 1, the initial damage ratio comes from multiple loading cases (correspondingly, multiple binary databases, defined by Card 7.2). The value of INFTG should be ≤ 10.

S-N Curve Cards. NFTG additional cards for FATIGUE keyword option of a combination of Cards 7.1a and 7.1b. Each Card 7.1a or Card 7.1b defines one zone for fatigue analysis and the corresponding S - N fatigue curve for that zone. Card 7.1a is included for LCID > 0.

Card 7.1a	1	2	3	4	5	6	7	8
Variable	PID	LCID	PTYPE	LTYPE				SNLIMT
Type	I	I	I	I				I
Default	none	none	0	0				0

VARIABLE	DESCRIPTION
PID	Part ID, part set ID, or element (solid, shell, beam, thick shell) set ID
LCID	S - N fatigue curve ID for the current part or part set: GT.0: S - N fatigue curve ID EQ.-1: S - N fatigue curve uses equation $NS^b = a$ EQ.-2: S - N fatigue curve uses equation $\log(S) = a - b\log(N)$ EQ.-3: S - N fatigue curve uses equation $S = a\,N^b$

VARIABLE	DESCRIPTION
	EQ.-4: S - N fatigue curve uses equation $S = a - b\log(N)$
PTYPE	Type of PID. EQ.0: Part (default) EQ.1: Part set EQ.2: SET_SOLID EQ.3: SET_BEAM EQ.4: SET_SHELL EQ.5: SET_TSHELL
LTYPE	Type of LCID. EQ.0: Semi-log interpolation (default) EQ.1: Log-log interpolation EQ.2: Linear-linear interpolation
SNLIMT	Flag setting algorithm used when stress is lower than the lowest stress on S - N curve (if LCID > 0): EQ.0: Use the life at the last point on S - N curve EQ.1: Extrapolation from the last two points on S - N curve EQ.2: Infinity

S-N Curve Cards. NFTG additional cards for FATIGUE keyword option of a combination of Cards 7.1a and 7.1b. Each Card 7.1a or Card 7.1b defines one zone for fatigue analysis and the corresponding S - N fatigue curve for that zone. Card 7.1b is included for LCID < 0.

Card 7.1b	1	2	3	4	5	6	7	8
Variable	PID	LCID	PTYPE		A	B	STHRES	SNLIMT
Type	I	I	I		F	F	F	I
Default	none	none	0		none	none	0.	0

VARIABLE	DESCRIPTION
PID	Part ID, part set ID, or element (solid, shell, beam, thick shell) set ID
LCID	S - N fatigue curve ID for the current part or part set: GT.0: S - N fatigue curve ID EQ.-1: S - N fatigue curve uses equation $NS^b = a$ EQ.-2: S - N fatigue curve uses equation $\log(S) = a - b\log(N)$ EQ.-3: S - N fatigue curve uses equation $S = a\,N^b$ EQ.-4: S - N fatigue curve uses equation $S = a - b\log(N)$
PTYPE	Type of PID. EQ.0: Part (default) EQ.1: Part set EQ.2: SET_SOLID EQ.3: SET_BEAM EQ.4: SET_SHELL EQ.5: SET_TSHELL
A	Material parameter a in S - N fatigue equation.
B	Material parameter b in S - N fatigue equation.
STHRES	Fatigue threshold
SNLIMT	Flag setting algorithm used when stress is lower than STHRES: EQ.0: Use the life at STHRES EQ.1: Ignored EQ.2: Infinity

Initial Damage Card. INFTG additional cards for FATIGUE keyword option when INFTG > 0.

Card 7.2	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	d3ftg							

VARIABLE	DESCRIPTION
FILENAME	Path and name of existing binary database for fatigue information.

Remarks:

1. **Historical Background.** This command evaluates the structural random vibration response due to aero acoustic loads, base excitation, or nodal force. This capability originated in Boeing's in-house code N-FEARA, which is a NIKE3D-based Finite Element tool for performing structural analysis with vibro-acoustic loads. The main developer of N-FEARA is Mostafa Rassaian from the Boeing Company.

2. **Fatigue.** MSTRES must be set to 1 in the keyword *CONTROL_IMPLICIT_EIGENVALUE for the FATIGUE keyword option because the fatigue analysis is depending on stresses.

3. **IPANELU and IPANELV.** The number of strips the in U and V-directions are used to group the elements and thereby reduce the number integration domains reducing computational expense. This option is only available for VAFLAG = 5, 6, and 7.

4. **Restarting.** Restart option RESTRT = 1 is used when mode analysis has been done previously. In this case, LS-DYNA skips modal analysis and reads in the d3eigv files from the prior execution. For RESTRM = 1, always use MDMIN = 1 and set MDMAX to the number of modes in the previous run (this can be found in the ASCII file eigout, or it can be extracted from the d3eigv files using LS-PrePost). Restart option RESTRT = 2 is used to sum up PSD and RMS results from multiple runs to provide total PSD and RMS response of the same model, subjected to multiple loading resources. The file name and path of the PSD and RMS binary databases (by default, d3psd and d3rms) to be summed, are defined by the keywords *DATABASE_FREQUENCY_BINARY_D3PSD_SUMMA-

TION, and *DATABASE_FREQUENCY_BINARY_D3RMS_SUMMATION. The multiple loading resources can be of different loading type (defined by VAFLAG), and they are applied to the model simultaneously.

5. **Accumulated Fatigue.** The fatigue damage ratio can be accumulated over multiple load cases by setting INFTG = 1. This is useful when a structure is subjected to multiple independent random vibrations. LS-DYNA calculates the total damage ratio by adding the damage ratio from the current calculation to the damage ratio of the previous calculation which are stored in the previous calculation's fatigue database (d3ftg by default). The previous d3ftg file will be overwritten by the new one if it is in the same directory.

6. **Automatic Method Selection.** If METHOD = 0, LS-DYNA uses modal superposition method for cases (VAFLAG) 4, 5, 6, 7. For cases 1, 2, 3 and 8, LS-DYNA uses modal superposition method when preload condition is present and uses modal acceleration method when preload condition is not present.

7. **Units.** In a set of consistent units, the unit for acceleration is defined as

$$1\ (\text{acceleration unit}) = \frac{1(\text{length unit})}{[1(\text{time unit})]^2}$$

Some users in industry prefer to use g (acceleration due to gravity) as the unit for acceleration. For example,

$$1\text{g} = 9.81\frac{\text{m}}{\text{s}^2} = 386.089\frac{\text{inch}}{\text{s}^2}$$

If the input and output use g as the unit for acceleration, select UNIT = 1, 2, or 3.

If UNIT = -1, a multiplier (UMLT) for converting g to [length unit]/[time unit]^2 is needed and it is defined by

$$1\text{g} = \text{UMLT} \times \frac{[\text{length unit}]}{[\text{time unit}]^2}$$

For more information about the consistent units, see GS.21 (GETTING STARTED).

8. **Restrictions on Load Curves.** The load curves LDPSD, LDVEL, LDFLW, and LDSPN must all be defined using the same number of points. The number of points in the load curve LDDAMP can be different from those for LDPSD, LDVEL, LDFLW, and LDSPN.

9. **Wave Direction.** Wave direction is determined by DOF and CID/VID. CID/VID represents a local *U-V-W* coordinate system for defining acoustic wave direction; only partially correlated waves (VAFLAG=5, 6, 7) need this local coordinate system. For nodal force, base excitation, plane wave or random pressure, CID represents a vector ID defining the load direction (DOF = ±4).

10. **Stress / Strain Computation.** To get stress results (PSD and RMS) from random vibration analysis, the MSTRES field of the *CONTROL_IMPLICIT_EIGENVALUE keyword should be set to 1. To get strain results (PSD and RMS) the STRFLG field of *DATABASE_EXTENT_BINARY should be set to 1. To get stress component results for beam elements (which are not based on resultant formulation), the BEAMIP field of *DATABASE_EXTENT_BINARY should be set greater than 0.

11. **Binary Plot Databases.** PSD and RMS results are given for all nodes and elements. PSD results are written in binary to a file named d3psd. Similarly, RMS results are written in binary to a file named d3rms. See the keyword *DATABASE_FREQUENCY_BINARY_*{OPTION}* for more details.

12. **ASCII Output for Displacement.** Displacement, velocity, and acceleration PSD results are output into ASCII file nodout_psd. The set nodes for which data is written to nodout_psd is specified with the *DATABASE_HISTORY_NODE keyword.

13. **ASCII Output for Stress.** Stress PSD results are output into ASCII file elout_psd. The set of solid, beam, shell, and thick shell elements to be written to the elout_psd file are specified with the following keywords:

    *DATABASE_HISTORY_SOLID

    *DATABASE_HISTORY_BEAM

    *DATABASE_HISTORY_SHELL

    *DATABASE_HISTORY_TSHELL

14. **Cross PSD.** The cross PSD can be defined as complex variables to consider phase difference. In that case, two curves are needed to define the cross PSD (LCPSD1 and LCPSD2). Two load IDs are needed to define the cross PSD (LOAD_I and LOAD_J). They are simply the ordering numbers by which the auto PSDs are defined. For example, the first Card 5 defines load 1 and the second Card 5 defines the load 2. No cross PSD is required if two loads are uncorrelated. Cross PSD for any pair of two correlated loads is defined only once – from lower load ID to higher load ID (e.g. 1->2, 1->3, 2->3, …). The cross PSD from higher load ID to lower load ID (e.g. 2->1, 3->1, 3->2, …) is added by LS-DYNA automatically by using the relationship

$$G_{ji} = \overline{G_{ij}}$$

where G_{ij} is the cross PSD from load i to load j, and $\overline{\ }$ represents the complex conjugate.

15. **Large Mass Method.** For the cases with enforced motion excitation, such as nodal velocity, acceleration, or displacement, the large mass method can be used to compute the random vibration response. The excitation input can be given as enforced motion curves (VAFLAG = 11, 12, 13). To use the large mass method, a large mass must be attached to the nodes where the enforced motion is applied by using the keyword *ELEMENT_MASS_*{OPTION}*; MPN must also be set in the keyword *CONTROL_FREQUENCY_DOMAIN. For more details, please refer to *CONTROL_FREQUENCY_DOMAIN.

16. **Cross Correlation.** Cross correlation can be defined only for same type of excitations (e.g. nodal force, random pressure). Correlation between different types of excitations is not allowed.

17. **Output for Fatigue Data.** When the FATIGUE option is used, a binary plot file, d3ftg, is written. Five results are included in d3ftg:

    Result 1. Cumulative damage ratio

    Result 2. Expected fatigue life

    Result 3. Zero-crossing frequency

    Result 4. Peak-crossing frequency

    Result 5. Irregularity factor

    These results are given as element variables. Irregularity factor is a real number from 0 to 1. A sine wave has an irregularity factor of 1, while white noise has an irregularity factor of 0. The lower the irregularity factor, the closer the process is to the broad band case.

18. **Stress Threshold for Fatigue.** In some materials, the S – N curve flattens out eventually, so that below a certain threshold stress STHRES failure does not occur no matter how long the loads are cycled. SNLIMT can be set to 2 in this case. For other materials, such as aluminum, no threshold stress exists and SNLIMT should be set to 0 or 1 for added level of safety.

19. **Restriction on Fatigue Cards.** When the FATIGUE option is used, all fatigue cards (Card 7) *must* be of the same PTYPE (PART or SET of ELEMENTS).

20. **Format for S - N Curves.** S - N curves can be defined by *DEFINE_CURVE or by using a predefined equation by setting LCID < 0. When specified with curves using *DEFINE_CURVE, the abscissa values (first column) represent N (number of cycles to failure) and the ordinate values represent S (stress). The predefined equations are listed as follows:

    a) *LCID = -1*.

$$NS^b = a$$

b) *LCID* = *-2*.

$$\log(S) = a - b\log(N)$$

c) *LCID* = *-3*.

$$S = a\,N^b$$

d) *LCID* = *-4*.

$$S = a - b\log(N)$$

Here N is the number of cycles for fatigue failure and S is the stress amplitude. Please note that the first three equations can be converted to each other with some minor manipulations on the constants a and b.

*FREQUENCY_DOMAIN_RESPONSE_SPECTRUM_{OPTION}

Available options include:

<BLANK>

DDAM

Purpose: Obtain the peak response of a structure by performing a response spectrum computation. The structure is subjected to an input response spectrum load, such as the acceleration spectrum load in earthquake engineering. The maximum response is, then, evaluated using the modal superposition method. With the DDAM option, LS-DYNA performs a Dynamic Design Analysis Method (DDAM) shock spectrum analysis. DDAM is a U.S. Navy methodology for qualifying shipboard equipment and supporting structures subject to dynamic loading caused by underwater explosions (UNDEX).

Card Summary:

Card 1. This card is required.

MDMIN	MDMAX	FNMIN	FNMAX	RESTRT	MCOMB	RELATV	MPRS

Card 2.1. This card is included if MCOMB = 99 in Card 1.

MCOMB1	MCOMB2						

Card 2.2. This card is included if MCOMB = 99 in Card 1.

W1	W2						

Card 3. This card is included if MPRS = 2 in Card 1.

R40							

Card 4. This card is required.

DAMPF	LCDAMP	LDTYP	DMPMAS	DMPSTF			

Card 5a. This card is included if the keyword option is unset (<BLANK>). This card can be repeated if 2 or more input spectra exist (multiple-point response spectrum).

LCTYP	DOF	LC/TBID	SF	VID	LNID	LNTYP	INFLAG

Card 5b. This card is included if the DDAM keyword option is used.

STD	UNIT	AMIN	VID	XC	YC	ZC	EFFMAS

Card 6a. This card is included if STD > 0 in Card 3b.

SHPTYP	MOUNT	MOVEMT	MATTYP				

Card 6b.1. This card is included if STD = -1 in Card 3b.

AF	AA	AB	AC	AD			

Card 6b.2. This card is included if STD = -1 in Card 3b.

VF	VA	VB	VC				

Card 7. This card is included if the DDAM keyword option is used and MCOMB = -14.

SID							

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	MDMIN	MDMAX	FNMIN	FNMAX	RESTRT	MCOMB	RELATV	MPRS
Type	I	I	F	F	I	I	I	I
Default	1	optional	0.0	optional	0	0	0	0

VARIABLE	DESCRIPTION
MDMIN	First mode in modal superposition method (optional)
MDMAX	Last mode in modal superposition method (optional)
FNMIN	Minimum natural frequency in modal superposition method (optional)
FNMAX	Maximum natural frequency in modal superposition method (optional)
RESTRT	Restart option: EQ.0: A new run including modal analysis, EQ.1: Restart with d3eigv family files created elsewhere.

VARIABLE	DESCRIPTION
MCOMB	Method for combination of modes: EQ.-14: NRL-SUM method with CSM (Closely Spaced Modes) treatment, where the CSM pairs are defined by SID (Mode set ID, see *SET_MODE) in Card 5 EQ.-4: NRL-SUM method with CSM (Closely Spaced Modes) treatment. The CSM pairs are automatically identified. EQ.0: SRSS method EQ.1: NRC Grouping method EQ.2: Complete Quadratic Combination method (CQC) EQ.3: Double Sum method based on Rosenblueth-Elorduy coefficient EQ.4: NRL-SUM method EQ.5: Double Sum method based on Gupta-Cordero coefficient EQ.6: Double Sum method based on modified Gupta-Cordero coefficient EQ.7: Rosenblueth method EQ.8: Absolute value method (ABS) EQ.99: Combining results provided by two mode combination methods defined in Card 2.1 with corresponding weights defined in Card 2.2
RELATV	Type of nodal displacement, velocity and acceleration results: EQ.0: Relative values (with respect to the ground) EQ.1: Absolute values
MPRS	Multi-point or multidirectional response combination method: EQ.0: SRSS EQ.1: 100-40-40 rule (Newmark method) (see Remark 7) EQ.2: 100-40-40 rule (Newmark method) with coefficient 0.4 replaced by R40 in Card 3.

Additional card included when MCOMB = 99 on Card 1.

Card 2.1	1	2	3	4	5	6	7	8
Variable	MCOMB1	MCOMB2						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
MCOMB*i*	i^{th} mode combination method for which results will be combined to the other combination method. It can have any value from the MCOMB description other than 99.

Additional card included when MCOMB = 99 on Card 1.

Card 2.2	1	2	3	4	5	6	7	8
Variable	W1	W2						
Type	F	F						
Default	0.5	0.5						

VARIABLE	DESCRIPTION
W*i*	Weight for the results given by the MCOMB*i* combination

Included when MPRS = 2 on Card 1.

Card 3	1	2	3	4	5	6	7	8
Variable	R40							
Type	F							
Default	0.4							

VARIABLE	DESCRIPTION
R40	Coefficient to replace 0.4 in 100-40-40 rule (see Remark 7)

Card 4	1	2	3	4	5	6	7	8
Variable	DAMPF	LCDAMP	LDTYP	DMPMAS	DMPSTF			
Type	F	I	I	F	F			
Default	none	0	0	0.0	0.0			

VARIABLE	DESCRIPTION
DAMPF	Modal damping ratio, ζ. Ignore if LCDAMP is defined.
LCDAMP	Load Curve ID for defining frequency dependent modal damping ratio ζ
LDTYP	Type of load curve for LCDAMP: EQ.0: Abscissa value defines frequency, EQ.1: Abscissa value defines mode number.
DMPMAS	Mass proportional damping constant α in Rayleigh damping
DMPSTF	Stiffness proportional damping constant β in Rayleigh damping

Standard Spectrum Analysis Card. Include if the keyword option is unset. This card can be repeated if 2 or more input spectra exist (multiple-point response spectrum).

Card 5a	1	2	3	4	5	6	7	8
Variable	LCTYP	DOF	LC/TBID	SF	VID	LNID	LNTYP	INFLAG
Type	I	I	I	F	I	I	I	I
Default	none	none	0	1.0	0	none	none	0

VARIABLE	DESCRIPTION
LCTYP	Load curve type for defining the input spectrum:

VARIABLE	DESCRIPTION
	EQ.0: Base velocity (as a function of natural frequency), EQ.1: Base acceleration (as a function of natural frequency), EQ.2: Base displacement (as a function of natural frequency), EQ.3: Nodal force (as a function of natural frequency), EQ.4: Pressure (as a function of natural frequency), EQ.5: Base velocity (as a function of natural period), EQ.6: Base acceleration (as a function of natural period), EQ.7: Base displacement (as a function of natural period), EQ.8: Nodal force (as a function of natural period), EQ.9: Pressure (as a function of natural period), EQ.10: Base velocity time history, EQ.11: Base acceleration time history, EQ.12: Base displacement time history.
DOF	Applicable degrees-of-freedom for excitation input: EQ.1: *x*-translational degree-of-freedom, EQ.2: *y*-translational degree-of-freedom, EQ.3: *z*-translational degree-of-freedom, EQ.4: Translational movement in direction given by VID.
LC/TBID	Load curve or table ID (see *DEFINE_TABLE) defining the response spectrum for frequencies. If the table definition is used, a family of curves are defined for discrete critical damping ratios.
SF	Scale factor for the input load spectrum
VID	Vector ID for DOF values of 4
LNID	Node ID, node set ID, or segment set ID where the excitation is applied. If the input load is given as a base excitation spectrum, LNID = 0.
LNTYP	Set type for LNID: EQ.1: Node, see *NODE, EQ.2: Node set, see *SET_NODE,

VARIABLE	DESCRIPTION
	EQ.3: Segment set, see *SET_SEGMENT, EQ.4: Part, see *PART, EQ.5: Part set, see *SET_PART.
INFLAG	Frequency interpolation option: EQ.0: Logarithmic interpolation, EQ.1: Semi-logarithmic interpolation, EQ.2: Linear interpolation.

DDAM Spectrum Analysis Card. Include for the DDAM keyword option.

Card 5b	1	2	3	4	5	6	7	8
Variable	STD	UNIT	AMIN	VID	XC	YC	ZC	EFFMAS
Type	I	I	F	I	F	F	F	F
Default	1	1	6	0	none	none	none	80

VARIABLE	DESCRIPTION
STD	Design spectrum standard for shock load: EQ.1: NRL-1396, EQ.-1: Spectrum constants defined through Cards 4b.1 and 4b.2.
UNIT	Unit system: EQ.1: MKS (kg, m, s, N, Pa) EQ.2: GPA (kg, mm, ms, kN, GPa) EQ.3: MPA (ton, mm, s, N, MPa) EQ.4: BIN (lbf-s^2/in, in, s, lbf, psi) EQ.5 miu_MKS (gm, mm, ms, N, N/mm2) EQ.6: CGS (gm, cm, s, dyne, dyne/cm2)
AMIN	Minimum acceleration (in g - gravity acceleration)
VID	Direction of shock load

VARIABLE	DESCRIPTION
	EQ.1: x-direction EQ.2: y-direction EQ.3: z-direction LT.0: Direction is given by vector |VID|
XC	X-directional cosine of shock load (if VID is undefined)
YC	Y-directional cosine of shock load (if VID is undefined)
ZC	Z-directional cosine of shock load (if VID is undefined)
EFFMAS	Minimum percentage requirement of total modal mass

NRL-1396 Design Spectrum Standard Card. Include when STD > 0 for the DDAM option.

Card 6a	1	2	3	4	5	6	7	8
Variable	SHPTYP	MOUNT	MOVEMT	MATTYP				
Type	I	I	I	I				
Default	1	1	1	1				

VARIABLE	DESCRIPTION
SHPTYP	Ship type: EQ.1: Submarine EQ.2: Surface ship
MOUNT	Mount type: EQ.1: Hull Mounted System EQ.2: Deck Mounted System EQ.3: Shell Plating Mounted System
MOVEMT	Movement type: EQ.1: Vertical

VARIABLE	DESCRIPTION
	EQ.2: Athwartship
	EQ.3: Fore and Aft
MATTYP	Material type:
	EQ.1: Elastic
	EQ.2: Elasto-plastic

Acceleration Spectrum Coefficients Card. This card is included for the DDAM keyword option if STD = -1.

Card 6b.1	1	2	3	4	5	6	7	8
Variable	AF	AA	AB	AC	AD			
Type	F	F	F	F	F			
Default	0.0	0.0	0.0	0.0	0.0			

VARIABLE	DESCRIPTION
AF, AA-AD	Coefficients to define the acceleration spectrum (see Remark 11)

Velocity Spectrum Coefficients Card. This card is included for the DDAM keyword option if STD = -1.

Card 6b.2	1	2	3	4	5	6	7	8
Variable	VF	VA	VB	VC				
Type	F	F	F	F				
Default	0.0	0.0	0.0	0.0				

VARIABLE	DESCRIPTION
VF, VA-VC	Coefficients to define the velocity spectrum (see Remark 11)

Mode Set Card. This card is included for the DDAM option with MCOMB = -14.

Card 7	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
SID	Mode set ID (see *SET_MODE)

Remarks:

1. **Modal Analysis.** Modal analysis must be performed preceding the response spectrum analysis. Thus, the keywords *CONTROL_IMPLICIT_GENERAL and *CONTROL_IMPLICIT_EIGENVALUE are expected in the input file.

2. **Input Spectrum.** MDMIN, MDMAX, FNMIN and FNMAX should be set appropriately to cover all the natural modes inside the input spectrum.

3. **Stress Results.** To include stress results, modal stress computation has to be requested in *CONTROL_IMPLICIT_EIGENVALUE (set MSTRES = 1).

4. **Base Excitation Output.** For base excitation cases, relative values or absolute values for displacement, velocity and acceleration results can be output.

5. **Restarts.** RESTRT = 1 enables a fast restart run based on d3eigv family files generated in the last run or elsewhere. LS-DYNA reads d3eigv family files to get the natural vibration frequencies and mode shapes. If the d3eigv family files are located in a directory other than the working directory, the directory must be specified in *FREQUENCY_DOMAIN_PATH.

6. **Double Sum Method and Earthquake Duration.** For Double Sum method (MCOMB = 3), earthquake duration time is given by ENDTIM in the keyword *CONTROL_TERMINATION.

7. **100-40-40 rule.** The 100-40-40 gives a way of evaluating the maximum response for multi-directional / multi-point loading. As described by Nie et al, the 100-40-40 rule (ASCE 4-98) determines the maximum response, *R*, of a three-dimensional seismic input by taking all the possible permutations of the maxima directional responses:

$$R = \pm\left[R_x \pm 0.4R_y \pm 0.4R_z\right], \text{or } \pm\left[R_y \pm 0.4R_z \pm 0.4R_x\right], \text{or } \pm\left[R_z \pm 0.4R_x \pm 0.4R_y\right]$$

R_x, R_y, and R_z are found by looking at the response from each of the loadings that make up the multi-directional / multi-point loading. For instance, R_x may be the response due to the acceleration in the x-direction of a node. This rule assumes that when one direction of loading occurs, the responses in the other directions are 40% of their maxima. The field R40 allows the user to adjust this 40% value.

8. **Frequency Interpolation.** Three interpolation options are available for frequency interpolation when reading response spectrum values.

   a) When INFLAG = 0 (default), logarithmic interpolation is used, that is,

   $$\frac{\log y - \log y_1}{\log x - \log x_1} = \frac{\log y_2 - \log y_1}{\log x_2 - \log x_1} \ .$$

   b) When INFLAG = 1, semi-logarithmic interpolation is used, that is,

   $$\frac{\log y - \log y_1}{x - x_1} = \frac{\log y_2 - \log y_1}{x_2 - x_1} \ .$$

   c) When INFLAG = 2, linear interpolation is used, that is,

   $$\frac{y - y_1}{x - x_1} = \frac{y_2 - y_1}{x_2 - x_1} \ .$$

9. **Interpolation and Damping Ratios.** Linear interpolation is used for interpolation with respect to damping ratios.

10. **Base Velocity, Acceleration and Displacement Time History.** If the load curve is defined as base velocity, base acceleration or base displacement time history (LCTYP = 10, 11 or 12), an ASCII xyplot database spectrum_curve_printID is generated. It shows the intermediate base acceleration spectrum converted from the time history data. ID is the ordering of the input spectra (defined in Card 3a). For single point response spectrum, ID is 1.

11. **User Define Velocity and Acceleration Spectra for DDAM.** The user defined acceleration input spectrum is defined as:

$$A = \begin{cases} A_f \times A_a \dfrac{(A_b + W) \times (A_c + W)}{(A_d + W)^2} & \text{if } A_d \neq 0 \\ A_f \times A_a \dfrac{(A_b + W)}{A_c + W} & \text{if } A_d = 0 \end{cases}$$

where W is the modal weight in thousands of pounds (Kips).

The user defined velocity input spectrum is defined as

$$V = V_f \times V_a \ \frac{(V_b + W)}{(V_c + W)} \ .$$

*FREQUENCY_DOMAIN_SEA_CONNECTION

Purpose: Define connection of subsystems in a SEA model.

Card Summary:

Card 1. This card is required.

CONID	CTYPE	NSUB	IBEAM				

Card 2. This card is required.

SUB1	SUB2	SUB3	SUB4	SUB4	SUB6	SUB7	SUB8

Card 3a.1. This card is required for CTYPE = 1.

ANGLE1	ANGLE2	ANGLE3	ANGLE4	ANGLE5	ANGLE6	ANGLE7	ANGLE8

Card 3a.2. This card is required for CTYPE = 1.

LENGTH							

Card 3b. This card is required for CTYPE = 2.

ABSORB	THICK						

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	CONID	CTYPE	NSUB	IBEAM				
Type	I	I	F	F				
Default	none	1	none	0				

VARIABLE	DESCRIPTION
CONID	Connection ID

VARIABLE	DESCRIPTION
CTYPE	Type of connection: EQ.1: plate-plate EQ.2: plate-cavity EQ.3: plate-cavity-cavity EQ.4: plate-beam
NSUB	Number of subsystems in this connection
IBEAM	Flag for plate connected to plate EQ.0: plate-plate connection. EQ.1: plate-plate-beam connection.

Card 2	1	2	3	4	5	6	7	8
Variable	SUB1	SUB2	SUB3	SUB4	SUB5	SUB6	SUB7	SUB8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
SUB*i*	ID of the i^{th} subsystem

Card 3a.1	1	2	3	4	5	6	7	8
Variable	ANGLE1	ANGLE2	ANGLE3	ANGLE4	ANGLE5	ANGLE6	ANGLE7	ANGLE8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
ANGLE*i*	Connection angle of the plate *i*

Card 3a.2	1	2	3	4	5	6	7	8
Variable	LENGTH							
Type	F							
Default	0							

VARIABLE	DESCRIPTION
LENGTH	Length of the edge in connection

Card 3b	1	2	3	4	5	6	7	8
Variable	ABSORB	THICK						
Type	F	F						
Default	none	none						

VARIABLE	DESCRIPTION
ABSORB	Absorption coefficient
THICK	Thickness of the plate

Remarks:

1. **Number of subsystems in connection.** At this time, up to 8 subsystems can be included in one connection.

*FREQUENCY_DOMAIN_SEA_INPUT

Purpose: Define input power for a subsystem in SEA model.

Card Summary:

Card 1. This card is required.

SUBID	SUBTYP	LOADTYP					

Card 2. This card is required

BWAVE	LWAVE	SWAVE	TWAVE				

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SUBID	SUBTYP	LOADTYP					
Type	I	I	I					
Default	none	1	1					

VARIABLE	DESCRIPTION
SUBID	ID of subsystem
SUBTYP	Type of subsystem: EQ.1: plate EQ.2: cavity EQ.3: beam
LOADTYP	Input power type: EQ.1: power EQ.2: force EQ.3: velocity EQ.4: bending wave power for plate EQ.5: shear wave power for plate.

Card 2	1	2	3	4	5	6	7	8
Variable	BWAVE	LWAVE	SWAVE	TWAVE				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
BWAVE	Bending wave
LWAVE	Longitudinal wave
SWAVE	Shear wave
TWAVE	Torsional wave (required only for beams, SUBTYP = 3)

Remarks:

1. **Input power in torsional wave.** TWAVE (input power in torsional wave) is not required for plate and cavity subsystems (SUBTYP = 1 or 2).

*FREQUENCY_DOMAIN_SEA_SUBSYSTEM

Purpose: Define input power for a subsystem in SEA model.

Card Summary:

Card 1. This card is required.

FMIN	FMAX	NFREQ	NFSPACE	LCFREQ	IREAD		

Card 2. This card is required.

SUBID	SUBTYP	DENSITY	E	PR	OUTPUT		

Card 3a.1. This card is required for plate (SUBTYP = 1).

A	PERIM	THICK	WIDTH	LENGTH			

Card 3a.2. This card is required for plate (SUBTYP = 1).

DAMPB	DAMPL	DAMPS	LC1	LC2	LC3		

Card 3b.1. This card is required for cavity (SUBTYP = 2).

A	PERIM	VOLUME	WIDTH	LENGTH	HEIGHT		

Card 3b.2. This card is required for cavity (SUBTYP = 2).

DAMPB	LC1						

Card 3c.1. This card is required for beam (SUBTYP = 3).

A	ISS	ITT	J	LENGTH			

Card 3c.2. This card is required for beam (SUBTYP = 3).

DAMPB	DAMPL	DAMPS	DAMPT	LC1	LC2	LC3	LC4

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	FMIN	FMAX	NFREQ	NFSPACE	LCFREQ	IREAD		
Type	I	I	I	F				
Default	none	1	1	0				

VARIABLE	DESCRIPTION
FMIN	Minimum frequency for SEA output (cycles/time)
FMAX	Maximum frequency for SEA output (cycles/time)
NFREQ	Number of frequencies for SEA output (cycles/time)
FSPACE	Frequency spacing option for SEA output: EQ.0: linear EQ.1: logarithmic EQ.2: biased
LCFREQ	Load curve ID defining the frequencies for SEA output
IREAD	Type of SEA run: EQ.0: run SEA analysis. EQ.1: read FEM keyword input deck and create SEA model.

Card 2	1	2	3	4	5	6	7	8
Variable	SUBID	SUBTYP	DENSITY	E	PR	OUTPUT		
Type	I	I	F	F	F	I		
Default	none	none	none	none	none	0		

VARIABLE	DESCRIPTION
SUBID	ID of subsystem
SUBTYP	Type of subsystem: EQ.1: plate EQ.2: cavity EQ.3: beam
DENSITY	Mass density of subsystem
E	Young's modulus of subsystem
PR	Poisson's ratio of subsystem
OUTPUT	Include this subsystem in output: EQ.0: no EQ.1: yes

Card 3a.1	1	2	3	4	5	6	7	8
Variable	A	PERIM	THICK	WIDTH	LENGTH			
Type	F	F	F	F	F			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
A	Plate area
PERIM	Plate perimeter
THICK	Plate thickness
WIDTH	Plate width
LENGTH	Plate length

Card 3a.2	1	2	3	4	5	6	7	8
Variable	DAMPB	DAMPL	DAMPS	LC1	LC2	LC3		
Type	F	F	F	I	I	I		
Default	none	none	none	0	0	0		

VARIABLE	DESCRIPTION
DAMPB	Damping factor for bending wave
DAMPL	Damping factor for longitudinal wave
DAMPS	Damping factor for shear wave
LC1	Load curve for damping factor for bending wave
LC2	Load curve for damping factor for longitudinal wave
LC3	Load curve for damping factor for shear wave

Card 3b.1	1	2	3	4	5	6	7	8
Variable	A	PERIM	VOLUME	WIDTH	LENGTH	HEIGHT		
Type	F	F	F	F	F			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
A	Cavity area
PERIM	Cavity perimeter
VOLUME	Cavity volume
WIDTH	Cavity width
LENGTH	Cavity length

VARIABLE	DESCRIPTION
HEIGHT	Cavity height

Card 3b.2	1	2	3	4	5	6	7	8
Variable	DAMPB	LC1						
Type	F	I						
Default	none	0						

VARIABLE	DESCRIPTION
DAMPB	Damping factor for bending wave
LC1	Load curve for damping factor for bending wave

Card 3c.1	1	2	3	4	5	6	7	8
Variable	A	ISS	ITT	J	LENGTH			
Type	F	F	F	F	F			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
AREA	Beam area
ISS	I_{ss}, area moment of inertia about local s-axis
ITT	I_{tt}, area moment of inertia about local t-axis
J	J, torsional constant
LENGTH	Beam length

Card 3c.2	1	2	3	4	5	6	7	8
Variable	DAMPB	DAMPL	DAMPS	DAMPT	LC1	LC2	LC3	LC4
Type	F	F	F	F	I	I	I	I
Default	none	none	none	none	0	0	0	0

VARIABLE	DESCRIPTION
DAMPB	Damping factor for bending wave
DAMPL	Damping factor for longitudinal wave
DAMPS	Damping factor for shear wave
DAMPT	Damping factor for torsional wave
LC1	Load curve for damping factor for bending wave
LC2	Load curve for damping factor for longitudinal wave
LC3	Load curve for damping factor for shear wave
LC4	Load curve for damping factor for torsional wave

Remarks:

1. **Damping Factor Load Curves.** When LC1, LC2, etc. are defined, the damping factors for the corresponding waves are frequency dependent and the values defined in these curves will override the constant damping factor values defined by DAMPB, DAMPL, etc.

***FREQUENCY_DOMAIN_SSD**_*{OPTION}*

Available options include:

DIRECT

DIRECT_FREQUENCY_DEPENDENT

FATIGUE

FRF

ERP

SUBCASE

Purpose: Compute steady state dynamic response due to given spectrum of harmonic excitations.

When the FATIGUE option is applied, LS-DYNA also calculates the cumulative fatigue damage ratio. When the FRF option is applied, LS-DYNA calculates the steady state dynamic response due to unit load, which is equivalent to Frequency Response Function (FRF). When the ERP option is used, LS-DYNA also calculates the Equivalent Radiated Power (ERP) due to vibration.

When the DIRECT or DIRECT_FREQUENCY_DEPENDENT option is applied, LS-DYNA performs the steady state dynamic analysis using a direct method, instead of the mode-based method.

When the SUBCASE option is applied, multiple loading cases can be included in one run (see Remark 16).

Card Summary:

Card 1. This card is required.

MDMIN	MDMAX	FNMIN	FNMAX	RESTMD	RESTDP	LCFLAG	RELATV

Card 2. This card is required.

DAMPF	LCDAM	LCTYP	DMPMAS	DMPSTF	DMPFLG		

Card 3. This card is required.

	ISTRESS	MEMORY	NERP	STRTYP	NOUT	NOTYP	NOVA

Card 4. Include this card if the ERP keyword option is used.

RO	C	ERPRLF	ERPREF	RADEFF			

Card 5. Include this card if the ERP keyword option is used and NERP > 0.

PID	PTYP						

Card 6. Include this card if the SUBCASE keyword option is used. A set of this keyword and NLOAD copies of Card 7 are included for each case. See Remark 16.

CASEID	TITLE	NLOAD

Card 7. When the SUBCASE option is used, for each case include NLOAD of this card following the Card 6 for that case (see Remark 16). Otherwise include as many of definitions of this card as needed.

NID	NTYP	DOF	VAD	LC1	LC2	SF	VID

Card 8. Include this card if the FATIGUE keyword option is used.

LCFTG							

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	MDMIN	MDMAX	FNMIN	FNMAX	RESTMD	RESTDP	LCFLAG	RELATV
Type	I	I	F	F	I	I	I	I
Default	1	optional	0.0	optional	0	0	0	0

VARIABLE	DESCRIPTION
MDMIN	The first mode in modal superposition method (optional).
MDMAX	The last mode in modal superposition method (optional). See Remark 3. MDMAX should not be 0 for a restart run based on existing modal analysis results (RESTMD = 1 or 2); see Remark 4.
FNMIN	The minimum natural frequency in modal superposition method (optional).

VARIABLE	DESCRIPTION
FNMAX	The maximum natural frequency in modal superposition method (optional). See Remark 3.
RESTMD	Restart option: EQ.0: A new modal analysis is performed, EQ.1: Restart with d3eigv, EQ.2: Restart with modeshp binary scratch file.
RESTDP	Restart option: EQ.-1:A new run with writing dumpssd for future restart, EQ.0: A new run without writing dumpssd, EQ.1: Restart with dumpssd with writing new dumpssd for future restart, EQ.2: Restart with dumpssd without writing new dumpssd.
LCFLAG	Load curve definition flag: EQ.0: Load curves are given as amplitude / phase angle (defined in degrees in the range (-180°, 180°]). EQ.1: Load curves are given as real / imaginary components.
RELATV	Flag for displacement, velocity and acceleration results: EQ.0: Absolute values are requested. EQ.1: Relative values are requested (for VAD = 2, 3 and 4 only; see Card 7).

Damping Card. See Remark 5.

Card 2	1	2	3	4	5	6	7	8
Variable	DAMPF	LCDAM	LCTYP	DMPMAS	DMPSTF	DMPFLG		
Type	F	I	I	F	F	I		
Default	0.0	0	0	0.0	0.0	0		

VARIABLE	DESCRIPTION
DAMPF	Modal damping coefficient, ζ.
LCDAM	Load Curve ID defining mode dependent modal damping coefficient ζ.
LCTYP	Type of load curve defining modal damping coefficient: EQ.0: Abscissa value defines frequency. EQ.1: Abscissa value defines mode number.
DMPMAS	Mass proportional damping constant α, in Rayleigh damping.
DMPSTF	Stiffness proportional damping constant β, in Rayleigh damping
DMPFLG	Damping flag: EQ.0: Use modal damping coefficient ζ defined by DAMPF or LCDAM or Rayleigh damping defined by DMPMAS and DMPSTF in this card. EQ.1: Use damping defined by *DAMPING_PART_MASS and *DAMPING_PART_STIFFNESS.

Card 3	1	2	3	4	5	6	7	8
Variable		ISTRESS	MEMORY	NERP	STRTYP	NOUT	NOTYP	NOVA

Default		0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
ISTRESS	Stress computation flag (for keyword option DIRECT only): EQ.0: Stress results are not requested. EQ.1: Stress results are requested.
MEMORY	Memory flag: EQ.0: Modal superposition will be performed in-core. This option runs faster.

VARIABLE	DESCRIPTION
	EQ.1: Modal superposition will be performed out-of-core. This is needed for some large scale problems that cannot fit in main memory. This method incurs a performance penalty associated with disk speed.
NERP	Number of ERP panels.
STRTYP	Stress used in fatigue analysis: EQ.0: Von Mises stress, EQ.1: Maximum principal stress, EQ.2: Maximum shear stress.
NOUT	Part, part set, segment set, or node set ID for response output (use with acoustic computation). See NOTYP below. See Remark 6.
NOTYP	Type of NOUT: EQ.0: Part set ID (not implemented) EQ.1: Part ID (not implemented) EQ.2: Segment set ID EQ.3: Node set ID EQ.-2: Segment set ID which mismatches with acoustic boundary nodes. Mapping of velocity or acceleration to the acoustic boundary nodes is performed.
NOVA	Response output type: EQ.0: velocity, EQ.1: acceleration.

ERP Card. This card is read only when the ERP keyword option is used.

Card 4	1	2	3	4	5	6	7	8
Variable	R0	C	ERPRLF	ERPREF	RADEFF			
Type	F	F	F	F	I			
Default	none	none	1.0	0.0	0			

VARIABLE	DESCRIPTION
RO	Fluid density
C	Sound speed of the fluid
ERPRLF	ERP radiation loss factor. LT.0: Curve ID = (-ERPRLF) specifies frequency dependent radiation loss factor.
ERPREF	ERP reference value. This is used to convert the absolute ERP value to ERP in decibels (dB).
RADEFF	Radiation efficiency computation flag: EQ.0: Radiation efficiency computation is not requested. EQ.1: Radiation efficiency computation is requested.

ERP Part Cards. This card is read NERP times if the ERP keyword option is used.

Card 5	1	2	3	4	5	6	7	8
Variable	PID	PTYP						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
PID	Part, part set, or segment set ID for ERP computation. See PTYP below. Note that ERP computation works only on part or part set of shell elements, or set segments (2D surfaces).
PTYP	Type of PID: EQ.0: Part ID EQ.1: Part set ID EQ.2: Segment set ID

SUBCASE Cards. This card is read if the SUBCASE keyword option is used. A set of this card with NLOAD instantiations of Card 7 specifies a case. Include as many cases as needed.

Card 6	1	2	3	4	5	6	7	8
Variable	CASEID	TITLE						NLOAD
Type	C	C						I
Default	none	none						1

VARIABLE	DESCRIPTION
CASEID	Identification string to be used as the case ID (must include at least one letter).
TITLE	A description of the current loading case (can be blank)
NLOAD	Number of loads for this loading case

Excitation Loads. When the SUBCASE option is used, for each case include NLOAD of this card following the Card 6 for that case (see Remark 16). Otherwise repeat this card as many times as needed if multiple excitation loads are present.

Card 7	1	2	3	4	5	6	7	8
Variable	NID	NTYP	DOF	VAD	LC1	LC2	SF	VID
Type	I	I	I	I	I	I	F	I
Default	none	0	none	none	none	none	1.0	0

VARIABLE	DESCRIPTION
NID	Node, node set, or segment set ID for excitation input. See NTYP below. See Remark 7.
NTYP	Type of NID: EQ.0: Node ID EQ.1: Node set ID

VARIABLE	DESCRIPTION
	EQ.2: Segment set ID
DOF	Applicable degrees-of-freedom for excitation input (ignored if VAD = 1): EQ.1: x-translational degree-of-freedom or x-rotational degree-of-freedom (for torque excitation, VAD = 8) EQ.2: y-translational degree-of-freedom, or y-rotational degree-of-freedom (for torque excitation, VAD = 8) EQ.3: z-translational degree-of-freedom, or z-rotational degree-of-freedom (for torque excitation, VAD = 8) EQ.4: Translational movement in direction given by vector VID, or rotational movement with axis given by vector VID (for torque excitation, VAD = 8)
VAD	Excitation input type: EQ.0: Nodal force EQ.1: Pressure EQ.2: Base velocity EQ.3: Base acceleration EQ.4: Base displacement EQ.5: Enforced velocity by large mass method (see Remark 8) EQ.6: Enforced acceleration by large mass method (see Remark 8) EQ.7: Enforced displacement by large mass method (see Remark 8) EQ.8: Torque EQ.9: Base angular velocity EQ.10: Base angular acceleration EQ.11: Base angular displacement EQ.12: Enforced velocity (for DIRECT type keyword options only) EQ.13: Enforced acceleration (for DIRECT type keyword options only) EQ.14: Enforced displacement (for DIRECT type keyword options only)

VARIABLE	DESCRIPTION
LC1	Load Curve ID defining amplitude (LCFLAG = 0) or real (in-phase) part (LCFLAG = 1) of load as a function of frequency. It is not used if the keyword option FRF is active.
LC2	Load Curve ID defining phase angle (LCFLAG = 0) or imaginary (out-phase) part (LCFLAG = 1) of load as a function of frequency. It is not used if the keyword option FRF is active.
SF	Scale factor for the load. This scale factor applies to the amplitude of load (LCFLAG = 0) or real and imaginary parts of load (LCFLAG = 1).
VID	Vector ID for DOF = 4 for excitation input; see *DEFINE_VECTOR.

Load Duration Card. This card is read only when the FATIGUE keyword option is used.

Card 8	1	2	3	4	5	6	7	8
Variable	LCFTG							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
LCFTG	Load Curve ID defining duration of excitation for each frequency

Remarks:

1. **Direct Methods.** When the option DIRECT or DIRECT_FREQUENCY_DEPENDENT is not used, this feature computes steady state dynamic response due to harmonic excitation spectrum by modal superposition method. When the keyword option DIRECT or DIRECT_FREQUENCY_DEPENDENT is used, a direct method is used. For the direct method, the unknown primary variables are the nodal displacements. A system of dynamic equations is formed in frequency domain and solved directly, without projecting the displacement variables into the modal space.

2. **Modal Superposition Method and Required Keywords.** Natural frequencies and mode shapes are needed for running the modal superposition method.

Thus, the keyword *CONTROL_IMPLICIT_EIGENVALUE *must* be included in input.

3. **Modes.** MDMIN/MDMAX and FNMIN/FNMAX together determine which modes are used in modal superposition method. The first mode must have a mode number ≥ MDMIN, and frequency ≥ FNMIN; the last mode must have mode number ≤ MDMAX, and frequency ≤ FNMAX. When MDMAX or FNMAX is not given, the last mode in modal superposition method is the last mode available in FILENM.

4. **Restarts.** Restart option RESTMD = 1 is used if mode analysis has been done previously. In this case, LS-DYNA skips modal analysis and reads in d3eigv family files generated previously. Restart option RESTMD = 2 is used if a SSD analysis has been done for the same model previously and the binary scratch file modeshp exists. The modeshp file saves the condensed modal shape (and modal stress if there is any) data. Therefore, the SSD analysis can be restarted with the existing modeshap file if no changes have been made to the modal structure, boundary conditions, and material models. Restarting SSD with RESTMD = 2 is faster than restarting SSD with RESTMD = 1 because of the saved modal shapes. For RESTMD = 1 or 2, always use MDMIN = 1 and MDMAX = number of modes given by modal analysis (can be found from ASCII file eigout or from d3eigv files using LS-PREPOST).

   To add the contribution of additional modes to previous SSD results, restart option RESTDP = 1 is used. In this case, LS-DYNA reads in the binary dump file dumpssd which contains previous SSD results and adds the contribution from new modes. For RESTDP = 1, the new modal analysis (RESTMD = 0) or the d3eigv family files created elsewhere (RESTMD = 1) should exclude the modes used in previous SSD computation. To do this, set LFLAG (and RFLAG, if necessary) and a nonzero LFTEND (and RHTEND) in *CONTROL_IMPLICIT_EIGENVALUE. The RESTDP option can also be used if the frequency range for modal analysis is divided into segments and modal analysis is performed for each frequency range separately.

   To add some acoustic field nodes and run BEM/FEM acoustic computation after SSD, the RESTMD and RESTDP options still work even if the number of nodes may be changed after a previous modal analysis, provided that the IDs of the old nodes are not changed.

5. **Damping.** Damping can be prescribed in several ways:

   a) To use a constant modal damping coefficient ζ for all the modes, define DAMPF only. LCDMP, LCTYP, DMPMAS and DMPSTF are ignored.

b) To use mode dependent modal damping, define a load curve (*DEFINE_-CURVE) and specify that if the abscissa value defines the frequency or mode number by LCTYP. DMPMAS and DMPSTF are ignored.

c) To use Rayleigh damping, define DMPMAS (α) and DMPSTF (β). Keep DAMPF as its default (0.0) and keep LCDMP and LCTYP as 0. The damping matrix in Rayleigh damping is defined as $\mathbf{C} = \alpha\mathbf{M} + \beta\mathbf{K}$, where, **C**, **M** and **K** are the damping, mass and stiffness matrices, respectively.

6. **Nodal Output and Acoustic Analysis.** NOUT and NOTYP are used to define the nodes where velocity or acceleration are requested to be written to a binary file bin_ssd or other filename defined by "bem=filename" (see keyword *FREQUENCY_DOMAIN_ACOUSTIC_BEM) on the command line. The velocity or acceleration data in this file can be used by the BEM or FEM acoustic solver to perform a vibro-acoustic analysis. If structure nodes and acoustic boundary nodes are mismatched, the option NOTYP = -2 can be used. The velocity or acceleration data given at a structure segment set NOUT is mapped to acoustic boundary nodes.

7. **Base Velocity, Acceleration and Displacement.** For base velocity, base acceleration or base displacement (VAD=2, 3 or 4) excitations, the parameters NID, NTYP are not used and can be blank. The base velocity, base acceleration and base displacement cases are treated by applying inertia force to the structure.

8. **Large Mass Method.** For the cases with enforced motion excitation such as nodal velocity, acceleration, or displacement, the large mass method can be used to compute the SSD results. The excitation input can be given as enforced motion curves (VAD = 5, 6, 7). To use the large mass method, a large mass must be attached to the nodes where the enforced motion is applied by using the keyword *ELEMENT_MASS_*{OPTION}*, and the large mass per node (MPN) must be reported in the keyword *CONTROL_FREQUENCY_DOMAIN. For more details, please refer to *CONTROL_FREQUENCY_DOMAIN.

9. **Displacement, Velocity, and Acceleration Results.** Displacement, velocity and acceleration results are output into ASCII file NODOUT_SSD. The nodes to be output to NODOUT_SSD are specified by card *DATABASE_HISTORY_-NODE. The frequencies for the nodal results in NODOUT_SSD are specified by card *DATABASE_FREQUENCY_ASCII_NODOUT_SSD. If the card *DATABASE_FREQUENCY_ASCII_NODOUT_SSD is not defined, the frequencies for the nodal results in NODOUT_SSD are same as those in D3SSD binary database, which is defined by card *DATABASE_FREQUENCY_BINARY_D3SSD.

10. **Stress and Strain Results.** Stress (and strain) results are output into ASCII file ELOUT_SSD. The solid, beam, shell and thick shell elements to be output to ELOUT_SSD are specified by the following cards:

DATABASE_HISTORY_SOLID_*{OPTION}

DATABASE_HISTORY_BEAM_*{OPTION}

DATABASE_HISTORY_SHELL_*{OPTION}

DATABASE_HISTORY_TSHELL_*{OPTION}

The frequencies for the element stress / strain results in ELOUT_SSD are specified by card *DATABASE_FREQUENCY_ASCII_ELOUT_SSD. If the card *DATABASE_FREQUENCY_ASCII_ELOUT_SSD is not defined, the frequencies for the element stress / strain results in ELOUT_SSD are same as those in D3SSD binary database, which is defined by card *DATABASE_FREQUENCY_BINARY_D3SSD.

11. **Phase Angle Units.** The phase angle is given in degrees in the range (-180°, 180°], for both the input decks and output databases (e.g. D3SSD, NODOUT_SSD, and ELOUT_SSD).

12. **Fatigue.** When the FATIGUE keyword option is used, the cumulative fatigue damage ratio due to the harmonic vibration is computed and saved in binary plot database d3ftg. The *MATERIAL_ADD_FATIGUE keyword is needed to define the S-N fatigue curve for each material.

13. **FRF.** When the FRF keyword option is present, LS-DYNA calculates the steady state dynamic response due to unit load spectrum. Numerically it is equivalent to Frequency Response Function (FRF). In this case, LC1 and LC2 are not used and can be blank. LS-DYNA generates unit load spectrum, according to the excitation location, the excitation degree-of-freedom and the excitation type defined by NID, NTYP, DOF and VAD in Card 7. This is useful if the user is interested in getting FRF fringe plot at some frequencies, or if the user would like to get the stress (and strain) FRF results. The name of the binary database is changed to D3FRF.

14. **Frequency Dependent Material Properties.** For the option DIRECT_FREQUENCY_DEPENDENT, the damping and stiffness matrices can change with frequency, as the material properties can change with frequency. The keyword *MAT_ADD_PROPERTY_DEPENDENCE can be used to define the properties of a material model, which change with frequency.

15. **Radiation Efficiency.** For the keyword option ERP and RADEFF = 1, radiated acoustic power can be computed using the Rayleigh integral. Radiation efficiency is computed as the ratio between the radiated acoustic power and the absolute ERP values. The radiated acoustic power results are saved in an ASCII xyplot database radiated_power. The radiation efficiency results are saved in an ASCII xyplot database radiation_efficiency. The computation is suitable for a

baffled plate vibrating in out-of-plane motion and placed in light fluid, such as air.

16. **SUBCASE.** With the keyword option SUBCASE, multiple loading cases can be included with one keyword. Each loading case includes one set of Card 6 and Card 7. Card 7 can be repeated for each case if the current loading case has multiple excitation loads. CASEID defined in Card 6 is used as a prefix for the output databases (such as D3SSD and binout). An automatic case ID is assigned (meaning CASE1.D3SSD, CASE2.D3SSD, …) if CASEID is defined as "case" or "CASE". The TITLE field, when defined, is used as the title for the output databases (D3SSD, NODOUT_SSD, ELOUT_SSD, and NODFOR_SSD). Otherwise, the output databases use the global title, defined by the keyword *TITLE. The multiple loading cases may share the same output frequencies (defined by *DATABASE_FREQUENCY_BINARY_D3SSD, *DATABASE_FREQUENCY_ASCII_NODOUT_SSD, *DATABASE_FREQUENCY_ASCII_ELOUT_SSD, and *DATABASE_FREQUENCY_ASCII_NODFOR_SSD). They can also have different output frequencies by appending the option SUBCASE to the corresponding database keywords. With this option, you can set FMIN, FMAX, NFREQ, FSPACE, and LCFREQ for each loading case sequentially.

*HOURGLASS

Purpose: Define hourglass and bulk viscosity properties which are referenced using HGID in the *PART command. Properties specified here, when invoked for a particular part, override those in *CONTROL_HOURGLASS and *CONTROL_BULK_VISCOSITY.

An additional option **TITLE** may be appended to *HOURGLASS keywords. If this option is used, then an additional line is read for each section in 80a format which can be used to describe the section. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

Card 1	1	2	3	4	5	6	7	8
Variable	HGID	IHQ	QM	IBQ	Q1	Q2	QB, VDC	QW
Type	I/A	I	F	I	F	F	F	F
Default	0	Rem 9	.10	not used	1.5	0.06	QM, 0.	QM

VARIABLE	DESCRIPTION
HGID	Hourglass ID. A unique number or label must be specified. This ID is referenced by HGID in the *PART command.
IHQ	Hourglass control type. For solid elements six options are available. For quadrilateral shell and membrane elements the hourglass control is based on the formulation of Belytschko and Tsay, that is, options 1-3 are identical, and options 4-5 are identical. See Remark 1. EQ.0: See Remark 9. EQ.1: Standard LS-DYNA viscous form EQ.2: Flanagan-Belytschko viscous form EQ.3: Flanagan-Belytschko viscous form with exact volume integration for solid elements EQ.4: Flanagan-Belytschko stiffness form EQ.5: Flanagan-Belytschko stiffness form with exact volume integration for solid elements.

VARIABLE	DESCRIPTION
	EQ.6: Belytschko-Bindeman [1993] assumed strain co-rotational stiffness form for 2D and 3D solid elements only. See Remark 4.
	EQ.7: Linear total strain form of type 6 hourglass control. (See Remark 6 below).
	EQ.8: Activates the full projection warping stiffness for shell formulations 9, 16 and -16. A speed penalty of 25% is common for this option.
	EQ.9: Puso [2000] enhanced assumed strain stiffness form for 3D hexahedral elements. See Remark 8.
	EQ.10: Cosserat Point Element (CPE) developed by Jabareen and Rubin [2008] and Jabareen et.al. [2013]; see *CONTROL_HOURGLASS.
	A discussion of the viscous and stiffness hourglass control for shell elements follows at the end of this section.
QM	Hourglass coefficient. See Remark 7. Values of QM that exceed 0.15 may cause instabilities for brick elements used with forms IHQ = 0 to 5 and all the IHQ forms applicable to shell elements. The stiffness forms can stiffen the response especially if deformations are large and therefore should be used with care. For the shell and membrane elements QM is taken as the membrane hourglass coefficient, the bending as QB, and warping as QW. These coefficients can be specified independently, but generally, QM = QB = QW is adequate. For type 6 solid element hourglass control, see Remark 4 below. For hourglass type 9, see Remark 8.
IBQ	Not used. Bulk viscosity is always on for solids. Bulk viscosity for beams and shells can only be turned on using the variable TYPE in *CONTROL_BULK_VISCOSITY; however, the coefficients can be set using Q1 and Q2 below.
Q1	Quadratic bulk viscosity coefficient. See Remark 3.
Q2	Linear bulk viscosity coefficient. See Remark 3.
QB	Hourglass coefficient for shell bending. By default, QB = QM. See Remark 5.

VARIABLE	DESCRIPTION
VDC	Viscous damping coefficient to help suppress hourglass modes. VDC only applies to type 1 solids with type 6 or 7 hourglass control and to tshell formulations 5 and 6. VDC is a unitless coefficient in which VDC = 1.0 corresponds to critical damping.
QW	Hourglass coefficient for shell warping. By default, QB = QW. See Remark 5.

Remarks:

1. **Viscous versus Stiffness Control.** Viscous hourglass control is recommended for problems deforming with high velocities. Stiffness control is often preferable for lower velocities, especially if the number of time steps are large. For solid elements the exact volume integration provides some advantage for highly distorted elements.

2. **Automotive Crash Hourglass Control.** For automotive crash the stiffness form of the hourglass control with a coefficient (QM) of 0.05 is preferred by many users.

3. **Bulk Viscosity.** Bulk viscosity is necessary to propagate shock waves in solid materials. Generally, the default values are okay except in problems where pressures are very high, larger values may be desirable. In low density foams, it may be necessary to reduce the viscosity values since the viscous stress can be significant. It is not advisable to reduce it by more than an order of magnitude.

4. **Belytschko-Bindeman Hourglass Control.** Type 6 hourglass control is for 2D and 3D solid elements only. Based on elastic constants and an assumed strain field, it produces accurate coarse mesh bending results for elastic material when QM = 1.0. For plasticity models with a yield stress tangent modulus that is much smaller than the elastic modulus, a smaller value of QM (0.001 to 0.1) may produce better results. For foam or rubber models, larger values (0.5 to 1.0) may work better. For any material, keep in mind that the stiffness is based on the elastic constants, so if the material softens, a QM value smaller than 1.0 may work better. For anisotropic materials, an average of the elastic constants is used. For fluids modeled with null material, type 6 hourglass control is viscous and is scaled to the viscosity coefficient of the material (see *MAT_NULL).

5. **One-Point Quadrature and Hourglass Deformation Modes.** In part, the computational efficiency of the Belytschko-Lin-Tsay and the under integrated Hughes-Liu shell elements are derived from their use of one-point quadrature in the plane of the element. To suppress the hourglass deformation modes that accompany one-point quadrature, hourglass viscous or stiffness based stresses

are added to the physical stresses at the local element level. The discussion of the hourglass control that follows pertains to all one-point quadrilateral shell and membrane elements in LS-DYNA.

The hourglass shape vector τ_I is defined as

$$\tau_I = h_I - \left(h_J \hat{x}_{\alpha J}\right) B_{\alpha I} \ ,$$

where $\hat{x}_{\alpha J}$ are the element coordinates in the local system at the I^{th} element node and $B_{\alpha I}$ is the strain displacement matrix. The hourglass basis vector is:

$$h = \begin{bmatrix} +1 \\ -1 \\ +1 \\ -1 \end{bmatrix} \ ,$$

the basis vector that generates the deformation mode that is neglected by one-point quadrature. In the above equations and the remainder of this subsection, the Greek subscripts have a range of 2, that is, $\hat{x}_{\alpha I} = (\hat{x}_{1I}\ , \hat{x}_{2I}) = \left(\hat{x}_I\ , \hat{y}_I\right)$.

The hourglass shape vector then operates on the generalized displacements to produce the generalized hourglass strain rates

$$\begin{aligned} \dot{q}_\alpha^M &= \tau_I \hat{v}_{\alpha I} \\ \dot{q}_\alpha^B &= \tau_I \hat{\theta}_{\alpha I} \\ \dot{q}_3^W &= \tau_I \hat{v}_{zI} \end{aligned}$$

where the superscripts M, B, and W denote membrane, bending, and warping modes, respectively. The corresponding hourglass stress rates are then given by

$$\begin{aligned} \dot{Q}_\alpha^M &= \frac{\text{QM} \times EtA}{8} B_{\beta I} B_{\beta I} \dot{q}_\alpha^M \\ \dot{Q}_\alpha^B &= \frac{\text{QB} \times Et^3 A}{192} B_{\beta I} B_{\beta I} \dot{q}_\alpha^B \\ \dot{Q}_3^W &= \frac{\text{QW} \times \kappa G t^3 A}{12} B_{\beta I} B_{\beta I} \dot{q}_3^B \end{aligned}$$

where t is the shell thickness. The hourglass coefficients: QM, QB, and QW are generally assigned values between 0.05 and 0.10.

Finally, the hourglass stresses which are updated using the time step, Δt, from the stress rates in the usual way, that is,

$$\mathbf{Q}^{n+1} = \mathbf{Q}^n + \Delta t \dot{\mathbf{Q}} \ ,$$

and the hourglass resultant forces are then

$$\begin{aligned} \hat{f}_{\alpha I}^H &= \tau_I Q_\alpha^M \\ \hat{m}_{\alpha I}^H &= \tau_I Q_\alpha^B \\ \hat{f}_{3I}^H &= \tau_I Q_3^W \end{aligned}$$

where the superscript H emphasizes that these are internal force contributions from the hourglass deformations.

6. **Linear Total Strain Formulation.** IHQ=7 is a linear total strain formulation of the Belytschko-Bindeman [1993] stiffness form for 2D and 3D solid elements. This linear form was developed for visco-elastic material and guarantees that an element will spring back to its initial shape regardless of the severity of deformation.

7. **QM Default Value.** The default value for QM is 0.1 unless superseded by a nonzero value of QH in *CONTROL_HOURGLASS. A nonzero value of QM supersedes QH.

8. **Puso Hourglass Control.** Hourglass type 9 is available for hexahedral elements and is based on physical stabilization using an enhanced assumed strain method. In performance it is similar to the Belytschko-Bindeman hourglass formulation (type 6) but gives more accurate results for distorted meshes, such as for skewed elements. If QM = 1.0, it produces accurate coarse bending results for elastic materials. The hourglass stiffness is by default based on elastic properties, hence the QM parameter should be reduced to about 0.1 for plastic materials in order not to stiffen the structure during plastic deformation. For materials 3, 18 and 24 a negative value of QM may be used. With this option, the hourglass stiffness is based on the current material properties, that is, the plastic tangent modulus, and is scaled by |QM|.

9. **IHQ Default Values.** The default value for IHQ, if not defined on *CONTROL_-HOUGRGLASS is as follows:

   a) *Shells.* Viscous type (1 = 2 = 3) for explicit; stiffness type (4=5) for implicit.

   b) *Solids.* Type 2 for explicit; type 6 for implicit.

   c) *Tshell Formulation 1.* Type 2.

10. **IHQ for Implict Analysis.** For implicit analysis, hourglass forms 6, 7, 9, and 10 are available for solid elements, and the stiffness form (4 = 5) is available for shells.

11. **Tshells and Hourglass Control.** Hourglass control applicability for tshells depends on the formulation.

    a) Tshell formulations 2 and 3 have 2 × 2 in-plane integration and therefore do not use hourglass control.

    b) In the case of tshell formulation 1, there are two viscous hourglass types (IHQ = 1,2) and one stiffness type (IHQ > 2).

c) The hourglass type IHQ has no bearing on tshell formulations 5 and 6 as these formulations are based on an assumed strain field, similar to formulation 1 solids with hourglass type 6. The hourglass coefficient QM does affect the behavior of tshell formulations 5 and 6.

*IGA

The *IGA keywords set up and control the isogeometric-related capabilities of LS-DYNA. The *IGA keyword cards may be classified into two sets. Keywords included in the first set are used to describe basic geometric objects. Keywords in the second set are used to create isogeometric elements for the numerical model. In addition, keywords referenced and used in combination with the *IGA keywords are also listed. Keywords in each group are listed in alphabetical order.

Keywords to define geometry:

*IGA_1D_BREP

*IGA_1D_NURBS_UVW

*IGA_1D_NURBS_XYZ

*IGA_2D_BEZIER_XYZ

*IGA_2D_BREP

*IGA_2D_NURBS_UVW

*IGA_2D_NURBS_XYZ

*IGA_3D_BEZIER_XYZ

*IGA_3D_NURBS_XYZ

*IGA_EDGE_UVW

*IGA_EDGE_XYZ

*IGA_FACE_UVW

*IGA_FACE_XYZ

*IGA_INCLUDE_BEZIER (obsolete as of R14)

*IGA_POINT_UVW

*IGA_VOLUME_XYZ

Keywords to create isogeometric elements:

*IGA_SHELL

*IGA_SOLID

Additional IGA related keywords:

*IGA_TIED_EDGE_TO_EDGE

*SECTION_IGA_SHELL

*SECTION_IGA_SOLID

*SET_IGA_EDGE

*SET_IGA_FACE

*SET_IGA_POINT_UVW

*IGA_1D_BREP

Purpose: Define a one-dimensional boundary representation, that is, a closed loop, composed of parametric edges(s).

Card 1	1	2	3	4	5	6	7	8
Variable	BRID							
Type	I							
Default	none							

Parametric Edge Cards. Include as many cards in the following format as desired, see Remark 1. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	EID1	EID2	EID3	EID4	EID5	EID6	EID7	EID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
BRID	One-dimensional boundary representation ID. A unique number must be chosen.
EID*i*	Parametric edge IDs, see *IGA_EDGE_UVW.

Remarks:

1. **Parametric Edge Ordering.** Parametric edges listed on Card 2 need to be ordered such that they form a closed loop. That is, the start and end points of an arbitrary parametric edge should coincide with the end point of the previous and starting point of the next parametric edge, respectively. If the loop is comprised of a single parametric edge only, its start and end points should be identical.

*IGA_1D_NURBS_UVW

Purpose: Define a parametric univariate non-uniform rational B-spline (NURBS).

Card Summary:

Card 1. This card is required.

PATCHID	NR	PR					

Card 2. This card is required.

UNIR							

Card 3a. Include ceil[(NR + PR + 1)/4] of this card if UNIR = 0.

R1	R2	R3	R4

Card 3b. Include this card if UNIR ≠ 0.

RFIRST	RLAST		

Card 4. Include NR of this card.

U	V	W	WGT

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PATCHID	NR	PR					
Type	I	I	I					

VARIABLE	DESCRIPTION
PATCHID	Parametric univariate NURBS patch ID. A unique number must be chosen.
NR	Number of control points in the local *r*-direction
PR	Polynomial degree of the basis in the local *r*-direction

Card 2	1	2	3	4	5	6	7	8
Variable	UNIR							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
UNIR	Knot vector type in the local *r*-direction: EQ.0: Specify the entire knot vector in the local *r*-direction EQ.1: Uniform open knot vector in the local *r*-direction EQ.2: Uniform periodic vector in the local *r*-direction

Knot Vector Cards for the *r*-direction. Include ceil[(NR + PR + 1)/4] cards if UNIR = 0.

Card 3a	1	2	3	4	5	6	7	8
Variable	R1		R2		R3		R4	
Type	F		F		F		F	

VARIABLE	DESCRIPTION
R*i*	Knot values in the local *r*-direction with *i* = 1, …, NR + PR + 1

Knot Vector Cards for the *r*-direction. Include this card if UNIR ≠ 0. See Remark 1.

Card 3b	1	2	3	4	5	6	7	8
Variable	RFIRST		RLAST					
Type	F		F					

VARIABLE	DESCRIPTION
RFIRST	First knot value in the local *r*-direction

VARIABLE	DESCRIPTION
RLAST	Last knot value in the local *r*-direction

Control Point and Weight Cards. Include NR cards; see Remark 2.

Card 4	1	2	3	4	5	6	7	8
Variable	U		V		W		WGT	
Type	F		F		F		F	
Default	none		none		none		1.0	

VARIABLE	DESCRIPTION
U*j*	Nonhomogeneous control point coordinates in the parametric *u*-direction with *j* = 1, …, NR
V*j*	Nonhomogeneous control point coordinates in the parametric *v*-direction with *j* = 1, …, NR
W*j*	Nonhomogeneous control point coordinates in the parametric *w*-direction with *j* = 1, …, NR
WGT*j*	Control weights with *j* = 1, …, NR, see Remark 3.

Remarks:

1. **Uniform Knot Vectors.** RFIRST and RLAST define the interval for uniform knot spans. As an example suppose that NR = 4, PR = 3, RFIRST = 1, and RLAST = 8 which yields the following uniform open and uniform periodic vectors [1 1 1 1 8 8 8 8] and [1 2 3 4 5 6 7 8] for UNIR = 1 and UNIR = 2, respectively.

2. **Parametric Curve.** A parametric curve may be defined in the parametric space of an *n*-variate physical NURBS, such as *IGA_*n*D_NURBS_XYZ with *n* = 2 or 3, which requires the definition of (U, V) and (U, V, W) coordinates, respectively. Note that the parametric *u*-, *v*-, *w*-directions and (U, V, W) coordinates are equivalent to the local *r*-, *s*-, *t*-directions and (R, S, T) coordinates in the parametric space of the physical NURBS. This notation is adopted here only to distinguish between the parametric space of the parametric univariate NURBS and the parametric space of the physical bi- or trivariate NURBS in which it is embedded.

3. **Control Weights.** Control weights must be positive and will otherwise be reset to the default unit value.

*IGA_1D_NURBS_XYZ

Purpose: Define a physical univariate non-uniform rational B-spline (NURBS).

Card Summary:

Card 1. This card is required.

PATCHID	NR	PR					

Card 2. This card is required.

UNIR							

Card 3a. Include ceil[(NR + PR + 1)/4] of this card if UNIR = 0.

R1	R2	R3	R4

Card 3b. Include this card if UNIR ≠ 0.

RFIRST	RLAST		

Card 4. Include NR of this card.

X	Y	Z	WGT

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PATCHID	NR	PR					
Type	I	I	I					

VARIABLE	DESCRIPTION
PATCHID	Physical univariate NURBS patch ID. A unique number must be chosen.
NR	Number of control points in the local *r*-direction
PR	Polynomial degree of the basis in the local *r*-direction

Card 2	1	2	3	4	5	6	7	8
Variable	UNIR							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
UNIR	Knot vector type in the local *r*-direction: EQ.0: Specify the entire knot vector in the local *r*-direction EQ.1: Uniform open knot vector in the local *r*-direction EQ.2: Uniform periodic knot vector in the local *r*-direction

Knot Vector Cards for the *r*-direction. Include ceil[(NR + PR + 1)/4] cards if UNIR = 0.

Card 3a	1	2	3	4	5	6	7	8
Variable	R1		R2		R3		R4	
Type	F		F		F		F	

VARIABLE	DESCRIPTION
R*i*	Knot values in the local *r*-direction with $i = 1, \ldots, NR + PR + 1$

Knot Vector Cards for the *r*-direction. Include this card if UNIR ≠ 0, see Remark 1.

Card 3b	1	2	3	4	5	6	7	8
Variable	RFIRST		RLAST					
Type	F		F					

VARIABLE	DESCRIPTION
RFIRST	First knot value in the local *r*-direction

VARIABLE	DESCRIPTION
RLAST	Last knot value in the local *r*-direction

Control Point and Weight Cards. Include NR cards.

Card 4	1	2	3	4	5	6	7	8
Variable	X		Y		Z		WGT	
Type	F		F		F		F	
Default	none		none		none		1.0	

VARIABLE	DESCRIPTION
X*j*	Non-homogeneous control point coordinates in the global *x*-direction with *j* = 1, …, NR
Y*j*	Non-homogeneous control point coordinates in the global *y*-direction with *j* = 1, …, NR.
Z*j*	Non-homogeneous control point coordinates in the global *z*-direction with *j* = 1, …, NR.
WGT*j*	Control weights with *j* = 1, …, NR, see Remark 2.

Remarks:

1. **Uniform Knot Vectors.** RFIRST and RLAST define the interval for uniform knot spans. As an example suppose that NR = 4, PR = 3, RFIRST = 1, and RLAST = 8 which yields the following uniform open and uniform periodic knot vectors [1 1 1 1 8 8 8 8] and [1 2 3 4 5 6 7 8] for UNIR = 1 and UNIR = 2, respectively.

2. **Control Weights.** Control weights have to be positive and will otherwise be reset to the default unit value.

*IGA_2D_BEZIER_XYZ

Purpose: Define a physical bivariate (rational) spline using Bézier extraction.

Data Card. Include as many cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PATCHID	FILENAME						
Type	I	A70						

VARIABLE	DESCRIPTION
PATCHID	Physical bivariate (rational) spline patch ID
FILENAME	Name of file containing patch data; see Remark 1.

Remarks:

1. **Filename.** The current description of the input data is available as a separate document.

*IGA_2D_BREP

Purpose: Define a two-dimensional boundary representation composed of parametric faces(s).

Card 1	1	2	3	4	5	6	7	8
Variable	BRID							
Type	I							
Default	none							

Parametric Face Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	FID1	FID2	FID3	FID4	FID5	FID6	FID7	FID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
BRID	Two-dimensional boundary representation ID. A unique number must be chosen.
FID*i*	Parametric face IDs, see *IGA_FACE_UVW.

*IGA_2D_NURBS_UVW

Purpose: Define a parametric bivariate non-uniform rational B-spline (NURBS).

Card Summary:

Card 1. This card is required.

PATCHID	NR	NS	PR	PS			

Card 2. This card is required.

UNIR	UNIS						

Card 3a. Include ceil[(NR + PR + 1)/4] of this card if UNIR = 0.

R1	R2	R3	R4

Card 3b. Include this card if UNIR ≠ 0.

RFIRST	RLAST		

Card 4a. Include ceil[(NS + PS + 1)/4] of this card if UNIS = 0.

S1	S2	S3	S4

Card 4b. Include this card if UNIS ≠ 0.

SFIRST	SLAST		

Card 5. Include NR × NS of this card.

U	V	W	WGT

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PATCHID	NR	NS	PR	PS			
Type	I	I	I	I	I			

VARIABLE	DESCRIPTION
PATCHID	Parametric bivariate NURBS patch ID. A unique number must be chosen.
NR	Number of control points in the local *r*-direction
NS	Number of control points in the local *s*-direction
PR	Polynomial degree of the basis in the local *r*-direction
PS	Polynomial degree of the basis in the local *s*-direction

Card 2	1	2	3	4	5	6	7	8
Variable	UNIR	UNIS						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
UNIR	Knot vector type in the local *r*-direction: EQ.0: Specify the entire knot vector in the local *r*-direction. EQ.1: Uniform open knot vector in the local *r*-direction. EQ.2: Uniform periodic knot vector in the local *r*-direction.
UNIS	Knot vector type in the local *s*-direction: EQ.0: Specify the entire knot vector in the local *s*-direction. EQ.1: Uniform open knot vector in the local *s*-direction. EQ.2: Uniform periodic knot vector in the local *s*-direction.

Knot Vector Cards for the *r*-direction. If UNIR = 0, include ceil[(NR + PR + 1)/4] cards.

Card 3a	1	2	3	4	5	6	7	8
Variable	R1		R2		R3		R4	
Type	F		F		F		F	

VARIABLE	DESCRIPTION
R*i*	Knot values in the local *r*-direction with *i* = 1, …, NR + PR + 1

Knot Vector Cards for the *r*-direction. Include this card if UNIR ≠ 0; see Remark 1.

Card 3b	1	2	3	4	5	6	7	8
Variable	RFIRST		RLAST					
Type	F		F					

VARIABLE	DESCRIPTION
RFIRST	First knot value in the local *r*-direction
RLAST	Last knot value in the local *r*-direction

Knot Vector Cards for the *s*-direction. Include ceil[(NS + PS + 1)/4] cards if UNIS = 0.

Card 4a	1	2	3	4	5	6	7	8
Variable	S1		S2		S3		S4	
Type	F		F		F		F	

VARIABLE	DESCRIPTION
S*j*	Knot values in the local *s*-direction with *j* = 1, …, NS + PS + 1

Knot Vector Cards for the s-direction. Include this card if UNIS ≠ 0. See Remark 1.

Card 4b	1	2	3	4	5	6	7	8
Variable	SFIRST		SLAST					
Type	F		F					

VARIABLE	DESCRIPTION
SFIRST	First knot value in the local *s*-direction
SLAST	Last knot value in the local *s*-direction

Control Point and Weight Cards. Include NR × NS cards reflecting the connectivity. See Remark 2.

Card 5	1	2	3	4	5	6	7	8
Variable	U		V		W		WGT	
Type	F		F		F		F	
Default	none		none		none		1.0	

VARIABLE	DESCRIPTION
U*k*	Nonhomogeneous control point coordinates in the parametric *u*-direction with *k* = 1, …, NR × NS
V*k*	Nonhomogeneous control point coordinates in the parametric *v*-direction with *k* = 1, …, NR × NS
W*k*	Nonhomogeneous control point coordinates in the parametric *w*-direction with *k* = 1, …, NR × NS
WGT*k*	Control weights with *k* = 1, …, NR × NS; see Remark 3.

Remarks:

1. **Uniform Knot Vectors.** RFIRST and RLAST (SFIRST and SLAST) define the interval for uniform knot spans in the local *r*-direction (*s*-direction). As an

example suppose that NR = 4, PR = 3, RFIRST = 1, and RLAST = 8 which yields the following uniform open and uniform periodic knot vectors [1 1 1 1 8 8 8 8] and [1 2 3 4 5 6 7 8] for UNIR = 1 and UNIR = 2, respectively.

2. **Parametric Surface.** A parametric surface may be defined in the parametric space of a trivariate physical NURBS, meaning *IGA_3D_NURBS_XYZ, which requires the definition of (U, V, W) coordinates. Note that the parametric *u*-, *v*-, *w*-directions and (U, V, W) coordinates are equivalent to the local *r*-, *s*-, *t*-directions and (R,S,T) coordinates in the parametric space of the physical NURBS. The notation is adopted here only to distinguish between the parametric space of the parametric bivariate NURBS and the parametric space of the physical trivariate NURBS in which it is embedded in.

3. **Control Weights.** Control weights must be positive and will otherwise be reset to the default unit value.

*IGA_2D_NURBS_XYZ

Purpose: Define a physical bivariate non-uniform rational B-spline (NURBS).

Card Summary:

Card 1. This card is required.

PATCHID	NR	NS	PR	PS			

Card 2. This card is required.

UNIR	UNIS						

Card 3a. Include ceil[(NR + PR + 1)/4] of this card if UNIR = 0.

R1	R2	R3	R4

Card 3b. Include this card if UNIR ≠ 0.

RFIRST	RLAST		

Card 4a. Include ceil[(NS + PS + 1)/4] of this card if UNIS = 0.

S1	S2	S3	S4

Card 4b. Include this card if UNIS ≠ 0.

SFIRST	SLAST		

Card 5. Include NR × NS of this card.

X	Y	Z	WGT

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PATCHID	NR	NS	PR	PS			
Type	I	I	I	I	I			

VARIABLE	DESCRIPTION
PATCHID	Physical bivariate NURBS patch ID. A unique number must be chosen.
NR	Number of control points in the local *r*-direction
NS	Number of control points in the local *s*-direction
PR	Polynomial degree of the basis in the local *r*-direction
PS	Polynomial degree of the basis in the local *s*-direction

VARIABLE	DESCRIPTION
UNIS	Knot vector type in the local *s*-direction: EQ.0: Specify the entire knot vector in the local *s*-direction EQ.1: Uniform open knot vector in the local *s*-direction EQ.2: Uniform periodic knot vector in the local *s*-direction
UNIT	Knot vector type in the local *t*-direction: EQ.0: Specify the entire knot vector in the local *t*-direction EQ.1: Uniform open knot vector in the local *t*-direction EQ.2: Uniform periodic knot vector in the local *t*-direction

Knot Vector Cards for the *r*-direction. Include ceil[(NR + PR + 1)/4] cards if UNIR = 0.

Card 3a	1	2	3	4	5	6	7	8
Variable	R1		R2		R3		R4	
Type	F		F		F		F	

VARIABLE	DESCRIPTION
R*i*	Knot values in the local *r*-direction with *i* = 1, …, NR + PR + 1

Knot Vector Cards for the *r*-direction. Include this card if UNIR ≠ 0. See Remark 1.

Card 3b	1	2	3	4	5	6	7	8
Variable	RFIRST		RLAST					
Type	F		F					

VARIABLE	DESCRIPTION
RFIRST	First knot value in the local *r*-direction
RLAST	Last knot value in the local *r*-direction

Knot Vector Cards for the *s*-direction. Include ceil[(NS + PS + 1)/4] cards if UNIS = 0.

Card 4a	1	2	3	4	5	6	7	8
Variable	S1		S2		S3		S4	
Type	F		F		F		F	

VARIABLE	DESCRIPTION
S*j*	Knot values in the local *s*-direction with *j* = 1, …, NS + PS + 1

Knot Vector Cards for the *s*-direction. Include this card if UNIS ≠ 0. See Remark 1.

Card 4b	1	2	3	4	5	6	7	8
Variable	SFIRST		SLAST					
Type	F		F					

VARIABLE	DESCRIPTION
SFIRST	First knot value in the local *s*-direction
SLAST	Last knot value in the local *s*-direction

Knot Vector Cards for the *t*-direction. Include ceil[(NT + PT + 1)/4] cards if UNIT = 0.

Card 5a	1	2	3	4	5	6	7	8
Variable	T1		T2		T3		T4	
Type	F		F		F		F	

VARIABLE	DESCRIPTION
T*k*	Knot values in the local *t*-direction with *k* = 1, …, NT + PT + 1

Knot Vector Cards for the *t*-direction. Include this card if UNIT ≠ 0. See Remark 1.

Card 5b	1	2	3	4	5	6	7	8
Variable	TFIRST		TLAST					
Type	F		F					

VARIABLE	DESCRIPTION
TFIRST	First knot value in the local *t*-direction
TLAST	Last knot value in the local *t*-direction

Control Point and Weight Cards. Include NR × NS × NT cards reflecting the connectivity.

Card 6	1	2	3	4	5	6	7	8
Variable	X		Y		Z		WGT	
Type	F		F		F		F	
Default	none		none		none		1.0	

VARIABLE	DESCRIPTION
X*l*	Nonhomogeneous control point coordinates in the global *x*-direction with *l* = 1, …, NR × NS × NT
Y*l*	Nonhomogeneous control point coordinates in the global *y*-direction with *l* = 1, …, NR × NS × NT
Z*l*	Non-homogeneous control point coordinates in the global *z*-direction with *l* = 1, …, NR × NS × NT
WGT*l*	Control weights with *l* = 1, …, NR × NS × NT. See Remark 2.

Remarks:

1. **Uniform Knot Vectors.** RFIRST and RLAST (SFIRST and SLAST or TFIRST and TLAST) define the interval for uniform knot spans in the local *r*-direction (*s*-

direction or *t*-direction). As an example suppose that NR = 4, PR = 3, RFIRST = 1, and RLAST = 8 which yields the following uniform open and uniform periodic knot vectors [1 1 1 1 8 8 8 8] and [1 2 3 4 5 6 7 8] for UNIR = 1 and UNIR = 2, respectively.

2. **Control Weights.** Control weights must be positive and will otherwise be reset to the default unit value.

*IGA_EDGE_UVW

Purpose: Define a parametric edge, meaning a trimmed and oriented parametric univariate non-uniform rational B-spline (NURBS). Parametric edges are used to compose one-dimensional boundary representations, see *IGA_1D_BREP, and trim parametric as well as physical faces, see *IGA_FACE_UVW and *IGA_FACE_XYZ. In addition, a parametric edge may play a role in defining (1) topological relations among physical faces and (2) boundary conditions and/or constraints; see Remarks 1 and 2, respectively.

Edge Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	EXYZID	PATCHID	SENSE	RSTART		REND	
Type	I	I	I	I	F		F	
Default	none	none	none	0	RFIRST		RLAST	

VARIABLE	DESCRIPTION
EID	Parametric edge ID. A unique number must be chosen.
EXYZID	Physical edge ID. See *IGA_EDGE_XYZ and Remark 1 and 3.
PATCHID	Parametric univariate NURBS patch ID. See *IGA_1D_NURBS_UVW and Remarks 2 and 3.
SENSE	Sense of orientation with respect to the physical edge. See Remark 3. EQ.0: Same (default) EQ.1: Reversed
RSTART	Parametric coordinate defining the start of the trimmed parametric NURBS. See Remark 4.
REND	Parametric coordinate defining the end of the trimmed parametric NURBS. See Remark 4.

Remarks:

1. **Topology.** Parametric edges are the constituents of one-dimensional boundary representations (see *IGA_1D_BREP) which specify the exterior of a physical face (see *IGA_FACE_XYZ). Parametric edges referencing the same physical edge, meaning EXYZID, identify the topological relation between their parent physical faces.

2. **Boundary Conditions and Constraints.** A parametric edge may be invoked to define a curve segment in/on an isogeometric shell or solid; see *IGA_SHELL and *IGA_SOLID. In this case, the control points of a parametric univariate NURBS referenced by PATCHID is defined in the parametric space of its parent physical object. Consequently, a parametric edge may be defined in the parametric space of an n-variate physical NURBS, such as *IGA_nD_NURBS_XYZ with $n = 2$ or 3, which requires the definition of (U, V) or (U, V, W) control point coordinates, respectively.

3. **Sense of Orientation.** The orientation of the parametric edge and the parametric univariate NURBS always agree. The SENSE flag indicates if the orientation of the parametric and physical edges agrees. Consider for instance two patches connected along an edge as schematically shown in the figure below. The parametric edges f_2 and f_8 share the same physical edge e_2. The direction of f_2 and e_2 is the same, consequently SENSE = 0. In contrast, f_8 and e_2 point in opposite directions, hence SENSE = 1.

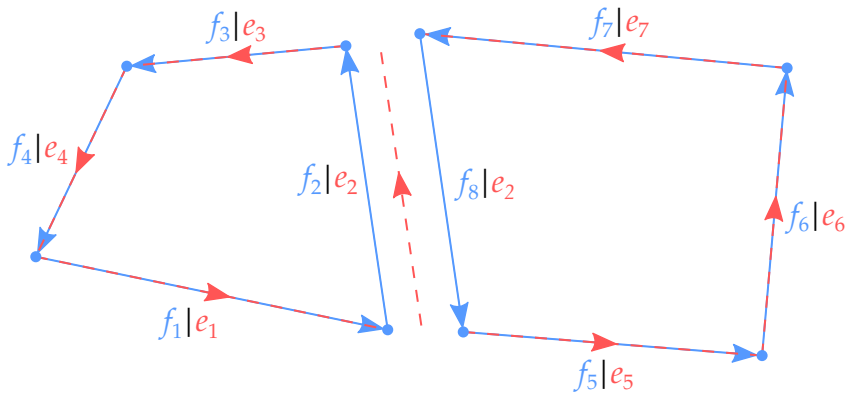

Figure 25-1. Schematic of two patches connected along an edge. Parametric edges are blue while physical edges are red.

4. **Trimming.** Parametric coordinates are used to trim the underlying parametric univariate NURBS. The parametric coordinates should have distinct values such that RSTART < REND. Out of bound parametric coordinates are disregarded and no trimming is performed at the respective ends.

*IGA_EDGE_XYZ

Purpose: Define a physical edge, meaning a trimmed and oriented physical univariate non-uniform rational B-spline (NURBS). A physical edge is currently only used to define topological relations among different physical faces; see *IGA_EDGE_UVW and *IGA_-FACE_XYZ for more details.

Edge Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	PATCHID	ORI	PIDSTART	PIDEND	PSID		
Type	I	I	I	I	I	I		
Default	none	none	0	0	0	none		

VARIABLE	DESCRIPTION
EID	Physical edge ID. A unique number must be chosen.
PATCHID	Physical univariate NURBS patch ID; see *IGA_1D_NURBS_XYZ.
ORI	Orientation with respect to the physical univariate NURBS. See Remark 1. EQ.0: Same (default) EQ.1: Reversed
PIDSTART	Parametric point ID defining the start of the trimmed physical NURBS. If PIDSTART = 0, the physical univariate NURBS is not trimmed at its start; see Remarks 1, 2, and 3.
PIDEND	Parametric point ID defining the end of the trimmed physical NURBS. If PIDEND = 0, the physical univariate NURBS is not trimmed at its end; see Remarks 1, 2, and 3.
PSID	Parametric point set ID. See *IGA_POINT_UVW and *SET_-IGA_-POINT_UVW. See Remark 4.

Remarks:

1. **Orientation.** The orientation of a physical edge is defined by the parametric points referenced by PIDSTART and PIDEND or, if none of the parametric points are defined, by the orientation flag ORI. Simultaneous use of the parametric points and the orientation flag is only required if the underlying physical NURBS curve is closed. The orientation convention is illustrated in the figure below where the blue solid line is the physical univariate NURBS curve, the red dashed line is the physical edge, and the black circle and dot denote the parametric points specifying the start and end of the edge, respectively.

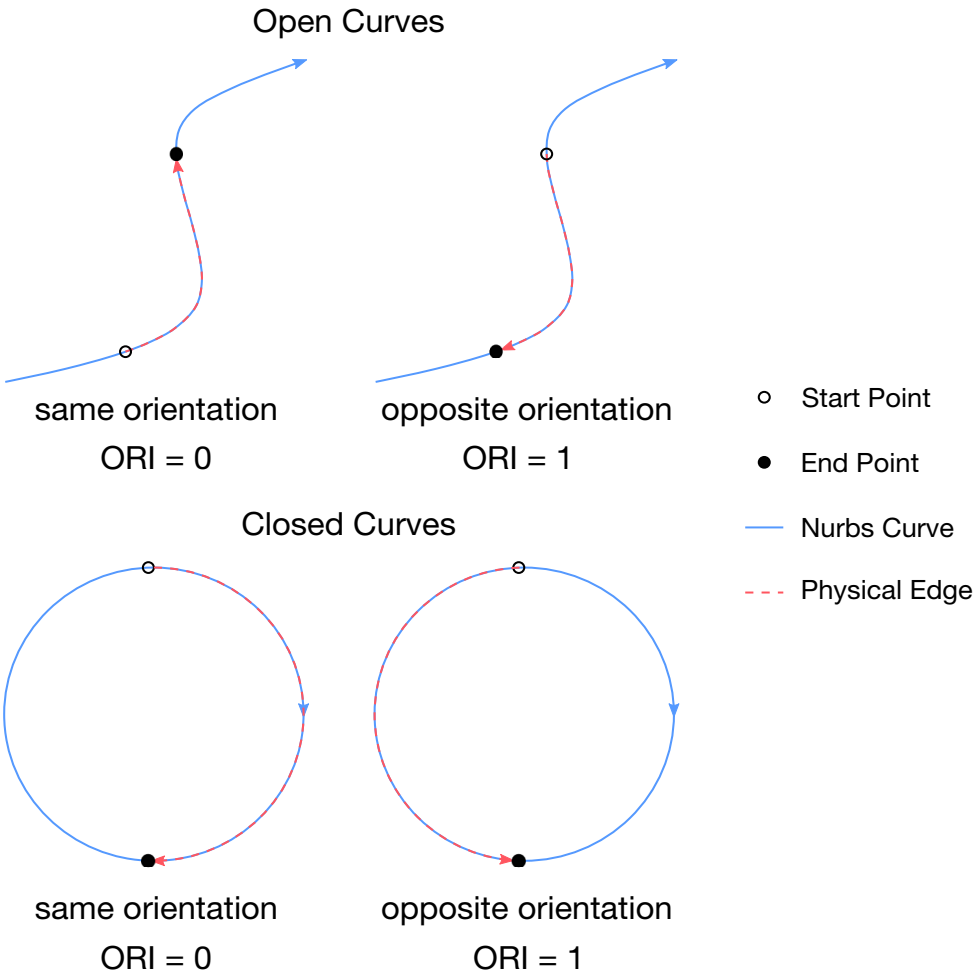

Figure 25-2. Orientation for different physical edges compared to the physical NURBS curve

2. **Trimming.** Parametric points determine where to trim the underlying physical univariate NURBS. Thus, the parametric points should be within the knot vector. An out of bound parametric point is disregarded with no trimming performed at that end.

3. **Topology.** Parametric points are also help establish topological relations among different physical edges.

4. **Dependent Parametric Point Set.** The collection of parametric points is defined within the parametric space of the underlying univariate NURBS and used in boundary condition and/or constraint definition(s).

*IGA_FACE_UVW

Purpose: Define a parametric face, meaning a trimmed and oriented parametric bivariate non-uniform rational B-spline (NURBS). Parametric faces are used to compose two-dimensional boundary representations, see *IGA_2D_BREP, and trim physical volumes, see *IGA_VOLUME_XYZ. In addition, a parametric face may play a role in defining (1) topological relations among physical volumes and (2) boundary conditions and/or constraints; see Remarks 1 and 2, respectively.

Card 1	1	2	3	4	5	6	7	8
Variable	FID	FXYZID	PATCHID	SENSE				
Type	I	I	I	I				
Default	none	none	none	0				

Boundary Representation Cards. Include boundary representations defining the parametric face, see Remark 1. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	BRID1	BRID2	BRID3	BRID4	BRID5	BRID6	BRID7	BRID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
FID	Parametric face ID. A unique number must be chosen.
FXYZID	Physical face ID. See *IGA_FACE_XYZ and Remarks 1 and 3.
PATCHID	Parametric bivariate NURBS patch ID; see *IGA_2D_NURBS_UVW and Remarks 2 and 3.
SENSE	Sense of orientation with respect to the physical face (see Remark 3): EQ.0: Same (default)

VARIABLE	DESCRIPTION
	EQ.1: Reversed
BRID*i*	One-dimensional boundary representation IDs (see *IGA_1D_BREP) with $i = 1, \ldots, n$ and $n > 0$

Remarks:

1. **Topology.** Parametric faces are the constituents of two-dimensional boundary representations (see *IGA_2D_BREP) which specify the exterior of a physical volume (see *IGA_VOLUME_XYZ). Parametric faces referencing the same physical face, meaning FXYZID, identify the topological relation between their parent physical volumes.

2. **Boundary Conditions and Constraints.** A parametric face may be invoked to define a surface segment in/on an isogeometric solid; see *IGA_SOLID. In this case, the control points of a parametric bivariate NURBS referenced by PATCHID is defined in the parametric space of its parent physical object. Consequently, a parametric face may be defined in the parametric space of a trivariate physical NURBS (see *IGA_3D_NURBS_XYZ) which requires the definition (U, V, W) control point coordinates.

3. **Sense of Orientation.** The orientation of the parametric face and the parametric bivariate NURBS always agree. The SENSE flag indicates if the orientation of the parametric and physical faces agrees.

*IGA_FACE_XYZ

Purpose: Define a physical face, meaning a trimmed and oriented physical bivariate non-uniform rational B-spline (NURBS). A physical face is used to define isogeometric shells (see *IGA_SHELL) as well as boundary conditions and/or constraint on its (sub)surface.

Card 1	1	2	3	4	5	6	7	8
Variable	FID	PATCHID	ORI	PSID	ESID			
Type	I	I	I	I	I			
Default	none	none	0	none	none			

Boundary Representation Cards. Include boundary representations defining the physical face, see Remarks 1 and 2. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	BRID1	BRID2	BRID3	BRID4	BRID5	BRID6	BRID7	BRID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
FID	Physical face ID. A unique number must be chosen.
PATCHID	Physical bivariate patch ID: LT.0: Absolute value is the BEZIER patch ID; see *IGA_2D_BEZIER_XYZ. GT.0: NURBS patch ID; see *IGA_2D_NURBS_XYZ.
ORI	Orientation with respect to the physical bivariate NURBS. EQ.0: Same (default) EQ.1: Reversed

VARIABLE	DESCRIPTION
PSID	Parametric point set ID; see *IGA_POINT_UVW, *SET_IGA_-POINT_UVW, and Remark 3.
ESID	Parametric edge set ID; see *IGA_EDGE_UVW, *SET_IGA_-EDGE_UVW, and Remark 3.
BRID*i*	One-dimensional boundary representation IDs, with $i = 1, \ldots, n$ and $n > 0$. See *IGA_1D_BREP and Remarks 1 and 2.

Remarks:

1. **Trimming.** One-dimensional boundary representations, also called trimming loops, are used to trim the underlying bivariate NURBS. The orientation of the trimming loops uniquely define trimming, meaning travelling along the loop. The domain on the right-hand side of the loop is removed.

2. **Topology.** To establish topological relations among physical faces, at least a single boundary representation must be included.

3. **Dependent Parametric Object Sets.** The collection of parametric points and edges are defined within the parametric space of the underlying bivariate NURBS and used in boundary condition and/or constraint definition(s).

*IGA_INCLUDE_BEZIER

Purpose: Include novel computer-aided geometric definitions by virtue of Bézier extraction to perform isogeometric analysis. For more information on the include file format, please contact LS-DYNA support.

> **NOTE:** As of R14, this keyword is obsolete. Please use *IGA_2D_BEZIER_XYZ and *IGA_3D_BEZIER_XYZ to define bi- and trivariate (rational) splines using Bézier extraction, respectively.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	FILETYPE	PID	DIM					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
FILENAME	Name of the file to be included; see Remark 1.
FILETYPE	Type of the file to be included: EQ.1: ASCII
PID	Part ID
DIM	Parametric dimension: EQ.2: Surface EQ.3: Volume

Remarks:

1. **Multiple Patches.** The include file may contain multiple patches of the same parametric dimension which will also share the same part, and consequently, material and section IDs. Some properties may be set on a patch by patch basis (see *IGA_SHELL and *IGA_SOLID for DIM = 2 and DIM = 3, respectively)

*IGA_POINT_UVW

Purpose: Define a parametric point. A parametric point may play a role in defining (1) topological relations among physical edges and (2) boundary conditions and/or constraints; see Remarks 1 and 2, respectively.

Point Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	NID	U		V		W	
Type	I	I	F		F		F	
Default	none	none	none		none		none	

VARIABLE	DESCRIPTION
PID	Parametric point ID. A unique number must be chosen.
NID	Node IDs; see *NODE and Remark 3.
U	Coordinates in the parametric u-direction
V	Coordinates in the parametric v-direction
W	Coordinates in the parametric w-direction

Remarks:

1. **Topology.** Parametric points may specify the starting and ending point of a physical edge; see *IGA_EDGE_XYZ. Parametric points referencing the same node (also interpreted as a physical point), meaning NID, identify the topological relation between their parent physical edges.

2. **Boundary Conditions and Constraints.** A parametric point may be invoked to define a discrete location in/on an isogeometric shell or solid; see *IGA_SHELL and *IGA_SOLID. In this case, the coordinates of the parametric point are defined in the parametric space of its parent physical object. Consequently, a parametric point may be defined in the parametric space of an n-variate physical NURBS, that is, *IGA_nD_NURBS_XYZ with n = 1, 2, or 3, which requires the definition of (U), (U,V), and (U,V,W) coordinates, respectively.

3. **The Role of Nodes.** Nodes can be interpreted as physical points.

*IGA_SHELL

Purpose: Define a set of isogeometric shell elements.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	PID	NISR	NISS			IDFNE	
Type	I	I	F	F			I	
Default	none	none	0.	0.			0	

VARIABLE	DESCRIPTION
SID	Isogeometric shell (patch) ID; see Remarks 1 and 2. A unique number must be chosen.
PID	Part ID
NISR	Interpolation elements in the local *r*-direction (see Remark 3): LT.0.0: |NISR| is the average edge length of the interpolation elements in the local *r*-direction. EQ.0.0: The number of interpolation elements per isogeometric element is equal to the polynomial degree in the local *r*-direction. GT.0.0: Number of interpolation elements per isogeometric element in the local *r*-direction. NISR must be an integer.
NISS	Interpolation elements in the local *s*-direction (see Remark 3): LT.0.0: |NISS| is the average edge length of the interpolation elements in the local *s*-direction. EQ.0.0: The number of interpolation elements per isogeometric element is equal to the polynomial degree in the local *s*-direction. GT.0.0: Number of interpolation elements per isogeometric element in the local *s*-direction. NISS must be an integer.
IDFNE	Element ID of the first IGA element (knot span) within this isogeometric shell (patch) definition

Remarks:

1. **Discretized Shells.** A shell ID is a physical face ID; see *IGA_FACE_XYZ.

2. **Mass Matrix.** Like the standard convention in the structural solver, the row sum mass matrix formulation is invoked by default. A consistent mass matrix may be used at the model level by invoking the *CONTROL_IMPLIC-IT_CONSISTENT_MASS keyword.

3. **Interpolation Elements.** Contact treatment and post-processing are presently dealt with interpolation elements defined by interpolation nodes. These nodes and elements are automatically created.

*IGA_SOLID

Purpose: Define a set of isogeometric solid elements.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	PID	NISR	NISS	NIST			
Type	I	I	F	F	F			
Default	none	none	0.	0.	0.			

VARIABLE	DESCRIPTION
SID	Isogeometric solid (patch) ID; see Remarks 1 and 2. A unique number must be chosen.
PID	Part ID
NISR	Interpolation elements in the local *r*-direction (see Remark 3): LT.0.0: |NISR| is the average edge length of the interpolation elements in the local *r*-direction. EQ.0.0: The number of interpolation elements per isogeometric element is equal to the polynomial degree in the local *r*-direction. GT.0.0: Number of interpolation elements per isogeometric element in the local *r*-direction. NISR must be an integer.
NISS	Interpolation elements in the local *s*-direction (see Remark 3): LT.0.0: |NISS| is the average edge length of the interpolation elements in the local *s*-direction. EQ.0.0: The number of interpolation elements per isogeometric element is equal to the polynomial degree in the local *s*-direction. GT.0.0: Number of interpolation elements per isogeometric element in the local *s*-direction. NISS must be an integer.

VARIABLE	DESCRIPTION
NIST	Interpolation elements in the local *t*-direction (see Remark 3): LT.0.0: |NIST| is the average edge length of the interpolation elements in the local *t*-direction. EQ.0.0: The number of interpolation elements per isogeometric element is equal to the polynomial degree in the local *t*-direction. GT.0.0: Number of interpolation elements per isogeometric element in the local *t*-direction. NIST must be an integer.

Remarks:

1. **Discretized Solids.** A solid ID is a physical volume ID; see *IGA_VOLUME_XYZ.

2. **Mass Matrix.** Similar to the standard convention in the structural solver, the row sum mass matrix formulation is invoked by default. A consistent mass matrix may be used at the model level by invoking the *CONTROL_IMPLICIT_CONSISTENT_MASS keyword.

3. **Interpolation Elements.** Contact treatment and post-processing are presently dealt with interpolation elements defined by interpolation nodes. These nodes and elements are automatically created.

*IGA_TIED_EDGE_TO_EDGE

Purpose: Mechanically couple entities along topologically connected edges. The topology is given implicitly using the relation between parametric and physical edges; see *IGA_EDGE_UVW and *IGA_EDGE_XYZ.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYPE	FORM	SFD	SFR	SFT		
Type	I	I	I	F	F	F		
Default	0	0	0	1.0	1.0	1.0		

VARIABLE	DESCRIPTION
ID	Apply coupling to entities referenced by the ID field along topologically connected edges. The next field, TYPE, specifies the type of entity to which ID refers because entities of different kinds, such as parts and part sets, are not uniquely numbered. Currently (as of June 2020), Currently, no types requiring an ID are supported. This field is reserved for future enhancements.
TYPE	Type of ID: EQ.0: Include all topological connections in the model. No ID required.
FORM	Coupling formulation: EQ.0: Penalty-based tied contact
SFD	Scaling factor for displacement penalty stiffness
SFR	Scaling factor for rotational penalty stiffness
SFT	Scaling factor for thin constraint penalty stiffness (rotation free elements)

*IGA_VOLUME_XYZ

Purpose: Define a physical volume, that is, a physical trivariate non-uniform rational B-spline (NURBS). A physical volume is used to define isogeometric solids (see *IGA_SOLID) as well as boundary conditions and/or constraints on its (sub)volume.

Card 1	1	2	3	4	5	6	7	8
Variable	VID	PATCHID	PSID	ESID	FSID			
Type	I	I	I	I	I			
Default	none	none	none	none	none			

Boundary Representation Cards. Include boundary representations defining the physical volume, see Remark 1. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	BRID1	BRID2	BRID3	BRID4	BRID5	BRID6	BRID7	BRID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
VID	Parametric volume ID. A unique number must be chosen.
PATCHID	Physical trivariate patch ID: LT.0: Absolute value is the BEZIER patch ID; see *IGA_3D_BEZIER_XYZ. GT.0: NURBS patch ID; see *IGA_3D_NURBS_XYZ.
PSID	Parametric point set ID; see *IGA_POINT_UVW and *SET_IGA_POINT_UVW. See Remark 2.
ESID	Parametric edge set ID; see *IGA_EDGE_UVW and *SET_IGA_EDGE_UVW. See Remark 2.

VARIABLE	DESCRIPTION
FSID	Parametric face set ID; see *IGA_FACE_UVW and *SET_IGA_-FACE_UVW. See Remark 2.
BRID*i*	Two-dimensional boundary representation IDs (see *IGA_2D_-BREP) with $i = 1, \ldots, n$ and $n > 0$.

Remarks:

1. **Topology.** To establish topological relations among physical volumes, at least a single boundary representation must be included.

2. **Dependent Parametric Object Sets.** The collection of parametric points, edges, and faces identify, in the topological sense reduced, subsets of the underlying trivariate NURBS parameterization that are used in boundary condition and/or constraint definition(s).

*INCLUDE

The keyword *INCLUDE provides a means of reading independent input files containing model data. The file contents are placed directly at the location of the *INCLUDE line.

INCLUDE_*{OPTION}

*INCLUDE_AUTO_OFFSET

*INCLUDE_COMPENSATION_BEFORE_SPRINGBACK

*INCLUDE_COMPENSATION_BLANK_AFTER_SPRINGBACK

*INCLUDE_UNITCELL

*INCLUDE_WD_FINAL_PART

*INLUDE_WD_INITIAL_BLANK

*INCLUDE_WD_WELDING_CURVE

*INCLUDE_{OPTION}

Purpose: Include independent input files containing model data.

Available options include:

<BLANK>

BINARY

NASTRAN

TRANSFORM

TRANSFORM_BINARY

The BINARY and TRANSFORM_BINARY options specify that the initial stress file, dynain, is written in a binary format. See the keyword *INTERFACE_SPRINGBACK.

The TRANSFORM and TRANSFORM_BINARY options allow for node, element, and set IDs to be offset and for coordinates and constitutive parameters to be transformed and scaled.

Card Summary:

Card 1a. This card is included if the keyword option is unset (<BLANK>). Include as many of this card as needed. The next keyword ("*") card terminates this input.

FILENAME

Card 1b. This card is included if the keyword option is set.

FILENAME

Card 2a. This card is included if the NASTRAN keyword option is used.

BEAMDF	SHELLDF	SOLIDDF					

Card 2b.1. This card is included if the TRANSFORM keyword option is used.

IDNOFF	IDEOFF	IDPOFF	IDMOFF	IDSOFF	IDFOFF	IDDOFF	

Card 2b.2. This card is included if the TRANSFORM keyword option is used.

IDROFF		PREFIX	SUFFIX				

Card 2b.3. This card is included if the TRANSFORM keyword option is used.

FCTMAS	FCTTIM	FCTLEN	FCTTEM	INCOUT1	FCTCHG		

Card 2b.4. This card is included if the TRANSFORM keyword option is used.

TRANID							

Data Card Definitions:

File name without Keyword Option Card. Include this card if the keyword option is unset (<BLANK>). Multiple file names can be specified (each on its own line(s)) which are processed sequentially. Note that each file name can be multiple lines (see Remark 2). File names are read until the next keyword ("*") card.

Card 1a	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

VARIABLE	DESCRIPTION
FILENAME	File name of file to be included (see Remark 2)

File name with Keyword Option Card. Include this card if the keyword option is set. Only one file name can be specified.

Card 1a	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

VARIABLE	DESCRIPTION
FILENAME	File name of file to be included (see Remark 2)

Nastran Card. Additional card for the NASTRAN keyword option.

Card 2a	1	2	3	4	5	6	7	8
Variable	BEAMDF	SHELLDF	SOLIDDF					
Type	I	I	I					
Default	2	21	18					

VARIABLE	DESCRIPTION
BEAMDF	LS-DYNA beam element type. Defaults to type 2.
SHELLDF	LS-DYNA shell element type. Defaults to type 21.
SOLIDDF	LS-DYNA solid element type. Defaults to type 18.

Transform Card 1. Additional card for TRANSFORM keyword option.

Card 2b.1	1	2	3	4	5	6	7	8
Variable	IDNOFF	IDEOFF	IDPOFF	IDMOFF	IDSOFF	IDFOFF	IDDOFF	
Type	I	I	I	I	I	I	I	

VARIABLE	DESCRIPTION
IDNOFF	Offset to node ID
IDEOFF	Offset to element ID
IDPOFF	Offset to part ID, nodal rigid body ID, constrained nodal set ID, rigidwall ID, and cross section ID (see *DATABASE_CROSS_SECTION)
IDMOFF	Offset to material ID and equation of state ID
IDSOFF	Offset to set ID
IDFOFF	Offset to function ID, table ID, and curve ID
IDDOFF	Offset to any ID defined through *DEFINE, except the FUNCTION, TABLE, and CURVE options (see IDFOFF)

Transform Card 2. Additional card for TRANSFORM keyword option.

Card 2b.2	1	2	3	4	5	6	7	8
Variable	IDROFF		PREFIX	SUFFIX				
Type	I		A	A				

VARIABLE	DESCRIPTION
IDROFF	Used for all offsets except for those listed above
PREFIX	Prefix added to the beginning of the titles/heads defined in the keywords (like *MAT, *PART, *SECTION, *DEFINE, for examples) of the included file. A dot, ".", is automatically added between the prefix and the existing title.
SUFFIX	Suffix added to the end of the titles/heads defined in the keywords of the included file. A dot, ".", is automatically added between the suffix and the existing title.

Transform Card 3. Additional card for TRANSFORM keyword option.

Card 2b.3	1	2	3	4	5	6	7	8
Variable	FCTMAS	FCTTIM	FCTLEN	FCTTEM	INCOUT1	FCTCHG		
Type	F	F	F	A	I	F		

VARIABLE	DESCRIPTION
FCTMAS	Mass transformation factor. For example, FCTMAS = 1000 when the original mass unit is in tons and the new unit is kg.
FCTTIM	Time transformation factor. For example, FCTTIM = .001 when the original time unit is in milliseconds and the new time unit is seconds.
FCTLEN	Length transformation factor
FCTTEM	Temperature transformation factor consisting of a four character flag: FtoC (Fahrenheit to Centigrade), CtoF, FtoK, KtoF, KtoC, and CtoK.

VARIABLE	DESCRIPTION
INCOUT1	Set to 1 for the creation of a file, DYNA.INC, which contains the transformed data. The data in this file can be used in future include files and should be checked to ensure that all the data was transformed correctly.
FCTCHG	Electric charge transformation factor. It currently only applies to piezoelectric material related cards, see *MAT_ADD_PZELECTRIC for details.

Transform Card 4. Additional card for TRANSFORM keyword option.

Card 2b.4	1	2	3	4	5	6	7	8
Variable	TRANID							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
TRANID	Transformation ID. If 0, no transformation will be applied. See *DEFINE_TRANSFORMATION.

Remarks:

1. **Scalability.** To make the input file easy to maintain, this keyword allows the input file to be split into subfiles. Each subfile can again be split into sub-subfiles and so on. This option is beneficial when the input data deck is very large. Consider the following example:

```
*TITLE
full car model
*INCLUDE
carfront.k
*INCLUDE
carback.k
*INCLUDE
occupantcompartment.k
*INCLUDE
dummy.k
*INCLUDE
bag.k
```

```
*CONTACT
⋮
*END
```

Note that the command *END terminates the include file.

The carfront.k file can again be subdivided into rightrail.k, leftrail.k, battery.k, wheel-house.k, shotgun.k, etc.. Each *.k file can include nodes, elements, boundary conditions, initial conditions, and so on.

```
*INCLUDE
rightrail.k
*INCLUDE
leftrail.k
*INCLUDE
battery.k
*INCLUDE
wheelhouse.k
*INCLUDE
shotgun.k
⋮
*END
```

2. **File Name Length Limitations.** File names are limited to 236 characters spread over up to three 80 character lines. When 2 or 3 lines are needed to specify the filename or pathname, end the preceding line with "␣+" (space followed by a plus sign) to signal that a continuation line follows. Note that the "␣+" combination is, itself, part of the 80 character line; hence the maximum number of allowed characters is 78 + 78 + 80 = 236.

3. **NASTRAN Option.** The transformed LS-DYNA deck for *INCLUDE_NASTRAN will be automatically written to file DYNA.INC.

INCLUDE_AUTO_OFFSET_*{OPTION}

Purpose: This particular *INCLUDE keyword offsets node and element IDs to avoid duplication during stamping simulations. In single process stamping simulations the rigid tools often undergo several iterations of modifications, so the node or element IDs comprising the new tools sometimes conflict with other parts of the model. In a multiple process simulation, the IDs of rigid tools from later processes may overlap the IDs of the tools or the formed sheet blank from the previous processes, which makes it difficult to automate the process simulation. This keyword automatically checks for and offsets the duplicate IDs. It works on shell, solid, beam and discrete (*ELEMENT_DISCRETE) elements. The *CONTROL_FORMING_MAXID keyword is related.

Available option includes:

<BLANK>

USER

The USER option allows for specifying offset IDs of the nodes and elements (shells, solids and beams) for the included file.

Note this keyword does not work on the dynain file with stress and strain information. Thus, in a multiple included files case, the dynain file for the blank should always be included first using simply *INCLUDE; see example below.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

User Set Offset Card. This card is included if and only if the USER option is used.

Card 2	1	2	3	4	5	6	7	8
Variable	NOFFSET	NEOFFSET						
Type	I	I						

VARIABLE	DESCRIPTION
FILENAME	Name of file to be included

VARIABLE	DESCRIPTION
NOFFSET	An offset value for the node IDs of the included file
NEOFFSET	An offset value for the element IDs of the included file

***INCLUDE_AUTO_OFFSET (without option):**

This keyword can be used to offset element and node IDs of the tooling. *This keyword will not offset IDs of meshes with initial stress and strain information*. As such, the sheet blank (including dynain file) should always be included first using the *INCLUDE keyword, followed by *INCLUDE_AUTO_OFFSET to offset tooling mesh IDs which do not have stress and strain information.

Incoming element and node IDs of the rigid tooling mesh files, such as the punch, die, and binder, could be overlapped with each other or overlapped with those on the sheet blank. Multiple *INCLUDE_AUTO_OFFSET keywords can be used to include the punch, die, and binder separately, if desired. For example, four different components of the tooling, the upper die, lower punch, binder and gage pins, can be included and their element and node IDs properly offset after those of a gravity-loaded sheet blank:

```
*INCLUDE
gravity.dynain
*INCLUDE_AUTO_OFFSET
upperdie.k
*INCLUDE_AUTO_OFFSET
lowerpunch.k
*INCLUDE_AUTO_OFFSET
binder.k
*INCLUDE_AUTO_OFFSET
pins.k
```

All of the included meshes can have conflicting node and element IDs starting from 1. Node and element IDs will be offset and reordered in the order of the included files. Included tool files whose node and element IDs do not overlap with those on either the blank or other tools will not be offset or reordered. In many circumstances this feature allows for bypassing a metal forming setup GUI when updating just one or two tooling pieces.

***INCLUDE_AUTO_OFFSET_USER:**

This option gives you more control on the starting node and element IDs of the included files. It applies to shell, solid and beam elements. The following example shows node and element IDs of multiple included files, upper.k, lower.k, binder.k, pins.k, and formed.dynain (formed sheet blank), are offset by 1000000, 2000000, 3000000, 4000000, and 5000000, respectively. As stated above, this option does not allow for the offset of the IDs of the sheet blank with stress and strain information, so formed.dynain file should be included first using just the keyword *INCLUDE. Care should be taken that the offset IDs

defined for all the rigid tools do not overlap with those in formed.dynain and also do not overlap each other.

```
*INCLUDE
./formed.dynain
*INCLUDE_AUTO_OFFSET_USER
./upper.k
1000000, 1000000
*INCLUDE_AUTO_OFFSET_USER
./lower.k
2000000, 2000000
*INCLUDE_AUTO_OFFSET_USER
./binder.k
3000000, 3000000
*INCLUDE_AUTO_OFFSET_USER
./pins.k
4000000, 4000000
```

Revision Information:

- This feature is available in SMP and MPP in LS-DYNA Revision 92417. Support for shell elements only.
- Revision 123467 extends to beams (used to model draw beads, for example) and solids.
- Revision 122115: extends to *ELEMENT_DISCRETE.
- Revision 123467: the option USER is available.

*INCLUDE_COMPENSATION

Purpose: This group of keywords allows for the inclusion of stamping tool and blank information for springback compensation. In addition, trim curves from the target geometry can be included for mapping onto the intermediate compensated tool geometry, which can be used for the next compensation iteration. Furthermore, compensation can be done for a localized tool region.

Basic options to perform springback compensation include the following:

*INCLUDE_COMPENSATION_BLANK_BEFORE_SPRINGBACK

*INCLUDE_COMPENSATION_BLANK_AFTER_SPRINGBACK

*INCLUDE_COMPENSATION_DESIRED_BLANK_SHAPE

*INCLUDE_COMPENSATION_COMPENSATED_SHAPE

*INCLUDE_COMPENSATION_CURRENT_TOOLS

*INCLUDE_COMPENSATION_ORIGINAL_TOOL

*INCLUDE_COMPENSATION_COMPENSATED_SHAPE_NEXT_STEP

If springback prediction is performed after trimming, the trimming curves need to be modified based on the boundary change of the blank due to springback. The keyword to do that is:

*INCLUDE_COMPENSATION_TRIM_CURVE

Compensation can be performed locally with

*INCLUDE_COMPENSATION_CURVE

To reduce the number of iterations in springback compensation, the following keywords must be used with *INTERFACE_COMPENSATION_3D_ACCELERATOR:

*INCLUDE_COMPENSATION_ORIGINAL_DYNAIN

*INCLUDE_COMPENSATION_SPRINGBACK_INPUT

If the part has a symmetric condition, this keyword ensures that the compensated rigid tools are also symmetric:

*INCLUDE_COMPENSATION_SYMMETRIC_LINES

If there are regions with undesired mesh quality, the surface can be smoothed locally with the following keyword together with *INTERFACE_COMPENSATION_3D_LOCAL_SMOOTH:

*INCLUDE_COMPENSATION_ORIGINAL_RIGID_TOOL

After compensation, the default file name for the new rigid tool is rigid.new. However, the user can change its name using

*INCLUDE_COMPENSATION_NEW_RIGID_TOOL

After compensation has been completed, if some minor part change is needed, the compensated tool may be modified without redoing the iteration using the following keywords and *INTERFACE_COMPENSATION_3D_PART_CHANGE:

*INCLUDE_COMPENSATION_UPDATED_BLANK_SHAPE

*INCLUDE_COMPENSATION_UPDATED_RIGID_TOOL

During a hot forming process, due to the thickness change of the blank, the gap between the blank and the rigid tools is not homogeneous which will cause inhomogeneity in cooling. The following keyword is used with *INTERFACE_THICKNESS_CHANGE_COMPENSATION to modify the tool surface and ensure a homogenous gap:

*INCLUDE_COMPENSATION_BEFORE_SPRINGBACK

*INCLUDE_COMPENSATION_CURRENT_TOOLS

To ensure tangency continuity in the neighborhood of a trim curve, the following keyword can be used. These nodes can also be generated from *INTERFACE_COMPENSATION_3D_REFINE_RIGID.

*INCLUDE_COMPENSATION_TRIM_NODE

If the user does not want to change the tangency along the punch boundary, the following keyword can be used:

*INCLUDE_COMPENSATION_TANGENT_CONSTRAINT

Full Example of a Springback Compensation:

The following example is for compensation of a localized area, defined by the file curves.k. Trim lines are mapped onto the new compensated rigid tool, with trimcurves.k. Both files which were generated by *LS-PrePost* 4.0 are in the XYZ format. A detailed explanation of each keyword is given in the manual pages related to *INTERFACE_COMPENSATION_3D.

```

*END
```

*INCLUDE_COMPENSATION_BEFORE_SPRINGBACK

Purpose: In a hot forming process, the gap between the blank and rigid tools is not homogeneous due the thickness change of the blank which will cause inhomogeneity in cooling. This keyword when used with *INTERFACE_THICKNESS_CHANGE_COMPENSATION modifies the tool surface and ensures a homogeneous gap. The stamping tool set should be included with *INCLUDE_COMPENSATION_CURRENT_TOOLS. See *INTERFACE_THICKNESS_CHANGE_COMPENSATION for more details.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	A dynain file from a forming simulation; the varied, non-homogenous thickness of the sheet blank will be used to change the uniform tool gap.

Revision Information:

This keyword is available as of Revision 106357.

*INCLUDE_COMPENSATION_BLANK_AFTER_SPRINGBACK

Purpose: Include the mesh information in keyword format for the last state (from d3plot) of the springback simulation or the dynain file after springback. This keyword is used with *INTERFACE_COMPENSATION_3D to compensate stamping tool shapes for springback with an iterative method.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	spbk.tmp							

VARIABLE	DESCRIPTION
FILENAME	File that includes the nodes and element information with adaptive constraints if they exist for the last state of the springback simulation.

Remarks:

Sheet blanks included using the following related keyword options of *INCLUDE_COMPENSATION must have the same number of nodes and elements for a compensation simulation:

BLANK_AFTER_SPRINGBACK

BLANK_BEFORE_SPRINGBACK

*INCLUDE_COMPENSATION_BLANK_BEFORE_SPRINGBACK

Purpose: Include the mesh information in keyword format for the first state (from d3plot) of the springback simulation or the dynain file after trimming (before springback and with no mesh coarsening). This keyword is used with *INTERFACE_COMPENSATION_NEW to compensate stamping tool shapes for springback with an iterative method.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	blank0.tmp							

VARIABLE	DESCRIPTION
FILENAME	File that includes the nodes and element information with adaptive constraints if they exist for the first state of the springback simulation.

Remarks:

Sheet blanks included using the following related keyword options of *INCLUDE_COMPENSATION must have the same number of nodes and elements for a compensation simulation:

BLANK_AFTER_SPRINGBACK

BLANK_BEFORE_SPRINGBACK

*INCLUDE_COMPENSATION_COMPENSATED_SHAPE

Purpose: Include the mesh information in a dynain file for the first iteration (same as INCLUDE_COMPENSATION_DESIRED_BLANK_SHAPE). For the following compensation iterations, this file is obtained from disp.tmp which is generated as an output file during the previous compensation iteration. This keyword is used with *INTERFACE_COMPENSATION_NEW to compensate stamping tool shapes for springback with an iterative method.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	reference1.dat							

VARIABLE	DESCRIPTION
FILENAME	File that includes the nodes and element information with adaptive constraints if they exist for the first compensation iteration.

Remarks:

Sheet blanks included using the following related keyword options of *INCLUDE_COMPENSATION must have the same number of nodes and elements for a compensation simulation:

DESIRED_BLANK_SHAPE

COMPENSATED_SHAPE

*INCLUDE_COMPENSATION_COMPENSATED_SHAPE_NEXT_STEP

Purpose: Enable compensation of tools for the next die process. This keyword is used with *INTERFACE_COMPENSATION_3D_MULTI_STEPS.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	File that includes the nodes and element information with adaptive constraints if they exist for ?

Remarks:

Sheet blanks included using the following related keyword options of *INCLUDE_COMPENSATION must have the same number of nodes and elements for a compensation simulation:

DESIRED_BLANK_SHAPE

COMPENSATED_SHAPE`

COMPENSATED_SHAPE_NEXT_STEP

Revision Information:

This keyword is available as of Revision 61406.

*INCLUDE_COMPENSATION_CURRENT_TOOLS

Purpose: Include the tool mesh information in keyword format. This file is the tool mesh used for the current forming simulation. This keyword is used with *INTERFACE_COMPENSATION_3D to compensate stamping tool shapes for springback with an iterative method.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	rigid.tmp							

VARIABLE	DESCRIPTION
FILENAME	File that includes the nodes and element information for the last state of the springback simulation. If the file is named as rigid0.tmp, the elements of the tools get refined along the outline of the part. Draw bead nodes must be included in this file so that they will be modified together with the rigid tools.

*INCLUDE_COMPENSATION_CURVE

Purpose: Perform compensation on localized tooling areas by defining a compensation zone. This keyword allows for die face compensation of a local region in a stamping die.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	Name of the keyword file containing x, y, z coordinates of two curves defining the compensation zone, using keywords: *DEFINE_CURVE_COMPENSATION_CONSTRAINT_BEGIN, and, *DEFINE_CURVE_COMPENSATION_CONSTRAINT_END.

Revision Information:

This keyword is available as of Revision 62038.

*INCLUDE_COMPENSATION_DESIRED_BLANK_SHAPE

Purpose: Include the dynain file for the blank after trimming or before springback in the first compensation iteration. This file is the target for compensation, so it never changes in all subsequent compensation iterations. This keyword is used with *INTERFACE_-COMPENSATION_3D to compensate stamping tool shapes for springback with an iterative method.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	reference0.dat							

VARIABLE	DESCRIPTION
FILENAME	File that includes the nodes and element information with adaptive constraints if they exist for the blank after trimming in the first compensation iteration.

Remarks:

Sheet blanks included using the following related keyword options of *INCLUDE_COMPENSATION must have the same number of nodes and elements for a compensation simulation:

DESIRED_BLANK_SHAPE

COMPENSATED_SHAPE

*INCLUDE_COMPENSATION_NEW_RIGID_TOOL

Purpose: Change the file name for the new rigid tool following compensation from "rigid.new."

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	File name for new rigid tool.

Revision Information:

This keyword is available as of Revision 73850.

*INCLUDE_COMPENSATION_ORIGINAL_DYNAIN

Purpose: This keyword is to be used in conjunction with *INTERFACE_COMPENSATION_3D_ACCELERATOR and INCLUDE_COMPENSATION_SPRINGBACK_INPUT for a springback compensation with a faster convergence rate and a simplified user interface. For detailed usage, please refer to the manual pages under *INTERFACE_COMPENSATION_3D_{*OPTION*}.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	The dynain file name from an LS-DYNA simulation that contains model information, adaptive constraints, and stress and strain tensor information.

Revision Information:

This keyword is available as of Revision 61264.

*INCLUDE_COMPENSATION_ORIGINAL_RIGID_TOOL

Purpose: Locally smooth mesh in regions with undesired mesh quality.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	Keyword file that contains the meshes of the rigid tools.

Remarks:

This keyword is used together with *INTERFACE_COMPENSATION_NEW_LOCAL_-SMOOTH and *SET_NODE_LIST_SMOOTH to smooth local areas of distorted meshes of a tooling surface. Details can be found in the manual pages for *INTERFACE_COM-PENSATION_NEW_LOCAL_SMOOTH.

Revision Information:

This keyword is available as of Revision 73850.

*INCLUDE_COMPENSATION_ORIGINAL_TOOL

Purpose: Obtain a smoother mesh for the addendum and binder region for the current compensation by using the original tool mesh (of better quality) instead of the last compensated tool mesh (maybe distorted). This method reduces the accumulative error in mesh extrapolation outside of the trim lines. Details can be found in the manual pages for *INTERFACE_COMPENSATION_3D.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	Original tool (without any compensation) mesh file that contains node and element information in keyword format.

Revision Information:

This keyword is a available as of Revision 82701.

*INCLUDE_COMPENSATION_SPRINGBACK_INPUT

Purpose: This keyword is to be used in conjunction with *INTERFACE_COMPENSATION_3D_ACCELERATOR and INCLUDE_COMPENSATION_ORIGINAL_DYNAIN for a springback compensation with a faster convergence rate and a simplified user interface. For detailed usage, please refer to the manual pages under *INTERFACE_COMPENSATION_3D_{*OPTION*}.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	File name of springback simulation input deck for the baseline iteration zero simulation.

Revision Information:

This keyword is available as of Revision 61264.

*INCLUDE_COMPENSATION_SYMMETRIC_LINES

Purpose: Ensure the compensated rigid tools are symmetric if the part has a symmetrical condition. This keyword is used with *INTERFACE_COMPENSATION_3D for METHOD = 7 or 8.

Card 1	1	2	3	4	5	6	7	8
Variable	SYMID	SYMXY	X0	Y0				
Type	I	I	F	F				
Default	1	none	0.0	0.0				

VARIABLE	DESCRIPTION
SYMID	ID of the symmetric condition being defined.
SYMXY	Code defining symmetric boundary conditions: EQ.1: symmetric about *y*-axis. EQ.2: symmetric about *x*-axis.
X0, Y0	Coordinates of a point on the symmetric plane.

Example:

In a complete keyword input example below, part set ID 1 is being compensated with symmetric boundary condition about *x*-axis. The symmetric plane passes a point with coordinates of $x = 101.5$, and $y = 0.0$.

```

Revision Information:

This keyword is available as of revision 63618. It was updated in Revision 83711.

*INCLUDE_COMPENSATION_TANGENT_CONSTRAINT

Purpose: Maintain tangency in the part boundary (along trim curves) between compensated and uncompensated areas of the tool. It also preserves the tangential transition off the rigid tool area at the trim curves to the addendum part of the tool. This keyword was replaced by the TANGENT variable under *INTERFACE_COMPENSATION_3D.

Card 1	1	2	3	4	5	6	7	8
Variable	UFLAG							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
UFLAG	Tangency flag: EQ.1: Maintain tangency between compensated and uncompensated parts of the tool and maintain tangential transition off the rigid tool area at the trim curves to the addendum part of the tool.

*INCLUDE_COMPENSATION_TRIM_CURVE

Purpose: Map trim curves of current tools onto the compensated tools. This keyword is used when springback predication is performed after trimming.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	Name of the keyword file containing x, y, z coordinates as defined using keyword *DEFINE_CURVE_TRIM_3D (only TCTYPE = 0 or 1 is supported). This option is used to map the trim curve to the new, compensated tooling mesh for next iterative simulation.

Remarks:

If the trimming curve is in IGES format, a new file, geocur.trm, will be generated after trimming. The file contains XYZ data of the trim curves under the keyword *DEFINE_-CURVE_TRIM_{OPTIONS}, which is used for the compensation run. Note that the variable TCTYPE in the keyword must be set to "0" (or "1") for the compensation. Length of lines everywhere in the compensated part are calculated according to springback amounts (including the die expansion factors, therefore no die expansion needs to be included in the NC machining of the compensated tooling). The manual pages for *INTERFACE_BLANKSIZE contain a procedure to convert IGES files to XYZ format in LS-PrePost.

Revision Information:

This keyword is available as of Revision 60398.

*INCLUDE_COMPENSATION_TRIM_NODE

Purpose: Ensure tangency continuity in the neighborhood of a trim curve. These nodes can also be generated from *INTERFACE_COMPENSATION_3D_REFINE_RIGID.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	bndnd0.tmp							

VARIABLE	DESCRIPTION
FILENAME	File that contains a list of nodes (in type I10 per line) along part trim curves to ensure tangency during compensation. This file can be generated from *INTERFACE_COMPENSATION_3D_-REFINE_RIGID.

Revision Information:

This keyword is available as of Revision 114206.

*INCLUDE_COMPENSATION_UPDATED_BLANK_SHAPE

Purpose: After compensation has been done, modify the compensated tool without the need to re-do the iterations to compensate the tool. This keyword must be used with *INCLUDE_COMPENSATION_UPDATED_RIGID_TOOL and *INTERFACE_COMPENSATION_3D_PART_CHANGE. Note that these options are intended only for small part changes that do not substantially affect the amount of springback. More details can be found in the manual pages for *INTERFACE_COMPENSATION_3D_PART_CHANGE.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	updatedpart.tmp							

VARIABLE	DESCRIPTION
FILENAME	Updated blank shape mesh that has been formed (or trimmed) to the shape based on the new tool geometry.

Revision Information:

This keyword is available as of Revision 82698.

*INCLUDE_COMPENSATION_UPDATED_RIGID_TOOL

Purpose: After compensation has been done, modify the compensated tool without the need to re-do the iterations to compensate the tool. This keyword must be used with *INCLUDE_COMPENSATION_UPDATED_BLANK_SHAPE and *INTERFACE_COMPENSATION_3D_PART_CHANGE. Note that these options are intended only for small part changes that do not substantially affect the amount of springback. More details can be found in the manual pages for *INTERFACE_COMPENSATION_3D_PART_CHANGE.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	newrigid.tmp							

VARIABLE	DESCRIPTION
FILENAME	Updated rigid tool mesh.

Revision Information:

This keyword is available as of Revision 82698.

*INCLUDE_COSIM

Purpose: To define an include file specifying the coupling interface across two models in different scales (global and local) running on an MPI based co-simulation. The input deck for each model should contain this keyword. The included file for each model gives the interface(s) for that model.

This feature requires MPP LS-DYNA version R13.1, R14.0 and newer versions.

The method invoked with this keyword differs from the method used with *INCLUDE_-MULTISCALE in that it imposes strong coupling. In the weak coupling method, the large-scale model imposes kinematic constraints on the small-scale model at the coupling interface and drives its deformation. The failure of the large-scale representative beams is determined by the small-scale analysis. The strong coupling method invoked with this keyword, in contrast, is a fully concurrent simulation across two scales. The large-scale model imposes the kinematic constraints on the small-scale model and obtains the kinetic response in return. Therefore, you do not provide a simplified representation of the small-scale model in the large-scale model.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	Name of a keyword input file that contains the coupling information, which includes sets of segments in the global scale model and sets of nodes in the local scale one. See Remark 1 and the example below.

Remarks:

1. **Overview of Multiscale Coupling Method.** This keyword is for specifying the coupling interface to exchange kinematic and kinetic information between global (large-scale) and local (small-scale) models running on two LS-DYNA MPP jobs. The global model is usually a large-scale structure, such as a full car model or printed circuit board (PCB). The local model should be much smaller in dimension. For instance, it could be spot welds, rivets, or solders. The smaller

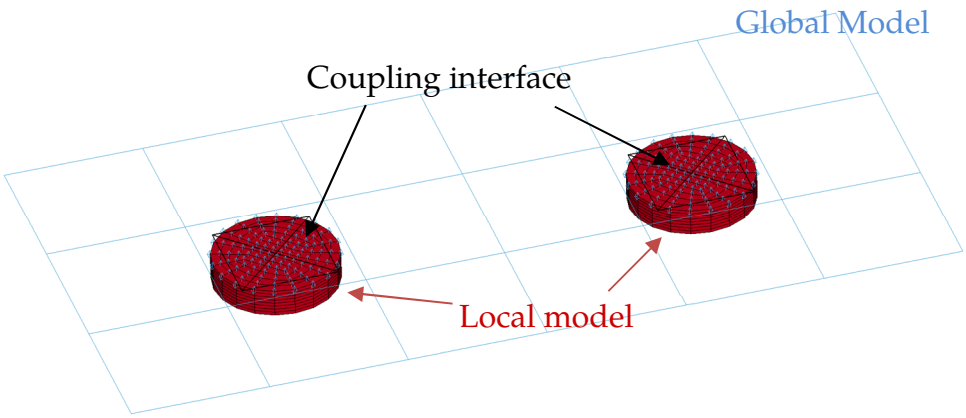

Figure 26-1. Example of tied contact coupling

dimension leads to a smaller mesh and time step size in explicit analysis. To accelerate the computation across global and local scales, you use two input files and run two LS-DYNA MPP jobs simultaneously with different time step sizes. The synchronization of time stepping information across the coupling interface is performed automatically at every time step of global model. The time step size of the local model is adjusted accordingly to guarantee the numerical consistency and accuracy of state variables at the coupling interface in the spatial and temporal domains.

For the global model, the interface is specified with a segment set (see *SET_SEGMENT). For the local model, the interface is specified with a node set (see *SET_NODE). These two sets must have the same set ID (SID) so that LS-DYNA knows how to couple the global and local models. Multiple sets of segments and nodes can be defined in the included files using *INCLUDE_COSIM for different coupling interfaces.

Two types of coupling algorithms are currently implemented:

a) *Tied contact*. With tied contact, the set of segments in the global model drives the motion of the set of nodes in the local model by imposing kinematic constraints on nodal translational DOFs. The local model returns the constraint forces interpolated onto the nodes of the set of global segments. To invoke this type of coupling, you must set the flag ITS to 1 for both the segment set and node set.

b) *Solid-in-shell immersion*. With solid-in-shell immersion, the local solid model occupies the same space as the global shell model at the coupling interface. The set of nodes in local model follows both the translational and rotational motion of the set of shell segments in the global model, while the nodes of the global segments obtain the constraint forces and moments in return. To

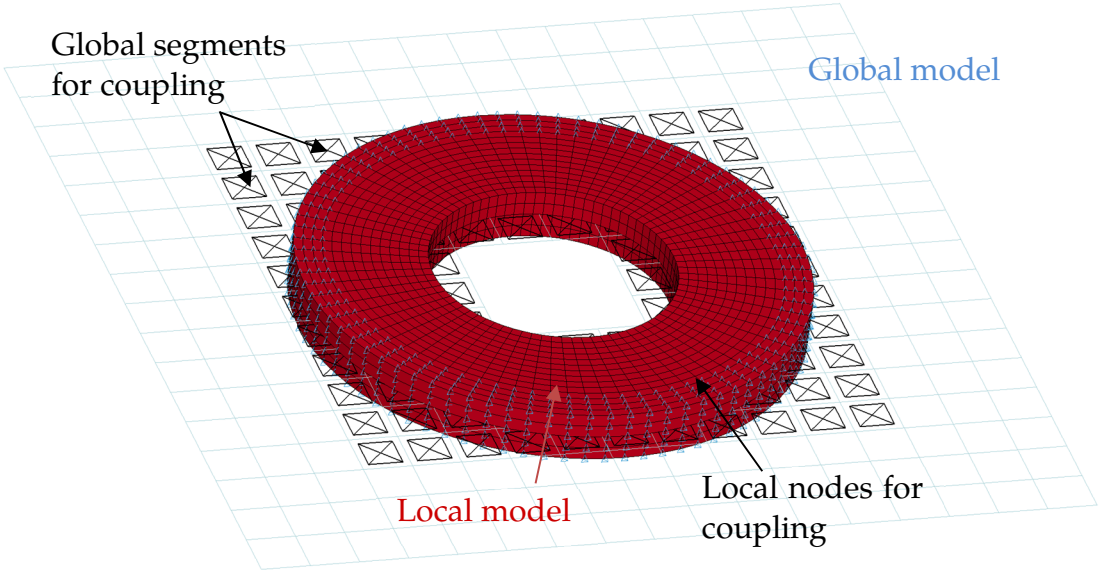

Figure 26-2. Example of solid-in-shell immersed coupling

invoke this type of coupling, you must set the flag ITS to 2 for both the segment set and node set.

2. **Running two LS-DYNA MPP jobs.** The specifics of running two LS-DYNA MPP jobs are installation dependent. The following is an example of running two LS-DYNA MPP jobs for two different scales, respectively:

mpirun -np 36 mppdyna i=input.k ncsp=24 jobid=jid

The "ncsp" flag informs LS-DYNA that the local model runs on a separated job using 24 out of the total 36 MPI processes. The main input file of the local model has to be named by that of the global model prefixed by 'cs_', and the main input files of both global and local models have to be in the same working folder. In practice, you can create an appfile file with the following lines:

```
-np 36 mppdyna i=input.k ncsp=24 jobid=jid
```

Then, for Linux, you run the problem with mpirun -f appfile. For Windows, the running command is mpiexec -configfile appfile.

The LS-DYNA message file contains a category called 'Two-scale Cosim' at normal termination. This timing information under this category gives the CPU time spent on the data exchange between two jobs through MPI communication. For good load balance between the two jobs, the number of MPI processes for the two jobs needs to be adjusted according to the time step size difference and other factors, such as number of elements and contacts.

All the LS-DYNA output and temporary files are separate for the two jobs. The 'cs_' is prefixed to all those files of local job run in order to avoid conflicts with the files from the global job.

3. **Termination Time.** The global and local files must have the same termination time specified with *CONTROL_TERMINATION.

4. **d3plot Output Interval.** The time interval of d3plot output set in both inputs must be the same to have time-consistent postprocessing database.

Example:

```

```

*INCLUDE_MULTISCALE

Purpose: Provide a detailed local model for a coupled multiscale simulation. The local model is coupled to heuristic beams in the large-scale model. Failure of the heuristic beams is determined through this local model. This type of simulation allows you to include details necessary for failure without using an infeasible time step. See the Remarks section for how this type of simulation should be set up and performed. This keyword is an extension of *INCLUDE_MULTISCALE_SPOTWELD for a more general local model.

This capability is available *only* in the MPP version of LS-DYNA.

Card 1	1	2	3	4	5	6	7	8
Variable	ID							
Type	I							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

VARIABLE	DESCRIPTION
ID	ID for this multiscale local model. This ID is used in the keyword *DEFINE_MULTISCALE. Any unique integer will do.
FILENAME	Name of file from which to read the local model definition.

Remarks:

With the multiscale feature, heuristic beams models are replaced with zoomed-in geometrically and constitutively correct continuum models, which, in turn are coupled to the large-scale calculation without reducing the time step. Because the detailed local models

are run in a separate process, they can run at a much smaller time step without slowing down the rest of the simulation. A brief outline of their use looks like this:

- You create one (or more) detailed local model of their beams and include these definitions into your model using the keyword *INCLUDE_MULTISCALE. In the large-scale model, the beams must be on the microscale model side of a tied interface.
- You indicate which beams should be coupled to these models with *DEFINE_-MULTISCALE.
- When MPP-DYNA is started, a special (MPI dependent) invocation is required to run in a "multiple program" mode. Effectively, two separate instances of MPP-DYNA are started together, one to run the full model and a separate instance to run the local models.
- As the macroscale process runs, each cycle it communicates to the microscale process deformation information for the area surrounding each coupled beam. The microscale process imposes this deformation on the detailed solid local models, computes a failure flag for each, and communicates this back to the macroscale process.
- The coupled beams in the macroscale process have their failure determined solely by these failure flags.

The file referred to on the *INCLUDE_MULTISCALE card should contain one generic instance of a detailed local model. For each coupled beam in the main model, a specific instance of this beam will be generated which is translated, rotated, and scaled to match the solid local model to which it is coupled. In this way, many beams can be coupled with only a single *INCLUDE_MULTISCALE. The included file should contain everything required to define a detailed local model, such as *MAT and *PART definitions, any required *DEFINE_CURVEs, etc., as well as *NODE and *ELEMENT definitions. For the translation and scaling to work properly, we make the following assumptions about the detailed local model:

- It consists entirely of solid elements.
- The z-axis is aligned with the coupled local model in the main model, with $z = 0$ and $z = 1$ at the two ends of the local model.
- The cross-sectional area of the local model in the xy-plane is equal to 1.
- That portion of the "top" and "bottom" of the local model that are coupled are identified using a single *SET_NODE_LIST card.
- One *BOUNDARY_COUPLED card referencing the *SET_NODE_LIST of the boundary nodes is required. It must specify a coupling type of 2 and a coupling program of 1.
- The detailed local model can include multiple parts.
- The detailed local model does not support *INCLUDE cards.

Failure of the local model is determined topologically. Any element of the detailed local model having all four nodes of one of its faces belonging to the *SET_NODE_LIST of tied nodes is classified as a "tied" element. The "tied" elements are partitioned into two disjoint sets: the "top," and "bottom". When there is no longer a complete path from any "top" to any "bottom" element (where a "path" passes through non-failed elements that share a common face), then this detailed model has failed. Note that this places some restrictions on the *SET_NODE_LIST and element geometry, namely that some "tied" elements exist, and the set of "tied" elements consists of exactly two disjoint subsets.

The specifics of launching a multi-program MPI program are installation dependent. But the idea behind running a coupled model is that you want to run one set of MPI ranks as if you were running a normal MPP-DYNA job, such as:

mpirun –np 4 mppdyna i=**input.k** memory=**200m** p=**pfile**

and a second set with just the command line argument "microscale" (no input file):

mpirun –np 4 mppdyna microscale memory=**100m** p=**pfile**

In practice, you can create an appfile file with the following:

```
-np 4 mppdyna i= input.k
-np 4 mppdyna microscale
```

Then, for Linux, run the problem with mpirun -f appfile. For Windows, the running command is mpiexec -configfile appfile.

The main instance knows to look for the microscale model (because of the presence of the *INCLUDE_MULTISCALE card) and will run the main model. The "microscale" instance will run all the detailed local models. Due to the nature of the coupling, the main model cannot progress when the detailed local models are being processed, nor can the detailed local models run while the main model is being computed. From a processor efficiency standpoint, it therefore makes sense to run as many microscale processes as macroscale processes, and run them on the same CPUs, so that each processing core has one microscale and one macroscale process running on it. But you don't have to – the processes are independent and you can have any number of either.

*INCLUDE_MULTISCALE_SPOTWELD

Purpose: Define a type of multiscale spot weld to be used for coupling and for modeling of spot weld failure.

Card 1	1	2	3	4	5	6	7	8
Variable	TYPE							
Type	I							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

VARIABLE	DESCRIPTION
TYPE	TYPE for this multiscale spot weld. This type is used in the keyword *DEFINE_SPOTWELD_MULTISCALE. Any unique integer will do.
FILENAME	Name of file from which to read the spot weld definition.

Remarks:

This capability is available *only* in the MPP version of LS-DYNA.

With the multiscale spot weld feature, heuristic spot weld models are replaced with zoomed-in geometrically and constitutively correct continuum models, which, in turn are coupled to the large-scale calculation without reducing the time step. In some respects, multiscale models are similar to the "hex spot weld assemblies," capability but more general in terms of their geometry. Because the spot weld models are run in a separate process, they can run at a much smaller time step without slowing down the rest of the simulation. A brief outline of their use looks like this:

- You create one (or more) detailed models of your spot welds and include these definitions into your model using the keyword *INCLUDE_MULTISCALE_-SPOTWELD. In the large-scale model, the spot weld must be on the tracked (SURFA) side of a tied interface.
- You indicate which beam (or hex assembly) spot welds should be coupled to these models with the keyword *DEFINE_SPOTWELD_MULTISCALE
- When MPP-DYNA is started, a special (MPI dependent) invocation is required in order to run in a "multiple program" mode. Effectively, two separate instances of MPP-DYNA are started together, one to run the full model (macroscale) and a separate instance to run the spot welds (microscale).
- As the macroscale process runs, each cycle it communicates deformation information for the area surrounding each coupled spot weld to the microscale process. The microscale process imposes this deformation on the detailed spot welds, computes a failure flag for each, and communicates this back to the macroscale process.
- The coupled spot welds in the macroscale process have their failure determined solely by these failure flags.

The file referred to on the *INCLUDE_MULTISCALE_SPOTWELD card should contain one generic instance of a detailed spot weld. For each coupled spot weld in the main model, a specific instance of this spot weld will be generated which is translated, rotated, and scaled to match the spot weld to which it is coupled. In this way, many spot welds can be coupled with only a single *INCLUDE_MULTISCALE_SPOTWELD. The included file should contain everything required to define the spot weld, such as *MAT and *PART definitions, any required *DEFINE_CURVEs, etc., as well as *NODE and *ELEMENT definitions. For the translation and scaling to work properly, we assume the following about the spot weld model:

- It consists entirely of solid elements.
- The z-axis is aligned with the coupled spot weld in the main model, with $z = 0$ and $z = 1$ at the two ends of the spot weld.
- The cross-sectional area of the spot weld in the xy-plane is equal to 1.
- The portion of the "top" and "bottom" of the spot weld that are coupled are identified using a single *SET_NODE_LIST card.
- One *BOUNDARY_COUPLED card referencing the *SET_NODE_LIST of the boundary nodes is required. It must specify a coupling type of 2 and a coupling program of 1.
- The spot weld model does not support *INCLUDE cards.

Failure of the microscale model is determined topologically. Any element of the spot weld having all four nodes of one of its faces belonging to the *SET_NODE_LIST of tied nodes is classified as a "tied" element. The "tied" elements are partitioned into two

disjoint sets: "top" and "bottom". When there is no longer a complete path from any "top" to any "bottom" element (where a "path" passes through non-failed elements that share a common face), then the spot weld has failed. Note that this places some restrictions on the *SET_NODE_LIST and element geometry, namely that some "tied" elements exist, and the set of "tied" elements consists of exactly two disjoint subsets.

The specifics of launching a multi-program MPI program are installation dependent. But the idea behind running a coupled model is that you want to run one set of MPI ranks as if you were running a normal MPP-DYNA job, such as:

mpirun –np 4 mppdyna i=**input.k** memory=**200m** p=**pfile**

and a second set with just the command line argument "microscale" (no input file):

mpirun –np 4 mppdyna microscale memory=**100m** p=**pfile**

The main instance knows to look for the microscale instance (because of the presence of the *INCLUDE_MULTISCALE_SPOTWELD card) and will run the main model. The "microscale" instance will run all the detailed spot weld models. Due to the nature of the coupling, the main model cannot progress when the detailed spot welds are being processed, nor can the detailed spot welds run while the main model is being computed. From a processor efficiency standpoint, it therefore makes sense to run as many microscale processes as macroscale processes, and run them on the same CPUs, so that each processing core has one microscale and one macroscale process running on it. But you don't have to: the processes are independent, and you can have any number of either.

***INCLUDE_PATH**_{OPTION}

Available options include:

<BLANK>

RELATIVE

Purpose: Define directories in which to look for include files. LS-DYNA's default behavior is to search for files in the local directory first. If an include file is not found and the filename has no path, LS-DYNA will search for it in all the directories defined by *INCLUDE_PATH.

When the RELATIVE option is used, all directories are relative to the location of the input file. For example, if "i=/home/test/problems/input.k" is given on the command line, and the input contains

```
*INCLUDE_PATH_RELATIVE
includes
../includes
```

then the two directories /home/test/problems/includes and /home/test/includes will be searched for include files.

Pathname Card. Directory paths are read until the next keyword ("*") card is encountered. A directory path can have up to 236 characters (see Remark 2).

Card 1	1	2	3	4	5	6	7	8
Variable	PATHNAME							
Type	C							

VARIABLE	DESCRIPTION
PATHNAME	Directory path. If the RELATIVE keyword option is used, this directory is relative to the input file.

Remarks:

1. **Pathname Length Limitations.** Pathnames are limited to 236 characters spread over up to three 80 character lines. When 2 or 3 lines are needed to specify the pathname, end the preceding line with "␣+" (space followed by a plus sign) to signal that a continuation line follows. Note that the "␣+" combination is, itself,

part of the 80 character line; hence the maximum number of allowed characters is 78 + 78 + 80 = 236.

***INCLUDE_STAMPED**_*OPTION1_{OPTION2}_{OPTION3}_{OPTION4}*

Purpose: Map the plastic strain and thickness distribution of a shell part or part set from a stamping simulation (source part or part) to a shell part or part set in a crash model (target part or part set). This keyword only applies to shell elements.

Available options for *OPTION1* include:

PART

SET

For PART a stamped part is mapped while for SET a stamped part set is mapped.

OPTION2 only applies when *OPTION1* is PART:

<BLANK>

SET

If SET is used, PID will be a part set ID. All the parts included in this set will be considered in this mapping. Note that *INCLUDE_STAMPED_PART_SET and *INCLUDE_-STAMPED_SET are equivalent keyword names, meaning they call the same subroutines in LS-DYNA.

The available options for *OPTION3* are:

<BLANK>

MATRIX

If MATRIX is used, the transformation matrix with a translation vector will be read directly, and the orientation nodes will be ignored.

The available options for *OPTION4* are:

<BLANK>

INVERSE

INVERSE can only be included if MATRIX is included in *OPTION3*. If used, the matrix will be inverted. This keyword option is useful for the case where you have the transformation from the crash part to the stamped part.

When STAMPED_SET or STAMPED_PART_SET is used, the target is a part set. Between the stamped part and the crash part, note the following points:

1. The outer boundaries of the parts do not need to match since only the regions of the crash part which overlap the stamped part are initialized.
2. Arbitrary mesh patterns are assumed.
3. Element formulations can change.
4. Three nodes on each part are used to reorient the stamped part for the mapping of the strain and thickness distributions. After reorientation, the three nodes on each part should approximately coincide.
5. The number of in plane integrations points can change.
6. The number of through thickness integration points can change. Full interpolation is used.
7. The node and element IDs between the stamped part and the crash part do not need to be unique.

Card Summary:

Card 1. This card is required.

FILENAME

Card 2. This card is required.

PID	THICK	PSTRN	STRAIN	STRESS	INCOUT		RMAX

Card 3a. This card is included if the keyword option MATRIX is not used.

Card 3b.2. This card is included if the keyword option MATRIX is used.

R21	R22	R23	YP				

Card 3b.3. This card is included if the keyword option MATRIX is used.

R31	R32	R33	ZP				

Card 4. This card is optional.

ISYM	IAFTER	PERCELE	IORTHO		ISRCOUT		

Card 5. This card is optional.

X01	Y01	Z01					

Card 6. This card is optional.

X02	Y02	Z02	X03	Y03	Z03		

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

VARIABLE	DESCRIPTION
FILENAME	Name of file to be included; see Remark 2. This is the dynain file containing the metal stamping result.

Card 2	1	2	3	4	5	6	7	8
Variable	PID	THICK	PSTRN	STRAIN	STRESS	INCOUT		RMAX
Type	I	I	I	I	I	I		F
Default	none	0	0	0	0	0		20.0

VARIABLE	DESCRIPTION
PID	Part or part set ID of crash part/parts for remapping
THICK	Thickness remap: EQ.0: Map thickness EQ.1: Do not map thickness EQ.2: Average value inside a circle defined by RMAX

VARIABLE	DESCRIPTION
PSTRN	Plastic strain remap: EQ.0: Map plastic strain EQ.1: Do not map plastic strain EQ.2: Average value inside a circle defined by RMAX
STRAIN	Strain remap: EQ.0: Map strains EQ.1: Do not map strains
STRESS	Stress tensor remap: EQ.0: Map stress tensor and history variables EQ.1: Do not map stress tensor, only history variables EQ.2: Do not map stress tensor or history variables EQ.-1: Map stress tensor in an internal large format (binary files) EQ.-3: Do not map stress tensor in an internal large format, only history variables (binary files)
INCOUT	Save mapped data: EQ.1: Save the mapped data for the part/part set (PID) to a file called dyna.inc. This option is useful for when the mapped data may be required in a future simulation. EQ.2: Save the mapped data for the specified part or part set (PID) to a file called dynain_xx (xx is the part or part set ID). EQ.3: Save the mapped data for the specified part or part set (PID) to a file called nastran_xx (in nastran format). xx is the part or part set ID. Note that INCOUT does *not* account for changes in the number of in-plane or through thickness integration points.
RMAX	Search radius. LS-DYNA remaps history variables from the mesh of the stamped part to the mesh of the crash part with a spatial tolerance of RMAX. If an element in the crash part lies within RMAX of the stamped part, data will be mapped to that element. If set less than 0.001, RMAX automatically assumes the default value of 20.

Nodal Orientation Card. This card is included if the MATRIX option is *not* used.

Card 3a	1	2	3	4	5	6	7	8
Variable	N1S	N2S	N3S	N1C	N2C	N3C	TENSOR	THKSCL
Type	I	I	I	I	I	I	I	F
Default	0	0	0	0	0	0	0	1.0
Remarks	1	1	1	1	1	1	3	

VARIABLE	DESCRIPTION
N1S	First of 3 nodes needed to reorient the stamped part or part set
N2S	Second of 3 nodes needed to reorient the stamped part or part set
N3S	Third of 3 nodes needed to reorient the stamped part or part set
N1C	First of 3 nodes needed to reorient the crash model part or part set
N2C	Second of 3 nodes needed to reorient the crash model part or part set
N3C	Third of 3 nodes needed to reorient the crash model part or part set
TENSOR	Tensor remap: EQ.0: Map tensor data from history variables. EQ.1: Do not map tensor data from history variables
THKSCL	Thickness scale factor

Transformation Matrix Card 1. This card is included if the MATRIX keyword option is used.

Card 3b.1	1	2	3	4	5	6	7	8
Variable	R11	R12	R13	XP				
Type	F	F	F	F				
Default	0	0	0	0				

Transformation Matrix Card 2. This card is included if the MATRIX keyword option is used.

Card 3b.2	1	2	3	4	5	6	7	8
Variable	R21	R22	R23	YP				
Type	F	F	F	F				
Default	0	0	0	0				

Transformation Matrix Card 3. This card is included if the MATRIX keyword option is used.

Card 3b.3	1	2	3	4	5	6	7	8
Variable	R31	R32	R33	ZP				
Type	F	F	F	F				
Default	0	0	0	0				

VARIABLE	DESCRIPTION
R*ij*	Components of the transformation matrix (see Remark 1)
XP, YP, ZP	Translational distance (see Remark 1)

This card is optional.

Card 4	1	2	3	4	5	6	7	8
Variable	ISYM	IAFTER	PERCELE	IORTHO		ISRCOUT		
Type	I	I	F	I		I		

VARIABLE	DESCRIPTION
ISYM	Symmetric switch EQ.0: No symmetric mapping EQ.1: *yz* plane symmetric mapping EQ.2: *zx* plane symmetric mapping EQ.3: *zx* and *yz* planes symmetric mapping EQ.4: User defined symmetric plane mapping
IAFTER	Mirroring sequence switch EQ.0: Generate a symmetric part before transformation EQ.1: Generate a symmetric part after transformation
PERCELE	Percentage of elements that should be mapped for the simulation to proceed (default = 0); otherwise an error termination occurs. See Remark 5.
IORTHO	Location of the material direction cosine in the array of history variables of an orthotropic material. See Remark 4.
ISRCOUT	Optional output of stamped part after transformation(s) EQ.0: No output is written. NE.0: Keyword output file "srcmsh_<ISRCOUT>" is created.

This card is optional.

Card 5	1	2	3	4	5	6	7	8
Variable	X01	Y01	Z01					
Type	F	F	F					

This card is optional.

Card 6	1	2	3	4	5	6	7	8
Variable	X02	Y02	Z02	X03	Y03	Z03		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
X01, Y01, Z01	First point in the symmetric plane (required if ISYM ≠ 0)
X02, Y02, Z02	Second point in the symmetric plane
X03, Y03, Z03	Third point in the symmetric plane

Remarks:

1. **Reorienting the Result of a Stamping Simulation.** The target mesh must be read in before including the stamped part with this keyword.

   If the MATRIX keyword is not used, N1S, N2S, N3S, N1C, N2C, and N3C are used for transforming the stamped part to the crash part, such that it is in the same position as the crash part. If the stamped part is in the same position as the crash part then N1S, N2S, N3S, N1C, N2C, N3C can all be set to 0. Note that if these 6 nodes are input as 0, LS-DYNA will not transform the stamped part. With the MATRIX keyword option, a transformation matrix with a translation vector reorients the part instead of nodes.

   When symmetric mapping is used (ISYM is nonzero), the three points should not be in one line. If ISYM = 1, 2, or 3, only the first point, namely (X01, Y01, Z01), is needed. If ISYM = 4, all three points are needed.

2. **File Name Length Limitations.** Filenames are limited to 236 characters spread over up to three 80 character lines. When 2 or 3 lines are needed to specify the filename or pathname, end the preceding line with "␣+" (space followed by a plus sign) to signal that a continuation line follows. Note that the "␣+" combination is, itself, part of the 80 character line; hence the maximum number of allowed characters is 78 + 78 + 80 = 236.

3. **Mapping Material Data for Springback.** Certain material models (notably Material 190) have tensor data stored within the history variables. Within material subroutines this data is typically stored in element local coordinate systems. In

order to properly map this information between models it is necessary to have the tensor data present on the *INITIAL_STRESS_SHELL card and have it stored in global coordinates. During mapping the data is then converted into the local coordinate system of the crash mesh. This data can be dumped into the dynain file that is created at termination time if the parameter FTENSR is set to 0 on the *INTERFACE_SPRINGBACK_LSDYNA card. Currently, the only material model that supports mapping of element history tensor data is Material 190.

4. **IORTHO.** If IORTHO is set, correct mapping between non-matching meshes is invoked for the directions of orthotropic materials. A list of appropriate values for several materials is given here:

   IORTHO.EQ.1: materials 23, 122, 157, 234

   IORTHO.EQ.3: materials 22, 33, 36, 133, 189, 233, 243

   IORTHO.EQ.4: material 59

   IORTHO.EQ.6: materials 58, 104, 158

   IORTHO.EQ.8: materials 54, 55

   IORTHO.EQ.9: material 39

   IORTHO.EQ.10: material 82

   IORTHO.EQ.13: materials 2, 86, 103

5. **Mapping Mismatch.** Sometimes during mapping the two meshes (stamping mesh and crash mesh) do not match exactly, and therefore not all elements of the new mesh obtain results from the old mesh. The message file contains the total number of crash elements which are / are not mapped. By default (PERCELE = 0), the calculation continues even when no elements are mapped. PERCELE > 0 allows you to define the minimum percentage of required mapped elements for the calculation to proceed. If a percentage less than PERCELE is mapped, the calculation stops with an error termination.

*INCLUDE_STAMPED_PART_SOLID_TO_SOLID

This keyword maps the final stress and strain tensors, history variables, and plastic strain of a solid part in one model (source part) to the corresponding solid part in a second model (target part). The total thickness of the target part is adjusted as necessary to match the final thickness of the source part. This feature was designed for the situation where the source part is a thick blank from a forming analysis and the target part is in a vehicle crash model. The mesh refinements of the two parts may differ. Differences in the spatial location of the target part and source part are allowed (see fields on Card 3). This keyword has several limitations which are discussed in the next paragraph and in Remark 2.

This mapping feature applies only to 8-noded hexahedral and 6-noded pentahedral elements as consistent, through-thickness orientation of solid element normals is required. *INCLUDE_STAMPED_PART_SOLID_TO_SOLID *must* be the final keyword in the second input deck.

Card Summary:

Card 1. This card is required.

FILENAME

Card 2. This card is required.

PID	THICK	PSTRN	STRAIN	STRESS			

Card 3. This card is required.

N1SORC	N2SORC	N3SORC	N1TRGT	N2TRGT	N3TRGT		

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

VARIABLE	DESCRIPTION
FILENAME	File name of the dynain file created by *INTERFACE_SPRINGBACK_LSDYNA in the source model.

Card 2	1	2	3	4	5	6	7	8
Variable	PID	THICK	PSTRN	STRAIN	STRESS			
Type	I	I	I	I	I			
Default	none	0	0	0	0			

VARIABLE	DESCRIPTION
PID	Part ID of the target part onto which the source model's results in FILENAME will be mapped. LT.0: part ID of the target part is |PID| and the normals of the target part are flipped before mapping. A negative PID would be used if the target part's normals were oriented exactly opposite those of the source part.
THICK	Flag to map part thickness. The thickness direction is determined from the element normals, hence the need for consistency in the element normals. The thicknesses of the target part elements are adjusted so the target part thickness matches the source part thickness at any given location. Currently, this variable is hardwired so that thickness mapping is always on.
PSTRN	Flag to map effective plastic strain. Currently setting this flag with any integer will map the effective plastic strain, and there is no other option. EQ.0: map effective plastic strain. NE.0: do not map effective plastic strain.
STRAIN	Flag to map the strain tensor. Currently setting this flag with any integer will map the tensorial strains, and there is no other option available. Note "STRFLG" in *DATABASE_EXTENT_BINARY must be set to "1" for output to d3plot as well as dynain files. EQ.0: map strain tensor. NE.0: do not map strain tensor.

VARIABLE	DESCRIPTION
STRESS	Flag to map stress tensor. Currently setting this flag with any integer will map the stresses and history variables, and there is no other option available. Only the history variables included in the dynain file specified by FILENAME are mapped; see "NSHV" in *INTERFACE_SPRINGBACK_LSDYNA for control of history variable output to dynain. EQ.0: map stress tensor and history variables. NE.0: do not map stress tensor and history variables.

Card 3	1	2	3	4	5	6	7	8
Variable	N1SORC	N2SORC	N3SORC	N1TRGT	N2TRGT	N3TRGT		
Type	I	I	I	I	I	I		
Default	0	0	0	0	0	0		

VARIABLE	DESCRIPTION
N1SORC	First of 3 nodes needed to reorient the source part. No transformation if undefined.
N2SORC	Second of 3 nodes needed to reorient the source part. No transformation if undefined.
N3SORC	Third of 3 nodes needed to reorient the source part. No transformation if undefined.
N1TRGT	First of 3 nodes needed to reorient the target part. No transformation if undefined.
N2TRGT	Second of 3 nodes needed to reorient the target part. No transformation if undefined.
N3TRGT	Third of 3 nodes needed to reorient the target part. No transformation if undefined.

Remarks:

1. **Element Normals.** The solid element normals in the source model and the target model part must be consistent with each other and in the through-thickness direction of the part. The first three nodes of the solid determine the bottom face and the element normal is the normal to that face using the right-hand rule. Solid element normals can be displayed and modified using *EleTol* → *Normal* → *Solid* in LS-PrePost.

2. **Geometry Limitations.** This keyword was designed with a particular application in mind: mapping results from a forming analysis of a thick blank. It is not designed to handle situations where the target part's geometry is dissimilar from the source part's geometry, such as where the target part has a hole but the source part does not. See *INITIAL_LAG_MAPPING for a more general solid-to-solid mapping capability.

Example:

The following keyword example maps the stress and strain tensors, history variables and effective plastic strain from a stamped (source) solid blank mesh drawn.dynain with PID 1, onto a coarser mesh (target) s1.k with PID 2.

The mapping may be checked from the dynain file created after a single time step (note that the termination time is set to 0.0 for this purpose).

Revision Information:

This feature is available starting in Dev. 129927. Strain tensor output is available starting in Dev. 135317. Output suppression is available for strain, stress tensor or effective plastic strain starting in Dev. 135892. The requirements for blank Cards 4, 5 and 6 were removed starting in Dev. 135480.

*INCLUDE_TRIM

Purpose: The naive procedure to trim a part imported using the *INCLUDE keyword involves: (1) including the part using *INCLUDE; (2) designating the part for trimming using *CONTROL_FORMING_TRIMMING; and (3) defining trim curves using *DEFINE_TRIM_CURVE. By replacing *INCLUDE in step (1) with this keyword, namely, *INCLUDE_TRIM, LS-DYNA is directed to filter the included part while reading in the include file (as opposed to after reading in), thereby saving memory that would otherwise be allocated to store the (immediately) discarded data. This feature has been developed in conjunction with the *Ford Motor Company Research and Advanced Engineering Laboratory*.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							

VARIABLE	DESCRIPTION
FILENAME	File name of the part to be trimmed

Remarks:

Similar to the trimming method with *INCLUDE, the name of the file to be trimmed must be put into the FILENAME field. Unlike the *INCLUDE method, all information about the included part (such as stress and strain) should be in the named file (as opposed to split across several files). *INCLUDE_TRIM *cannot* be used unless the included file contains stress and strain information. Namely, the dynain file must contain *INITIAL_STRESS_SHELL and *INITIAL_STRAIN_SHELL cards; otherwise the *INCLUDE keyword should be used instead.

For solid element trimming, the keyword *INCLUDE_TRIM *must* be used. In other words, the dynain file from a previous process (for example, a forming simulation) must be included in a main trim file using *INCLUDE_TRIM (not *INCLUDE). Refer to the *DEFINE_CURVE_TRIM manual entry for more details.

For example, a drawn panel from a previous simulation can be included in a current simulation for trimming as follows,

```
*INCLUDE_TRIM
Drawnpanel.dynain
*CONTROL_FORMING_TRIMMING
      ⋮
*DEFINE_CURVE_TRIM_3D
```

```
        ⋮
*CONTROL_ADAPTIVE_CURVE
        ⋮
```

Performance Improvements:

Referring to the table below (parts courtesy of the *Ford Motor Company*), compared with *INCLUDE, the *INCLUDE_TRIM keyword reduces memory requirements by more than 50%. Levels of CPU time reductions exceed in some cases 50%.

Performance Improvements

		Roof	Hood Inr	B-Plr	Fender	BSA Otr	Door Otr	Wheel House (2 in 1)	Boxside Otr
#Element		410810	1021171	351007	189936	380988	315556	261702	1908369

	new	4m	9m18s	2m56s	1m22s	4m54s	3m35s	2m30s	13m59s
Memory (MW)	old	282	616	221	119	233	217	157	1150
	new	112	383	117	50	130	114	75	539

Revision Information:

This feature is available in LS-DYNA Revision 62207 or later releases, where the output of strain tensors for the shells is included. Prior Revisions do not include strain tensors for the shells.

*INCLUDE_UNITCELL

Purpose: This card creates a unit cell model with periodic boundary conditions using *CONSTRAINED_MULTIPLE_GLOBAL.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	INPT	OUPT	NEDOF					
Type	I	I	I					
Default	0	0	0					
Remarks	1		2					

Card 3	1	2	3	4	5	6	7	8
Variable	DX	DY	DZ	NEX	NEY	NEZ	NNPE	TOL
Type	F	F	F	I	I	I	I	F
Default	1.0	1.0	1.0	1	1	1	8	↓

Card 4	1	2	3	4	5	6	7	8
Variable	NOFF	EOFF	PNM					
Type	I	I	I					
Default	none	none	none					

Card 5	1	2	3	4	5	6	7	8
Variable	CNX	CNY	CNZ					
Type	I	I	I					
Default	none	none	none					

Node ID Cards. Included as many cards as needed. See Remark 2. Input is terminated at the next keyword ("*") card

Card 6	1	2	3	4	5	6	7	8
Variable	ECNX	ECNY	ECNZ					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
FILENAME	Name of the file containing the information about the unit cell
INPT	Type of input: EQ.0: Read *NODE information from the include file and add periodic boundary conditions to the include file. EQ.1: Create a unit cell mesh with periodic boundary conditions, and output to the include file.

VARIABLE	DESCRIPTION
OUPT	Type of output: EQ.1: Create a new main keyword file where the keyword *INCLUDE_UNITCELL is replaced by *INCLUDE with the include file name.
NEDOF	Number of extra nodal degrees of freedom (DOFs) for user-defined element. In the current implementation, the limit of NEDOF is 15.
DX	Length of the unit cell in the x-direction
DY	Length of the unit cell in the y-direction
DZ	Length of the unit cell in the z-direction
NEX	Number of elements along the x-direction
NEY	Number of elements along the y-direction
NEZ	Number of elements along the z-direction
NNPE	Number of nodes per element. The current implementation supports only 4-node tetrahedron or 8-node hexahedron elements.
TOL	Tolerance for searching for each pair of nodes in the periodic positions to create the periodic boundary conditions. This tolerance may be needed because numerical errors in the mesh can cause the coordinates of the pairs of nodes to *not* be exactly in the periodic positions. The default tolerance is computed based on the size of unit cell.
NOFF	Offset of node IDs
EOFF	Offset of element IDs
PNM	Part ID
CNX	Node ID of the 1st control point for the constraint in the x direction
CNY	Node ID of the 2nd control point for the constraint in the y direction
CNZ	Node ID of the 3rd control point for the constraint in the z direction
ECNX	Node ID of extra control point for the constraint in x direction of 3 extra nodal DOFs

VARIABLE	DESCRIPTION
ECNY	Node ID of extra control point for the constraint in y direction of 3 extra nodal DOFs
ECNZ	Node ID of extra control point for the constraint in z direction of 3 extra nodal DOFs

Remarks:

1. **Include File Field.** If INPT = 0, the geometry and discretization information for the unit cell are from the include file. In this case, the parameters set on Cards 3 and 4 are ignored.

2. **Extra Degrees of Freedom.** The extra degrees of freedom (DOFs) specified by NEDOF > 0 are represented by extra nodes with regular x, y and z DOFs. When NEDOF = 7, for example, the following chart shows the mapping from the extra DOFs to the regular ones of extra nodes:

Extra Node #	Extra DOFs	Regular DOFs
1	1	x
	2	y
	3	z
2	4	x
	5	y
	6	z
3	7	x

In this case, 3 control points for x, y, and z directions, respectively, need to be defined for each extra node.

*INCLUDE_WD

The *INCLUDE_WD keywords are needed during a weld line development calculation caused by including *INTERFACE_WELDLINE_DEVELOPMENT in the input deck. This feature outputs either the initial or final predicted welding curve. This feature requires the following *INCLUDE_WD keywords listed below in the order that they must appear in the input deck following *INCLUDE_WELDLINE_DEVELOPMENT:

*INCLUDE_WD_INITIAL_BLANK

*INCLUDE_WD_FINAL_PART

*INCLUDE_WD_WELDING_CURVE

*INCLUDE_WD_FINAL_PART

Purpose: Include the keyword format file that consists of geometry information for the final formed blank. This file is read to perform a weld line development calculation. This keyword must be used with *INTERFACE_WELDLINE_DEVELOPMENT and must follow *INCLUDE_WD_INITIAL_BLANK in the keyword deck. See *INTERFACE_WELDLINE_DEVELOPMENT for more details.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	File name of the final formed blank in keyword format, consisting of *NODE and *ELEMENT_SHELL information

*INCLUDE_WD_INITIAL_BLANK

Purpose: Include the keyword format file that defines the geometry information for the initial sheet blank. This file is read to perform a weld line development calculation. This keyword must be used with and must directly follow *INTERFACE_WELDLINE_DEVELOPMENT (see there for more details).

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	File name of the initial sheet blank in keyword format, consisting of *NODE and *ELEMENT_SHELL information.

*INCLUDE_WD_WELDING_CURVE

Purpose: Include the keyword format file that defines the welding curve (see *DEFINE_-CURVE_TRIM_3D) to perform a weld line development calculation. This keyword must be used with *INTERFACE_WELDLINE_DEVELOPMENT. Depending on the value of IOPTION on *INTERFACE_WELDLINE_DEVELOPMENT, this file defines either the final or initial welding curve. This keyword must follow *INCLUDE_WD_FINAL_PART directly. See *INTERFACE_WELDLINE_DEVELOPMENT for more details.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	File name of the welding curve in keyword format (see *DEFINE_-CURVE_TRIM_3D). If IOPTION = 1 on *INTERFACE_WELD-LINE_DEVELOPMENT, it should define the final welding curve. If IOPTION = -1, it should define the initial welding curve.

*INITIAL

The keyword *INITIAL provides a way of initializing velocities and detonation points. The keyword control cards in this section are defined in alphabetical order:

*INITIAL_AIRBAG_PARTICLE_POSITION

*INITIAL_ALE_MAPPING

*INITIAL_AXIAL_FORCE_BEAM

*INITIAL_CONTACT_WEAR

*INITIAL_CRASHFRONT

*INITIAL_DETONATION

*INITIAL_DETONATION_GEOMETRY

*INITIAL_EOS_ALE

INITIAL_FATIGUE_DAMAGE_RATIO_*{OPTION}

INITIAL_FOAM_REFERENCE_GEOMETRY_*{OPTION}

*INITIAL_GAS_MIXTURE

*INITIAL_HISTORY_NODE

*INITIAL_HYDROSTATIC_ALE

INITIAL_IMPULSE_MINE

INITIAL_INTERNAL_DOF_SOLID_*OPTION

INITIAL_LAG_MAPPING_*{OPTION}

*INITIAL_MOMENTUM

INITIAL_PWP_DEPTH_*{OPTION}

*INITIAL_PWP_NODAL_DATA

*INITIAL_SOLID_VOLUME

*INITIAL_STRAIN_IGA_SHELL

INITIAL_STRAIN_SHELL_*{OPTION}

*INITIAL_STRAIN_SHELL_NURBS_PATCH

INITIAL_STRAIN_SOLID_*{OPTION}

*INITIAL_STRAIN_SOLID_NURBS_PATCH

*INITIAL_STRAIN_TSHELL

*INITIAL_STRESS_BEAM

INITIAL_STRESS_DEPTH_*{OPTION}

*INITIAL_STRESS_DES

*INITIAL_STRESS_IGA_SHELL

*INITIAL_STRESS_SECTION

INITIAL_STRESS_SHELL_*{OPTION}

*INITIAL_STRESS_SHELL_NURBS_PATCH

INITIAL_STRESS_SOLID_*{OPTION}

*INITIAL_STRESS_SOLID_NURBS_PATCH

*INITIAL_STRESS_SPH

*INITIAL_STRESS_TSHELL

INITIAL_TEMPERATURE_*OPTION

*INITIAI_VAPOR_PART

*INITIAL_VEHICLE_KINEMATICS

There are two alternative sets of keywords for setting initial velocities. Cards from one set cannot be combined with cards from the other. **Standard velocity cards:**

*INITIAL_VELOCITY

*INITIAL_VELOCITY_NODE

*INITIAL_VELOCITY_RIGID_BODY

Alternative initial velocity cards supporting initial rotational about arbitrary axes and start times. **Alternative velocity cards:**

*INITIAL_VELOCITY_GENERATION

*INITIAL_VELOCITY_GENERATION_START_TIME

INITIAL_VOID_*OPTION

INITIAL_VOLUME_FRACTION_*{OPTION}

*INITIAL_VOLUME_FRACTION_GEOMETRY

*INITIAL_AIRBAG_PARTICLE_POSITION

Purpose: This card initializes the position of CPM initial air particle to the location specified.

Card 1	1	2	3	4	5	6	7	8
Variable	Bag_ID							
Type	I							
Default	none							

Particle Cards. The i^{th} card specifies the location of the i^{th} particle. LS-DYNA expects one card for each particle, if fewer cards are supplied the coordinates will be reused and particles may share the same location at the beginning of the simulation.

Card	1	2	3	4	5	6	7	8
Variable		X	Y	Z				
Type	8x	F	F	F				
Default								

VARIABLE	DESCRIPTION
Bag_ID	Airbag ID defined in *AIRBAG_PARTICLE_ID card
X	*x* coordinate
Y	*y* coordinate
Z	*z* coordinate

*INITIAL_ALE_MAPPING

Purpose: This card initializes the current ALE run with data from the last cycle of a previous ALE run. Data are read from a mapping file specified by "map=" on the command line (see Remark 6). To map data histories (not just the last cycle) to a region of selected elements, see *BOUNDARY_ALE_MAPPING.

The following transitions are allowed:

1D → 2D	2D → 2D	3D → 3D
1D → 3D	2D → 3D	3D → 2D

Card 1	1	2	3	4	5	6	7	8
Variable	PID	TYP	AMMSID					
Type	I	I	I					
Default	none	none	none					

Card 2	1	2	3	4	5	6	7	8
Variable	XO	YO	ZO	VECID	ANGLE	SYM	TBEG	
Type	F	F	F	I	F	I	F	
Default	0.0	0.0	0.0	none	none	0	0.0	

VARIABLE	DESCRIPTION
PID	Part ID or part set ID.
TYP	Type of "PID" (see Remark 1): EQ.0: Part set ID (PSID). EQ.1: Part ID (PID).
AMMSID	Set ID of ALE multi-material groups defined in *SET_MULTI-MATERIAL_GROUP. See Remark 1.
XO	Origin position in global x-direction. See Remarks 2 and 5.

VARIABLE	DESCRIPTION
YO	Origin position in global y-direction. See Remarks 2 and 5.
ZO	Origin position in global z-direction. See Remarks 2 and 5.
VECID	ID of the symmetric axis defined by *DEFINE_VECTOR. See Remarks 3 and 5.
ANGLE	Angle of rotation in degrees around an axis defined by *DEFINE_VECTOR for the 3D to 3D mapping. See Remark 4.
SYM	Treatment of the elements and nodes that are out of the mapping bounds (meaning the coordinates of their projections on the previous mesh are outside this mesh). SYM is a 6-digit parameter. Each digit represents a plane for a box that encloses the previous mesh. These planes are parallel to the previous coordinate system. The value of the digit determines the rule to be applied, so any combination of rules may be used. EQ.00000p: Rule for the X-plane along the lower previous mesh bound EQ.0000p0: Rule for the X-plane along the upper previous mesh bound EQ.000p00: Rule for the Y-plane along the lower previous mesh bound EQ.00p000: Rule for the Y-plane along the upper previous mesh bound EQ.0p0000: Rule for the Z-plane along the lower previous mesh bound EQ.p00000: Rule for the Z-plane along the upper previous mesh bound The value of p defines the rule to be applied to the given plane: p.EQ.0: Do nothing. p.EQ.1: Translational symmetry (direction of translation orthogonal to the box plane) p.EQ.2: Mirror-image symmetry about the box plane p.EQ.3: Continuity of boundary elements and nodes along the box's plane

VARIABLE	DESCRIPTION
TBEG	Time to start the run. It replaces the termination time of the previous run that generated the mapping file if TBEG is larger.

Remarks:

1. **Mapping of Ale Multi-Material Groups.** The routines of this card need to know which mesh will be initialized with the mapping data, and more specifically, which multi-material groups. The first two fields, PID, and TYP, define the mesh. The third field, AMMSID, refers to a multi-material group list ID; see the *SET_MULTI-MATERIAL_GROUP_LIST card. The group list AMMSID should have as many elements as there are groups in the previous calculation (see *ALE_MULTI-MATERIAL_GROUP).

   Example: If the previous model has 3 groups, the current one has 5 groups and the following mapping is wanted.

   Group 1 from the previous run → Group 3 in the current run
   Group 2 from the previous run → Group 5 in the current run
   Group 3 from the previous run → Group 4 in the current run

   The *SET_MULTI-MATERIAL_GROUP_LIST card should be set as follows:

```
*SET_MULTI-MATERIAL_GROUP_LIST
300
3,5,4
```

   In special cases, a group can be replaced by another. If Group 4 in the previous example should be replaced by Group 3, the keyword setup would be modified to have -3 instead of 4. The minus sign is a way for the code to know that the replacing group (-3 replaces 4) is a complement of the group 3:

```
*SET_MULTI-MATERIAL_GROUP_LIST
300
3,5,-3
```

2. **Coordinate System Origin.** The location to which the data is mapped is controlled by the origin of the coordinate system (XO, YO, ZO).

3. **Symmetry Axis.** For a mapping file created by a previous axisymmetric model, the symmetric axis orientation in the current model is specified by VECID. For a mapping file created by a 3D or 1D spherical model, VECID is read but ignored. For a mapping file created by a 1D plane strain model, the vector specified with VECID orients the beams in the current mesh. For a 3D to 3D mapping the vector is used if the parameter ANGLE is defined (see Remark 4).

4. **Rotating 3D Data Onto a 3D calculation.** For a mapping from a previous 3D run to a current 3D model the previous 3D data will be rotated about the vector, VECID, through an angle specified in the ANGLE field.

5. **Plain Strain, and 3D to 2D.** The definitions of X0, Y0, Z0 and VECID change in the case of the following mappings:

   a) plain strain 2D (ELFORM = 13 in *SECTION_ALE2D) to plain strain 2D

   b) plain strain 2D to 3D

   c) 3D to 2D

   While VECID still defines the *y*-axis in the 2D domain, the 3 first parameters in *DEFINE_VECTOR, additionally, define the location of the origin. The 3 last parameters define a position along the *y*-axis. For this case when 2D data is used in a 3D calculation the point X0, Y0, Z0 together with the vector, VECID, define the plane.

6. **Mapping File.** Including the command line argument "map=" will invoke the creation of a mapping file. When the keyword INITIAL_ALE_MAPPING is not in the input deck, but the argument "map=" is present on the command line, the ALE data from the last cycle is written in the mapping file. This file contains the following nodal and element data:

   - nodal coordinates (last step)
   - nodal velocities
   - part IDs
   - element connectivities
   - element centers
   - densities
   - volume fractions
   - stresses
   - plastic strains
   - internal energies
   - bulk viscosities
   - relative volumes

7. **Chained Mappings.** To chain mapping operations so that LS-DYNA both reads and writes a mapping file the command line argument "map1=" is necessary. If the keyword INITIAL_ALE_MAPPING is in the input deck and the prompt "map=" is in the command line, the ALE data is read from the mapping file

defined by "map=" to initialize the run. Data from the last cycle are written in the mapping file defined by "map1=".

*INITIAL_AXIAL_FORCE_BEAM

Purpose: Initialize the axial force resultants in beam elements that are used to model bolts. This option works for beam type 9 (a Hughes-Liu type beam) with *MAT_SPOTWELD only and for beam type 1 with any material.

Card 1	1	2	3	4	5	6	7	8
Variable	BSID	LCID	SCALE	KBEND				
Type	I	I	F	I				
Default	none	none	1.0	0				

VARIABLE	DESCRIPTION
BSID	Beam set ID
LCID	Load curve ID defining preload force versus time. When the load curve ends or goes to zero, the initialization is assumed to be completed. See Remark 2 below.
SCALE	Scale factor on load curve.
KBEND	Bending stiffness flag EQ.0: Bending stiffness is negligible since all integration points are assigned the same axial stress. EQ.1: Bending stiffness is retained by keeping the axial stress gradient. EQ.2: Same as 1, but also allows for lining up several beams with prescribed axial force. See Remark 3.

Remarks:

1. **Damping.** To achieve convergence during explicit dynamic relaxation, the application of the damping options is very important. If contact is active, contact damping is recommended with a value between 10-20 percent. Additional damping applied using *DAMPING_PART_STIFFNESS also speeds up convergence where a coefficient of 0.10 is effective. If damping is not used, convergence may not be possible.

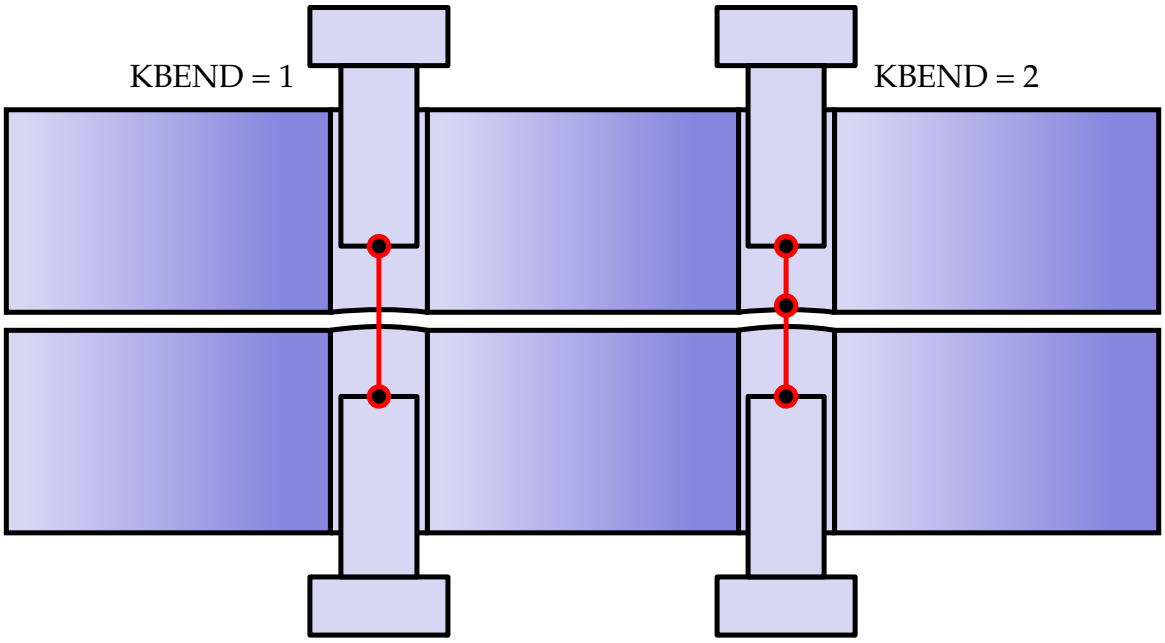

Figure 27-1. Illustration of modeling strategies for different values of KBEND

2. **Ramping.** When defining the load curve, LCID, a ramp starting at the origin should be used to increase the force to the desired value. The time duration of the ramp should produce a quasistatic response. When the end of the load curve is reached, or when the value of the load decreases from its maximum value, the initialization stops. If the load curve begins at the desired force value, that is, no ramp, convergence will take much longer, since the impulsive-like load created by the initial force can excite nearly every frequency in the structural system where force is initialized.

3. **Modeling Strategy.** When preloading bolts, users commonly reserve *one* beam element along the shank/threaded part of each bolt for the *INITIAL_AXIAL_-FORCE_BEAM keyword. The selected beam element must be long enough such that it does not reduce to zero length by the end of preload. The formulation of the beam causing crimping upon loading. Mesh connections, boundary conditions or contact prevent crimping. We illustrate this strategy with the left bolt in Figure 27-1. The beam to be load is red. Note that the loaded beam must be significantly longer than the sum of *(i)* the gap between the two plates and *(ii)* the two gaps between the plates and bolt heads. We use only one beam because otherwise the position of any node connecting two preloaded beam elements cannot be determined from the equations of equilibrium; the positions of intermediate nodes along the axis of the bolt are arbitrary. With KBEND = 2, you can load more than one beam as shown by the right bolt in the figure. LS-DYNA internally imposes additional constraints for intermediate nodes to make the problem well posed. The length reduction is displacement controlled to avoid excessive dynamic effects. Dynamic effects might otherwise occur if the bolt

heads impact the plates to be clamped at high speed. Note that the previously discussed differences apply even if only one beam element is used for the pre-load.

*INITIAL_CONTACT_WEAR

Purpose: Initialize contact wear for simulation of wear processes. Define as many cards as desired. See Remarks.

Note that this card is not supposed to be manually inserted; rather it is supposed to be generated by LS-DYNA during wear processes.

Card 1	1	2	3	4	5	6	7	8
Variable	CID	NID	WDEPTH	NX	NY	NZ	ISEQ	NCYC
Type	I	I	F	F	F	F	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
CID	Contact Interface ID.
NID	Node ID.
WDEPTH	Wear depth, in units of length.
NX, NY, NZ	Direction vector for wear, internally normalized.
ISEQ	Simulation sequence number for the entire process.
NCYC	The wear on this card will be processed NCYC times to modify the worn geometry. This means that *one* LS-DYNA simulation is used to predict the wear for *NCYC* repetitions of the process to save simulation time. This number should be chosen with care; a negative number means that LS-DYNA will not apply this card. See Remarks below.

Remarks:

This card is not supposed to be manually inserted, but is automatically generated by LS-DYNA when simulating wear processes; see *CONTACT_ADD_WEAR and parameters NCYC on *INTERFACE_SPRINGBACK_LSDYNA and SPR/MPR on *CONTACT. A sequence of identical simulations, except for perturbation of the geometry of certain components due to wear, is undertaken. For a given contact interface and node ID, the corresponding node is perturbed by the wear depth in the direction of wear. If the cycle

number NCYC is negative, the geometry has been already processed in LS-PrePost and the card is ignored by LS-DYNA. If a node appears multiple times, the wear from the individual sequences is accumulated.

*INITIAL_CRASHFRONT

Purpose: For some composite materials, the strength of an element is reduced if one of its neighboring elements fails due to damage. The damaged nodes are considered crash-front. In general, all nodes are initially perfect and there are no initial crashfront nodes. However, this card allows the user to initialize crashfront nodes for damage that may occur prior to the simulation, such as during the manufacturing process. Any elements connected to these crashfront nodes are initialized with reduced strength.

The crashfront node set can be initialized using the nodes that are in a set of segments, shell elements, parts, or nodes. This keyword works with material models 17, 54, 55, 58, 169, 261, and 262.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	STYPE						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
SID	Set ID from which the initial crashfront nodes are defined.
STYPE	ID type of SID: EQ.0: segment set ID, EQ.1: shell element set ID, EQ.2: part set ID, EQ.3: part ID, EQ.4: node set ID.

*INITIAL_DETONATION

Purpose: Define points to initiate the location of high explosive detonations in part ID's that use *MAT_HIGH_EXPLOSIVE_BURN (*MAT_008). Also see *CONTROL_EXPLOSIVE_SHADOW. If no *INITIAL_DETONATION is defined, detonation occurs in all the high explosive elements at time = 0.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	X	Y	Z	LT		MMGSET	
Type	I	F	F	F	F		I	
Default	all HE	0.	0.	0.	0.		0	

Acoustic Boundary Card. Additional card for PID = -1.

Card 2	1	2	3	4	5	6	7	8
Variable	PEAK	DECAY	XS	YS	ZS	NID		
Type	F	F	F	F	F	I		

VARIABLE	DESCRIPTION
PID	Part ID of the high explosive to be lit, except in the case where the high explosive is modeled using an ALE formulation, in which case PID is the part ID of the mesh where the high explosive material to be lit initially resides. However, two other options are available: EQ.-1: an acoustic boundary, also, *BOUNDARY_USA_SURFACE, EQ.0: all high explosive materials are considered. LT.-1: |PID| is the ID of a part set (*SET_PART)
X	x-coordinate of detonation point, see Figure 27-2.
Y	y-coordinate of detonation point.
Z	z-coordinate of detonation point.

VARIABLE	DESCRIPTION
LT	Lighting time for detonation point. This time is ignored for an acoustic boundary.
MMGSET	ID of *SET_MULTI-MATERIAL_GROUP_LIST selecting the explosive ALE groups to be lit in the mesh defined by PID.
PEAK	Peak pressure, p_o, of incident pressure pulse. See Remark 3.
DECAY	Decay constant, τ. See Remark 3.
XS	x-coordinate of standoff point; see Figure 27-2.
YS	y-coordinate of standoff point
ZS	z-coordinate of standoff point
NID	Reference node ID near structure

Remarks:

1. **Lighting Time.** For solid elements (not acoustic) two options are available. If the control card option, *CONTROL_EXPLOSIVE_SHADOW, is not used the lighting time for an explosive element is computed using the distance from the center of the element to the nearest detonation point, L_d; the detonation velocity, D; and the lighting time for the detonator, t_d:

$$t_L = t_d + \frac{L_d}{D}.$$

The detonation velocity for this default option is taken from the element whose lighting time is computed and does not account for the possibilities that the detonation wave may travel through other explosives with different detonation velocities or that the line of sight may pass outside of the explosive material.

If the control card option, *CONTROL_EXPLOSIVE_SHADOW, is defined, the lighting time is based on the shortest distance through the explosive material. If inert obstacles exist within the explosive material, the lighting time will account for the extra time required for the detonation wave to travel around the obstacles. The lighting times also automatically accounts for variations in the detonation velocity if different explosives are used. No additional input is required for this option, but care must be taken when setting up the input. This option works for two and three-dimensional solid elements. It is recommended that for best results:

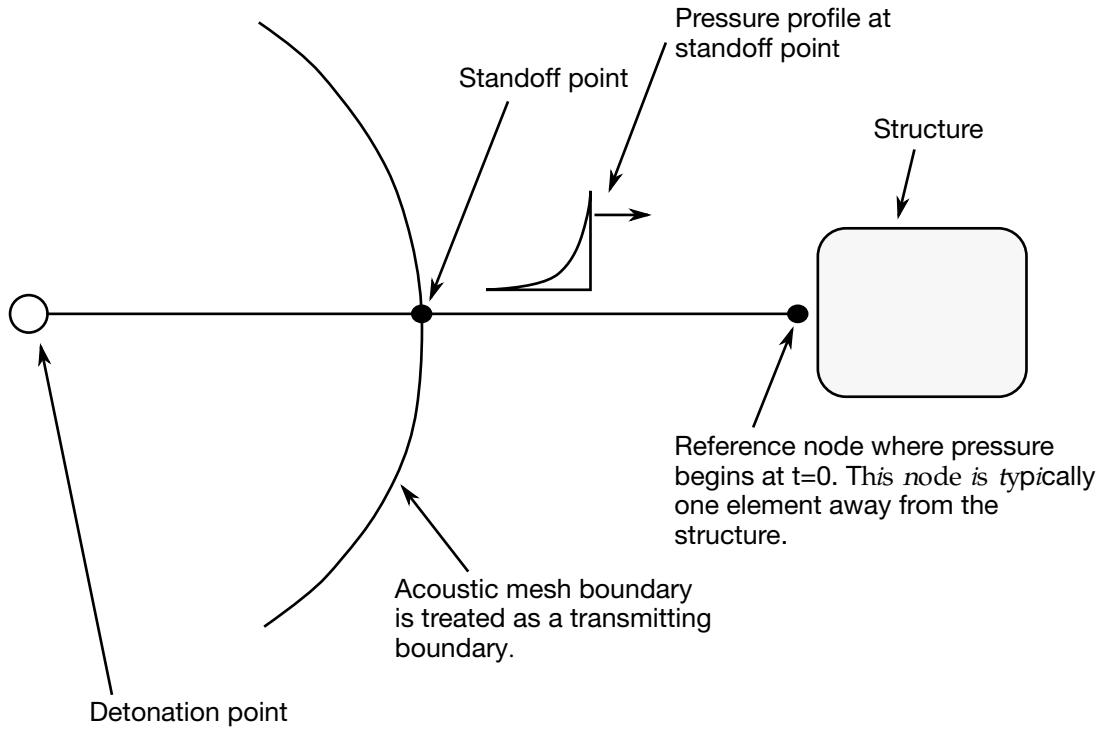

Figure 27-2. Initialization of the initial pressures due to an explosive disturbance is performed in the acoustic media. LS-DYNA automatically determines the acoustic mesh boundary and applies the pressure time history to the boundary. This option is only applicable to the acoustic element formulation, see *SECTION_SOLID.

a) Keep the explosive mesh as uniform as possible with elements of roughly the same dimensions.

b) Inert obstacle such as wave shapers within the explosive must be somewhat larger than the characteristic element dimension for the automatic tracking to function properly. Generally, a factor of two should suffice. The characteristic element dimension is found by checking all explosive elements for the largest diagonal.

c) The detonation points should be either within or on the boundary of the explosive. Offset points may fail to initiate the explosive. When LT is nonzero, the detonation point is fixed to the explosive material at $t = 0$ and moves as the explosive material moves prior to detonation.

d) Check the computed lighting times in the post processor LS-PrePost. The lighting times may be displayed at time = 0., state 1, by plotting component 7 (a component normally reserved for plastic strain) for the explosive material. The lighting times are stored as negative numbers. The negative lighting time is replaced by the burn fraction when the element ignites.

2. **Line Detonations.** Line detonations may be approximated by using a sufficient number of detonation points to define the line. Too many detonation points may result in significant initialization cost.

3. **Acoustic Boundary.** The pressure as a function of time curve for the acoustic boundary is defined by:

$$p(t) = p_o e^{-\frac{t}{\tau}}.$$

*INITIAL_DETONATION_GEOMETRY

Purpose: Define detonation points that are selected based on a specified geometry. These points ignite high explosives defined by parts that use *MAT_HIGH_EXPLOSIVE_BURN (*MAT_008).

Also see *INITIAL_DETONATION and *CONTROL_EXPLOSIVE_SHADOW.

Card Summary:

Card 1. This card is required.

HEID	HETYP	MMGSET					

Card 2. This card is required.

GEOTYP	LT	DGEO					

Card 3a. This card is included if GEOTYP = 1.

VID1							

Card 3b. This card is included if GEOTYP = 2.

VID1	VID2	VID3					

Card 3c. This card is included if GEOTYP = 3.

VID1	VID2	VID3					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	HEID	HETYP	MMGSET					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
HEID	ID specifying the high explosives to be lit

VARIABLE	DESCRIPTION
HETYP	Type of HEID: EQ.0: Part set ID (*SET_PART)
MMGSET	ID of *SET_MULTI-MATERIAL_GROUP_LIST selecting the explosive ALE groups to be lit

Card 2	1	2	3	4	5	6	7	8
Variable	GEOTYP	LT	DGEO					
Type	I	F	F					
Default	none	0.	↓					

VARIABLE	DESCRIPTION
GEOTYP	Type of geometry formed by the detonation points: EQ.1: Plane EQ.2: Cylindrical surface EQ.3: Spherical or ellipsoidal surface
LT	Lighting time for detonation point
DGEO	Maximum distance from the detonation geometry for determining which HE elements become detonation points. If the element center for the specified HE is less than this distance away from the detonation geometry, then the element center becomes a detonation point. If zero or undefined, DGEO becomes the length of the largest specified HE element.

Plane Geometry Card. This card is included if GEOTYP = 1.

Card 3a	1	2	3	4	5	6	7	8
Variable	VID1							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
VID1	ID of the vector (see *DEFINE_VECTOR) that gives the plane's normal vector. The tail of VID1 is a point in the plane.

Cylindrical Surface Geometry Card. This card is included if GEOTYP = 2.

Card 3b	1	2	3	4	5	6	7	8
Variable	VID1	VID2	VID3					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
VID1, …, VID3	IDs of vectors (see *DEFINE_VECTOR) for specifying the orientation and location of the cylinder with either circular or elliptical bases. The cylinder can also be oblique. For either elliptical or circular bases, the tail of VID1 gives the center of one of the bases of the cylinder, the length of VID2 gives the length of the cylinder's axis, and the direction of VID2 gives the direction of the cylinder's axis. For circular bases, the length of VID1 is the radius of the circle. The bases lie in planes formed by VID1 and the cross product of VID1 with VID2. VID3 should not be input for this case. See Figure 27-3. For elliptical bases, the lengths of VID1 and VID3 are the lengths of the two axes. The direction of the axis with the length of VID1 is in the direction of VID1. The direction for the axis with the length

VARIABLE	DESCRIPTION
	given by VID3 is in the direction given by the cross product of VID1 with VID2. See Figure 27-4.

Spherical or Ellipsoidal Surface Geometry Card. This card is included if GEOTYP = 3.

Card 3c	1	2	3	4	5	6	7	8
Variable	VID1	VID2	VID3					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
VID1, …, VID3	IDs of vectors (see *DEFINE_VECTOR) for specifying the orientation and location of the sphere or ellipsoid. In each case, the center of the surface is given by the tail of VID1. For a sphere, only specify VID1. The length of VID1 is the radius of the sphere. For an ellipsoid with two axes of equal length, specify VID1 and VID2. The length of VID1 is used for the axes of equal length which are in the directions VID1 and the cross product of VID1 with VID2. The length of VID2 gives the length of the third axis which is orthogonal to VID1 and the cross product of VID1 with VID2. See Figure 27-5. For an ellipsoid with all axes of different length, specify VID1, VID2, and VID3. One axis is in the direction of VID1 with the length of VID1. Another axis is in the direction of the cross product of VID1 with VID2 with the length given by the length of VID3. The third axis is orthogonal to the other two axes and has a length equal to the length of VID2. See Figure 27-6.

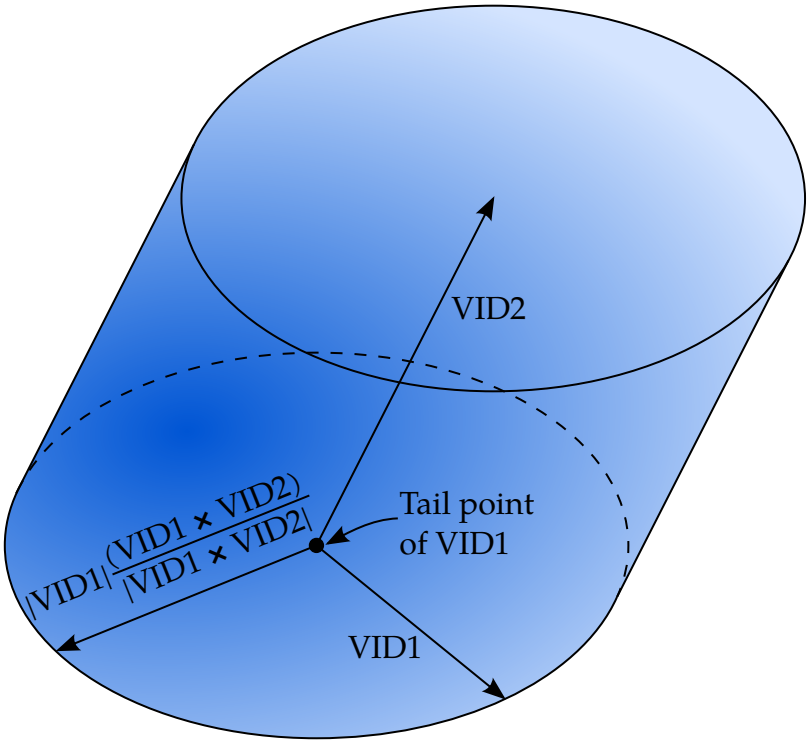

Figure 27-3. Oblique cylinder with circular bases (GEOTYP = 2)

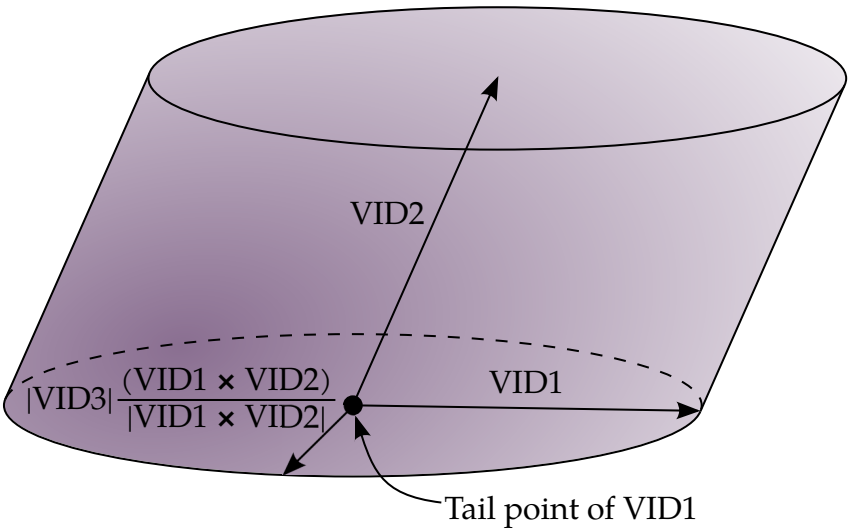

Figure 27-4. Oblique cylinder with elliptical bases (GEOTYP = 2)

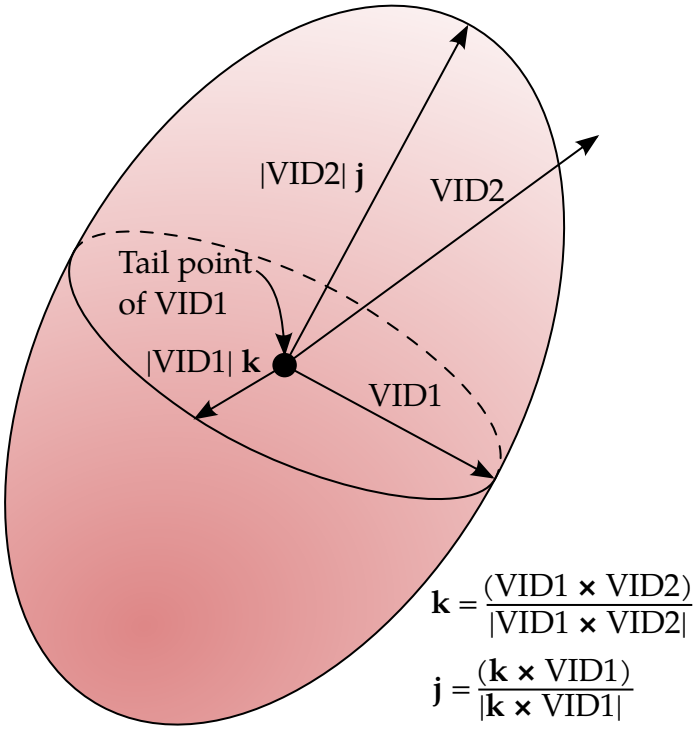

Figure 27-5. Ellipsoid with two equal axes (GEOTYP = 3)

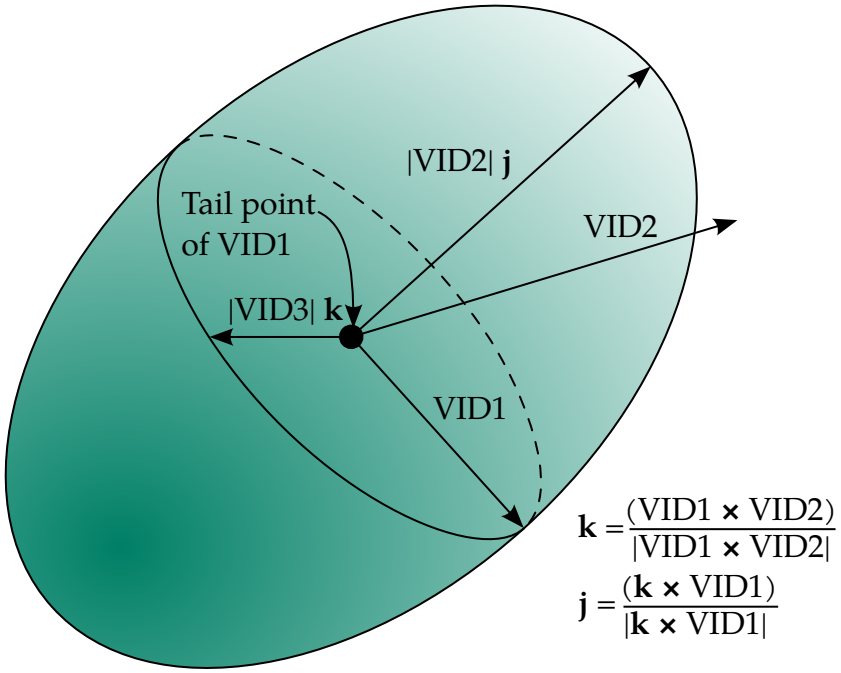

Figure 27-6. Ellipsoid with axes of different length (GEOTYP = 3)

*INITIAL_EOS_ALE

Purpose: This card initializes the pressure in ALE elements that have materials with *EOS.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYP	MMG	E0	V0	P0		
Type	I	I	I	F	F	F		
Default	none	none	none	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
ID	Part ID or part set ID or element set ID.
TYP	Type of "ID": EQ.0: part set ID. EQ.1: part ID. EQ.2: element set ID (*SET_BEAM in 1D, *SET_SHELL in 2D, *SET_SOLID in 3D).
MMG	Specifies the multi-material group. GT.0: ALE multi-material group. LT.0: Set ID of ALE multi-material groups defined in *SET_MULTI-MATERIAL_GROUP.
E0	Initial internal energy per reference volume unit (as defined in *EOS). See Remark 1.
V0	Initial relative volume (as defined in *EOS). See Remark 1.
P0	Initial pressure. See Remark 2.

Remarks:

1. **Initialization with Volume and Energy.** For most *EOS, E0 and V0 should be used to initialize the pressure. If only the internal energy is initialized, V0 should be 1.0 (If V0 = 0.0, E0 will not be applied).

2. **Initial Pressure with Derived Volume and Energy.** For *EOS_001, *EOS_004 and *EOS_006, the initial pressure P0 can be input directly. An iterative method will compute the initial internal energy and relative volume. This approach is applied if E0 = 0.0 and V0 = 0.0.

*INITIAL_FATIGUE_DAMAGE_RATIO_{OPTION}

Available options include:

<BLANK>

D3FTG

D3PLOT

Purpose: This card sets the initial damage ratio for fatigue analysis. The initial damage ratio may come from the previous loading cases. The initial damage ratio can be defined directly by the user or can be extracted from an existing binary database like D3FTG (using the option D3FTG) and D3PLOT (using the option D3PLOT).

Card Summary:

Card Sets. Include as many sets of the following cards as needed to include the initial damage ratio from each loading condition (for multiple loading condition cases). This input terminates with the next keyword ("*") card.

Card 1a. This card is included if and only if no keyword option is used (<BLANK>).

PID/SID	PTYP	DRATIO					

Card 1b. This card is included if and only if the D3FTG keyword option is used.

FILENAME

Card 1c.1. This card is included if and only if the D3PLOT keyword option is used.

FILENAME

Card 1c.2. This card is included if and only if the D3PLOT keyword option is used.

NSTATE	NEIPHD	NEIPSD					

Data Card Definitions:

Initial Damage Ratio Card. Card 1 for no option (<BLANK>)

Card 1a	1	2	3	4	5	6	7	8
Variable	PID/SID	PTYP	DRATIO					
Type	I	I	F					
Default	none	0	0.0					

VARIABLE	DESCRIPTION
PID/SID	Part ID or part set ID for which the initial damage ratio is defined
PTYP	Type of PID/PSID: EQ.0: part ID EQ.1: part set ID
DRATIO	Initial damage ratio

D3FTG Card. Card 1 for the D3FTG keyword option.

Card 1b	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	d3ftg							

D3PLOT Card. Card 1 for the D3PLOT keyword option.

Card 1c.1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	d3plot							

VARIABLE	DESCRIPTION
FILENAME	Path and name of existing binary database for fatigue information

D3PLOT Card. Card 2 for the D3PLOT keyword option.

Card 1c.2	1	2	3	4	5	6	7	8
Variable	NSTATE	NEIPHD	NEIPSD					
Type	I	I	I					
Default	1	1	1					

VARIABLE	DESCRIPTION
NSTATE	State ID in binary database (e.g. d3plot) for reading damage variables
NEIPHD	ID of additional integration point history variable which saves the damage for solid elements
NEIPSD	ID of additional integration point history variable which saves the damage for shell and thick shell elements

Remarks:

1. **Fatigue Problem Types.** This card works for both time domain fatigue and frequency domain fatigue problems.

2. **Transient Preload Cases.** The option D3PLOT can be used for users who want to use damage from transient preload cases (e.g. from GISSMO damage model)

as initial fatigue damage ratio. In this case, LS-DYNA will read the binary database defined in Card 1c.1 (e.g. d3plot) and extract the damage variables from the additional integration point history variables based on NSTATE, NEIPHD and NEIPSD defined in Card 1c.2.

*INITIAL_FIELD_SOLID

Purpose: This keyword is a simplified version of *INITIAL_STRESS_SOLID which can be used with hyperelastic materials. The keyword is used for history variable input. Data is usually in the form of the eigenvalues of diffusion tensor data. These are expressed in the global coordinate system.

> **NOTE:** As of LS-DYNA R5 in all contexts, other than *MAT_TISSUE_DISPERSED, this keyword is deprecated (and disabled). For all other materials this keyword has been superceded by *INITIAL_STRESS_SOLID.

Card Sets: Include as many pairs of Cards 1 and 2 as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	NINT	NHISV					
Type	I	I	I					
Default	none	none	0					

Card 2	1	2	3	4	5	6	7	8
Variable	FLD1	FLD2	FLD3	FLD4	FLD5	FLD6	FLD7	FLD8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
EID	Element ID
NINT	Number of integration points (should correspond to the solid element formulation).
NHISV	Number of field variables. If NHISV exceeds the number of integration point field variables required by the constitutive model, only the number required is output; therefore, if in doubt, set NHISV to a large number.

VARIABLE	DESCRIPTION
FLD*n*	Data for the n^{th} field (history) variable. NOTE that *MAT_TISSUE_DISPERSED only use FLD1 to FLD3 since NHISV = 3.

Remarks:

Add as many cards as necessary. The keyword input ends at the next keyword ("*") card. For example for two elements it can look as:

```
*INITIAL_FIELD_SOLID
$EID       NINT     NHISV
    1          1         3
$FLD1      FLD2      FLD3
  0.1       0.8       0.1
$EID       NINT     NHISV
    2          1         3
$FLD1      FLD2      FLD3
  0.3       0.2       0.5
```

*INITIAL_FOAM_REFERENCE_GEOMETRY_{OPTION}

Available options include:

<BLANK>

RAMP

Purpose: Define the reference geometry of a foam for stress initialization. LS-DYNA initializes the stresses using the reference geometry when the REF flag is turned on in the *MAT input for the following hyperelastic material models: 2, 5, 7, 21, 23, 27, 31, 38, 57, 73, 77, 83, 132, 179, 181, 183, and 189. Supported solid elements are the constant stress hexahedron (#1), the fully integrated S/R hexahedron (#2), the tetrahedron (#10), and the pentahedron (#15). With this keyword, dynamic relaxation can be avoided once a deformed configuration is obtained, usually on the first run of a particular problem.

To use this keyword, define the geometry of the low-density foam in a deformed configuration. The stresses depend only on the deformation gradient matrix, F_{ij}:

$$F_{ij} = \frac{\partial x_i}{\partial X_j}$$

where x_i is the deformed configuration and X_j is the undeformed configuration.

Some shell and solid elements modeling the fabric and foam, respectively, share nodes. The reference geometry specified by either *INITIAL_FOAM_REFERENCE_GEOMETRY or *AIRBAG_REFERENCE_GEOMETRY will be applied to both the shell and solid elements that share these nodes. However, having different reference geometry for shell and solid elements sharing common nodes can be achieved by using *INITIAL_FOAM_REFERENCE_GEOMETRY for solid elements and *AIRBAG_SHELL_REFERENCE_GEOMETRY for shell elements.

Card Summary:

Card 1. This card is included if the RAMP option is used.

NDTRRG							

Card 2. Include as many of this card as needed. The next keyword ("*") card terminates this input.

NID	X	Y	Z			

Data Card Definitions:

RAMP Card. Additional card for the option of RAMP.

Card 1	1	2	3	4	5	6	7	8
Variable	NDTRRG							
Type	I							
Default	0							

Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	NID	X		Y		Z				
Type	I	F		F		F				
Default	none	0.		0.		0.				

VARIABLE	DESCRIPTION
NDTRRG	Number of time steps taken for an element to restore its reference geometry. Definition of NDTRRG allows an element to ramp up to its reference shape in NDTRRG time steps. Currently LS-DYNA uses only one value of NDTRRG and applies it to all foam materials with reference geometries. If more than one NDTRRG is defined, the one defined last will be used.
NID	Node number
X	*x*-coordinate in reference configuration
Y	*y*-coordinate in reference configuration
Z	*z*-coordinate in reference configuration

*INITIAL_GAS_MIXTURE

Purpose: This command is used to specify (a) which ALE multi-material groups may be present inside an ALE mesh set at time zero, and (b) the corresponding reference gas temperature and density which define the initial thermodynamic state of the gases. The order of the species in the gas mixture corresponds to the order of different gas species defined in the associated *MAT_GAS_MIXTURE card. This card must be used together with a *MAT_GAS_MIXTURE card or, equivalently, a *MAT_ALE_GAS_MIXTURE card.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	STYPE	MMGID	TEMP				
Type	I	I	I	F				
Default	none	0	none	none				

Card 2	1	2	3	4	5	6	7	8
Variable	R01	R02	R03	R04	R05	R06	R07	R08
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
SID	Set ID for initialization. This SID defines the ALE mesh within which certain ALE multi-material group(s) may be present at $t = 0$.
STYPE	Set type for the SID above: EQ.0: SID is a part set ID EQ.1: SID is a part ID

VARIABLE	DESCRIPTION
MMGID	ALE multi-material group ID of the material that may be present at t = 0 in the ALE mesh set defined by SID. For general ALE, it must be AMMGID. For S-ALE, either AMMGID or AMMG name (AMMGNM) could be used here. Please refer to *ALE_STRUCTURED_MULTI-MATERIALS_GROUP for more details.
TEMP	Initial static temperature of the gas species occupying the ALE mesh. Note that all species in the mixture are assumed to be in thermal equilibrium (having the same T).
RO1-RO8	Initial densities of the ALE material(s) which may be occupying some region (or all) of the aforementioned ALE mesh, for up to eight different gas species. The order of the density input corresponds to the order of the materials defined in associated *MAT_GAS_MIXTURE card.

Remarks:

1. **Example.** Please see the example under the *MAT_GAS_MIXTURE card definition for an application of the *INITIAL_GAS_MIXTURE card.

2. **Initial Pressure.** The temperature is assumed to be the initial temperature which together with the gas density, will define the initial pressure of the gas species using the perfect gas law,

$$P|_{t=0} = \rho|_{t=0}(C_P - C_V)T|_{t=0} \ .$$

The user should manually check the initial pressure for consistency.

3. **ALE Multi-Material Groups.** Given an ALE mesh, this mesh may initially be occupied by one or more ALE multi-material groups (AMMG). For example, a background ALE mesh (H1) containing AMMG 1 may be partially filled with AMMG 2 using the volume filling command *INITIAL_VOLUME_FRACTION_GEOMETRY. Then there are 2 AMMGs to be initialized for this mesh H1. The commands look like the following.

```
$---------------------------------------------------------------------
$ One card is defined for each AMMG that will occupy some elements of a mesh
set

*INITIAL_HISTORY_NODE_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Initialize certain history variable values on a nodal basis for shells, thick shells, and solids. The value of the history variable at an integration point is then determined by interpolating the nodal values as described in more detail in Remark 1.

Card Sets per NODE. Define as many nodes or node sets in this section as desired. The input is assumed to terminate when a new keyword ("*") card is detected.

Node Card.

Card 1	1	2	3	4	5	6	7	8
Variable	NID/NSID	NHISV						
Type	I	I						
Default	none	none						

History Variable Cards. Include NHISV (see Card 1) cards, one card per history variable.

Card 2	1	2	3	4	5	6	7	8
Variable	HINDEX	VAL						
Type	I	F						
Default	none	0.0						

VARIABLE	DESCRIPTION
NID/NSID	Node ID or node set ID, see *SET_NODE_…
NHISV	Number of history variables to be initialized
HINDEX	Define the index in the history variable vector

VARIABLE	DESCRIPTION
VAL	Define the value of the history variable

Remarks:

1. **Interpolation Methods.** For shell elements, the values of the history variables assigned to its nodes are interpolated to the location of the in-plane integration points using the finite element shape functions associated to the individual element formulation. All the through thickness integration points will receive the same value as the one in the shell reference plane.

   For thick shell and solid elements, the values of the history variables assigned to its nodes are interpolated to the location of all the integration points using the finite element shape functions associated to the individual element formulation.

2. **Number of Nodes Required for Initialization.** Only integration points of an element where *at least one of* its associated nodes has a history value set with this keyword will be initialized. The values of the history variables of the uninitialized nodes are assumed to be 0.0.

3. **Keyword Limitations.** Note that initialization with nodes that are shared between two parts should be performed with caution since this keyword does not discriminate based on the part ID and more than one material may be involved. In the case of more than one material for a given node, LS-DYNA will issue an error saying that the history variable cannot be initialized. Also, this keyword should not be used for composite shells because of the material change through the thickness (see Remark 1).

4. **Comparison to *INITIAL_STRESS_SOLID/SHELL.** When defining initial values of history variables, this keyword serves a similar purpose to *INITIAL_STRESS_SOLID/SHELL. There are two big differences. The first is how the history variables are initialized. With this keyword you input the nodal values for the history variables which are then interpolated for the integration points. For *INITIAL_STRESS_SOLID/SHELL, you input the initial values at each integration point for an element. Another difference is that for this keyword only the desired history variables are initialized. For instance, if you want to initialize history variable 14, with INITIAL_STRESS_SHELL/SOLID you would have to initialize history variables 1 through 14, whereas with this keyword you would only initialize history variable 14:

```
*INITIAL_HISTORY_NODE_SET
nsid,1
14,50.0
```

   or like this

```
*INITIAL_HISTORY_STRESS_SHELL_SET
sid,1,1,14
0.0

,,,,,50.0
```

*INITIAL_HYDROSTATIC_ALE

Purpose: When an ALE model contains one or more regular (not reservoir-type) ALE parts (ELFORM = 11 and AET = 0), this command may be used to initialize the hydrostatic pressure field in the regular ALE domain due to gravity. The *LOAD_BODY_(OPTION) keyword must be defined.

Card 1	1	2	3	4	5	6	7	8
Variable	ALESID	STYPE	VECID	GRAV	PBASE			
Type	I	I	I	F	F			
Default	none	0	none	0.0	0.0			

Multi-material Layers Group Cards. Repeat card 2 as many times as the number of AMMG layers present in the model.

Card 2	1	2	3	4	5	6	7	8
Variable	NID	MMGBLO						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
ALESID	ALESID is a set ID defining the ALE domain/mesh whose hydrostatic pressure field due to gravity is being initialized by this keyword. See Remark 2 and 4.
STYPE	ALESID set type. See Remark 4. EQ.0: Part set ID (PSID), EQ.1: Part ID (PID), EQ.2: Solid set ID (SSID).
VECID	Vector ID of a vector defining the direction of gravity.

VARIABLE	DESCRIPTION
GRAV	Magnitude of the Gravitational acceleration. For example, in metric units the value is usually set to 9.80665 m/s^2.
PBASE	Nominal or reference pressure at the top surface of all fluid layers. By convention, the gravity direction points from the top layer to the bottom layer. Each fluid layer must be represented by an ALE multi-material group ID (AMMGID or MMG). See Remark 1.
NID	Node ID defining the top of an ALE fluid (AMMG) layer.
MMGBLO	AMMG ID of the fluid layer immediately below this NID. Each node is defined in association with one AMMG layer below it. See Remark 3. In case of S-ALE, AMMG name (AMMGNM) could be also used in place of AMMGID. See Remark 5.

Remarks:

1. **Pressure in Multi-Layer Fluids.** For models using multi-layer ALE Fluids the pressure at the top surface of the top fluid layer is set to PBASE and the hydrostatic pressure is computed as following

$$P = P_{\text{base}} + \sum_{i=1}^{N_{\text{layers}}} \rho_i g h_i \, .$$

2. **Limitations on Element Formulation.** This keyword applies only to the regular ALE parts with ELFORM = 11 and AET = 0 on the *SECTION_SOLID and *SECTION_ALE2D cards (not reservoir-type). This keyword cannot be used to initialize reservoir-type ALE parts (AET = 4). Also, ramping functions are not supported, so the loading is done in one step at $t = 0$. For initializing reservoir-type ALE domain, please review the *ALE_AMBIENT_HYDROSTATIC keyword.

3. **Limitation on EOS Model.** The keyword only supports *EOS_GRUNEISEN and *EOS_LINEAR_POLYNOMIAL, but only in the following two cases:

$$c_3 = c_4 = c_5 = c_6 = 0, \qquad E_0 = 0$$
$$c_4 = c_5 > 0, \qquad c_1 = c_2 = c_3 = c_6 = 0, \qquad V_0 = 0.$$

4. **Structured ALE usage.** When used with structured ALE, the PART and PART set options might not make too much sense. This is because all elements inside a structured ALE mesh are assigned to one single PART ID. If we want to prescribe initial hydrostatic pressure for all the elements inside the structured mesh, we can certainly use that PART ID. But if we only want to do that to some elements, we must generate a solid set which contains those structured ALE

elements. This is done by using the *SET_SOLID_GENERAL keyword with SALECPT option and STYPE = 2 (solid element set ID) on this keyword.

5. **AMMG NAME for S-ALE.** For the general ALE solver, you define each AMMG with *ALE_MULTI-MATERIAL_GROUP. In this case, each AMMG can only be referred to by their AMMGID. The AMMGID for each AMMG is based on the order of appearance of the AMMG in the input deck. For the S-ALE solver, you can define the AMMG using *ALE_STRUCTURED_MULTI-MATERIAL_-GROUP instead of *ALE_MULTI-MATERIAL_GROUP. With *ALE_STRUC-TURED_MULTI-MATERIAL_GROUP, you give each AMMG a name with the field AMMGNM. Each AMMG defined with that keyword can then be referred with either its name or its AMMGID (which is again based on order of appear-ance). We recommend using the name as it leads to fewer errors. For instance, if you add or delete AMMGs, then the AMMGIDs may change. Then, you must find all those references and change them accordingly. With the name, you do not need to modify the input deck for unchanged AMMGs.

Example:

Model Summary: Consider a model consisting of 2 ALE parts, air on top of water.
H1 = AMMG1 = Air part above.
H2 = AMMG2 = Water part below.

*INITIAL_IMPULSE_MINE

Purpose: Apply initial velocities to the nodes of a three-dimensional structure due to the impulse imparted by the detonation of a buried land mine. This keyword cannot be used with 2D models or with rigid parts. It is also not supported by MPP (see workaround in Remark 3). This feature is based on the empirical model developed by [Tremblay 1998].

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	MTNT	RHOS	DEPTH	AREA	SCALE	not used	UNIT
Type	I	F	F	F	F	F		I
Default	none	0.0	0.0	0.0	0.0	1.0		1
Remarks	1	4						

Card 2	1	2	3	4	5	6	7	8
Variable	X	Y	Z	NIDMC	GVID	TBIRTH	PSID	SEARCH
Type	F	F	F	I	I	F	I	F
Default	0.0	0.0	0.0	0	none	0.0	0	0.0

VARIABLE	DESCRIPTION
SSID	Segment set ID. See *SET_SEGMENT and Remark 1.
MTNT	Equivalent mass of TNT. See Remark 4.
RHOS	Density of overburden soil.
DEPTH	Burial depth from the ground surface to the center of the mine. This value must be positive.
AREA	Cross sectional area of the mine.
SCALE	Scale factor for the impulse.

VARIABLE	DESCRIPTION
UNIT	Unit system. This must match the units used by finite element model. EQ.1: inch, dozen slugs (i.e., lbf × s^2/in), second, PSI (default) EQ.2: meter, kilogram, second, Pascal EQ.3: centimeter, gram, microsecond, megabar EQ.4: millimeter, kilogram, millisecond, GPa EQ.5: millimeter, metric ton, second, MPa EQ.6: millimeter, gram, millisecond, MPa
X, Y, Z	*x*-, *y*-, and *z*- coordinates of mine center.
NIDMC	Optional node ID representing the mine center (see *NODE). If defined then X, Y and Z are ignored.
GVID	Vector ID representing the vertically upward direction, that is, the normal to the ground surface. See *DEFINE_VECTOR.
TBIRTH	Birth time. Impulse is activated at this time.
PSID	Part set ID identifying the parts affected by the mine. See *SET_-PART. If the segment set defined by SSID includes segments of more than one part, PSID may be used to load only segments of identified parts. Otherwise, if PSID is set to zero, the part affected by the mine defaults to the part comprised by the nodes of the segment set.
SEARCH	Limit the search depth into the structure. Initial nodal velocity is distributed from the segment to a depth equal to the SEARCH value. The value must be positive. If set to zero, the search depth is unlimited and extends through the part(s) identified by PSID.

Remarks:

1. **Orientation.** Segment normals should nominally point toward the mine.

2. **Element Types.** The segments should belong to 3D thin shell, solid, or thick shell elements. This keyword cannot be used with 2D geometries.

3. **Workaround to Use MPP.** Although this feature is unavailable in MPP, there is a simple workaround that involves performing the initialization in SMP and then using that initial velocity field in MPP.

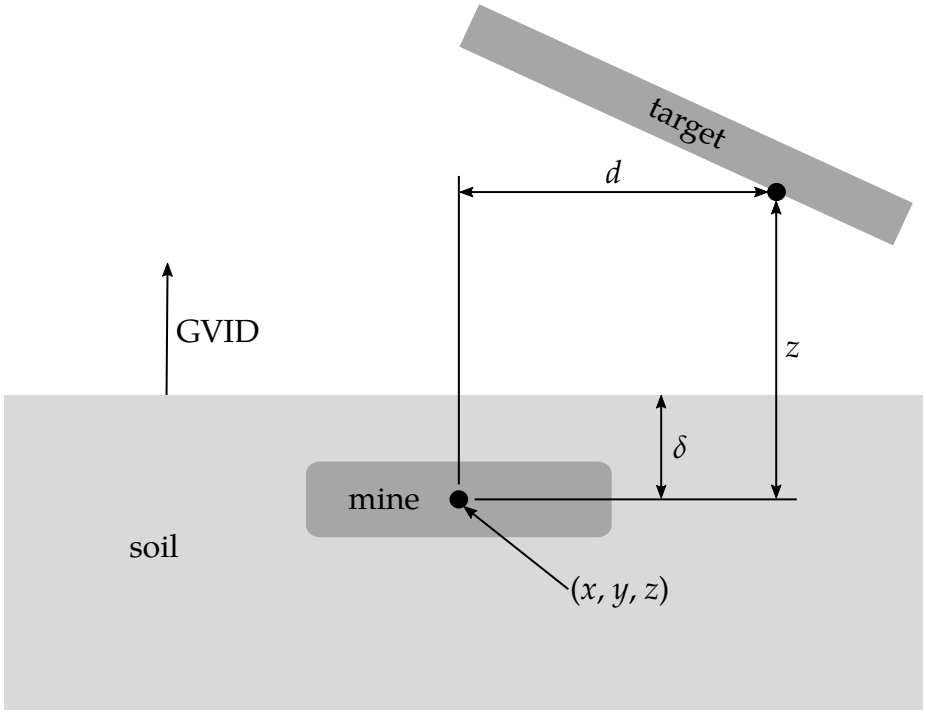

Figure 27-7. Schematic of the buried mine parameters.

4. **Equivalent Mass of TNT.** Several methods can be used to approximate the equivalent mass of TNT for a given explosive. One method involves scaling the mass by the ratio of the squares of the Chapman-Jouguet detonation velocities given by:

$$M_{\text{TNT}} = M_e \frac{v_e^2}{v_{\text{TNT}}^2}$$

where M_{TNT} is the equivalent TNT mass and $v_{\text{TNT}}$is the Chapman-Jouguet detonation velocity of TNT. M_e and v_e are, respectively, the mass and C-J velocity of the explosive under investigation. LS-DYNA takes the density of "Standard" TNT to be $1.57 \frac{\text{g}}{\text{cm}^3}$ and v_{TNT} to be $0.693 \frac{\text{cm}}{\mu\text{s}}$

5. **Energy Release.** This implementation assumes the energy release (heat of detonation) for 1 kilogram of TNT is 4.516 MJ.

6. **Error Bounds.** Prediction of the impulse relies on an empirical approach which involves fitting curves to experimental results. The upper error bound is 1.8 times the predicted value and the lower is the predicted value divided by 1.8. Thus, if the predicted impulse is 10 kN-seconds, then the solution space ranges from 5.6 kN-sec to 18 kN-sec.

7. **Limits of Model's Validity.** The computed impulse is valid when the following criteria are met:

$$0.106 \leq \frac{\delta}{z} \leq 1$$
$$6.35 \leq \frac{E/A}{\rho c^2 z} \leq 150$$
$$0.154 \leq \frac{\sqrt{A}}{z} \leq 4.48$$
$$0 \leq \frac{d}{z} \leq 19.3$$

where,

δ = the distance from the mine center to the ground surface (DEPTH)
z = the vertical distance from the mine center to the target point
E = the energy release of the explosive
A = the cross-sectional area of the mine (AREA)
ρ = the soil density (RHOS)
c = the wave speed in the soil
d = the lateral distance from the mine center to the target point.

See Figure 27-7.

***INITIAL_INTERNAL_DOF_SOLID**_*OPTION*

Available Options include:

TYPE3

TYPE4

Purpose: Initialize the internal degrees of freedom for solid element types 3 and 4.

Card 1	1	2	3	4	5	6	7	8
Variable	LID							
Type	I							
Default	none							

Value Cards. Include 12 cards for type 3 and 6 cards for type 4.

Card	1	2	3	4	5	6	7	8
Variable	VALX	VALY	VALZ					
Type	F	F	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
LID	Element ID.
VALX	*x* component of internal degree of freedom.
VALY	*y* component of internal degree of freedom.
VALZ	*z* component of internal degree of freedom.

Remarks:

1. **Internal DOF.** The internal degrees of freedom are specified in terms of the displacements of the corresponding mid-side nodes of the 20 node hex and the 10

node tetrahedron that are the basis of the type 3 and 4 solid elements, respectively.

*INITIAL_LAG_MAPPING_{OPTION}

The available options are

<BLANK>

WRITE

WRITE3DAXI

Purpose: This card initializes a 3D Lagrangian calculation with data from the last cycle of a preceding 2D or 3D Lagrangian calculation.

In its *INITIAL_LAG_MAPPING form (<BLANK> option), this keyword causes data to be read in from a *mapping file*. With the WRITE option active, this card is used to set which parts are written to the mapping file. The mapping file's filename is specified using the "lagmap=" command line argument (see Remarks 1 and 2). The option WRITE3DAXI causes LS-DYNA to output the mapping file for a 3D axisymmetric mesh as if it was generated by a 2D axisymmetric model.

The following transitions are allowed:

2D → 2D	3D → 3D
2D → 3D	3D → 2D

Card 1	1	2	3	4	5	6	7	8
Variable	SETID							
Type	I							

Mesh Mapping Card. Additional card for <BLANK> or WRITE3DAXI keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	XP	YP	ZP	VECID	ANGLE	NELANGL		
Type	F	F	F	I	F	I		
Default	0.0	0.0	0.0	none	none	0		

VARIABLE	DESCRIPTION
SETID	Part set ID. See Remarks 3 and 4.
XP	*x*-position of a point belonging to the plane from which the 3D mesh is generated (only for a 2D to 3D mapping or 3Daxi to 3D mapping). See Remark 5.
YP	*y*-position of a point belonging to the plane from which the 3D mesh is generated (only for a 2D to 3D mapping or 3Daxi to 3D mapping). See Remark 5.
ZP	*z*-position of a point belonging to the plane from which the 3D mesh is generated (only for a 2D to 3D mapping or 3Daxi to 3D mapping). See Remark 5.
VECID	ID of the rotation axis (symmetric axis for a 2D to 3D mapping or 3Daxi to 3D mapping) defined by *DEFINE_VECTOR. See Remark 5.
ANGLE	Angle of rotation around an axis defined by *DEFINE_VECTOR. See Remark 5.
NELANGL	Mapping parameter. See Remark 5. GT. 0: For a 2D to 3D mapping, number of elements to create in the azimuthal direction for ANGLE EQ.-1: No mesh is generated or projected. EQ.-2: For a 3D to 3D mapping, ANGLE only rotates the data from the mapping file (not the current mesh). EQ.-3: No mesh is generated or projected aside from the boundary nodes of the current mesh being projected onto the boundary faces of the previous mesh.

Remarks:

1. **The Mapping File as Output.** In the absence of a *INITIAL_LAG_MAPPING card, adding a "lagmap=" argument to the command line will cause LS-DYNA to write a mapping file. This file contains the following nodal and element data:
   - nodal coordinates (initial and last steps)
   - nodal velocities
   - nodal temperatures (if *CONTROL_THERMAL_SOLVER is used)
   - part IDs

- element connectivities
- element centers
- densities
- volume fractions
- stresses
- plastic strains
- internal energies
- bulk viscosities
- relative volumes
- strains (only if the strain tensor is flagged for output using the variable STRFLG in *DATABASE_EXTENT_BINARY)
- extra history variables

2. **The Mapping File as Input.** If the keyword INITIAL_LAG_MAPPING is in the input deck and the "lagmap=" argument is in the command line, then Lagrangian data is read from the mapping file defined by "lagmap=" to initialize the run.

3. **Part Sets (Write).** The part set, SETID, defines which parts are involved in the mapping. The WRITE option can be used to write data in the mapping file for *only* the parts specified by the set. If the keyword *INITIAL_LAG_MAPPING_WRITE is not included in the input deck, then *all* Lagrangian parts are written in the mapping file during the last cycle.

4. **Part Sets (Read).** The mapping initializes the data for every node and element defined by SETID within the domain swept by the 2D mesh or the region initially occupied by the previous 3D mesh. For nodes and elements outside of SETID it has no effect.

5. **Embedding.** The first point in the definition of the rotation axis VECID specifies the origin location for the mesh of the previous run in the current 3D space. The 2D to 3D mapping depends on whether or not a 3D mesh has already been defined. The 3D to 3D mapping requires a pre-existing mesh.

   a) *No Mesh Case for a 2D to 3D mapping*. If there is no 3D mesh (no element with parts in SETID), the point (XP,YP,ZP) together with the symmetry axis (VECID) are used to generate a mesh. The point defines the plane in which the 2D mesh is embedded. The 3D mesh is generated by rotating the 2D mesh around the axis. The point (XP,YP,ZP) must not be on the symmetry axis. ANGLE defines the angle of rotation in degrees. The rotation is

counterclockwise when viewed from the axis head. NELANGL is the number of elements to generate in the azimuthal direction.

b) *Pre-existing Mesh Case for a 2D to 3D mapping.* If there is a 3D mesh (elements with parts in SETID), the nodes should be within the domain swept by the initial positions of the 2D mesh. Then, the nodes are projected to new locations based on the positions of the previous run's last mesh. If NELANGL = -1, the nodes should be within the domain swept by the final positions of the 2D mesh and the mesh location is not modified.

c) *Pre-existing Mesh Case for a 3D to 3D mapping.* If there is a 3D mesh (elements with parts in SETID) and NELANGL ≠ -1, the nodes should be in the region initially occupied by the previous 3D mesh. Then, the nodes are mapped to new locations based on the previous run's last mesh positions. If ANGLE is defined, the pre-existing mesh is rotated by ANGLE about VECID. The first point in VECID is still the previous origin location and it can be used to translate the pre-existing mesh. However, if NELANGL = -1, the nodes should be in the region finally occupied by the previous 3D mesh and the mesh location is not modified.

d) *3D Axisymmetric to 3D (or 2D) mapping (keyword option WRITE3DAXI).* In the 3D axisymmetric model (1st step model with only solids and/or shells), the point (XP,YP,ZP) defines the radial plane of the 3D axisymmetric mesh used to generate the mapping file. The point (XP,YP,ZP) must not be on the symmetry axis defined by VECID. It is recommended to locate this point on one of the two radial boundaries of the 3D axisymmetric mesh as the nodes of these boundaries do not move out of their plane in the orthoradial direction. The solid faces and shell edges in the radial plane defined by the point (XP,YP,ZP) become shells and beams, respectively, in the mapping file as if a 2D axisymmetric model is run to output this file. The Remarks 5a) and 5b) are still valid to set up the 3D or 2D model of the 2nd step that reads the mapping file.

*INITIAL_MOMENTUM

Purpose: Define initial momentum to be deposited in solid elements. This keyword crudely simulates an impulsive type of loading.

Card	1	2	3	4	5	6	7	8
Variable	EID	MX	MY	MZ	DEPT			
Type	I	F	F	F	F			
Default	none	0.	0.	0.	0.			

VARIABLE	DESCRIPTION
EID	Element ID
MX	Initial *x*-momentum
MY	Initial *y*-momentum
MZ	Initial *z*-momentum
DEPT	Deposition time

Remarks:

Assuming an 8-noded brick element, the specified momentum is distributed equally to each node of the element, and the change in velocity due to this deposited momentum is added to the nodal velocity at the specified deposition time.

*INITIAL_PWP_DEPTH_{OPTION}

The available options include:

<BLANK>

SET

Purpose: Initialize pore water pressure in solid elements where a non-hydrostatic profile is required.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	LC						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
PID	Part ID or Part Set ID for the SET keyword option
LC	Curve of pore water pressure head (length units) as a function of *z*-coordinate

Remarks:

This feature overrides the automatically calculated hydrostatic pressure profile; the hydrostatic pressure profile is the default behavior for a part with pore fluid. The points in the curve must be ordered with the most negative *z*-coordinate first – this order looks "upside-down" on the page.

*INITIAL_PWP_NODAL_DATA

Purpose: Initialize nodal pore pressure data. This keyword is written by LS-DYNA to the dynain file if *CONTROL_PORE_FLUID is present, to enable subsequent analyses beginning from a state reached in a previous analysis. It is not expected that users will create or modify this keyword.

Card 1	1	2	3	4	5	6	7	8
Variable	NID	NHISV	PID					
Type	I	I	I					
Default	none	0	0					

History Variable Cards. Define as many cards as necessary to define NHISV variables. For example, if NHISV = 25, then 5 cards are required.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	HISV1		HISV2		HISV3		HISV4		HISV5	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
NID	Node ID
NHISV	Number of nodal pore pressure history variables.
PID	Part ID with which this node is associated for purposes of evaluating pore fluid related properties.
HISV*i*	Define NHISV history variables.

*INITIAL_SOLID_VOLUME

Purpose: Recalculate and reset initial volume of solid elements using material models with EOS before analysis if the original nodal position has been moved by nodal projections in contact initialization. This option eliminates calculation of non-physical initial hydrostatic pressure due to the nodal repositioning.

Card Sets.

Part Set Card. Define as many of this card as desired. The input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PSID	Part set ID.

*INITIAL_STRAIN_IGA_SHELL

Purpose: Initialize strain tensor and thicknesses at in-plane integration points for isogeometric shell elements, define via *IGA_SHELL. This keyword is primarily for multi-stage metal forming operations where the accumulated strain and the thickness change is of interest.

The strain tensors are defined at the inner and outer integration points and are used for post-processing only. There is no interpolation with this option, and the strains are defined in the global Cartesian coordinate system.

Card Sets. Define as many IGA_SHELL elements in this section as desired, *one set of cards per element*. The input is assumed to terminate when a new keyword ("*") card is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	NPLANE	ITHK	LARGE				
Type	I	I	I	I				
Default	none	none	0	0				

Strain Cards for LARGE = 0.

For the NPLANE integration points, define two pairs of cards below, one pair for the inner integration point and the other pair for the outer integration point, respectively.

Card 2	1	2	3	4	5	6	7	8
Variable	R	S	T					
Type	F	F	F					
Default	none	none	none					

Card 3	1	2	3	4	5	6	7	8
Variable	EPSXX	EPSYY	EPSZZ	EPSXY	EPSYZ	EPSZX	THKI	
Type	F	F	F	F	F	F	F	

Strain Cards for LARGE = 1.

For the NPLANE integration points, define two pairs of cards below, one pair for the inner integration point and the other pair for the outer integration point, respectively.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	R		S		T		EPSXX		EPSYY	
Type	F		F		F		F		F	

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	EPSZZ		EPSXY		EPSYZ		EPSZX		THKI	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
EID	IGA shell element ID
NPLANE	Number of in-plane integration points being output
ITHK	Flag for initialization of thicknesses at in-plane IPs: EQ.0: Off EQ.1: On
LARGE	Large format flag: EQ.0: Off EQ.1: On. Each strain field is twice as long for higher precision.

VARIABLE	DESCRIPTION
R	Parametric *r*-coordinate of location of in-plane integration point (with respect to *IGA_2D_NURBS_XYZ patch definition)
S	Parametric s-coordinate of location of in-plane integration point (with respect to *IGA_2D_NURBS_XYZ patch definition)
T	Parametric coordinate of through thickness integration point between -1 and 1 inclusive.
EPS*ij*	Define the *ij* strain component. The strains are defined in the *global* cartesian system.
THKI	Thickness value at in-plane integration point

*INITIAL_STRAIN_SHELL_{OPTION}

The available options include:

<BLANK>

SET

Purpose: Initialize strain tensor for a shell element. This option is primarily for multi-stage metal forming operations where the accumulated strain is of interest.

These strain tensors are defined at the inner and outer integration points and are used for post-processing only. There is no interpolation with this option and the strains are defined in the global Cartesian coordinate system. The *DATABASE_EXTENT_BINARY flag STRFLG must be set to unity for this option to work. When the keyword option is blank, the strains at all the integration points can be defined by providing nonzero NPLANE and NTHICK and setting INTOUT flag of *DATABASE_EXTENT_BINARY to either "STRAIN" or "ALL."

Card Sets. Define as many shell elements in this section as desired, *one set of cards per element*. The input is assumed to terminate when a new keyword is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	NPLANE	NTHICK	LARGE				ILOCAL
Type	I	I	I	I				I
Default	none	none	none	0				0

Ordering of Integration Points

When NPLANE and NTHICK are defined, include NPLANE × NTHICK cards below. For each through thickness point define NPLANE points. NPLANE should be either 1 or 4 corresponding to either 1 or 4 Gauss integration points. If four integration points are specified, they should be ordered such that their in-plane parametric coordinates are at:

$$\left(-\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\quad \left(\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\quad \left(\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right),\quad \left(-\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right)$$

respectively.

Strain Cards for LARGE = 0.

When NPLANE and NTHICK are not defined or when the SET option is used, define two cards below, one for the inner integration point and the other for the outer integration point, respectively. Otherwise define NPLANE × NTHICK cards, one card for each integration point.

Card 2	1	2	3	4	5	6	7	8
Variable	EPSxx	EPSyy	EPSzz	EPSxy	EPSyz	EPSzx	T	
Type	F	F	F	F	F	F	F	
Default	none	none	none	0.			0.	

Strain Cards for LARGE = 1.

When NPLANE and NTHICK are not defined or when the SET option is used, define two pairs of cards below, one pair for the inner integration point and the other pair for the outer integration point, respectively. Otherwise define NPLANE × NTHICK pairs of cards; one pair for each integration point.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	EPSxx		EPSyy		EPSzz		EPSxy		EPSyz	
Type	F		F		F		F		F	

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	EPSzx		T							
Type	F		F							

VARIABLE	DESCRIPTION
EID	Element ID or shell element set ID when the SET option is used.

VARIABLE	DESCRIPTION
NPLANE	Number of in-plane integration points being output (not read when the SET option is used).
NTHICK	Number of integration points through the thickness (not read when the SET option is used).
LARGE	Large format flag: EQ.0: off, EQ.1: on. Each strain field is twice as long for higher precision.
ILOCAL	Flag for coordinate system of strain components: EQ.0: global, EQ.1: local (not supported).
EPS*ij*	Define the *ij* strain component. The strains are defined in the GLOBAL Cartesian system.
T	Parametric coordinate of through thickness integration point between -1 and 1 inclusive.

*INITIAL_STRAIN_SHELL_NURBS_PATCH

Purpose: Initialize strain tensor and thicknesses at in-plane integration points for isogeometric shell elements. This option is primarily for multi-stage metal forming operations where the accumulated strain and the thickness change is of interest.

The strain tensors are defined at the inner and outer integration points and are used for post-processing only. There is no interpolation with this option and the strains are defined in the global Cartesian coordinate system.

Card Sets. Define as many NURBS shell elements in this section as desired, *one set of cards per element*. The input is assumed to terminate when a new keyword is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	NPLANE	ITHK	LARGE				
Type	I	I	I	I				
Default	none	none	0	0				

Strain Cards for LARGE = 0.

For the NPLANE integration points, define two pairs of cards below, one pair for the inner integration point and the other pair for the outer integration point, respectively.

Card 2	1	2	3	4	5	6	7	8
Variable	R	S	T					
Type	F	F	F					
Default	none	none	none					

Card 3	1	2	3	4	5	6	7	8
Variable	EPSXX	EPSYY	EPSZZ	EPSXY	EPSYZ	EPSZX	THKI	
Type	F	F	F	F	F	F	F	

Strain Cards for LARGE = 1.

For the NPLANE integration points, define two pairs of cards below, one pair for the inner integration point and the other pair for the outer integration point, respectively.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	R		S		T		EPSXX		EPSYY	
Type	F		F		F		F		F	

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	EPSZZ		EPSXY		EPSYZ		EPSZX		THKI	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
EID	NURBS element ID
NPLANE	Number of in-plane integration points being output
ITHK	Flag for initialization of thicknesses at in-plane IPs: EQ.0: off EQ.1: on
LARGE	Large format flag: EQ.0: off EQ.1: on. Each strain field is twice as long for higher precision.

VARIABLE	DESCRIPTION
R	Parametric *r*-coordinate of location of in-plane integration point (with respect to NURBS patch definition)
S	Parametric s-coordinate of location of in-plane integration point (with respect to NURBS patch definition)
T	Parametric coordinate of through thickness integration point between -1 and 1 inclusive.
EPS*ij*	Define the *ij* strain component. The strains are defined in the GLOBAL Cartesian system.
THKI	Thickness value at in-plane integration point

*INITIAL_STRAIN_SOLID_{OPTION}

The available options include:

<BLANK>

SET

Purpose: Initialize strain tensor at element center. This keyword can be used for multi-stage metal forming operations where the accumulated strain is of interest.

These strain tensors are defined at the element center and are used for post-processing only. The strains are defined in the global Cartesian coordinate system. The ones digit of STRFLG in *DATABASE_EXTENT_BINARY is automatically set to unity when *INITIAL_STRAIN_SOLID_{OPTION} is included in the input deck. This capability is not available for cohesive elements since it is based on displacements, not strains.

Card Sets. Define as many solid elements in this section as desired: *one pair of cards per element*. The input is assumed to terminate when a new keyword ("*") card is detected.

Element ID Cards.

Card 1	1	2	3	4	5	6	7	8
Variable	EID							
Type	I							
Default	none							

Strain Cards.

Card 2	1	2	3	4	5	6	7	8
Variable	EPSxx	EPSyy	EPSzz	EPSxy	EPSyz	EPSzx		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
EID	Element ID or solid element set ID when the SET keyword option is used.

VARIABLE	DESCRIPTION
EPS*ij*	Define the ij^{th} strain component. The strains are defined in the global cartesian system.

*INITIAL_STRAIN_SOLID_NURBS_PATCH

Purpose: Initialize strain at integration points for isogeometric solid elements.

These strain tensors are used for post-processing only. There is no interpolation with this option and the strains are defined in the global Cartesian coordinate system.

Card Sets. Define as many NURBs solid elements in this section as desired, *one set of cards per element*. The input is assumed to terminate when a new keyword ("*") card is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	NIP	LARGE					
Type	I	I	I					
Default	none	none	0					

Strain Cards for LARGE = 0.

For each NIP integration points, define a pair of cards below.

Card 2	1	2	3	4	5	6	7	8
Variable	R	S	T					
Type	F	F	F					
Default	none	none	none					

Card 3	1	2	3	4	5	6	7	8
Variable	EPSXX	EPSYY	EPSZZ	EPSXY	EPSYZ	EPSZX		
Type	F	F	F	F	F	F		

Strain Cards for LARGE = 1.

For each NIP integration points, define a pair of cards below.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	R		S		T		EPSXX		EPSYY	
Type	F		F		F		F		F	

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	EPSZZ		EPSXY		EPSYZ		EPSZX			
Type	F		F		F		F			

VARIABLE	DESCRIPTION
EID	NURBS element ID
NIP	Number of integration points being output
LARGE	Large format flag: EQ.0: off EQ.1: on. Each strain field is twice as long for higher precision.
R	Parametric *r*-coordinate of location of in-plane integration point (with respect to NURBS patch definition)
S	Parametric *s*-coordinate of location of in-plane integration point (with respect to NURBS patch definition)
T	Parametric *t*-coordinate of location of in-plane integration point (with respect to NURBS patch definition)
EPS*ij*	Define the *ij* strain component. The strains are defined in the GLOBAL Cartesian system.

*INITIAL_STRAIN_TSHELL_{OPTION}

The available options include:

<BLANK>

SET

Purpose: Initialize the strain tensors for thick shell elements.

Strain tensors are defined at the inner and outer integration points and are used for post-processing only. Strain tensors are defined in the global Cartesian coordinate system. The STRFLG flag on *DATABASE_EXTENT_BINARY must be set to unity for this keyword to work. Initialize as many elements as needed.

Card Sets. For each element, include a set of Cards 1, 2, and 3, where Card 2 is for the inner layer and Card 3 is for the outer layer. The input is assumed to terminate when a new keyword (*) card is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID/SID							
Type	I							
Default	none							

Strain Cards. Card 2 is the strain at the inner layer. Card 3 is the strain at the outer layer.

Cards 2, 3	1	2	3	4	5	6	7	8
Variable	EPSxx	EPSyy	EPSzz	EPSxy	EPSyz	EPSzx		
Type	F	F	F	F	F	F		
Default	0	0	0	0	0	0		

VARIABLE	DESCRIPTION
EID/SID	Element ID or thick shell element set ID when the SET option is used, see *SET_TSHELL.

VARIABLE	DESCRIPTION
EPS*ij*	Define the ij^{th} strain component. The strains are defined in the global cartesian system.

*INITIAL_STRESS_BEAM

Purpose: Initialize stresses, plastic strains and history variables for Hughes-Liu beam elements and truss beam elements, or the axial force, moment resultants and history variables for Belytschko-Schwer beam elements and discrete beams.

Card Summary:

Card Sets. Define as many beams in this section as desired. Each set consists of one Card 1 and several additional cards depending on variables NPTS, LARGE, NHISV, and NAXES. The input terminates when a new keyword ("*") card is detected.

Card 1. This card is required.

EID	RULE	NPTS	LOCAL	LARGE	NHISV	NAXES	

Card 2a. This card is included for Belytschko-Schwer beams if LARGE = 0.

F11	T11	M12	M13	M22	M23	PARM	

Card 2b.1. This card is included for Belytschko-Schwer beams if LARGE = 1.

F11	T11	M12	M13	M22

Card 2b.2. This card is included for Belytschko-Schwer beams if LARGE = 1. Include additional cards of this format to include all of the history variables.

M23	PARM	HISV1	HISV2	HISV3

Card 2c. Include this card NPTS times for Hughes-Liu or truss beams if LARGE = 0.

SIG11	SIG22	SIG33	SIG12	SIG23	SIG31	EPS	

Card 2d.1. Include NPTS sets of this card and Card 2d.2 for Hughes-Liu or truss beams if LARGE = 1.

SIG11	SIG22	SIG33	SIG12	SIG23

Card 2d.2. For each of the NPTS sets include additional cards of this format to include all of the history variables.

SIG31	EPS	HISV1	HISV2	HISV3

Card 3.1. This card is included if NAXES = 12.

AX1	AX2	AX3	AX4	AX5

Card 3.2. This card is included if NAXES = 12.

AX6	AX7	AX8	AX9	AX10

Card 3.3. This card is included if NAXES = 12.

AX11	AX12			

Card 1	1	2	3	4	5	6	7	8
Variable	EID	RULE	NPTS	LOCAL	LARGE	NHISV	NAXES	
Type	I	I	I	I	I	I	I	
Default	none	2	none	0	0	0	0	

VARIABLE	DESCRIPTION
EID	Element ID
RULE	Integration rule type number: EQ.1: 1 × 1 Gauss quadrature, EQ.2: 2 × 2 Gauss quadrature (default beam), EQ.3: 3 × 3 Gauss quadrature, EQ.4: 3 × 3 Lobatto quadrature, EQ.5: 4 × 4 Gauss quadrature.
NPTS	Number of integration points. For the Belytschko-Schwer resultant beam element, NPTS = 1.
LOCAL	Coordinate system for stresses: EQ.0: Stress components are defined in the global coordinate system. EQ.1: Stress components are defined in the local beam system. In the local system components SIG22, SIG33, and SIG23 are set to 0.0.
LARGE	Format size: EQ.0: Off,

VARIABLE	DESCRIPTION
	EQ.1: On. Each field is twice as long for higher precision.
NHISV	Number of additional history variables. Only available for LARGE = 1.
NAXES	Number of variables giving beam local axes (0 or 12)

Belytschko-Schwer Card for LARGE = 0. Additional card for the Belytschko-Schwer beam.

Card 2a	1	2	3	4	5	6	7	8
Variable	F11	T11	M12	M13	M22	M23	PARM	
Type	F	F	F	F	F	F	F	

Belytschko-Schwer Cards for LARGE = 1. Additional cards for the Belytschko-Schwer beam. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 2b.1	1	2	3	4	5	6	7	8	9	10
Variable	F11		T11		M12		M13		M22	
Type	F		F		F		F		F	

Card 2b.2	1	2	3	4	5	6	7	8	9	10
Variable	M23		PARM		HISV1		HISV2		HISV3	
Type	F		F		F		F		F	

Hughes-Liu Cards for LARGE = 0. Additional cards for the Hughes-Liu or truss beam. Include NPTS additional cards, one per integration point. See Remark 1.

Card 2c	1	2	3	4	5	6	7	8
Variable	SIG11	SIG22	SIG33	SIG12	SIG23	SIG31	EPS	
Type	F	F	F	F	F	F	F	

Hughes-Liu Cards for LARGE = 1. Additional cards for the Hughes-Liu or truss beam. Include NPTS additional card sets, one per integration point. Include as many cards in one card set as necessary to collect NHISV (see Card 1) history variables. See Remark 1.

Card 2d.1	1	2	3	4	5	6	7	8	9	10
Variable	SIG11		SIG22		SIG33		SIG12		SIG23	
Type	F		F		F		F		F	

Card 2d.2	1	2	3	4	5	6	7	8	9	10
Variable	SIG31		EPS		HISV1		HISV2		HISV3	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
F11	Axial force resultant along local beam axis 1
T11	Torsional moment resultant about local beam axis 1
M12	Moment resultant at node 1 about local beam axis 2
M13	Moment resultant at node 1 about local beam axis 3
M22	Moment resultant at node 2 about local beam axis 2
M23	Moment resultant at node 2 about local beam axis 3
PARM	Generally not used.
SIG*ij*	Define the *ij* stress component

VARIABLE	DESCRIPTION
EPS	Effective plastic strain
HISV*n*	Define the *n*th history variable

Optional Local Axes Cards for NAXES = 12. Additional cards for definition of local axes values. These 12 values are internally used by LS-DYNA for the mapping between local beam element system and global coordinate system. They are automatically written to the dynain file if *INTERFACE_SPRINGBACK_LSDYNA or *CONTROL_STAGED_CONSTRUCTION is used.

Card 3.1	1	2	3	4	5	6	7	8	9	10
Variable	AX1		AX2		AX3		AX4		AX5	
Type	F		F		F		F		F	

Card 3.2	1	2	3	4	5	6	7	8	9	10
Variable	AX6		AX7		AX8		AX9		AX10	
Type	F		F		F		F		F	

Card 3.3	1	2	3	4	5	6	7	8	9	10
Variable	AX11		AX12							
Type	F		F							

VARIABLE	DESCRIPTION
AX*n*	The *n*th local axes value

Remarks:

1. **Axial Stress for Truss Beams.** Note that only SIG11 is nonzero for truss elements since they only carry axial forces.

***INITIAL_STRESS_DEPTH**_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Initialize solid element stresses where stress is a function of depth. This feature is intended only for material models whose stresses are updated incrementally and whose stress state does not depend on internal history variables.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	RO_G	ZDATUM	KFACT	LC	LCH	LCK0	
Type	I	F	F	F	I	I	I	
Default	none	none	none	0.0	opt	opt	opt	

VARIABLE	DESCRIPTION
PID/PSID	Part ID or Part Set ID for the SET option
RO_G	Stress per unit elevation above datum, which is usually ρ_g = density × gravity.
ZDATUM	z-coordinate of datum
KFACT	x and y-stresses = KFACT × z-stress
LC	Optional curve of stress as a function of the z-coordinate (ZDATUM is ignored with this option)
LCH	Optional curve of horizontal stress as function of the z-coordinate (KFACT is ignored with this option)
LCK0	Optional curve of K0 (ratio of horizontal stress to vertical stress) as a function z-coordinate. KFACT and LCH are ignored with this option. The x-axis of the curve is the z-coordinate, the y-axis is K0.

Remarks:

1. **Model Description.** With this keyword stress is calculated according to,

$$\sigma_z = \mathrm{RO_G} \times (\mathrm{Z_{element}} - \mathrm{ZDATUM}) ,$$

where $\mathrm{Z_{element}}$ is the z-coordinate of the centroid of the element. It is assumed that the z-axis points vertically upwards. For a 2D problem (axisymmetric or plane strain), replace z in this documentation with y. To generate compressive stresses, the datum should be above the highest element, that is, the datum should have a more positive z-coordinate. For instance, this is at the surface of the soil in geotechnics simulations. If the curve, LC, is defined, it overrides RO_-G and ZDATUM. Note that the points in the curve should be ordered with most negative z-coordinate first.

2. **Pore Water.** If pore water is present, the stresses input here are effective (meaning soil skeleton stresses only, not including the pore pressure). The pore water pressures will automatically be initialized to hydrostatic, or by *INITIAL_-PWP_DEPTH or *BOUNDARY_PWP_TABLE if those cards are present. Effective vertical stress at a given depth is usually equal to the buoyant weight of the soil between that depth and the surface, where buoyant weight is calculated from the density of the saturated soil minus the density of water. The density of saturated soil is the RO given on the *MAT card, and the density of water is the PF_RHO given on *BOUNDARY_PORE_FLUID or *CONTROL_PORE_FLUID. Note also that the density of saturated soil is somewhat higher than the density of dry soil, and the value of RO on the *MAT card should reflect this.

3. **Stress at Integration Points.** For fully integrated elements, the stress calculated for the element centroid is applied at all the integration points. There is no stress gradation up the height of the element. This is to ensure equilibrium with gravity loading, which is applied at the nodes and therefore results in stress that is uniformly distributed up the height of the element.

*INITIAL_STRESS_DES

Purpose: Initialize stresses and coordination number for DES elements.

Element Cards. Define as many DES elements in this section as desired. The new keyword ("*") terminates this input.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	SIGXX	SIGYY	SIGZZ	SIGXY	SIGYZ	SIGZX	COOR
Type	I	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
EID	DES particle ID
SIG*ij*	Define the ij^{th} stress component. Stresses are defined in the global cartesian system.
COOR	Define the coordination number of the DES element

*INITIAL_STRESS_IGA_SHELL

Purpose: Initialize stresses, history variables, and the effective plastic strain for isogeometric shell elements, define via *IGA_SHELL. Materials that do not use an incremental formulation for the stress update may not be initializable with this card.

Card Sets per Element. Define as many IGA_SHELL elements in this section as desired. The input is assumed to terminate when a new keyword ("*") card is detected.

Element Card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	NPLANE	NTHICK	NHISV	LARGE			
Type	I	I	I	I	I			
Default	none	none	none	0	0			

Solid Mechanics Data Card for LARGE = 0.

The following set of cards: "Stress Cards" and "History Variable Cards" should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card1. Additional Card for LARGE = 0.

Card 2	1	2	3	4	5	6	7	8
Variable	R	S	T					
Type	F	F	F					

Stress Card2. Additional Card for LARGE = 0.

Card 3	1	2	3	4	5	6	7	8
Variable	SIGXX	SIGYY	SIGZZ	SIGXY	SIGYZ	SIGZX	EPSP	
Type	F	F	F	F	F	F	F	

History Variable Cards. Additional Cards for LARGE = 0. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 4	1	2	3	4	5	6	7	8
Variable	HISV1	HISV2	HISV3	HISV4	HISV5	HISV6	HISV7	HISV8
Type	F	F	F	F	F	F	F	F

Solid Mechanics Data Card for LARGE = 1.

The following set of cards: "Stress Cards" and "History Variable Cards" should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card 1. Additional Card for LARGE = 1.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	R		S		T		SIGXX		SIGYY	
Type	F		F		F		F		F	

Stress Card 2. Additional Card for LARGE = 1.

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	SIGZZ		SIGXY		SIGYZ		SIGZX		EPS	
Type	F		F		F		F		F	

History Variable Cards. Additional Cards for LARGE = 1. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 4	1	2	3	4	5	6	7	8	9	10
Variable	HISV1		HISV2		HISV3		HISV4		HISV5	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
EID	IGA shell element ID
NPLANE	Number of in-plane integration points being output
NTHICK	Number of integration points through the thickness
NHISV	Number of additional history variables.
LARGE	Format size. See cards above. EQ.0: Off EQ.1: On
R	Parametric *r*-coordinate of location of in-plane integration point (with respect to *IGA_2D_NURBS_XYZ-patch definition)
S	Parametric *s*-coordinate of location of in-plane integration point (with respect to *IGA_2D_NURBS_XYZ-patch definition)
T	Parametric coordinate of through thickness integration point between -1 and 1 inclusive.
SIG*ij*	Define the *ij* stress component. The stresses are defined in the *global* cartesian system.
EPS	Effective plastic strain
HISV*n*	Define the n^{th} history variable

*INITIAL_STRESS_SECTION

Purpose: Initialize (pre-load) the stress normal to a plane intersecting the model using a curve (*DEFINE_CURVE). The initialization is applied to a set of solid elements that are specified using the *DATABASE_CROSS_SECTION card. This option is compatible only with those material models that are incrementally updated (such as elastic, viscoelastic, and elastoplastic). Except as noted in Remark 3, rubbers, foams, and materials that are combined with equations-of-state cannot be initialized with this card.

Card 1	1	2	3	4	5	6	7	8
Variable	ISSID	CSID	LCID	PSID	VID	IZSHEAR	ISTIFF	
Type	I	I	I	I	I	I	I	
Default	none	none	none	none	none	0	0	

VARIABLE	DESCRIPTION
ISSID	ID for this card.
CSID	Cross-section ID. See *DATABASE_CROSS_SECTION.
LCID	Load curve ID defining preload stress as a function of time. When the load curve ends or goes to zero, the initialization is assumed to be completed. See Remark 2.
PSID	Part set ID. Stress is initialized on only those parts included in *both* PSID from this card and the PSID field from the associated *DATABASE_CROSS_SECTION card.
VID	Vector ID (see *DEFINE_VECTOR) specifies the direction normal to the cross section (CSID). VID *must* be set when the "SET" variant of *DATABASE_CROSS_SECTION (*DATABASE_CROSS_SECTION_SET) is used. If the cross section is defined using the PLANE option, the normal used in the definition of the plane is used when VID is left undefined.
IZSHEAR	Shear stress flag: EQ.0: Shear stresses are prescribed as zero during the time the curve is acting to prescribe normal stress.

VARIABLE	DESCRIPTION
	EQ.1: Shear stresses are allowed to develop during the time the curve is acting to prescribe normal stress. For implicit the section can also take bending and is identical to 2; see Remark 5.
	EQ.2: Shear and bending stresses are allowed to develop during the time the curve is acting to prescribe normal stress; see Remark 5.
ISTIFF	Artificial stiffness. Simulates additional linearly elastic "ghost" elements in the cross section. These elements prevent mesh distortion by stiffening up the structure.
	GT.0: Load curve ID defining stiffness fraction as a function of time. The stiffness of the ghost elements is the load curve value times the stiffness of the material in the part. Since the ghost element stress counteracts the preload stress the fraction should be low (1% or less). The total section stress is the preload stress minus the ghost element stress.
	LT.0: |ISTIFF| is the load curve ID for the stiffness fraction as a function of time. The preload stress is here automatically adjusted ($\pm$10% of original prestress values) such that the total section stress corresponds to the curve in LCID.

Remarks:

1. **Dynamic Relaxation Issues.** To achieve convergence during explicit dynamic relaxation, applying damping options is very important. If contact is active, contact damping is recommended with a value between 10 - 20 percent. Additional damping applied using *DAMPING_PART_STIFFNESS also speeds up convergence where a coefficient of 0.10 is effective. If damping is not used, convergence may not be possible.

2. **Best Practices for Quasi-Static Load Ramp-up.** When defining the load curve, LCID, a ramp starting at the origin should be used to increase the stress to the desired value. The time duration of the ramp should produce a quasi-static response. When the end of the load curve is reached, or when the value of the load decreases from its maximum value, the initialization stops. If the load curve begins at the desired stress value, that is, no ramp, convergence will take much longer, since the impulsive like load created by the initial stress can excite nearly every frequency in the structural system where stress is initialized.

3. **Supported Materials.** This option currently applies only to materials that are incrementally updated. Hyperelastic materials and materials that require an equation-of-state are not currently supported. However, materials 57, 73, and 83 can be initialized with this approach.

4. **Supported Elements.** Solid elements types 1, 2, 3, 4, 9, 10, 13, 15, 16, 17, and 18 are supported. ALE elements are not supported. Element forms 16 and 17 with mid-side nodes may only work well if the area of the cross-section where the preload stress is applied does not vary. In other words, element forms 16 or 17 will not work to preload a tapered part.

5. **IZSHEAR for Solid Elements.** By default, IZSHEAR = 0, that is, *only* the stress normal to the section is prescribed while *all* other stress components are set to zero. Therefore, the stress tensor components with respect to a local system aligned with the section would have $\sigma_{xx} = \sigma$ (the prescribed value) and $\sigma_{yy} = \sigma_{zz} = \sigma_{xy} = \sigma_{xz} = \sigma_{yz} = 0$, which holds for each integration point of each element in the section. This initialization in turn means that these elements, thus the entire section, are infinitely weak in bending and shear which might have a potential side effect of unexpected and nonsensical deformations for certain loading and surrounding geometry conditions.

   Turning on IZSHEAR = 1 will for *explicit analysis* essentially relax the zero constraint on the shear stresses, resulting in a stress tensor where σ_{xy}, σ_{xz} and σ_{yz} are updated according to the laws of the material model, thus adding some shear stiffness to the section to avoid spurious deformations.

   For *implicit analysis* (and currently only for low order element formulations -1, -2, 1, 2, 10, 13, 15 and 115 with sections defined using *DATABASE_CROSS_SECTION_PLANE or *DATABASE_CROSS_SECTION_SET), the following approach is taken for IZSHEAR = 1: Each collection of elements in a section (for example, of a bolt) is identified and seen as an entity for which only the *mean normal stress* of the section is prescribed, in contrast to imposing constraints on each integration point. For example, if the goal is to prestress 10 bolts modeled with solid elements, LS-DYNA will, based on element connectivity, identify the 10 unique sections (10 clusters of elements) corresponding to each bolt, and subsequently prescribe the mean stress in each of these sections independently. The advantage of this approach is that the section can globally resist bending and shear, and thus preserve the structural integrity of the bolt more adequately.

   The IZSHEAR = 1 approach for implicit is also available in explicit analysis through IZSHEAR = 2. Note that if this approach is used with *DATABASE_CROSS_SECTION_SET, the vector option must be used to define the normal direction. Using *DATABASE_CROSS_SECTION_SET leads to a better distribution of the stress than *DATABASE_CROSS_SECTION_PLANE by, for instance, imposing the stress for a sufficient length of the shank. Distributing

the stress with this method prevents elements from collapsing, thereby preserving structural integrity.

IZSHEAR = 2 can also be used when the initial stress (meaning stress at time zero) in the section is nonzero. For instance, bolts that are to be preloaded may have already gone through a sequence of load steps from prior simulations, resulting in a nonzero initial stress state. The load curve for the stress should still start at the origin and increase to the desired stress value. LS-DYNA will preserve stress continuity at the start of the simulation by internally scaling the curve appropriately.

***INITIAL_STRESS_SHELL**_{OPTION}_

Available options include:

<BLANK>

SET

Purpose: Initialize stresses, history variables, and the effective plastic strain for shell elements. Materials that do not use an incremental formulation for the stress update may not be initializable with this card.

Card Sets per Element. Define as many shell elements or shell element sets in this section as desired. The input is assumed to terminate when a new keyword ("*") card is detected.

Element Card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID/SID	NPLANE	NTHICK	NHISV	NTENSR	LARGE	NTHINT	NTHHSV
Type	I	I	I	I	I	I	I	I
Default	none	none	none	0	0	0	0	0

Ordering of Integration Points.

For each through thickness point define NPLANE points. NPLANE should be either 1 or 4 corresponding to either 1 or 4 Gauss integration points. If four integration points are specified, they should be ordered such that their in-plane parametric coordinates are at:

$$\left(-\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\quad \left(\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\quad \left(\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right),\quad \left(-\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right),$$

respectively. It is not necessary for the location of the through thickness integration points to match those used in the elements which are initialized. The data will be interpolated by LS DYNA.

Solid Mechanics Data Card for LARGE = 0.

The following set of cards, "Stress Card" through "Tensor Cards," should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card. Additional Card for LARGE = 0.

Card 2	1	2	3	4	5	6	7	8
Variable	T	SIGXX	SIGYY	SIGZZ	SIGXY	SIGYZ	SIGZX	EPS
Type	F	F	F	F	F	F	F	F

History Variable Cards. Additional Cards for LARGE = 0. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 3	1	2	3	4	5	6	7	8
Variable	HISV1	HISV2	HISV3	HISV4	HISV5	HISV6	HISV7	HISV8
Type	F	F	F	F	F	F	F	F

Tensor Cards. Additional card for LARGE = 0. Include as many cards as necessary to collect NTENSR (see Card 1) entries. Tensor cards contain only 6 entries per card.

Card 4	1	2	3	4	5	6	7	8
Variable	TENXX	TENYY	TENZZ	TENXY	TENYZ	TENZX		
Type	F	F	F	F	F	F		

Solid Mechanics Data Card for LARGE = 1.

The following set of cards, "Stress Card 1" through "Tensor Cards," should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card 1. Additional Card for LARGE = 1.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	T		SIGXX		SIGYY		SIGZZ		SIGXY	
Type	F		F		F		F		F	

Stress Card 2. Additional Card for LARGE = 1.

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	SIGYZ		SIGZX		EPS					
Type	F		F		F					

History Variable Cards. Additional Cards for LARGE = 1. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 4	1	2	3	4	5	6	7	8	9	10
Variable	HISV1		HISV2		HISV3		HISV4		HISV5	
Type	F		F		F		F		F	

Tensor Cards. Include as many pairs of Cards 5 and 6 as necessary to collect NTENSR entries. Note that Cards 5 and 6 must appear as pairs, and that Card 6 may include at most one value, as indicated below.

Card 5	1	2	3	4	5	6	7	8	9	10
Variable	TENXX		TENYY		TENZZ		TENXY		TENYZ	
Type	F		F		F		F		F	

Card 6	1	2	3	4	5	6	7	8	9	10
Variable	TENZX									
Type	F									

Thermal Data Cards for LARGE = 1.

For each element, thermal data cards come after the *entire* set of mechanical data cards. For each of the NTHINT thermal integration points, include the following set of cards.

Thermal Time History Cards. Additional cards for LARGE = 1. Include as many cards as needed to collect all the of NTHHSV time history variables per thermal integration point.

Card 7	1	2	3	4	5
Variable	THHSV1	THHSV2	THHSV3	THHSV4	THHSV5
Type	F	F	F	F	F

VARIABLE	DESCRIPTION
EID/SID	Element ID or shell set ID, see *SET_SHELL_…
NPLANE	Number of in plane integration points being output.
NTHICK	Number of integration points through the thickness.
NHISV	Number of additional history variables.
NTENSR	Number of components of tensor data taken from the element history variables stored.
LARGE	Format size. See cards above. EQ.0: off EQ.1: on
T	Parametric coordinate of through thickness integration point between -1 and 1 inclusive.
SIG*ij*	Define the *ij* stress component. The stresses are defined in the GLOBAL cartesian system.
EPS	Effective plastic strain.
HISV*n*	Define the n^{th} history variable.
TEN*ij*	Define the ij^{th} component of the tensor taken from the history variables. The tensor is defined in the GLOBAL Cartesian system. Define enough lines to provide a total of NTENSOR components, stored six components per line. This applies to material 190 only.
NTHINT	Number of thermal integration points.
NTHHSV	Number of thermal history variables per thermal integration point.

VARIABLE	DESCRIPTION
THHSV*n*	n^{th} history variable at the thermal integration point.

*INITIAL_STRESS_SHELL_NURBS_PATCH

Purpose: Initialize stresses, history variables, and the effective plastic strain for isogeometric shell elements. Materials that do not use an incremental formulation for the stress update may not be initializable with this card.

Card Sets per Element. Define as many NURBS shell elements in this section as desired. The input is assumed to terminate when a new keyword ("*") card is detected.

Element Card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	NPLANE	NTHICK	NHISV	LARGE			
Type	I	I	I	I	I			
Default	none	none	none	0	0			

Solid Mechanics Data Card for LARGE = 0.

The following set of cards: "Stress Cards" and "History Variable Cards" should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card1. Additional Card for LARGE = 0.

Card 2	1	2	3	4	5	6	7	8
Variable	R	S	T					
Type	F	F	F					

Stress Card2. Additional Card for LARGE = 0.

Card 3	1	2	3	4	5	6	7	8
Variable	SIGXX	SIGYY	SIGZZ	SIGXY	SIGYZ	SIGZX	EPSP	
Type	F	F	F	F	F	F	F	

History Variable Cards. Additional Cards for LARGE = 0. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 4	1	2	3	4	5	6	7	8
Variable	HISV1	HISV2	HISV3	HISV4	HISV5	HISV6	HISV7	HISV8
Type	F	F	F	F	F	F	F	F

Solid Mechanics Data Card for LARGE = 1.

The following set of cards: "Stress Cards" and "History Variable Cards" should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card 1. Additional Card for LARGE = 1.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	R		S		T		SIGXX		SIGYY	
Type	F		F		F		F		F	

Stress Card 2. Additional Card for LARGE = 1.

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	SIGZZ		SIGXY		SIGYZ		SIGZX		EPS	
Type	F		F		F		F		F	

History Variable Cards. Additional Cards for LARGE = 1. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 4	1	2	3	4	5	6	7	8	9	10
Variable	HISV1		HISV2		HISV3		HISV4		HISV5	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
EID	NURBS Element ID
NPLANE	Number of in plane integration points being output.
NTHICK	Number of integration points through the thickness.
NHISV	Number of additional history variables.
LARGE	Format size. See cards above. EQ.0: off EQ.1: on
R	Parametric *r*-coordinate of location of in-plane integration point (with respect to NURBS-patch definition)
S	Parametric *s*-coordinate of location of in-plane integration point (with respect to NURBS-patch definition)
T	Parametric coordinate of through thickness integration point between -1 and 1 inclusive.
SIG*ij*	Define the *ij* stress component. The stresses are defined in the GLOBAL cartesian system.
EPS	Effective plastic strain.
HISV*n*	Define the n^{th} history variable.

***INITIAL_STRESS_SOLID** *{OPTION}*

Available options include:

<BLANK>

SET

Purpose: Initialize stresses and plastic strains for solid elements.

Material models 2, 5, 7, 21, 23, 27, 31, 38, 57, 73, 77, 83,132, 179, 181, 183, and 189 support a reference configuration (see *INITIAL_FOAM_REFERENCE_GEOMETRY and the variable REF in the material description), and if that feature is invoked, it will take precedence over *INITIAL_STRESS_SOLID. Furthermore, if FMATRX = 2 in *CONTROL_SOLID, *INITIAL_STRESS_SOLID is ignored for the aforementioned material models.

For *MAT_014 and any material that requires an equation-of-state (*EOS), the specified initial stresses are adjusted to be in accordance with the initial pressure calculated from the equation of state.

Card Sets per Element or Element Set. For this keyword, each data card set consists of an element or element set card and all of its corresponding data cards, both thermal and mechanical. For LARGE = 1, this can involve several (even tens of) cards per set. Include cards for as many solid elements or solid element sets as desired. The input is assumed to terminate when a new keyword ("*") card is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID/SID	NINT	NHISV	LARGE	IVEFLG	IALEGP	NTHINT	NTHHSV
Type	I	I	I	I	I	I	I	I
Default	none	none	0	0	0	0	0	0

Ordering of Integration Points.

NINT may be 1, 8, or 14 for hexahedral solid elements, depending on the element formulation. If eight Gauss integration points are specified, they should be ordered such that their parametric coordinates are located at:

$$\left(-\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\left(\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\left(\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\left(-\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),$$

$$\left(-\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right),\left(\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right),\left(\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right),\left(-\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right),$$

respectively. If eight points are defined for 1 point LS-DYNA solid elements, the average value will be taken.

NINT may be 1, 4, or 5 for tetrahedral solid elements, depending on the element formulation and NIPTETS in *CONTROL_SOLID. NINT may be 1 or 2 for pentahedral solid elements, depending on the element formulation.

Solid Mechanics Data Card for LARGE = 0.

Stress Card. Additional Card for LARGE = 0. This card should be included NINT times (one for each integration point).

Card 2	1	2	3	4	5	6	7	8
Variable	SIGXX	SIGYY	SIGZZ	SIGXY	SIGYZ	SIGZX	EPS	
Type	F	F	F	F	F	F	F	

Mechanical Data Cards for LARGE = 1.

The following set of cards "Stress Card 1" through "Additional History Cards." Should be included NINT times (one set for each integration point).

Stress Card 1. Additional cards for LARGE = 1.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	SIGXX		SIGYY		SIGZZ		SIGXY		SIGYZ	
Type	F		F		F		F		F	

Stress Card 2. Additional cards for LARGE = 1.

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	SIGZX		EPS		HISV1		HISV2		HISV3	
Type	F		F		F		F		F	

Additional History Cards. Additional cards for LARGE = 1. If NHISV > 3 define as many additional cards as necessary. NOTE: the value of IVEFLG (see Card 1) can affect the number of history variables on these cards.

Card 4	1	2	3	4	5	6	7	8	9	10
Variable	HISV4		HISV5		HISV6		HISV7		HISV8	
Type	F		F		F		F		F	

Thermal Data Cards for LARGE = 1.

For each element, thermal data cards come after the *entire* set of mechanical data cards. For each of the NTHINT thermal integration points, include the following set of cards.

Thermal Time History Cards. Additional cards for LARGE = 1. Include as many cards as needed to capture all the of NTHHSV time history variables per thermal integration point.

Card 5	1	2	3	4	5	6	7	8	9	10
Variable	THHSV1		THHSV2		THHSV3		THHSV4		THHSV5	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
EID/SID	Element ID or solid set ID; see *SET_SOLID_...
NINT	Number of integration points (should correspond to the solid element formulation).
NHISV	Number of additional history variables, which is typically equal to the number of history variables stored at the integration point + IVEFLG.
LARGE	Format size. If zero, NHISV must also be set to zero (this is the format used by LS-DYNA versions 970 and earlier), and, if set to 1, a larger format is used and NHISV is used.

VARIABLE	DESCRIPTION
IVEFLG	Initial Volume/energy flag (**only used in large format**): EQ.0: Last history variable is used as normal. EQ.1: Last history variable is used as the initial volume of the element. One additional history variable is required if IVEFLG = 1. EQ.2: Last two history variables are used to define the initial volume and the internal energy per unit initial volume. Two additional history variables must be allocated; see NHISV above, if IVEFLG = 2. If the initial volume is set to zero, the actual element volume is used.
IALEGP	The ALE multi-material group (AMMG) ID; only if the element is of ALE multi-material formulation (ELFORM = 11). In this case, each AMMG has its own sets of stress and history variables, so we must specify to which AMMG the stress data are assigned. For mixed elements, multiple cards are needed to complete the stress initialization in this element as each AMMG needs to have its own set of stress data. EQ.0: Assuming the element is fully filled by the AMMG that the element part belongs to. Please refer to *ALE_MULTI-MATERIAL_GROUP card. EQ.n: Assigning the stress to nth AMMG in that element.
SIG*ij*	Define the ij^{th} stress component. Stresses are defined in the GLOBAL Cartesian system.
EPS	Effective plastic strain
HISV*i*	Define NHISV history variables.
NTHINT	Number of thermal integration points
NTHHSV	Number of thermal history variables per thermal integration point
THHSV*n*	n^{th} thermal time history variable

Remarks:

1. **Cohesive Elements.** The elastic material model for cohesive elements is a total Lagrangian formulation, and the initial stress will therefore be ignored for it.

2. **Tensorial History Variables.** If the history variable field contains tensorial quantities, such as back stresses or similar tensors (such as for *MAT_003), then *INCLUDE_TRANSFORM with *DEFINE_TRANSFORMATION including a rotation (options MIRROR, ROTATE, POS6P, POS6N) should not be used. Only the actual stress tensor is transformed correctly at the moment.

*INITIAL_STRESS_SOLID_NURBS_PATCH

Purpose: Initialize stresses, effective plastic strain, and history variables for isogeometric solid elements. This command is not applicable to hyperelastic materials or any material model based on a Total Lagrangian formulation.

Card Sets. Define as many NURBSsolid elements in this section as desired, *one set of cards per element*. The input is assumed to terminate when a new keyword ("*") card is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	NINT	NHISV	LARGE				
Type	I	I	I	I				
Default	none	none	0	0				

Solid Mechanics Data Card for LARGE = 0.

The following set of cards, "Stress Cards" and "History Variable Cards," should be included NINT times (one set for each integration point).

Stress Card1. Additional card for LARGE = 0.

Card 2	1	2	3	4	5	6	7	8
Variable	R	S	T					
Type	F	F	F					

Stress Card2. Additional card for LARGE = 0.

Card 2	1	2	3	4	5	6	7	8
Variable	SIGXX	SIGYY	SIGZZ	SIGXY	SIGYZ	SIGZX	EPS	
Type	F	F	F	F	F	F	F	

History Variable Cards. Additional card for LARGE = 0. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 3	1	2	3	4	5	6	7	8
Variable	HISV1	HISV2	HISV3	HISV4	HISV5	HISV6	HISV7	HISV8
Type	F	F	F	F	F	F	F	F

Solid Mechanics Data Card for LARGE = 1.

The following set of cards, "Stress Cards" and "History Variable Cards," should be included NINT times (one set for each integration point).

Stress Card 1. Additional card for LARGE = 1.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	R		S		T		SIGXX		SIGYY	
Type	F		F		F		F		F	

Stress Card 2. Additional card for LARGE = 1.

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	SIGZZ		SIGXY		SIGYZ		SIGZX		EPS	
Type	F		F		F		F		F	

History Variable Cards. Additional card for LARGE = 1. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

Card 4	1	2	3	4	5	6	7	8	9	10
Variable	HISV1		HISV2		HISV3		HISV4		HISV5	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
EID	NURBS Element ID
NINT	Number of in integration points being output.
NHISV	Number of additional history variables.
LARGE	Format size: EQ.0: off EQ.1: on
R	Parametric *r*-coordinate of location of in-plane integration point (with respect to NURBS patch definition)
S	Parametric *s*-coordinate of location of in-plane integration point (with respect to NURBS patch definition)
T	Parametric *t*-coordinate of location of in-plane integration point (with respect to NURBS patch definition)
SIG*ij*	Define the *ij* stress component. The stresses are defined in the GLOBAL cartesian system.
EPS	Effective plastic strain.
HISV*n*	Define the n^{th} history variable.

*INITIAL_STRESS_SPH

Purpose: Initialize stresses and plastic strains for SPH elements. This command is not applicable to hyperelastic materials or any material model based on a Total Lagrangian formulation. For *MAT_005, *MAT_014, and any material that requires an equation-of-state (*EOS), the initialized stresses are deviatoric stresses, not total stresses.

Element Cards. Define as many SPH elements in this section as desired. The input is assumed to terminate when a new keyword is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	SIGXX	SIGYY	SIGZZ	SIGXY	SIGYZ	SIGZX	EPS
Type	I	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
EID	SPH particle ID
SIG*ij*	Define the ij^{th} stress component. Stresses are defined in the GLOBAL Cartesian system.
EPS	Effective plastic strain.

*INITIAL_STRESS_TSHELL_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Initialize stresses and plastic strains for thick shell elements.

Card Sets per Element. Define as many thick shell elements in this section as desired. The input is assumed to terminate when a new keyword is detected.

Card 1	1	2	3	4	5	6	7	8
Variable	EID/SID	NPLANE	NTHICK	NHISV	LARGE			
Type	I	I	I	I	I			
Default	none	none	none	0	0			

Ordering of Integration Points.

For each through thickness point define NPLANE points. NPLANE should be either 1 or 4 corresponding to either 1 or 4 Gauss integration points. If four integration points are specified, they should be ordered such that their in plane parametric coordinates are at:

$$\left(-\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\quad \left(\frac{\sqrt{3}}{3},-\frac{\sqrt{3}}{3}\right),\quad \left(\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right),\quad \left(-\frac{\sqrt{3}}{3},\frac{\sqrt{3}}{3}\right)$$

respectively. It is not necessary for the location of the through thickness integration points to match those used in the elements which are initialized. The data will be interpolated by LS DYNA.

Data Card for LARGE = 0.

The following set of cards "Stress Card" and "History Cards." Should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card. Additional card for LARGE = 0.

Card 2	1	2	3	4	5	6	7	8
Variable	T	SIGXX	SIGYY	SIGZZ	SIGXY	SIGYZ	SIGZX	EPS
Type	F	F	F	F	F	F	F	F

History Cards. Additional Card for LARGE = 0. Include as many History Cards as needed to define all NHIST history variables.

Optional	1	2	3	4	5	6	7	8
Variable	HISV1	HSIV2	HSIV3	HSIV4	HSIV5	HSIV6	HSIV7	HSIV8
Type	F	F	F	F	F	F	F	F

Data Card for LARGE = 1.

The following set of cards "Stress Cards" and "History Cards." Should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card 1. Additional card for LARGE = 1.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	T		SIGXX		SIGYY		SIGZZ		SIGXY	
Type	F		F		F		F		F	

Stress Card 2. Additional card for LARGE = 1.

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	SIGYZ		SIGZX		EPS					
Type	F		F		F					

History Cards. Additional Card for LARGE = 1. Include as many History Cards as needed to define all NHIST history variables.

Optional	1	2	3	4	5	6	7	8	9	10
Variable	HISV1		HISV2		HISV3		HISV4		HISV5	
Type	F		F		F		F		F	

VARIABLE	DESCRIPTION
EID/SID	Thick shell element ID or for the SET keyword option thick shell set ID (see *SET_TSHELL_…)
NPLANE	Number of in plane integration points.
NTHICK	Number of integration points through the thickness.
T	Parametric coordinate of through thickness integration point between -1 and 1 inclusive.
NHISV	Number of additional history variables.
LARGE	Format size. See keywords above. EQ.0: off EQ.1: on
SIG*ij*	Define the *ij* stress component. The stresses are defined in the GLOBAL Cartesian system.
EPS	Effective plastic strain

***INITIAL_TEMPERATURE**_OPTION

Available options include:

NODE

SET

Purpose: Define initial nodal point temperatures using nodal set IDs or node numbers. These initial temperatures are used in a thermal only analysis or a coupled thermal/structural analysis. See also *CONTROL_THERMAL_SOLVER, *CONTROL_THERMAL_TIMESTEP, and CONTROL_THERMAL_NONLINEAR.

For thermal loading in a structural only analysis, see *LOAD_THERMAL_*OPTION*.

Node/Node set Cards. Include one card for each node or node set. This input ends at the next keyword ("*") keyword.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID/NID	TEMP	LOC					
Type	I	I	I					
Default	↓	0.	0					
Remarks	1							

VARIABLE	DESCRIPTION
NSID/NID	Nodal set ID or nodal point ID, see also *SET_NODES: EQ.0: all nodes are included (set option only).
TEMP	Temperature at node or node set.
LOC	For a thick thermal shell, the temperature will be applied to the surface identified by LOC. See parameter, THSHEL, on the *CONTROL_SHELL keyword. EQ.-1: lower surface of thermal shell element EQ.0: middle surface of thermal shell element EQ.1: upper surface of thermal shell element

Remarks:

1. **SPH Particles.** This keyword can be used to define initial nodal point temperatures for SPH particles by using nodal set IDs or node numbers from SPH particles.

*INITIAL_VAPOR_PART

Purpose: Initialization of a part as a vapor material for *PART using *MAT_NULL and *EOS_PHASE_CHANGE. All elements in the part are initialized as a vapor material.

Card 1	1	2	3	4	5	6	7	8
Variable	PID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PID	Part ID of the part to be initialized as a vapor material

*INITIAL_VEHICLE_KINEMATICS

Purpose: Define initial kinematical information for a vehicle. In its initial orientation, the vehicle's yaw, pitch, and roll axes must be aligned with the global axes. Successive simple rotations are taken about these body fixed axes.

Card 1	1	2	3	4	5	6	7	8
Variable	GRAV	PSID	X0	Y0	Z0	XF	YF	ZF
Type	I	I	F	F	F	F	F	F
Default	none	none	0.	0.	0.	0.	0.	0.

Card 2	1	2	3	4	5	6	7	8
Variable	VX	VY	VZ	AAXIS	BAXIS	CAXIS	IVADD	
Type	F	F	F	I	I	I	I	
Default	0.	0.	0.	0	0	0	2	

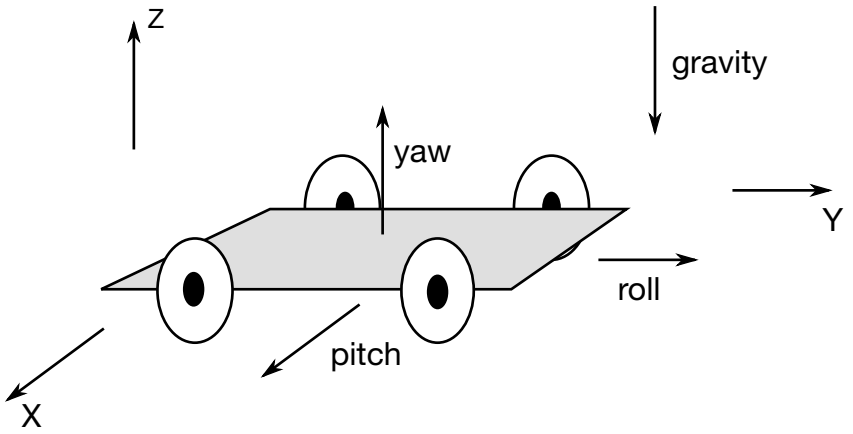

Figure 27-8. The vehicle pictured is to be oriented with a successive rotation sequence about the yaw, pitch, and roll axes, respectively. Accordingly, AAXIS = 3, BAXIS = 1, and CAXIS = 2. The direction of gravity is given by GRAV = -3.

Card 3	1	2	3	4	5	6	7	8
Variable	AANG	BANG	CANG	WA	WB	WC		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
GRAV	Gravity direction code (see Remark 1): EQ.0: gravity not considered EQ.1: global $+x$ direction EQ.-1: global $-x$ direction EQ.2: global $+y$ direction EQ.-2: global $-y$ direction EQ.3: global $+z$ direction EQ.-3: global $-z$ direction Note: this must be the same for all vehicles present in the model.
PSID	Part set ID

VARIABLE	DESCRIPTION
XO	x-coordinate of initial position of mass center
YO	y-coordinate of initial position of mass center
ZO	z-coordinate of initial position of mass center
XF	x-coordinate of final position of mass center
YF	y-coordinate of final position of mass center
ZF	z-coordinate of final position of mass center
VX	global x-component of mass center velocity
VY	global y-component of mass center velocity
VZ	global z-component of mass center velocity
AAXIS	First rotation axis code. EQ.1: initially aligned with global x-axis EQ.2: initially aligned with global y-axis EQ.3: initially aligned with global z-axis
BAXIS	Second rotation axis code
CAXIS	Third rotation axis code
IVADD	Flag for velocity overwrite / add: EQ.1: add to pre-defined velocities. EQ.2: overwrite pre-defined velocities (default).
AANG	Rotation angle about the first rotation axis (degrees)
BANG	Rotation angle about the second rotation axis (degrees)
CANG	Rotation angle about the third rotation axis (degrees)
WA	Angular velocity component for the x body-fixed axis (radian/second)
WB	Angular velocity component for the y body-fixed axis (radian/second)

VARIABLE	DESCRIPTION
WC	Angular velocity component for the *z* body-fixed axis (radian/second)

Remarks:

1. **GRAV.** The GRAV field is used to preserve the spatial location in the direction specified. To illustrate this feature, suppose a part set that represents a vehicle is initially oriented such that the wheels are on the ground (the ground plane) at $Z = 100$ and gravity is in the -Z-direction. To perform a roof drop simulation, the part set of the vehicle must be re-oriented, but the ground plane must be maintained. To do this, GRAV must be set to -3 which preserves $Z = 100$ as the lowest Z-coordinate, thereby maintaining the ground plane.

*INITIAL_VELOCITY

Purpose: Define initial nodal point velocities using nodal set ID's. This may also be used for sets in which some nodes have other velocities. See NSIDEX below.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	NSIDEX	BOXID	IRIGID	ICID			
Type	I	I	I	I	I			
Default	↓	{∅}	0	0	0			
Remark	1							

Card 2	1	2	3	4	5	6	7	8
Variable	VX	VY	VZ	VXR	VYR	VZR		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

Exempted Node Card. Additional card for NSIDEX > 0.

Card 3	1	2	3	4	5	6	7	8
Variable	VXE	VYE	VZE	VXRE	VYRE	VZRE		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
NSID	Nodal set ID, see *SET_NODES, containing nodes for initial velocity. If NSID = 0, the initial velocity is applied to all nodes.

VARIABLE	DESCRIPTION
NSIDEX	Nodal set ID, see *SET_NODES, containing nodes that are exempted from the imposed velocities and may have other initial velocities.
BOXID	All nodes in box which belong to NSID are initialized. Nodes outside the box are not initialized. Exempted nodes are initialized to velocities defined by VXE, VYE, and VZE below, regardless of their location relative to the box.
IRIGID	Option to overwrite rigid body velocities defined on *PART_INERTIA or *CONSTRAINED_NODAL_RIGID_BODY_INERTIA cards. GE.1: part set ID, containing ID of parts to overwrite. Center of gravity of part must lie within box BOXID. If BOXID is not defined, then all parts defined in the set are overwritten. EQ.-1: Overwrite velocities for all rigid bodies defined with *PART_INERTIA or *CONSTRAINED_NODAL_-RIGID_BODY_INERTIA that have a center of gravity within box BOXID. If BOXID is not defined, then all are overwritten. EQ.-2: Overwrite velocities for all rigid bodies defined with *PART_INERTIA or *CONSTRAINED_NODAL_-RIGID_BODY_INERTIA.
ICID	Local coordinate system ID. The initial velocity is specified in the local coordinate system if ICID is greater than zero. Furthermore, if ICID is greater than zero, *INCLUDE_TRANSFORM does not rotate the initial velocity values specified by VX, VY, …, VZRE.
VX	Initial translational velocity in x-direction
VY	Initial translational velocity in y-direction
VZ	Initial translational velocity in z-direction
VXR	Initial rotational velocity about the x-axis
VYR	Initial rotational velocity about the y-axis
VZR	Initial rotational velocity about the z-axis
VXE	Initial velocity in x-direction of exempted nodes

VARIABLE	DESCRIPTION
VYE	Initial velocity in y-direction of exempted nodes
VZE	Initial velocity in z-direction of exempted nodes
VXRE	Initial rotational velocity in x-direction of exempted nodes
VYRE	Initial rotational velocity in y-direction of exempted nodes
VZRE	Initial rotational velocity in z-direction of exempted nodes

Remarks:

1. **Deck Restrictions.** This generation input must not be used with *INITIAL_-VELOCITY_GENERATION keyword.

2. **Multiple Nodal Velocity Initializations.** If a node velocity is initialized on more than one input card set, then the last set input will determine its velocity. However, if the nodal velocity is also specified on a *INITIAL_VELOCITY_NODE card, then the velocity specification on this card will be used.

3. **Overwriting Rigid Body Velocities.** Unless the option IRIGID is specified, initial velocities for rigid bodies given by *PART_INERTIA will overwrite generated initial velocities. The IRIGID option will cause the rigid body velocities specified on the *PART_INERTIA input to be overwritten. To directly specify the motion of a rigid body without using the keyword, *PART_INERTIA, which also requires the definition of the mass properties, use the keyword option, *INITIAL_VELOCITY_RIGID_BODY.

4. **Rigid Body Motion Consistency.** Nodes which belong to rigid bodies must have motion consistent with the translational and rotational velocity of the center of gravity (c.g.) of the rigid body. During initialization the rigid body translational and rotational rigid body momentum's are computed based on the prescribed nodal velocity field. From this rigid body momentum, the translational and rotational velocities of the nodal points are computed and reset to the new values. These new values may or may not be the same as the values prescribed for the nodes that make up the rigid body. Sometimes this occurs in single precision due to numerical round-off. If a problem like this occurs, specify the velocity using the keyword *INITIAL_VELOCITY_RIGID_BODY.

5. **Mid-Side Nodes.** Mid-side nodes generated by *ELEMENT_SOLID_TET4TO10 will not be initialized since the node numbers are not known a priori to the user. Instead use *INITIAL_VELOCITY_GENERATION if you intend to initialize the velocities of the mid-side nodes.

*INITIAL_VELOCITY_NODE

Purpose: Define initial nodal point velocities for a node.

Card	1	2	3	4	5	6	7	8
Variable	NID	VX	VY	VZ	VXR	VYR	VZR	ICID
Type	I	F	F	F	F	F	F	I
Default	none	0.	0.	0.	0.	0.	0.	0

VARIABLE	DESCRIPTION
NID	Node ID
VX	Initial translational velocity in x-direction
VY	Initial translational velocity in y-direction
VZ	Initial translational velocity in z-direction
VXR	Initial rotational velocity about the x-axis
VYR	Initial rotational velocity about the y-axis
VZR	Initial rotational velocity about the z-axis
ICID	Local coordinate system ID. The specified velocities are in the local system if ICID is greater than zero. Furthermore, if ICID is greater than zero, *INCLUDE_TRANSFORM does not rotate the initial velocity values specificied by VX, VY, …, VZR.

See Remarks on *INITIAL_VELOCITY card.

*INITIAL_VELOCITY_RIGID_BODY

Purpose: Define the initial translational and rotational velocities at the center of gravity (c.g.) for a rigid body or a nodal rigid body. This input overrides all other velocity input for the rigid body and the nodes which define the rigid body.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	VX	VY	VZ	VXR	VYR	VZR	ICID
Type	I	F	F	F	F	F	F	I
Default	none	0.	0.	0.	0.	0.	0.	0

VARIABLE	DESCRIPTION
PID	Part ID of the rigid body or the nodal rigid body.
VX	Initial translational velocity at the c.g. in global x-direction.
VY	Initial translational velocity at the c.g. in global y-direction.
VZ	Initial translational velocity at the c.g. in global z-direction.
VXR	Initial rotational velocity at the c.g. about the global x-axis.
VYR	Initial rotational velocity at the c.g. about the global y-axis.
VZR	Initial rotational velocity at the c.g. about the global z-axis.
ICID	Local coordinate system ID. The specified velocities are in the local system if ICID is greater than zero. Furthermore, if ICID is greater than zero, *INCLUDE_TRANSFORM does not transform the initial velocity values specified by VX, VY, …, VZR.

See Remarks 3 and 4 of the *INITIAL_VELOCITY input description.

*INITIAL_VELOCITY_GENERATION

Purpose: Define initial velocities for rotating and/or translating bodies. These velocities are invoked at time = 0 unless a start time is specified with *INITIAL_VELOCITY_GENERATION_START_TIME (see Remark 7). If a dynamic relaxation phase is invoked, these velocities do not apply during that phase.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	STYP	OMEGA	VX	VY	VZ	IVATN	ICID
Type	I	I	F	F	F	F	I	I
Default	{all}	↓	0.	0.	0.	0.	0	global

Card 2	1	2	3	4	5	6	7	8
Variable	XC	YC	ZC	NX	NY	NZ	PHASE	IRIGID
Type	F	F	F	F	F	F	I	I
Default	0.	0.	0.	0.	0.	0.	0	0

VARIABLE	DESCRIPTION
ID	Part ID, part set ID, or node set ID. If zero, STYP is ignored, and all velocities are set. WARNING for if IVATN = 0: If a part ID of a rigid body is specified, only the nodes that belong to elements of the rigid body are initialized. Nodes added with *CONSTRAINED_EXTRA_NODES are not initialized. Set IVATN = 1 to initialize velocities of constrained nodes and parts.
STYP	Set type (see Remark 5): EQ.1: Part set ID (see *SET_PART) EQ.2: Part ID (see *PART) EQ.3: Node set ID (see *SET_NODE)
OMEGA	Angular velocity about the rotational axis. See Remark 6.

VARIABLE	DESCRIPTION
VX	Initial translational velocity in x-direction (see ICID below)
VY	Initial translational velocity in y-direction (see ICID below)
VZ	Initial translational velocity in z-direction (see ICID below)
IVATN	Flag for setting the initial velocities of constrained nodes and parts: EQ.0: Constrained parts are ignored. EQ.1: Constrained parts and nodes constrained to parts will be assigned initial velocities like the part to which they are constrained.
ICID	Local coordinate system ID. If ICID = 0, the specified translational velocities (VX,VY,VZ) and the direction cosines of the rotation axis (NX,NY,NZ) are in the global system; otherwise, they are in the local system specified by ICID. Therefore, if ICID is defined, *INCLUDE_TRANSFORM does not transform (VX,VY,VZ) and (NX,NY,NZ).
XC	Global x-coordinate on rotational axis
YC	Global y-coordinate on rotational axis
ZC	Global z-coordinate on rotational axis
NX	x-direction cosine. If set to -999, NY and NZ are interpreted as the 1st and 2nd nodes defining the rotational axis, in which case the coordinates of node NY are used as XC, YC, ZC. If ICID is defined, the direction cosine, (NX,NY,NZ), is projected along coordinate system ICID to yield the direction cosines of the rotation axis only if NX ≠ -999.
NY	y-direction cosine or the 1st node of the rotational axis when NX = -999.
NZ	z-direction cosine or the 2nd node of the rotational axis when NX = -999.
PHASE	Flag determining basis for initialization of velocity (see Remarks 6 and 7):

VARIABLE	DESCRIPTION
	EQ.0: Initial velocities are applied at $t = 0$ of the regular transient phase of the analysis and are based on the undeformed geometry. Rigid bodies whose velocities are initialized using this keyword should always use PHASE = 0. EQ.1: Initial velocities of deformable bodies are based on geometry that includes deformation incurred prior to the application of the initial velocities. That deformation could be due to a dynamic relaxation phase or due to a nonzero start time specified with *INITIAL_VELOCITY_GENERATION_START_TIME.
IRIGID	Controls hierarchy of initial velocities set with *INITIAL_VELOCITY_GENERATION versus those set with *PART_INERTIA / *CONSTRAINED_NODAL_RIGID_BODY_INERTIA when the commands conflict. EQ.0: *PART_INERTIA / *CONSTRAINED_NODAL_RIGID_BODY_INERTIA controls initial velocities. EQ.1: *INITIAL_VELOCITY_GENERATION controls initial velocities. This option does not apply if STYP = 3.

Remarks:

1. **Exclusions.** This generation input must not be used with *INITIAL_VELOCITY or *INITIAL_VELOCITY_NODE options.

2. **Order Dependence.** The velocities are initialized in the order the *INITIAL_VELOCITY_GENERATION input is defined. Later input using the *INITIAL_VELOCITY_GENERATION keyword may overwrite the velocities previously set.

3. **Consistency for Rigid Body Nodes.** Nodes which belong to rigid bodies must have motion consistent with the translational and rotational velocity of the rigid body. During initialization the translational and rotational rigid body momentums are computed based on the prescribed nodal velocities. From this rigid body motion the velocities of the nodal points are computed and reset to the new values. These new values may or may not be the same as the values prescribed for the node.

4. **SPH.** SPH elements can be initialized using the STYP = 3 option only.

5. **Constrained Nodal Rigid Bodies.** Part IDs of *CONSTRAINED_NODAL_-RIGID_BODYs that do not include the INERTIA option are not recognized by the code in the case of STYP = 1 or 2. Use STYP = 3 (a node set ID) when initializing velocity of such nodal rigid bodies.

6. **Rotating Bodies.** When velocities for a rotating body (nonzero OMEGA) are initialized at $t = 0$ following a dynamic relaxation phase in which body forces (*LOAD_BODY) serve to preload the spinning body, velocities of deformable parts/nodes of the spinning body should be included in an *INITIAL_VELOCITY_GENERATION command with PHASE = 1. Furthermore, any rigid parts/nodes of the spinning body should be initialized using a second *INITIAL_VELOCITY_GENERATION command with PHASE = 0.

7. **Nonzero Start Time for Initial Velocity.** A delayed start time for the velocity may be specified by including *INITIAL_VELOCITY_GENERATION_START_-TIME. A delayed start time requires that there be an *INITIAL_VELOCITY_-GENERATION command with PHASE = 1. Similar to the situation described in Remark 6, if there are any rigid body nodes whose velocity is being initialized, those nodes must be included in a second *INITIAL_VELOCITY_GENERATION command with PHASE = 0. Note that all velocity set with *INITIAL_VELOCITY_GENERATION will begin at the start time if there is at least one *INITIAL_VELOCITY_GENERATION keyword with PHASE = 1 in the input deck. If the deck *only* includes one *INITIAL_VELOCITY_GENERATION with PHASE = 0, then the start time will be ignored, and the velocity will be initialized at $t = 0$.

   The following example illustrates initialization of translational velocity in the y-direction to 8.8 for node set 55 at $t = 13$. Node set 55 includes both rigid body nodes and deformable body nodes. Note that the same all-inclusive node set may be used for both *INITIAL_VELOCITY_GENERATION commands.

```
$ *INITIAL_VELOCITY_GENERATION
$#      id      styp     omega        vx        vy        vz     ivatn      icid
        55         3                           8.8
$#      xc        yc        zc        nx        ny        nz     phase    irigid
                                                                     0
*INITIAL_VELOCITY_GENERATION
$#      id      styp     omega        vx        vy        vz     ivatn      icid
        55         3                           8.8
$#      xc        yc        zc        nx        ny        nz     phase    irigid
                                                                     1
*INITIAL_VELOCITY_GENERATION_START_TIME
$#   stime
       13.
```

*INITIAL_VELOCITY_GENERATION_START_TIME

Purpose: Define a time to initialize velocities after time zero. Time zero starts after dynamic relaxation if used for initialization.

Card 1	1	2	3	4	5	6	7	8
Variable	STIME							
Type	F							
Default	0.0							

VARIABLE	DESCRIPTION
STIME	Start time.

Remarks:

1. **One Start Time.** Only one *INITIAL_VELOCITY_GENERATION_START_TIME can be specified. Multiple start times are not allowed.

2. **Using Start Time.** All *INITIAL_VELOCITY_GENERATION commands adhere to the start time provided the requirement is met that at least one of those commands has PHASE set to 1.

3. **Velocities of Other Nodes.** When *INITIAL_VELOCITY_GENERATION_START_TIME is active, nodes that are not part of the initial velocity generation definitions will be re-initialized with velocities as they were at $t = 0$.

INITIAL_VOID_*OPTION

Available options include:

PART

SET

Purpose: Define initial voided part set IDs or part numbers. This command can be used only when ELFORM = 12 in *SECTION_SOLID. Void materials cannot be created during the calculation. Fluid elements which are evacuated, such as by a projectile moving through the fluid, during the calculation are approximated as fluid elements with very low densities. The constitutive properties of fluid materials used as voids must be identical to those of the materials which will fill the voided elements during the calculation. Mixing of two fluids with different properties is not permitted with this option.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID/PID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PSID/PID	Part set ID or part ID, see also *SET_PART:

Remarks:

This void option and multiple materials per element, see *ALE_MULTI-MATERIAL_-GROUP are incompatible and cannot be used together in the same run.

*INITIAL_VOLUME_FRACTION_{OPTION}

Available option:

<BLANK>

LSDA

NALEGP
