Purpose: Define initial volume fractions of different materials in multi-material ALE / S-ALE elements. Without the NALEGP or LSDA option, the keyword allows up to 7 ALE multi-material groups. The NALEGP option adds in an additional card immediately after the keyword to let users input the number of ALE multi-material groups to be read in for each element. The LSDA option is for S-ALE only. It allows you to include the lsda file produced from a previous S-ALE simulation that contained either *INITIAL_VOLUME_FRACTION_GEOMETRY or *ALE_STRUCTURED_MESH_VOLUME_FILLING. The default name of the lsda file is salevfrc.lsda. This file is used to pre-fill and trim the mesh which can save simulation time.

Card Summary:

Card 1a. This card is included if there is no keyword option. Repeat this card as many times as desired (one card for each element volume fraction to be defined). This input ends at the next keyword ("*") card.

EID	VF1	VF2	VF3	VF4	VF5	VF6	VF7

Card 1b. This card is included if the keyword option is NALEGP. This card set (Card 1b, 1b.1, and 1b.2) is repeated as many times as desired (one set for each element volume fraction to be defined).

NALEGP							

Card 1b.1. This card is included if the option is NALEGP.

EID	VF1	VF2	VF3	VF4	VF5	VF6	VF7

Card 1b.2. This card is included if the option is NALEGP and NALEGP > 7. Repeat this card in each set enough times to define NALEGP volume fractions.

VF*i*	VF(*i*+1)	VF(*i*+2)	VF(*i*+3)	VF(*i*+4)	VF(*i*+5)	VF(*i*+6)	VF(*i*+7)

Card 1c. Include this card if the LSDA keyword option is used.

FILENAME

Data Card Definitions:

Volume Fraction Card. This card is included if no keyword option is used. Include as many of this card as desired. This input ends at the next keyword ("*") card.

Card 1a	1	2	3	4	5	6	7	8
Variable	EID	VF1	VF2	VF3	VF4	VF5	VF6	VF7
Type	I	F	F	F	F	F	F	F
Default	none	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
EID	Element ID.
VF1	Volume fraction of multi-material group 1, AMMGID = 1.
VF2	Volume fraction of multi-material group 2. Only needed in simulations with at least 3 material groups. Otherwise VF2 = 1 − VF1.
VF3	Volume fraction of multi-material group 3, AMMGID = 3.
VF4	Volume fraction of multi-material group 4, AMMGID = 4.
VF5	Volume fraction of multi-material group 5, AMMGID = 5.
VF6	Volume fraction of multi-material group 6, AMMGID = 6.
VF7	Volume fraction of multi-material group 7, AMMGID = 7.

NALEGP Card. Include this card for the NALEGP keyword option. This card set (Card 1b, 1b.1, and 1b.2) is repeated as many times as desired (one set for each element volume fraction to be defined).

Card 1b	1	
Variable	NALEGP	
Type	I	

VARIABLE	DESCRIPTION
NALEGP	Number of volume fractions.

NALEGP Volume Fractions Card. Include this card for NALEGP keyword option. This card set (Card 1b, 1b.1, and 1b.2) is repeated as many times as desired (one set for each element volume fraction to be defined).

Card 1b.1	1	2	3	4	5	6	7	8
Variable	EID	VF1	VF2	VF3	VF4	VF5	VF6	VF7
Type	I	F	F	F	F	F	F	F
Default	none	0.0	0.0	0.0	0.0	0.0	0.0	0.0

NALEGP Extra Volume Fractions Card. This card is included if the option is NALEGP and NALEGP > 7. Repeat this card in each set enough times to define NALEGP volume fractions.

Card 1b.2	1	2	3	4	5	6	7	8
Variable	VF*i*	VF(*i*+1)	VF(*i*+2)	VF(*i*+3)	VF(*i*+4)	VF(*i*+5)	VF(*i*+6)	VF(*i*+7)
Type	I	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
EID	Element ID.
VF1	Volume fraction of multi-material group 1, AMMGID = 1.
VF2	Volume fraction of multi-material group 2. Only needed in simulations with at least 3 material groups. Otherwise VF2 = 1 − VF1.
VF3	Volume fraction of multi-material group 3, AMMGID = 3.
VF4	Volume fraction of multi-material group 4, AMMGID = 4.
VF5	Volume fraction of multi-material group 5, AMMGID = 5.

VARIABLE	DESCRIPTION
VF6	Volume fraction of multi-material group 6, AMMGID = 6.
VF7	Volume fraction of multi-material group 7, AMMGID = 7.
VF(N)	Volume fraction of multi-material group N, AMMGID = N. Define NALEGP volume fractions.

LSDA File Card. This card is included for keyword option LSDA.

Card 1c	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A							

VARIABLE	DESCRIPTION
FILENAME	Name of the lsda file produced in a previous S-ALE run that contained either *INITIAL_VOLUME_FRACTION_GEOMETRY or *ALE_STRUCTURED_MESH_VOLUME_FILLING. The default name of the lsda file is salevfrc.lsda.

*INITIAL_VOLUME_FRACTION_GEOMETRY

Purpose: This is a volume-filling command for defining the volume fractions of various ALE multi-material groups (AMMG) that initially occupy several spatial regions in an ALE mesh. This applies only to ELFORMs 11 and 12 in *SECTION_SOLID and ALE-FORM 11 in *SECTION_ALE2D. For ELFORM 12, AMMGID 2 is void. See Remark 2.

Card Summary:

Card 1. This card is required.

FMSID	FMIDTYP	BAMMG	NTRACE				

Card 2. For each container include this card (Container Card) and one geometry card (Card 3α). Include as many pairs as desired. This input ends at the next keyword ("*") card.

CNTTYP	FILLOPT	FAMMG	VX	VY	VZ		

Card 3a. Include this card if CNTTYP = 1.

SID	STYPE		XOFFST				

Card 3b. Include this card if CNTTYP = 2.

SGSID		XOFFST					

Card 3c. Include this card if CNTTYP = 3.

X0	Y0	Z0	XCOS	YCOS	ZCOS		

Card 3d. Include this card if CNTTYP = 4.

X0	Y0	Z0	X1	Y1	Z1	R1	R2

Card 3e. Include this card if CNTTYP = 5.

X0	Y0	Z0	X1	Y1	Z1	LCSID	

Card 3f. Include this card if CNTTYP = 6.

X0	Y0	Z0	R0				

Card 3g. Include this card if CNTTYP = 7.

IDFUNC							

Data Card Definitions:

Background ALE Mesh Card. Defines the background ALE mesh set & an AMMGID that initially fills it.

Card 1	1	2	3	4	5	6	7	8
Variable	FMSID	FMIDTYP	BAMMG	NTRACE				
Type	I	I	I	I				
Default	none	0	none	3				

VARIABLE	DESCRIPTION
FMSID	Background ALE (fluid) mesh SID to be initialized or filled with various AMMGs. This set ID refers to one or more ALE parts.
FMIDTYP	ALE mesh set ID type: EQ.0: FMSID is an ALE part set ID (PSID). EQ.1: FMSID is an ALE part ID (PID).
BAMMG	The background fluid group ID or ALE Multi-Material group ID (AMMGID) that initially fills the entire ALE mesh region defined by FMSID. For S-ALE, AMMG name (AMMGNM) could be also used in place of AMMGID. See Remark 8.
NTRACE	Number of sampling points for volume filling detection. Typically, NTRACE ranges from 3 to maybe 10 (or more). The higher it is, the finer the ALE element is divided so that small gaps between 2 Lagrangian shells may be filled in. See Remark 4.

Container Card. Defines the container type and the AMMGID that fills the region defined by the container type.

Card 2	1	2	3	4	5	6	7	8
Variable	CNTTYP	FILLOPT	FAMMG	VX	VY	VZ		
Type	I	I	I	F	F	F		
Default	none	0	none	0	0	0		

VARIABLE	DESCRIPTION
CNTTYP	A "container" defines a Lagrangian surface boundary of a spatial region, inside (or outside) of which, an AMMG would fill up. CNTTYP defines the container geometry type of this surface boundary (or shell structure). EQ.1: The container geometry is defined by a part ID (PID) or a part set ID (PSID), where the parts (see *PART or *SET_PART) should be defined by shell elements in 3D (beam elements in 2D). If the parts are meshed with solids in 3D (shells in 2D), their boundaries define the container geometry (see Remark 7). EQ.2: The container geometry is defined by a segment set (SGSID). EQ.3: The container geometry is defined by a plane: a point and a normal vector. EQ.4: The container geometry is defined by a conical surface: 2 end points and 2 corresponding radii (in 2D see Remark 6). EQ.5: The container geometry is defined by a cuboid or rectangular box: 2 opposing end points, minimum to maximum coordinates. EQ.6: The container geometry is defined by a sphere: 1 center point, and a radius. EQ.7: The container geometry is defined with a user-defined function implemented using *DEFINE_FUNCTION. The arguments of the function should be the coordinates of a point (x,y,z). The function should return 1.0 if the point is inside the geometry.

VARIABLE	DESCRIPTION
FILLOPT	A flag to indicate which side of the container surface the AMMG is supposed to fill. CNTTYP = 1, 2, and 3, the "head" side of a container surface/segment is defined as the side pointed to by the heads of the normal vectors of the segments ("tail" side refers to opposite direction to "head"). See Remark 5. Note that for CNTTYP = 1 and 2, the fluid interface can be offset from the container walls with XOFFST. XOFFST does not apply to the other container geometries. EQ.0: The "head" side of the geometry defined above will be filled with fluid (default). For CNTTYP = 4, 5, 6, and 7, the inside of the container is filled. EQ.1: The "tail" side of the geometry defined above will be filled with fluid. For CNTTYP = 4, 5, 6, and 7, the outside of the container is filled.
FAMMG	This defines the fluid group ID or ALE Multi-Material group ID (AMMGID) which will fill up the interior (or exterior) of the space defined by the "container". *The order of AMMGIDs is determined by the order in which they are listed under *ALE_MULTI-MATERIAL_GROUP card.* For example, the first data card under the *ALE_MULTI-MATERIAL_GROUP keyword defines the multi-material group with ID (AMMGID) 1, the second data card defined AMMGID = 2, and so on. In case of S-ALE, AMMG name (AMMGNM) could be also used in place of AMMGID. See Remark 8. LT.0: |FAMMG| is a *SET_MULTI-MATERIAL_GROUP_LIST ID listing pairs of group IDs. For each pair, the 2nd group replaces the first one in the "container".
VX	Initial velocity in the global *x*-direction for this AMMGID.
VY	Initial velocity in the global *y*-direction for this AMMGID.
VZ	Initial velocity in the global *z*-direction for this AMMGID.

Part/Part Set Container Card. Additional card for CNTTYP = 1.

Card 3a	1	2	3	4	5	6	7	8
Variable	SID	STYPE	NORMDIR	XOFFST				
Type	I	I	I	F				
Default	none	0	0	0.0				
Remark			obsolete					

VARIABLE	DESCRIPTION
SID	A set ID pointing to a part ID (PID) or part set ID (PSID) of the Lagrangian shell element structure defining the "container" geometry to be filled (see *PART or *SET_PART).
SSTYPE	Set ID type: EQ.0: Container SID is a Lagrangian part set ID (PSID). EQ.1: Container SID is a Lagrangian part ID (PID).
NORMDIR	Obsolete (see Remark 5).
XOFFST	|XOFFST| is the absolute length for offsetting the fluid interface from the nominal fluid interface LS-DYNA would otherwise define by default. The sign of XOFFST determines which direction the interface is offset. It is based on the normal vectors of the segments associated with the container. XOFFST.GT.0: Interface is offset along the positive direction of the segments of the container. XOFFST.LT.0: Interface is offset in the negative direction of the normal vectors of the segments of the container. This is applicable to cases in which high pressure fluid is contained within a container. The offset allows LS-DYNA time to prevent leakage. In general, this may be set to roughly 5-10% of the ALE element width. It may be important only for when ILEAK is turned ON to give the code time to "catch" the leakage (see *CONSTRAINED_LAGRANGE_IN_SOLID). If ILEAK is not ON, this may not be necessary.

Segment Set Container Card. Additional card for CNTTYP = 2.

Card 3b	1	2	3	4	5	6	7	8
Variable	SGSID	NORMDIR	XOFFST					
Type	I	I	F					
Default	none	0	0.0					
Remark		obsolete						

VARIABLE	DESCRIPTION
SGSID	Segment Set ID defining the "container", see *SET_SEGMENT.
NORMDIR	Obsolete (see Remark 5).
XOFFST	|XOFFST| is the absolute length for offsetting the fluid interface from the nominal fluid interface LS-DYNA would otherwise define by default. The sign of XOFFST determines which direction the interface is offset. It is based on the normal vectors of the segments associated with the container. XOFFST.GT.0: Interface is offset along the positive direction of the segments of the container. XOFFST.LT.0: Interface is offset in the negative direction of the normal vectors of the segments of the container. This is applicable to cases in which high pressure fluid is contained within a container. The offset allows LS-DYNA time to prevent leakage. In general, this may be set to roughly 5-10% of the ALE element width. It may be important only for when ILEAK is turned ON to give the code time to "catch" the leakage (see *CONSTRAINED_LAGRANGE_IN_SOLID). If ILEAK is not ON, this may not be necessary.

Plane Card. Additional card for CNTTYP = 3.

Card 3c	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	XCOS	YCOS	ZCOS		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
X0, Y0, Z0	x, y and z coordinate of a spatial point on the plane.
XCOS, YCOS, ZCOS	x, y and z direction cosines of the plane normal vector. The filling will occur on the side pointed to by the plane normal vector (or "head" side).

Cylinder/Cone Container Card. Additional Card for CNTTYP = 4 (see Remark 6 for 2D).

Card 3d	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	X1	Y1	Z1	R1	R2
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
X0, Y0, Z0	x, y and z coordinate of the center of the 1st base of the cone.
X1, Y1, Z1	x, y and z coordinate of the center of the 2nd base of the cone.
R1	Radius of the 1st base of the cone
R2	Radius of the 2nd base of the cone

Rectangular Box Container Card. Additional Card for CNTTYP = 5.

Card 3e	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	X1	Y1	Z1	LCSID	
Type	F	F	F	F	F	F	I	
Default	none	none	none	none	none	none	none	

VARIABLE	DESCRIPTION
X0, Y0, Z0	Minimum *x*, *y* and *z* coordinates of the box.
X1, Y1, Z1	Maximum *x*, y and *z* coordinates of the box.
LCSID	Local coordinate system ID, if defined, the box is aligned with the local coordinate system instead of global coordinate system. Please see *DEFINE_COORDINATE_*OPTION*for details.

Sphere Container Card. Additional card for CNTTYP = 6.

Card 3f	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	R0				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
X0, Y0, Z0	*x*, *y* and *z* coordinate of the center of the sphere.
R0	Radius of the sphere

User Defined Container Card. Additional card for CNTTYP = 7.

Card 3g	1	2	3	4	5	6	7	8
Variable	IDFUNC							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
IDFUNC	Function ID (*DEFINE_FUNCTION) for the function of the coordinates (x,y,z) that gives the container geometry. If the point (x,y,z) is in the container, the function should return 1.0.

Remarks:

1. **Structure of Data Cards.** After Card 1 which defines the basic mesh filled by a certain fluid group (AMMGID), each "filling action" will require 2 additional lines of input: Cards 2 and 3α, where α depends on the CNTTYP value. At the minimum there will be 3 cards required for this command (1, 2, and 3α) for 1 "filling action".

   There can be one or more "filling actions" prescribed for each instance of this command. The "filling actions" take place in the prescribed order and the effects are cumulative. Later "filling actions" will over-write the previous ones. Therefore, any complex filling logic will require some planning. For example, the following card sequence with 2 "filling actions" is allowable:

```
*INITIAL_VOLIME_FRACTION_GEOMETRY
[Card 1]
[Card 2, CNTTYP = 1]
[Card 3a]
[Card 2, CNTTYP = 3]
[Card 3c]
```

   This sequence of cards prescribes a background ALE mesh with 2 "filling actions" to be executed. The 1st is a filling of a CNTTYP = 1 and the 2nd of CNTTYP = 3.

2. **Group IDs for ELFORM 12.** If ELFORM = 12, the single-material-and-void element formulation, is used in *SECTION_SOLID, then the non-void material defaults to AMMG = 1 and the void to AMMG = 2. These multi-material groups

are implied even though no *ALE_MULTI-MATERIAL_GROUP card is required.

3. **Using Shells to Divide Space.** A simple ALE background mesh (for example, a cuboid mesh) can be constructed enveloping some Lagrangian shell structure (or container). The ALE region inside this Lagrangian shell container may be filled with one multi-material group (AMMG1), and the outside region with another (AMMG2). This approach simplifies the mesh generation requirements for ALE material parts with complex geometries.

4. **NTRACE.** The default number of sampling points is NTRACE = 3 in which case the total number is

$$(2 \times \text{NTRACE} + 1)^3 = 7^3$$

This means an ALE element is subdivided into $7 \times 7 \times 7$ regions. Each is to be filled in with the appropriate AMMG. An example of this application would be the filling of initial gas between multiple layers of Lagrangian airbag shell elements sharing the same ALE element.

5. **Interior/Exterior Fill Setting.** To set which side of a container is to be filled: (1) define the shell (or segment) container with inward normal vectors; then (2) set the FILLOPT field on "Card 2" to 0, corresponding to the head of the normal, for the interior, and to 1, corresponding to the tail of the normal, for the exterior.

6. **Two Dimensional Geometry.** If the ALE model is 2D (*SECTION_ALE2D instead of *SECTION_SOLID), CNTTYP = 4 defines a quadrilateral. In this case the fields which, in the 3D case define a cone, are interpreted as the corner coordinates of a clockwise defined (inward normal) quadrilateral having the vertices: (X1, Y1), (X2, Y2), (X3, Y3), and (X4, Y4). The CNTTYP = 4 input fields X0, Y0, Z0, X1, Y1, Z1, R1, and R2 becomes X1, Y1, X2, Y2, X3, Y3, X4, and Y4 respectively. CNTTYP = 6 should be used to fill a circle.

7. **3D Solid (2D Shell) Mesh for CNTTYP = 1.** If a part, *P*, defines the geometry container for CNTTYP = 1, is meshed with solids in 3D or shells in 2D, and is in the ALE group FAMMG (*P* should be in *ALE_MULTI-MATERIAL_GROUP and it should have the ALE formulation 11 in the *SECTION keyword), the ALE elements superimposed with *P* will be filled with FAMMG. The mesh of *P* will become a dummy rigid part.

8. **AMMG NAME for S-ALE.** For the general ALE solver, you define each AMMG with *ALE_MULTI-MATERIAL_GROUP. In this case, each AMMG can only be referred to by their AMMGID. The AMMGID for each AMMG is based on the order of appearance of the AMMG in the input deck. For the S-ALE solver, you can define the AMMG using *ALE_STRUCTURED_MULTI-MATERIAL_-GROUP instead of *ALE_MULTI-MATERIAL_GROUP. With *ALE_STRUCTURED_MULTI-MATERIAL_GROUP, you give each AMMG a name with the

field AMMGNM. Each AMMG defined with that keyword can then be referred with either its name or its AMMGID (which is again based on order of appearance). We recommend using the name as it leads to fewer errors. For instance, if you add or delete AMMGs, then the AMMGIDs may change. Then, you must find all those references and change them accordingly. With the name, you do not need to modify the input deck for unchanged AMMGs.

9. **Files Output for Subsequent Analyses.** This keyword causes file alevfrc.inc to be output for both ALE and S-ALE simulations at the end of the run. For S-ALE, it also outputs file salevfrc.lsda which is an lsda version of alefrc.inc. alefrc.inc can be included with *INCLUDE for subsequent analyses while salevfrc.lsda can be included with *INITIAL_VOLUME_FRACTION_LSDA. These files pre-fill the volume fractions and store the trimmed mesh which can save time for subsequent analyses.

Example:

Consider a simple ALE model with ALE parts H1-H5 (5 AMMGs possible) and 1 Lagrangian shell (container) part S6. Only parts H1 and S6 initially have their meshes defined. We will perform 4 "filling actions". The volume filling results after each step will be shown below to clarify the concept used. The input for the volume filling looks like this.

```
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
$ H1 = AMMG 1 = fluid 1 initially occupying whole ALE mesh= background mesh
$ H5 = AMMG 5 = fluid 5 fills below a plane = filling action 1 = CNTTYP=3
$ H2 = AMMG 2 = fluid 2 fills outside S6    = filling action 2 = CNTTYP=1
$ H3 = AMMG 3 = fluid 3 fills inside a cone = filling action 3 = CNTTYP=4
$ H4 = AMMG 4 = fluid 4 fills inside a box  = filling action 4 = CNTTYP=5
$ S6 =          Lagrangian shell container
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
*ALE_MULTI-MATERIAL_GROUP
         1         1
         2         1
         3         1
         4         1
         5         1
*INITIAL_VOLUME_FRACTION_GEOMETRY

```

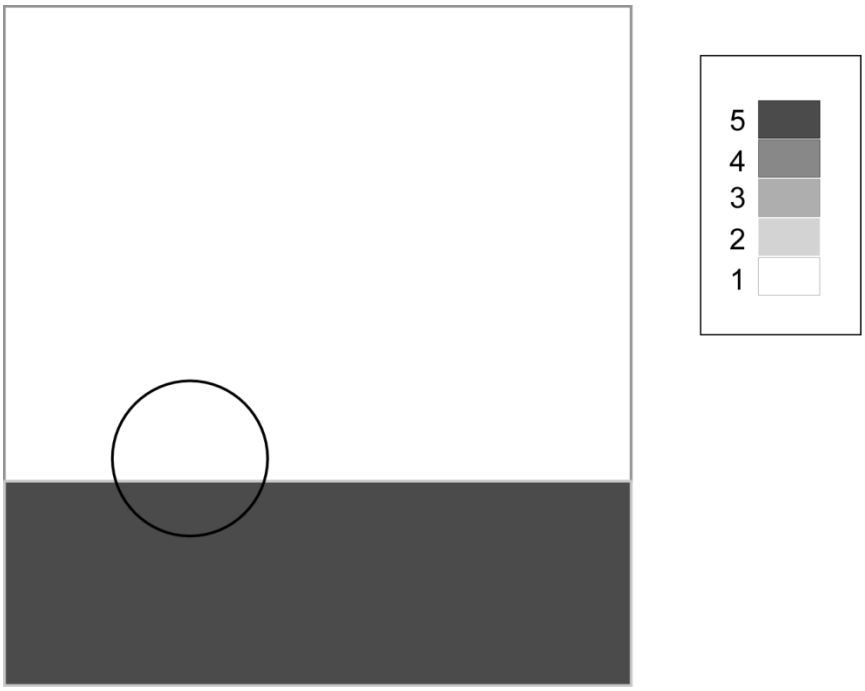

Figure 27-9. Before the 1st "filling action" the whole ALE mesh of part H1 is filled with AMMG 1 (white). After the 1st "filling action", AMMG 5 fills below the specified plane.

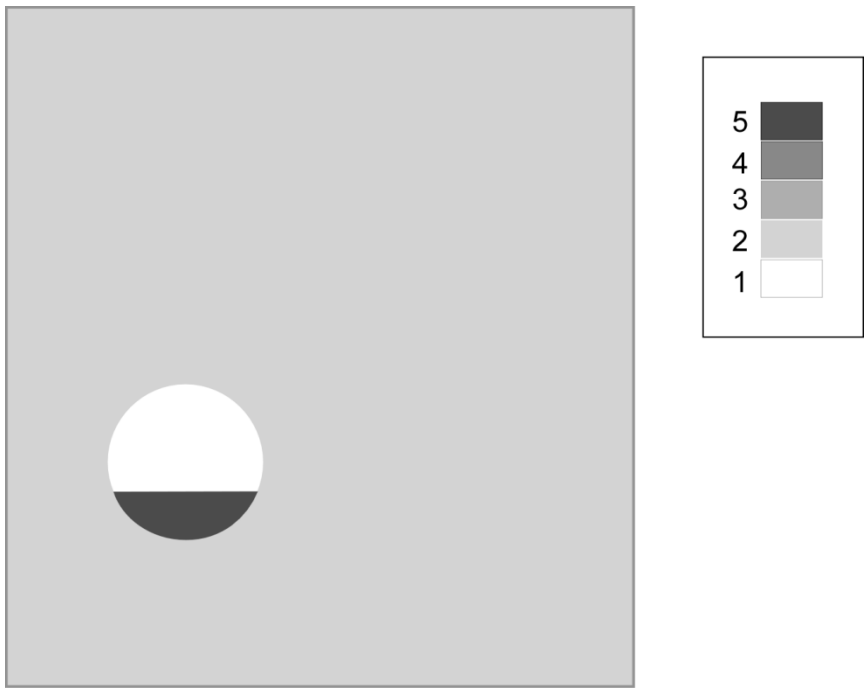

Figure 27-10. After the 1st and 2nd "filling actions", outside the shell (S6) is filled with AMMG 2.

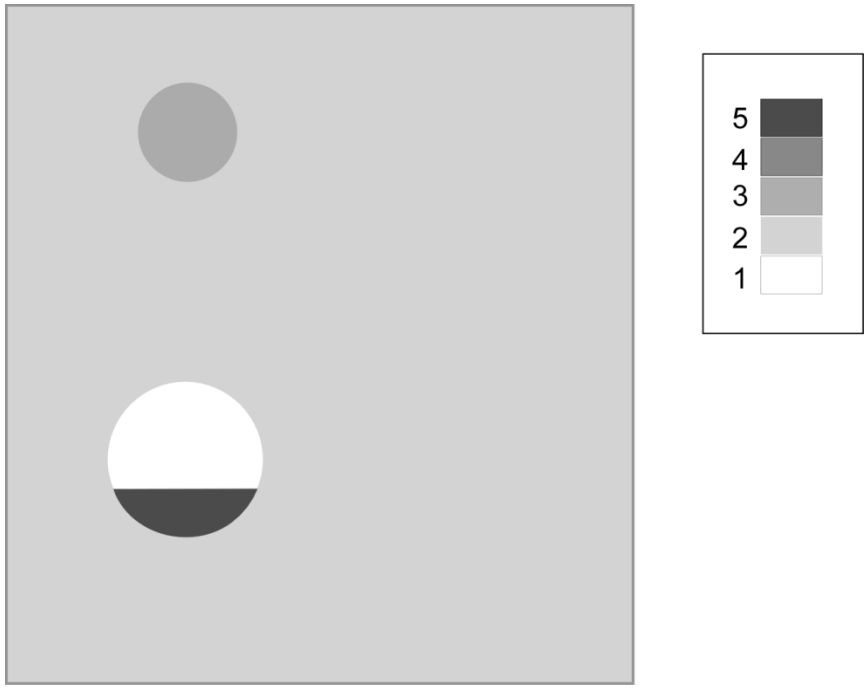

Figure 27-11. After the 1st, 2nd and 3rd "filling actions", it fills in the analytical sphere with AMMG 3.

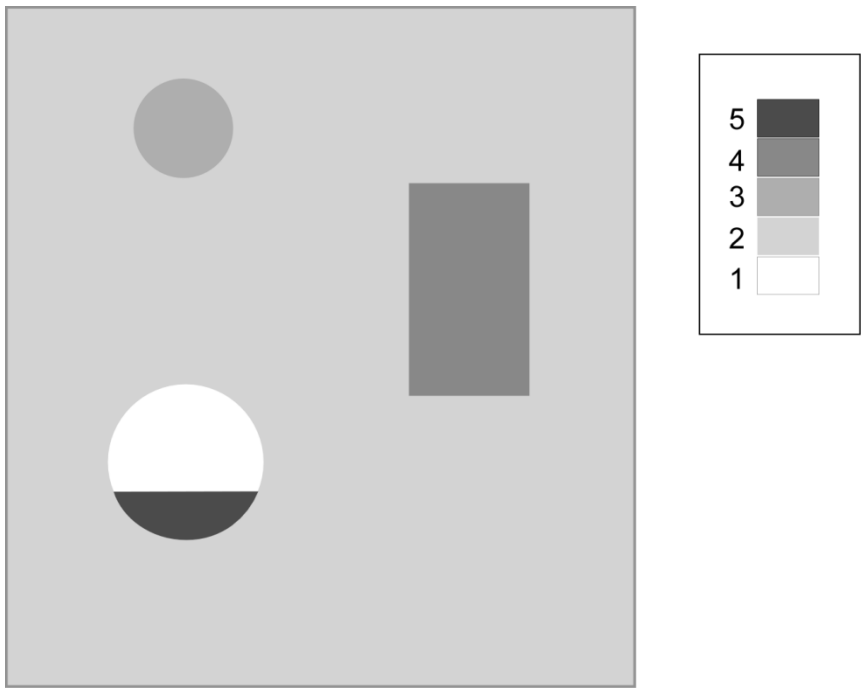

Figure 27-12. After the 1st, 2nd, 3rd and 4th "filling actions", the analytical box is filled with AMMG 4.

*INTEGRATION

In this section the user defined integration rules for beam and shell elements are specified. IRID refers to integration rule identification number on *SECTION_BEAM and *SECTION_SHELL cards respectively. Quadrature rules in the *SECTION_SHELL and *SECTION_BEAM cards need to be specified as a negative number. The absolute value of the negative number refers to user defined integration rule number. Positive rule numbers refer to the built in quadrature rules within LS-DYNA. The keyword cards in this section are:

*INTEGRATION_BEAM

*INTEGRATION_SHELL

*INTEGRATION_BEAM

Purpose: To support user defined through the thickness integration rules for the beam element.

Card 1	1	2	3	4	5	6	7	8
Variable	IRID	NIP	RA	ICST	K			
Type	I	I	F	I	I			
Default	none	0	0.0	0	0			

Standard Cross-Section Card. Additional card for ICST > 0.

Card 2	1	2	3	4	5	6	7	8
Variable	D1	D2	D3	D4	SREF	TREF	D5	D6
Type	F	F	F	F	F	F	F	F

Quadrature Cards. Include NIP additional cards below for NIP ≠ 0.

Card 3	1	2	3	4	5	6	7	8
Variable	S	T	WF	PID				
Type	F	F	F	I				

VARIABLE	DESCRIPTION
IRID	Integration rule ID. IRID refers to IRID on *SECTION_BEAM card.
NIP	Number of integration points; see also ICST.

VARIABLE	DESCRIPTION
RA	Relative area of cross section, that is, the actual cross-sectional area divided by the area defined by the product of the specified thickness in the s-direction and the thickness in the t-direction. See also ICST below and Figure 28-1.
ICST	Standard cross section type. If this type is nonzero, then NIP and the relative area above should be input as zero. See shapes in Figures 28-3 through 28-24.

EQ.01: I-Shape	EQ.12: Cross
EQ.02: Channel	EQ.13: H-Shape
EQ.03: L-shape	EQ.14: T-Shape 2
EQ.04: T-shape	EQ.15: I-Shape 3
EQ.05: Tubular box	EQ.16: Channel 2
EQ.06: Z-Shape	EQ.17: Channel 3
EQ.07: Trapezoidal	EQ.18: T-Shape 3
EQ.08: Circular	EQ.19: Box-Shape 2
EQ.09: Tubular	EQ.20: Hexagon
EQ.10: I-Shape 2	EQ.21: Hat-Shape
EQ.11: Solid Box	EQ.22: Hat-Shape 2

K	Integration refinement parameter, k, for standard cross section types. Select an integer ≥ 0. See Figures 28-3 through 28-24.
D1-D6	Cross-section dimensions. See Figures 28-3 through 28-24.
SREF	s_{ref}, location of reference surface normal to s, for the Hughes-Liu beam only. This option is only useful if the beam is connected to a shell or another beam on its outer surface. Overrides NSLOC in *SECTION_BEAM, even if SREF = 0.
TREF	t_{ref}, location of reference surface normal to t, for the Hughes-Liu beam only. This option is only useful if the beam is connected to a shell or another beam on its outer surface. Overrides NTLOC in *SECTION_BEAM, even if TREF = 0.
S	Normalized s-coordinate of integration point, $-1 \le s \le 1$.
T	Normalized t-coordinate of integration point, $-1 \le t \le 1$.

VARIABLE	DESCRIPTION
WF	Weighting factor, A_{ri}, that is the area associated with the integration point divided by actual cross sectional area $A_{ri} = A_i/A$; see Figure 28-2.
PID	Optional PID, used to identify material properties for this integration point. If zero, the PID referenced on *ELEMENT_BEAM will be used.

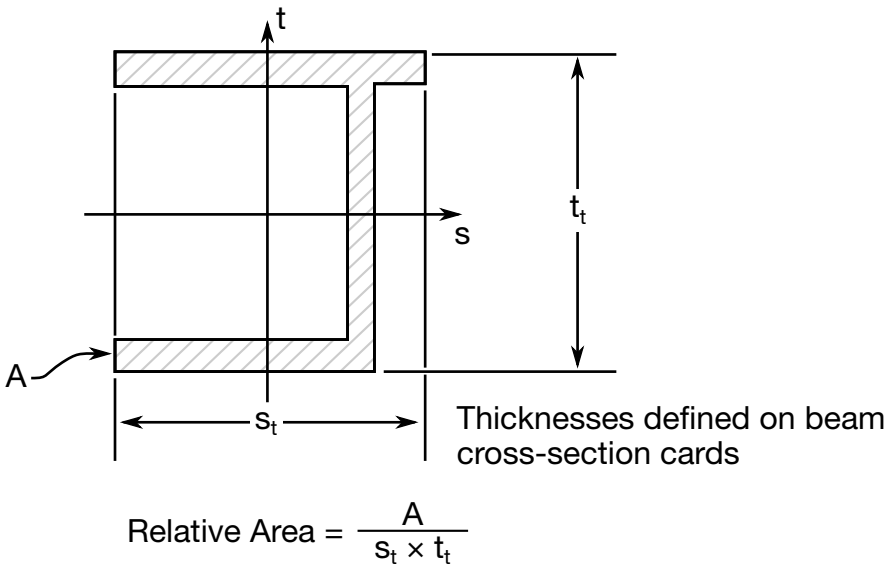

Figure 28-1. Definition of relative area for user defined integration rule.

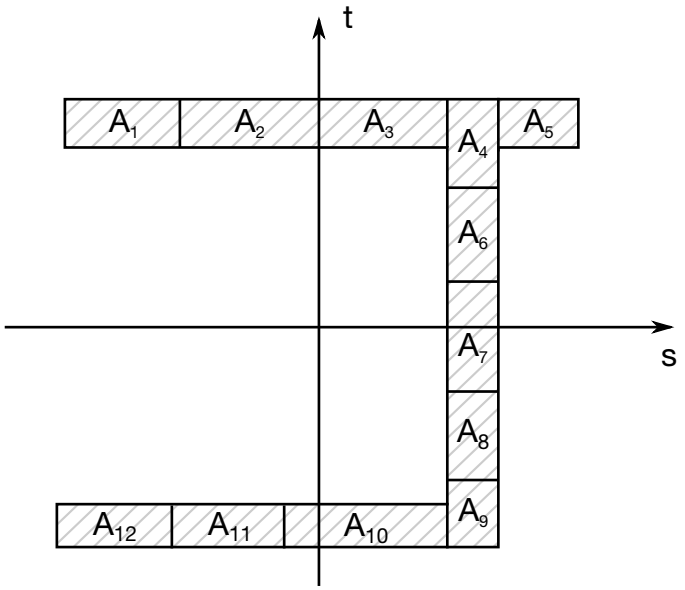

Figure 28-2. Definition of integration points for user defined integration rule.

Remarks:

The input for standard beam section types is defined below. In the following figures the dimensions are shown on the left and the location of the integration points are shown on the right. If a quantity is not defined in the sketch, then it should be set to zero in the input. The input quantities include:

D1 - D6 = Dimensions of section
k = Integration refinement parameter (an integer ≥ 0)

s_{ref} = location of reference surface normal to *s*, Hughes-Liu beam only
t_{ref} = location of reference surface normal to *t*, Hughes-Liu beam only

*INTEGRATION_SHELL

Purpose: Define user defined through the thickness integration rules for the shell element. This option applies to three-dimensional shell elements with three or four nodes (*SECTION_SHELL types 1-11, ±16, 17, 18, 20, 21, 23-27, 30, 41, 42, and 101-105), to eight node thick shell types 1, 2, and 6 (*SECTION_TSHELL), and to all IGA shell types (*SECTION_IGA_SHELL). See *PART_COMPOSITE for a simpler alternative to *PART + *SECTION_SHELL + *INTEGRATION_SHELL.

Card 1	1	2	3	4	5	6	7	8
Variable	IRID	NIP	ESOP	FAILOPT				
Type	I	I	I	I				

Define NIP cards below if ESOP = 0.

Card 2	1	2	3	4	5	6	7	8
Variable	S	WF	PID					
Type	F	F	I					

VARIABLE	DESCRIPTION
IRID	Integration rule ID (IRID refers to IRID on *SECTION_SHELL card).
NIP	Number of integration points
ESOP	Equal spacing of integration points option: EQ.0: Integration points are defined below, EQ.1: Integration points are equally spaced through thickness such that the shell is subdivided into NIP layers of equal thickness.
FAILOPT	Treatment of failure when mixing different constitutive types, which do and do not include failure models, through the shell thickness. For example, consider the case where a linear viscoelastic material model, which does not have a failure option, is mixed with a composite model, which does have a failure option. Note: If the failure option includes failure based on the time step size of

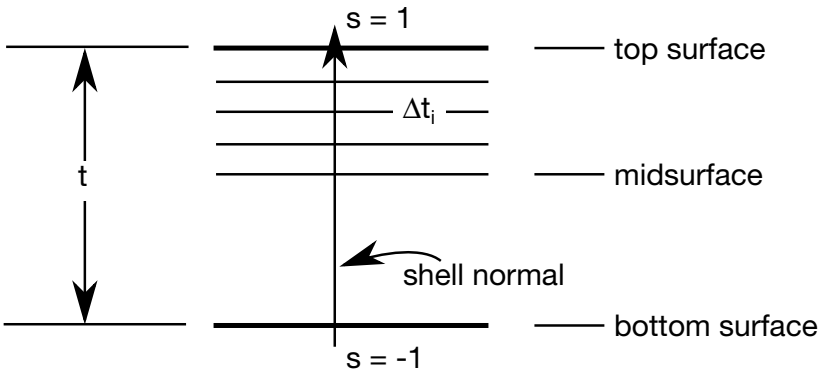

Figure 28-25. For the user defined shell integration rule the ordering of the integration points is arbitrary.

VARIABLE	DESCRIPTION
	the element, element deletion will occur regardless of the value of FAILOPT. EQ.0: Element is deleted when the layers which include failure, fail. EQ.1: Element failure cannot occur since some layers do not have a failure option.
S	Coordinate of integration point in range -1 to 1.
WF	Weighting factor. This is typically the thickness associated with the integration point divided by actual shell thickness, that is, the weighting factor for the i^{th} integration point = $\Delta t_i/t$ as seen in Figure 28-25.
PID	Optional part ID if different from the PID specified on the element card. The average mass density for the shell element is based on a weighted average of the density of each layer that is used through the thickness. When modifying the constitutive constants through the thickness, it is often necessary to defined unique part IDs without elements that are referenced only by the user integration rule. These additional part IDs only provide a density and constitutive constants with local material axes (if used) and orientation angles taken from the PID referenced on the element card. In defining a PID for an integration point, it is okay to reference a solid element PID. The material type through the thickness can vary.

*INTERFACE

Interface definitions may be used to define surfaces, nodal lines, and nodal points for which the time histories of nodal coordinates and if applicable (*INTERFACE_LINKING_NODE/EDGE) and available (beams, shells), nodal rotations, are saved at some user specified frequency. This data may then be used in subsequent analyses as an interface ID in the *INTERFACE_LINKING_DISCRETE_NODE as constraining nodes, in *INTERFACE_LINKING_SEGMENT as constraining segments and in *INTERFACE_LINKING_EDGE as the constraining edge for a series of nodes. This capability is especially useful for studying the detailed response of a small member in a large structure.

For the first analysis, the member of interest need only be discretized sufficiently that the displacements and velocities on its boundaries are reasonably accurate. After the first analysis is completed, the member can be finely discretized in the region bounded by the interfaces. Finally, the second analysis is performed to obtain highly detailed information in the local region of interest. When beginning the first analysis, specify a name for the interface segment file using the Z = parameter on the LS-DYNA execution line. When starting the second analysis, the name of the interface segment file created in the first run should be specified using the L = parameter on the LS-DYNA command line. Following the above procedure, multiple levels of sub-modeling are easily accommodated. The interface file may contain a multitude of interface definitions so that a single run of a full model can provide enough interface data for many component analyses. The interface feature represents a powerful extension of LS-DYNA's analysis capabilities. The keyword cards for this purpose are:

*INTERFACE_COMPENSATION_3D

*INTERFACE_COMPONENT_FILE

INTERFACE_COMPONENT_*OPTION

INTERFACE_LINKING_DISCRETE_NODE_*OPTION

*INTERFACE_LINKING_EDGE

*INTERFACE_LINKING_FILE

*INTERFACE_LINKING_FORCES

*INTERFACE_LINKING_NODE

*INTERFACE_LINKING_SEGMENT

INTERFACE_SPRINGBACK_*OPTION1_OPTION2

*INTERFACE

Interface definitions may also be employed to define soil-structure interfaces in earthquake analysis involving non-linear soil-structure interaction where the structure may be non-linear, but the soil outside the soil-structure interface is assumed to be linear. Free-field earthquake ground motions are required only at the soil-structure interface for such analysis. The keyword cards for this purpose are:

*INTERFACE_SSI

*INTERFACE_SSI_AUX

*INTERFACE_SSI_AUX_EMBEDDED

*INTERFACE_SSI_STATIC

As of R13, two interface keywords are available for performing a two-stage SPG analysis. The first keyword is for specifying that the current analysis is the first stage while the second keyword is for specifying the analysis is the second stage. These keywords are:

*INTERFACE_SPG_1

*INTERFACE_SPG_2

*INTERFACE_ACOUSTIC

Purpose: Create an interface file of boundary motions that can be used by *BOUNDARY_ACOUSTIC_INTERFACE for weakly coupled acoustic fluid-structure interaction in SSD analyses (see *CONTROL_IMPLICIT_SSD_DIRECT).

Card 1	1	2	3	4	5	6	7	8
Variable	IFID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
IFID	Segment set ID of structural faces for this interface. This structural IFID can be used by *BOUNDARY_ACOUSTIC_INTERFACE.

Remarks:

1. **Acoustic Interface Filename.** The motions of the structural segments will be written to the LSDB database "baifac.db" for every SSD solution step invoked with *CONTROL_IMPLICIT_SSD_DIRECT. Multiple interfaces from a single analysis may be saved in one interface file if they reference different IFID.

***INTERFACE_BLANKSIZE**_*OPTION*

Available options include:

DEVELOPMENT

INITIAL_TRIM

INITIAL_ADAPTIVE

SCALE_FACTOR

SYMMETRIC_PLANE

Purpose: This keyword causes LS-DYNA to run a blank-size development calculation instead of a finite element calculation. The input for this feature consists of (1) the result of a completed metal forming simulation, (2) the corresponding initial blank, and (3) the desired result from the simulation in the form of a boundary curve or full mesh. From these inputs, the *INTERFACE_BLANKSIZE method adjusts the initial blank so that the resulting formed piece more closely matches the target. Iterating may systematically improve the blank's starting geometry. This feature is available for both SMP and MPP but requires a double precision executable. A GUI for using this available in LS-PrePost as of version 4.2 under *APPLICATION → Metal Forming → Blank Size/Trim line*.

> **NOTE:** When this card is present, LS-DYNA *does not* proceed to the finite element simulation.

This keyword requires one or all three keyword options in the input deck, each corresponding to a different kind of forming operation:

1. **DEVELOPMENT.** This option takes as its target either a full mesh or a minimum boundary. It adjusts the blank so that the product more closely approximates the target. The computed blank-boundary is written to a file called trim-curves.ibo, which contains a *DEFINE_CURVE_TRIM_3D keyword.

2. **INITIAL_TRIM.** This option adjusts the blank so that trimming and mesh-refinement are mapped back onto the initial blank.

3. **INITIAL_ADAPTIVE.** This option reads in (1) the input mesh for a flanging simulation as well as (2) the adapted mesh calculated during flanging simulation. It maps the refinement back to the initial blank.

Reference Surface Card. See "Reference surface (ref4.k)" in Figure 29-1 and Example II.

Card 6	1	2	3	4	5	6	7	8
Variable	FILENAME13							
Type	A80							

VARIABLE	DESCRIPTION
IOPTION	Target curve definition input type:

VARIABLE	DESCRIPTION
	EQ.1: (Entire) blank mesh in keyword format. EQ.2: Consecutive position coordinates of blank boundary loop curve in XYZ format, defined by *DEFINE_TARGET_BOUNDARY. The blank mesh's normal vector and the closed boundary curve are consistently oriented according to the right-hand rule, see Figure 29-2. Note the target boundary curves must have enough points for a successful prediction of the initial blank size. EQ.-2: Consecutive position coordinates of blank boundary loop curve in XYZ format, defined by *DEFINE_TARGET_BOUNDARY. The blank mesh's normal vector and the closed boundary curve are consistently oriented according to the left-hand rule, see Figure 29-2. Note the target boundary curves must have enough points for a successful prediction of the initial blank size. **NOTE:** Starting in August 2015, the curve direction is desensitized, meaning *both* IOPTION = 2 and IOPTION = -2 give the same results. In LS-PrePost 4.0,use menu option *GeoTol* → *ID Measure* to show the flow direction of a boundary curve. To reverse the curve direction, use *Curve* → *Rever(se)*.
IADAPT	Adaptive mesh control flag. If IADAPT = 1, the number of elements in the meshes initial (FILENAME3) and simulated blank (FILENAME2) can be different, so it is not necessary to use the sheet blank from the file adapt.msh (created by setting IOFLAG = 1 in *CONTROL_ADAPTIVE) for the initial blank mesh.
MAXSIZE	The maximum change in initial blank size in each iteration. It is used to limit the blank size change in each iteration during mapping to avoid convergence problems when the initial blank is curved.
REF	Flag to indicate trim curve projection to a reference surface (mesh); see Figure 29-1:

VARIABLE	DESCRIPTION
	EQ.0: No projection. EQ.1: The trim curves will be projected to the reference surface. In addition, the mesh file for the reference surface is given in FILENAME4.
SPACE	Point spacing distance on the reference surface for the projected curve; see Figure 29-1. If the gap between two neighboring points in the modified trimming curve is larger than this value, extra nodes will be added in the final blank and projected to the reference surface. A smaller value should be used for large reference surface curvature.
MAXGAP	When REF is set to 1, the nodes from the final blank will be projected to the reference surface. However, if the distance between the nodes and the surface is larger than MAXGAP, the nodes will not be projected.
ORIENT	A flag to control iterative optimization efficiency or to include a reference surface file for the final formed blank. EQ.1: Activates a new algorithm to potentially reduce the number of iterations during the iterative blank size optimization loop. This activation should be used in conjunction with the keyword option SCALE_FACTOR (0.75~0.9). EQ.2: To include a reference surface FILENAME13 (in keyword mesh format) for the simulated (formed) blank. This is useful when the formed blank is smaller than intended and extended surfaces are not flat. See Example II and Figure 29-1.
FILENAME1	Target input file name. When a blank mesh is used (IOPTION = 1), the keyword file must contain *NODE and *ELEMENT_SHELL keywords. When using the blank boundary curve for target (|IOPTION| = 2), the file must consist of *DEFINE_TARGET_BOUNDARY. See the Target Boundaries (and IGES) in the Remarks section.
FILENAME2	Simulated (formed or flanged) sheet blank mesh in keyword format. This mesh can be obtained from the final state of any downstream process simulation.

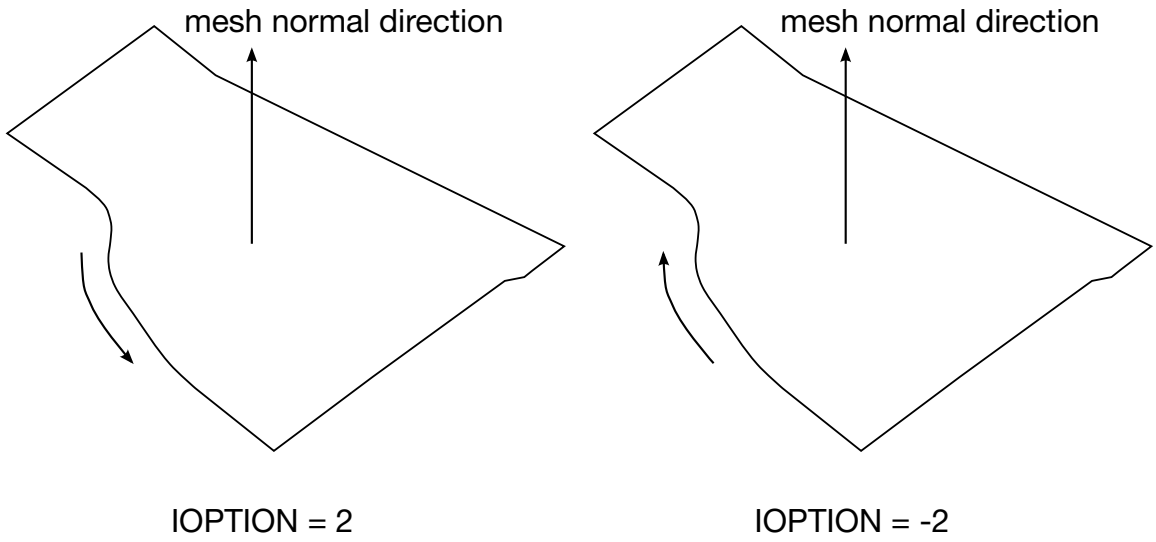

Figure 29-2. Differences between IOPTION 2 and -2.

VARIABLE	DESCRIPTION
FILENAME3	Initial sheet blank mesh in keyword format. This can be the first state mesh from any process simulation prior to FILENAME2 simulation. Set IADAPT = 1 if adaptive refinement is used in any simulation.
FILENAME4	Reference surface onto which adjustments to the blank's trim curves in its initial state are projected (ref3.k in Figure 29-1). This surface is typically a curved extension of the initial blank and must be defined as a mesh in keyword format. This file name must be defined when REF is set to 1. Also see extended reference surface for the final state (formed state), FILENAME13.
FILENAME13	Reference surface onto which adjustments to the blank's trim curves in its final state are projected (ref4.k in Figure 29-1). This surface is typically a curved extension of the formed blank and must be defined as mesh in keyword format. This file name must be defined when ORIENT is set to 2.

Card Set for *INTERFACE_BLANKSIZE_INITIAL_TRIM.

Initial Flat blank. FILENAME5 should specify the mesh of a blank that has been refined during a subsequent forming operation. FILENAME5 is usually set to the adapt.msh output. See "OP10 Initial Adapted blank mesh" in Figure 29-3.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME5							
Type	A80							

Formed blank. FILENAME6 specifies a dynain file from a forming simulation. See "OP10 Final blank" in Figure 29-3.

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME6							
Type	A80							

Trimmed Formed blank. A dynain file from a trimming simulation that started with the state given in FILENAME6. See "OP20 Final blank" in Figure 29-3.

Card 3	1	2	3	4	5	6	7	8
Variable	FILENAME7							
Type	A80							

Trimmed Flat blank (output). This field specifies the name for the file to which the trimmed flat blank is written. See "OP20 Flat New" in Figure 29-3.

Card 4	1	2	3	4	5	6	7	8
Variable	FILENAME8							
Type	A80							

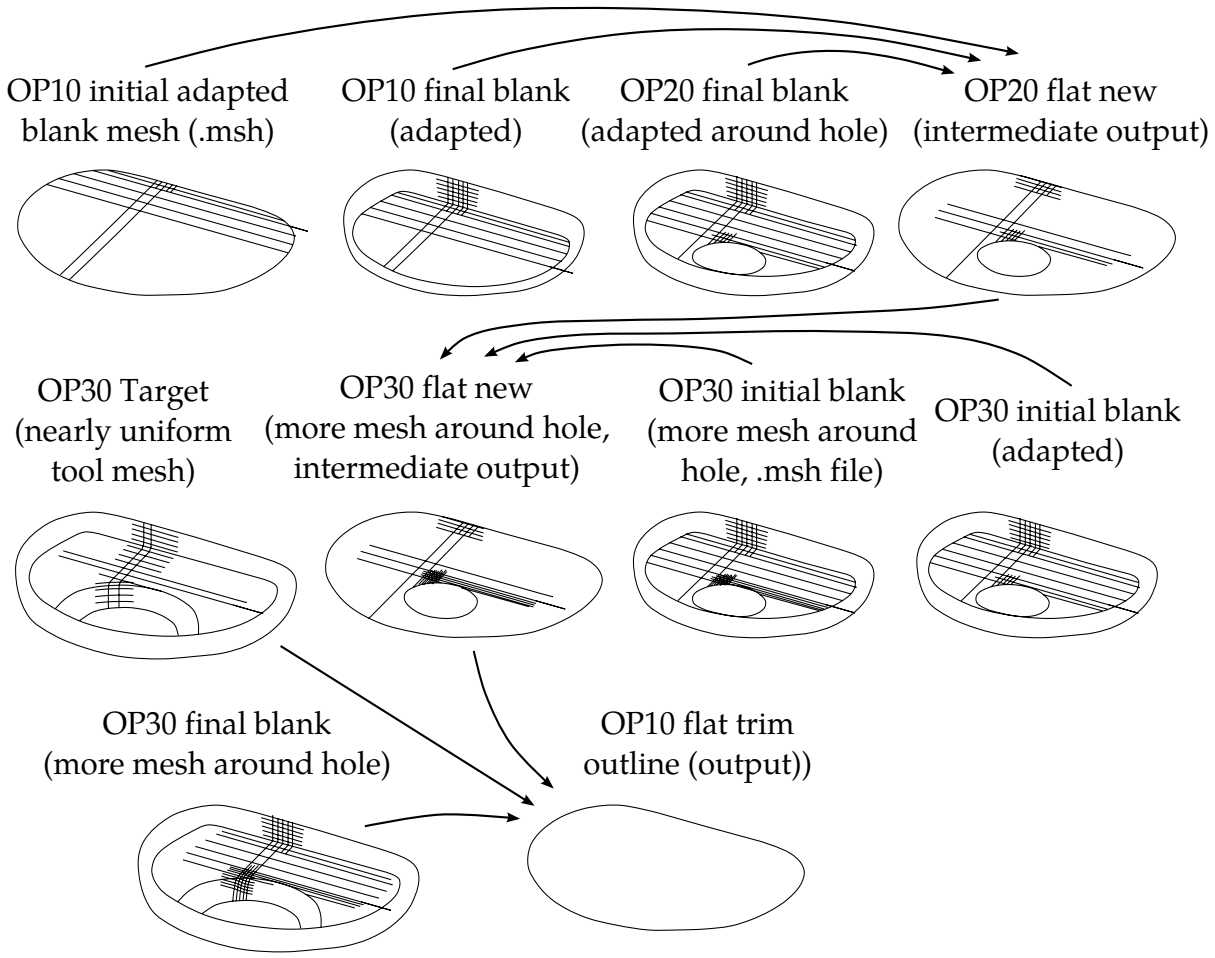

Figure 29-3. Inputs and outputs (*Courtesy of Metal Forming Analysis Corp.*). For exposition of labels OP10, OP20, and OP30 see Figure 29-4.

VARIABLE	DESCRIPTION
FILENAME5	Initial blank in its flat configuration *with* adapted mesh in keyword format. FILENAME5 usually points to an adapt.msh file. For example see OP10 in Figures 29-4, 29-22 and 29-3, in which FILENAME5 is the adapt.msh from a draw-forming calculation.
FILENAME6	Final formed blank in keyword format. This is usually the dynain file corresponding to the adapt.msh file mentioned above for FILENAME5; see Figures 29-4, 29-22 and 29-3.
FILENAME7	A trimmed blank in keyword format. This file should be derived from FILENAME6 as the dynain file from a trimming simulation. See OP20 in Figures 29-4, 29-22 and 29-3.
FILENAME8	This field specifies the name for the file in which the trimmed flat blank is to be written. See OP20 in Figures 29-4, 29-22 and 29-3.

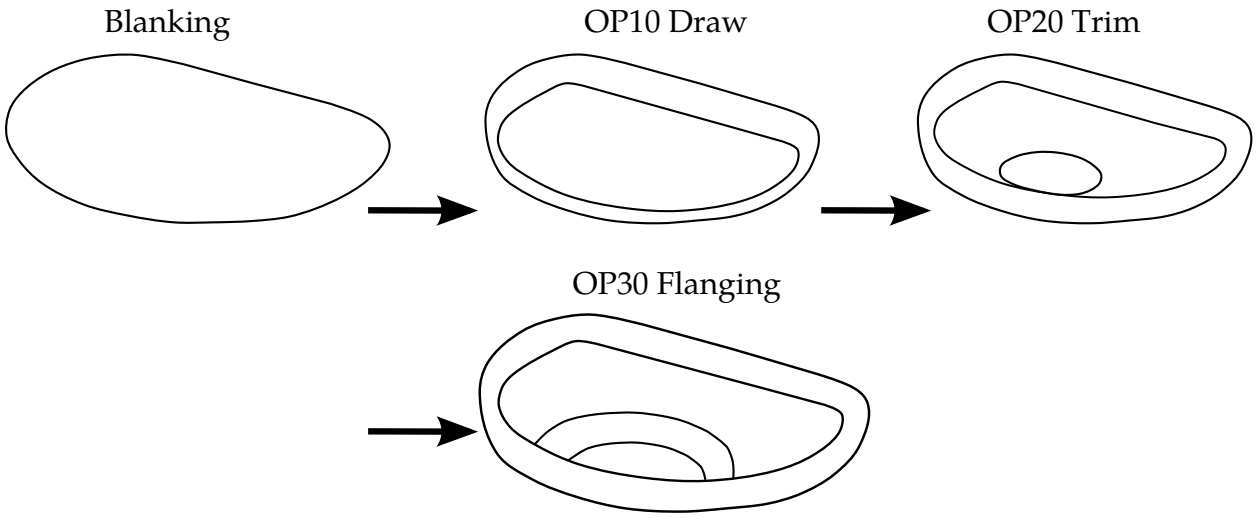

Figure 29-4. A stamping process consists of draw, trim and flanging (*Courtesy of Metal Forming Analysis Corporation*). The labels OP10, OP20, and OP30 are used *extensively* in the ensuing discussion.

Card Set for *INTERFACE_BLANKSIZE_INITIAL_ADAPTIVE.

Flat blank. FILENAME9 specifies the mesh of a blank in a flat configuration serving as the basis for a two-step metal forming process. The second-stage simulation produces an adapt.msh file, from which the refinements are to be mapped onto the flat-blank of FILENAME9. See, for example, "OP20 Flat New" in Figure 29-3 where FILENAME9 points to result, FILENAME8, of an INITIAL_TRIM calculation.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME9							
Type	A80							

Initial blank. FILENAME10 is the result from the first stage of a two-step process. See, for example, "OP30 Initial blank" in Figure 29-3 where FILENAME10 has been formed and trimmed and refined along the way.

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME10							
Type	A80							

Adapted Initial blank. FILENAME11 contains a refined version of the mesh in FILENAME10. It is expect to name the adapt.msh file from some operation performed on the mesh of FILENAME10. See, for example, "OP30 Initial blank (with more mesh)" in Figure 29-3, where the adapt.msh file comes from a flanging simulation.

Card 3	1	2	3	4	5	6	7	8
Variable	FILENAME11							
Type	A80							

Refined Flat blank (output). This field specifies the name of the file to which the refined flat blank is written. The blank's mesh is refined to *exactly* match the forming process. See, for example, "OP30 Flat New" in Figure 29-3.

Card 4	1	2	3	4	5	6	7	8
Variable	FILENAME12							
Type	A80							

VARIABLE	DESCRIPTION
FILENAME9	FILENAME9 should point to the blank defined by FILENAME8, as in Figures 29-4, 29-22 and 29-3.
FILENAME10	Initial-stage result file name. This may be extracted from d3plot files using LS-PrePost or it may be generated by LS-DYNA as a dynain file. See, for example, "OP30 Initial Blank" in Figure 29-3 where FILENAME10 has been formed, trimmed and refined along the way. To obtain from d3plot file the necessary mesh in keyword format using LS-PrePost4.0 select *POST* → *OUTPUT* → *Dynain ASCII* and check the box for *Exclude strain and stress*.
FILENAME11	FILENAME11 contains a refined version of the mesh in FILENAME10. FILENAME11 can be obtained from adapt.msh file from the same operation performed on the mesh of FILENAME10. See, for example, "OP30 Initial Blank (with more mesh)" in Figure 29-3, where the adapt.msh file comes from a flanging calculation.
FILENAME12	This field specifies the name of the file to which the refined flat blank is written. The blank's mesh is refined to *exactly* match the forming process. See, for example, "OP30 Flat New" in Figure 29-3.

Card Set for *INTERFACE_BLANKSIZE_SCALE_FACTOR.

Scale Factor Card. Define one card for each curve. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	IDCRV	SF	OFFX	OFFY	OFFZ			
Type	I	F	F	F	F			
Default	1	0.0	0.0	0.0	0.0			

VARIABLE	DESCRIPTION
IDCRV	Curve ID in the order of appearance as in FILENAME1 in the target card, as defined by *DEFINE_TARGET_BOUNDARY.
SF	Scale factor for the IDCRV defined above. It defines a fraction of the changes required for the predicted initial blank shape. For example, if SF is set to 0.0, the corresponding IDCRV will be excluded from the calculation (although the original initial curve still will be output); on the other hand, if SF is set to 1.0, full change will be applied to obtain the modified initial blank that reflects the forming process. A SF of 0.5 will apply 50% of the changes required to map the initial blank. This feature is especially important for inner holes that are small and hole boundary expansions are large, so the predicted initial hole can avoid "crisscross" situation. An example is provided in Scale Factor and Symmetric Plane.
OFFX, OFFY, OFFZ	Translational move of the target curve. This is useful when multiple target curves (e.g. holes) and formed curves are far away from each other. Input values of OFFX, OFFY and OFFZ helps establish one-to-one correspondence between each target curve and formed curve. OFFX.EQ.-10000.0: offset values are automatically calculated.

Card Set for *INTERFACE_BLANKSIZE_SYMMETRIC_PLANE.

Symmetric Plane Card.

Card 1	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	V1	V2	V3		
Type	F	F	F	F	F	F		
Default	0.0	0.0	0.0	1.0	0.0	0.0		

VARIABLE	DESCRIPTION
X0, Y0, Z0	*x*, *y*, *z* coordinates of a point on the symmetric plane. See example in Scale Factor and Symmetric Plane.
V1, V2, V3	Vector components of the symmetric plane's normal. See example in Scale Factor and Symmetric Plane.

Remarks and Examples

Inverse Methods for Optimizing Blank Size and Trim Lines:

Finding the minimal practicable blank size and developing an optimal set of trim lines is an integral part of the die engineering process. This card, *INTERFACE_BLANKSIZE, is one of several features that have been developed to solve the inverse problem: that is, to calculate an initial blank or blank boundary that will yield a desired product based mostly on the target geometry of that final product.

1. **The One-Step Method.** The *CONTROL_FORMING_ONESTEP card is suitable for early blank-size estimates. It invokes the total-strain theory of plasticity, thereby bypassing the, as of yet, undetermined specific details of the forming process.

2. **Unflanging.** Once the product design and process plan are complete, die development begins with addendum and binder creation, followed by secondary tooling development. In this stage, *CONTROL_FORMING_UNFLANGING can be used to develop trim lines for the secondary tooling; final (or intermediate) desired flange shapes are unfolded onto the addendum or binder to obtain the corresponding flange shapes in its initial shape. It also implements failure criteria to arrive at suggested final flange curves, with strains and thickness output on the unfolded flanges.

3. **Interface Blanksize.** This card, *INTERFACE_BLANKSIZE, can be used to *accurately* determine the optimal initial blank. To do so it requires an initial configuration, the corresponding simulated configuration, and a desired target configuration. This method takes into account the entire metal-forming process.

   a) One application of this keyword is to map trim curves between dies to calculate the trim curves needed for all trim dies. An example of the application can be found in Figures 29-18 through 29-21.

	Compulational Cost	Accuracy	Information Required	Physical Process
Blanksize	Full simulation	Exact	Full Simulation	Any
Unflanging	Fast	Approximate	Process Geometry	Inverse Flanging
Onestep	Fast	Approximate	None (*Path independent*)	Any

Table 29-1. Comparison of inverse methods.

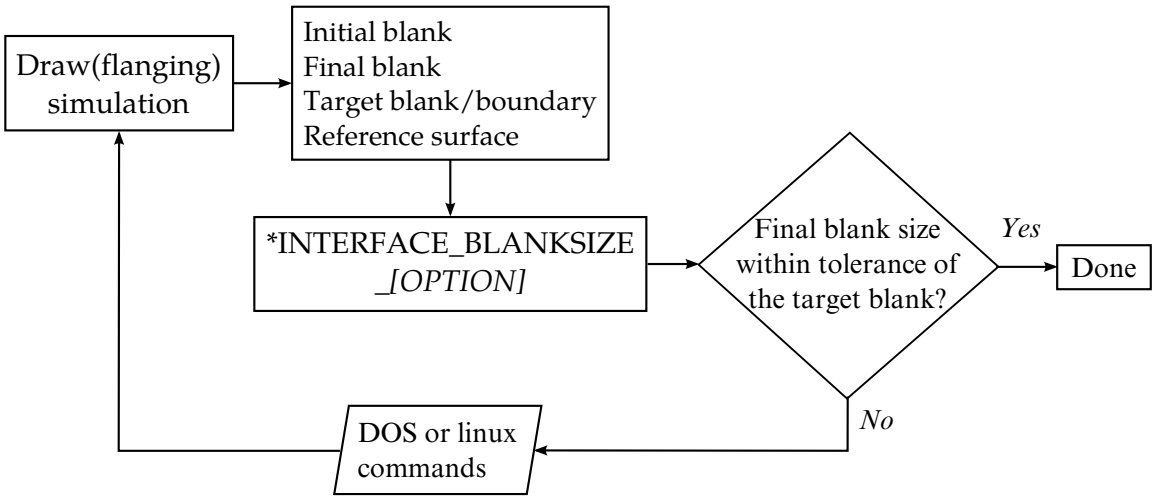

Figure 29-5. An iterative blank size development process.

b) The keyword can also be used to determine the precise minimal initial blank needed for a draw panel whose blank edge must be at specified distances from the edge of the draw beads.

Iterative Workflow:

The "interface blanksize" command produces an adjusted initial blank. It is not to be expected that the adjustment will be exact. However, this initial blank shape can be run through a second simulation to see if the final shape is close enough to the target blank. If it is not close enough, then the results from the second simulation can be used to repeat the process. Iterations can proceed until the final shape is within the range of the target shape. This iterative blank size development process is schematically presented in Figure 29-5 and exemplified in Figures 29-8 through 29-17.

Target Boundaries (and IGES):

When IOPTION = 2, or -2, a file with the keyword *DEFINE_TARGET_BOUNDARY must be present. This keyword can now be created from an IGES file using LS-PrePost 4.1 (or 4.2). To convert from IGES curves to keyword *DEFINE_TARGET_BOUNDARY in LS-PrePost 4.1, use menu option *Curve* → *Convert*→ *Method (To Keyword)* → *Select *DEFINE_TARGET_BOUNDARY*; pick the curves then hit *To Key*; write out the keyword file using *File* → *Save as* → *Save Keyword As*; and select *Output Version* as *V971_R7*. In LS-PrePost 4.2, select *Application* → *Metal Forming* → *Blanksize Trimline* to import the target curve directly in IGES format, the initial and final blank mesh and then write out a complete LS-DYNA input deck.

In addition, the target curves should be projected onto the final blank mesh if they do not exactly lie on the mesh surface. This can be done with LS-PrePost 4.1 using the menu

option *GeoTol* → *Project* → *Project*, select *Closest Projection*, select *Project to Elements*, then define the destination mesh and source curves, and hit *Apply*.

Computed Initial Blank Boundaries (and IGES):

Computed boundary curves are written with *DEFINE_CURVE_TRIM_3D keyword into a file called trimcurves.ibo. The format of this file follows the keyword's specification. LS-PrePost4.0 can convert the computed curve to IGES. See Figure 29-10. After hitting *Apply*, the curves will show up in the graphics window, and *File* → *Save as* → *Save Geom as* can be used to write the curves out in IGES format. In the LS-PrePost 4.2 GUI, under *Results*, trimcurves.ibo can be directly imported into the graphics window for viewing and to save in either STEP or IGES format.

To convert IGES to the *DEFINE_CURVE_TRIM_3D keyword format, import the IGES file into LS-PrePost4.0 and follow the procedures shown in Figure 29-11. After finishing step 2, "*curves have been converted to keyword format*" will be reported in the command prompt. Then use *File* → *Save* → *Save keyword* to write out the keyword file.

Support for Multi-Stage Processes with the Development Option:

Original Implementation.

Prior to Revision 88708 the development option required that the final blank (FILENAME2) differ from the initial blank (FILENAME3) by no more than a deformation and mesh refinement. In practice, this means that the two meshes must come from the same process simulation. For example, in a draw, trim and flanging process, the trimmed panel mesh is used for flanging simulation. Therefore, with the original implementation, LS-DYNA required that the initial blank state (FILENAME3) be trimmed when the final blank state (FILENAME2) is flanged on trimmed panel. Failure to observe this limitation may result in error termination.

Enhanced Implementation.

A more recent improvement to the blank size development (Revision 88708) removes the requirement that initial (FILENAME3) and final (FILENAME2) blanks must be from the same process simulations. The initial and final blank states *may* differ by a trimming process. This allows trimming and other process such as flanging to occur between the initial and final blanks, without the need of invoking the INITIAL_TRIM and INITIAL_-ADAPTIVE options. For example, the initial blank can be the blank mesh from "Blanking" in Figure 29-4, and the final blank can be the blank mesh from "Flanging," which is also in Figure 29-4.

Scale Factor and Symmetric Plane:

An example of using various scale factors ranging from 0.0 to 1.0 on a model involving an initial hole shape is shown in Figure 29-25. The target curve is given in targetline.k. All nodes along the symmetric plane are constrained by the SYMMETRIC_PLANE option. The symmetric plane is defined going through point coordinates $(-76, 2.63844, 0.38)$ with plane normal vector of $(1.0, 0.0, 0.0)$. A complete input is provided below:

```
*KEYWORD
*INTERFACE_BLANKSIZE_DEVELOPMENT
$  IOPTION              IADAPT
        -2                   1
$ target boundary curves
targetline.k
$ final formed mesh
final.k
$ initial mesh
initial.k
*INTERFACE_BLANKSIZE_SCALE_FACTOR
$    IDCRV        SF
         1       0.2
*INTERFACE_BLANKSIZE_SYMMETRIC_PLANE
$       X0         Y0         Z0         V1         V2         V3
       -76   2.63844       0.38        1.0        0.0        0.0
*END
```

If targetline.k consists of multiple curves, the following format can be used:

```
*INTERFACE_BLANKSIZE_SCALE_FACTOR
$    IDCRV        SF
         1       0.2
         2       0.8
         3       1.0
         ⋮         ⋮
```

Example I: Simple Example of the Development Option

Given the initial and final blank configuration and a target, this option calculates a new initial blank outline, corresponding to the target final blank boundary. In this example note that IADAPT = 1, meaning initial and final blank meshes may differ by an adaptively operation. The input and output files are detailed below, and output results are shown in Figure 29-6.

```
*KEYWORD
*INTERFACE_BLANKSIZE_DEVELOPMENT
$  IOPTION              IADAPT
         2                   1
$  input file for target mesh, or target position coordinates
targetpoints.k
$  input file for formed mesh
final.k
$  input file for initial blank mesh
initial.k
*END
```

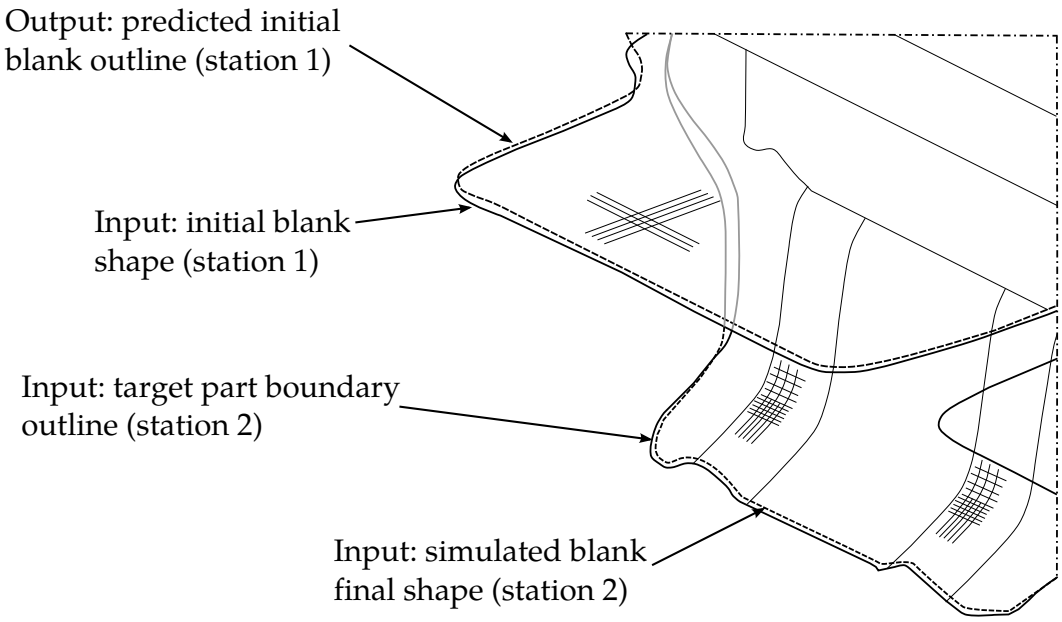

Figure 29-6. Blank size development in a progressive die with IADAPT = 1 in Example I.

The file, targetpoints.k partially shown below, was generated from IGES using *LS-Pre-Post 4.1*.

```
*KEYWORD
*DEFINE_TARGET_BOUNDARY
    -1.83355e+02    -5.94068e+02    -1.58639e+02
    -1.80736e+02    -5.94071e+02    -1.58196e+02
    -1.78126e+02    -5.94098e+02    -1.57813e+02
    -1.75546e+02    -5.94096e+02    -1.57433e+02
    -1.72888e+02    -5.94117e+02    -1.57026e+02
          ⋮               ⋮               ⋮
    -1.83355e+02    -5.94068e+02    -1.58639e+02
*END
```

The output is the modified initial blank outline in the file trimcurves.ibo.

Example II: The Reference Surface feature for the Development Option

For an initial blank that is not flat, the fields REF and FILENAME4 can be used to define a surface onto which changes in the boundary are needed. This is important when the adjusted boundary is not a simple tangential extension of the initial blank.

In a keyword example below, REF is set to "1" and the reference file for the extended initial shape is given as ref3.k. The maximum change between the initial and final blank size is set to be 20.0 mm per iteration. Point spacing distance (SPACE) of the calculated trim curve on the reference surface is set at 2.0 mm. Note that the inner holes and outer boundary curves are defined in target.xyz. The holes do not necessarily need to exist in the initial or final blank mesh. Also, since ORIENT is set to 2, a reference surface mesh

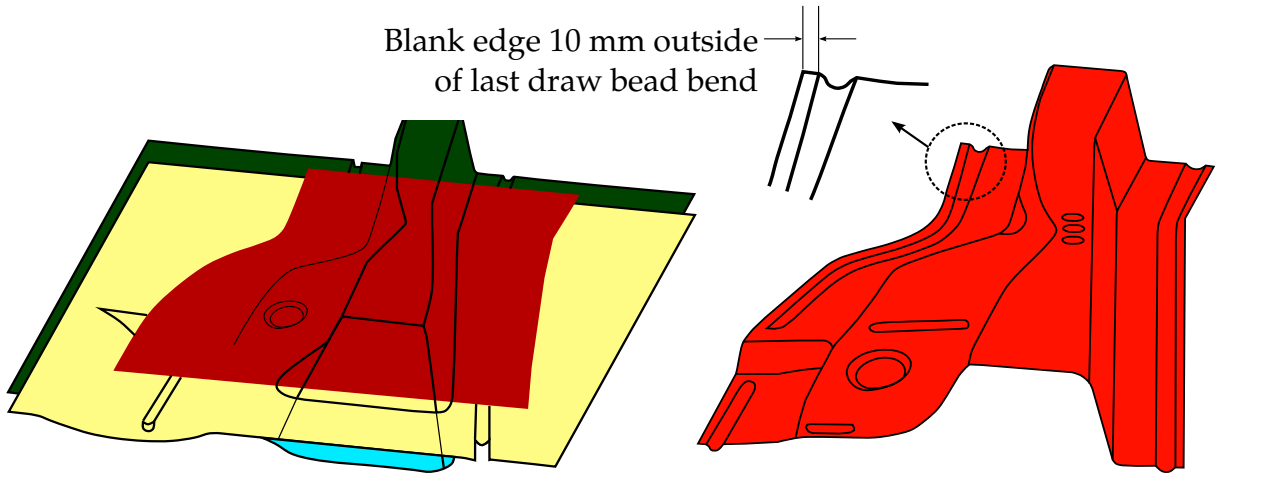

Figure 29-7. NUMISHEET 2005 cross member in Exmaple III.

file (ref4.k) is provided for the final (formed) state. The input details and output results are shown in Figure 29-1.

Example III: Development Feature Applied to a Draw Die with Physical Bead

In this example, which was created from NUMISHEET 2005, the DEVELOPMENT option has been used to design a blank such that, when formed, the edge is a specified distance outside of the last bend of a draw bead. In Figure 29-7, the tooling and blank set up is shown on the left. The right side of the figure shows the target blank, whose left and right edges everywhere are made 10 mm outside of the last bending radius of the draw beads. This setup is prototypical of one method to ensure a very stable and high-quality stamping process.

The first step towards setting up this analysis was to use *CONTROL_FORMING_ONESTEP to unfold the target blank and thereby obtain an initial guess of a flat blank, as shown to the left in Figure 29-12. The flat blank is then formed as one would usually do

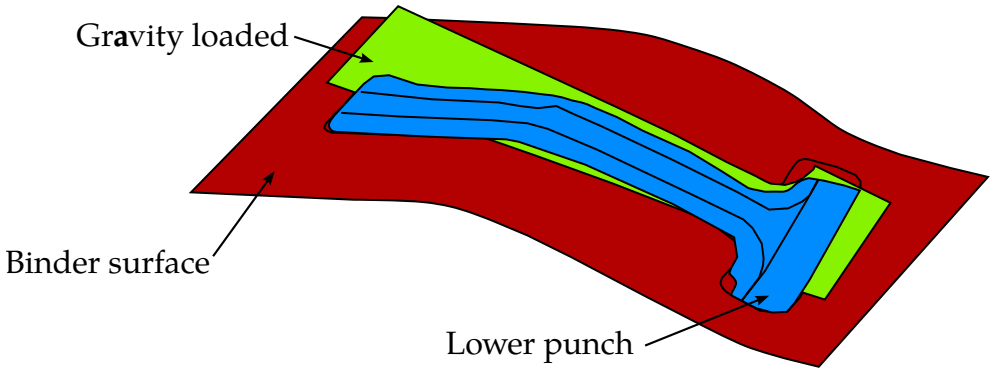

Figure 29-8. NUMISHEET 2008 B-pillar; Gravity loaded blank.

in a regular forming simulation as shown on the right side of the figure. The formed blank (Iteration 0) turns out to be larger than the target.

Next, the DEVELOPMENT is applied to generate a new and better initial blank that will lead to the target blank. The flat blank is used as input for the "initial blank mesh", the formed blank is used as input for the "simulated mesh", and the target blank mesh, or boundary points, is used to define the target.

In Figure 29-13 (left) the improved initial blank, called *the first compensated blank,* is superimposed onto the original one-step unfolded result. The one-step unfolded result is somewhat larger than the developed blank. When formed the improved blank (Iteration 1) nearly overlaps the target blank, shown in Figure 29-13 (right). If the final formed blank still deviates from the target, another iteration would ensue, until satisfactory results are obtained.

Example IV: Iterating with the Development Option

Because the NUMISHEET 2008 B-pillar model involves neither trimming nor flanging, it exmplifies the DEVELOPMENT option in its most direct use case. This model, illustrated in Figure 29-8, simulates a draw-die's action on a gravity-stressed flat blank. The B-pillar undergoes a stamping process including gravity, binder closing, and being drawn. In this example the DEVELOPMENT option is used to calculate the geometry for an initial blank that will exactly satisfy the design specification for a final formed panel. To highlight the efficiency of this feature, we start with an initial blank whose formed product deviates from the specification by a wide margin and then iterate using the DEVELOPMENT feature.

The target and the optimal initial blank are shown in Figure 29-14. The intial guess intentionally deviates from the optimal initial blank as shown in the left panel of Figure 29-15; the formed blank is compared with the target in the right panel.

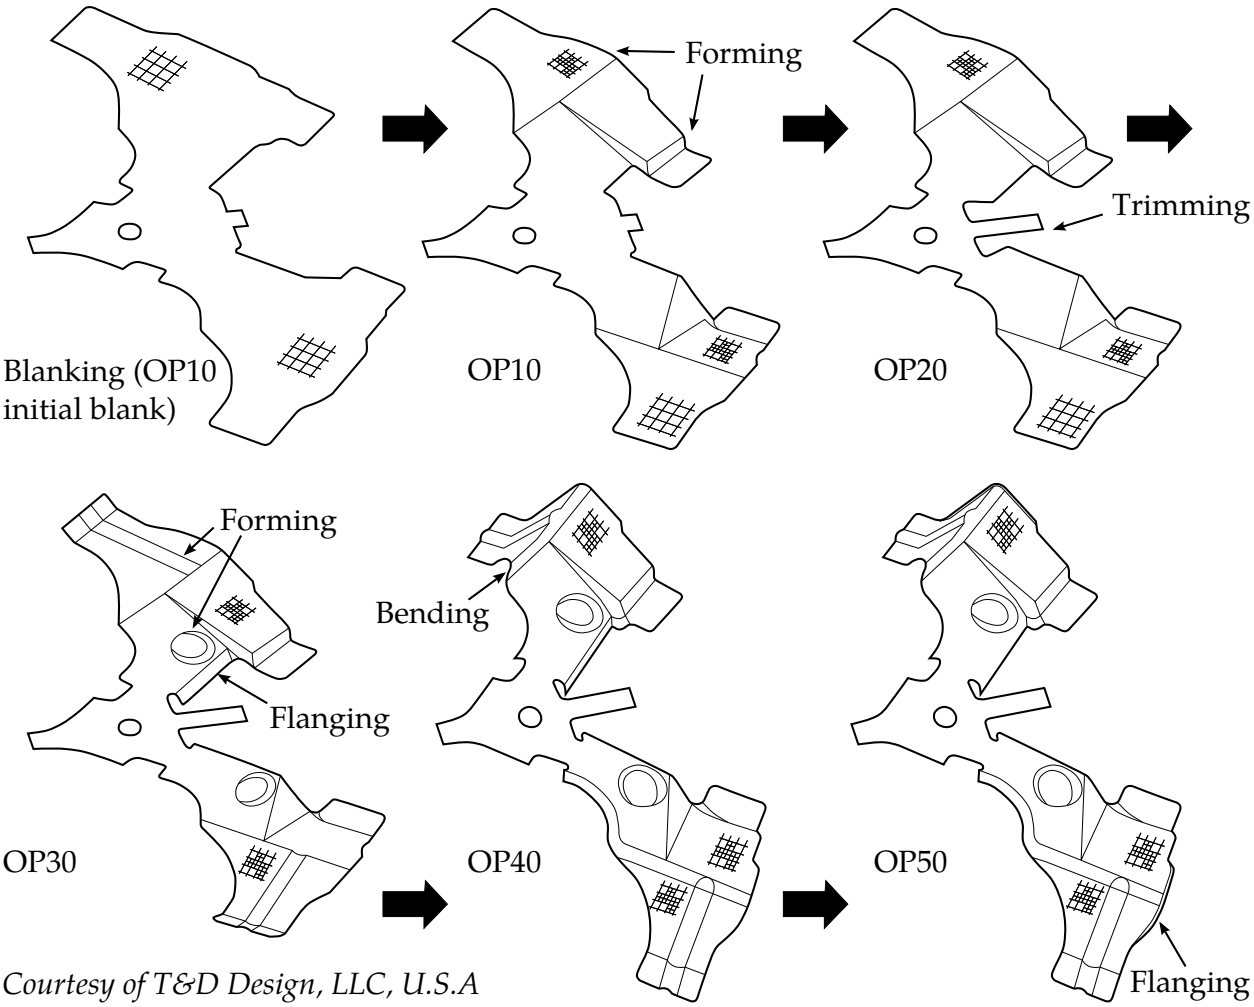

Figure 29-9. Enhanced DEVELOPMENT feature on a progressive die. Even though trimming occurs at OP20, the algorithm requires as input only OP10, OP50, and a target geometry.

In the first iteration a new initial blank is computed, and illustrated in the left panel of Figure 29-16, bearing the label *1st compensated blank*. The simulation is repeated using the first compensated blank, and in the right panel the result is compared to the target. The formed blank is narrower in the notched areas as compared with the target.

The second iteration is shown in the left panel of Figure 29-17 bearing the label, *2nd compensated blank*. Again, the simulation is repeated, but this time using the second compenated blank, and the result is compared to the target in the right panel of Figure 29-17. The resulting product is a good match to the target.

Because the initial blank intentionally deviated from its ideal shape by a large margin, this example requires two iterations to converge. Generally this processed is bootstrapped with the *CONTROL_FORMING_ONESTEP card, which calculates an initial guess by approximately unfolding the target shape.

Example V: Development Feature Applied to Flanging Process

In this example, which is schematically illustrated in Figure 29-18, the NUMISHEET 2002 fender outer is flanged along the hood line. The development feature adjusts the initial blank's boundary so that the formed piece matches the specified target flanged shape as shown in Figure 29-19. For demonstration purposes, the trimmed blank shape intentionally deviates from the optimal configuration by a large amount. This error is indicated in Figure 29-20 by the label *initial guess trim curves*. In Figure 29-20 the flanged product is shown to deviate substantially from the flanged target along the boundary. As shown in Figure 29-21 after one iteration the correct initial blank boundary is obtained.

Alternatively, *CONTROL_FORMING_UNFLANGING can be used to unfold the flanged target onto the addendum to obtain the initial blank size, or a starting guess for this process.

Example VI: Enhanced-Development Feature Applied to Progressive Die Process

In the example of Figure 29-9, *courtesy of T&D Design, LLC, U.S.A*, the blank-shape for a five stage progressive die process is calculated. Because this process involves a trimming step, the development capability prior to Revission 88708 does not support this example.

In this example, an initial blank at OP10, undergoes trimming, reforming, bending and flanging to arrive at the blank in OP50. In Figure 29-23 the computed product is compared with the specified target. A blank size development calculation produces the modified OP10 initial blank outline. The updated blank is used in a verification simulation. As seen in Figure 29-24, the blank size development feature produces a good result.

Trim lines are not optimized by the development feature, so trimming should only occur along the boundary of the target blank. The modified OP10 blank requires some refitting in the trimmed area.

***INTERFACE_COMPENSATION_3D** *{OPTION}*

Available options include:

<BLANK>

ACCELERATOR

MULTI_STEPS

LOCAL_SMOOTH

PART_CHANGE

REFINE_RIGID

FLANGE

Purpose: The springback compensation module is implemented to automatically modify the rigid tools to compensate for the springback deviations. Since springback compensation is not a linear problem, an iterative approach is proposed that usually requires two to three iterations to bring the deviation below the tolerance.

To use this module, you need to provide the following information: a) the target, which is the deformed part with the original unmodified tool; b) the current tool file at its home or final position; c) the part shape formed with the current tool; d) the part shape after springback with the current tool; and e) a bridging file from the previous compensation, (for the first compensation the target file is used, then a file named disp.tmp is generated and will be used for the next iteration). To make the inclusion order-independent, five keywords are used to include the files mentioned above:

a) *INCLUDE_COMPENSATION_DESIRED_BLANK_SHAPE

b) *INCLUDE_COMPENSATION_CURRENT_TOOLS

c) *INCLUDE_COMPENSATION_BLANK_BEFORE_SPRINGBACK

d) *INCLUDE_COMPENSATION_AFTER_SPRINGBACK

e) *INCLUDE_COMPENSATION_COMPENSATED_SHAPE

Depending on the die set-up, different kinds of compensation are required. For example, sometimes the binder is not allowed to be modified. Various compensation methods, therefore, are available. The most used methods are 6, 7, and 8. Linear and nonlinear methods are also available to modify the tool surface outside the blank outline.

The applications for this card include: (1) calculating the deviation of the stamped part from its intended design and automatically compensating the tool to minimize the

deviation; (2) mapping the existing trim curve to the modified tool; and (3) automatically detecting undercut. This keyword requires the double precision version of LS-DYNA. Note that the current methods sometimes fail to eliminate undercut.

> **NOTE:** The keyword *INTERFACE_COMPENSATION_3D replaces *INTERFACE_COMPENSATION_NEW starting in Revision 115517.

This feature is implemented and available in LS-PrePost under Application → Metal Forming →Easy Setup.

The ACCELERATOR option speeds up the convergence rate of compensation. This option also allows for a much simpler user interface.

The MULTI_STEPS option allows for tooling compensation of the next die process, based on target blank shape, compensated blank shape for the next step, and current tools. This feature is useful in line die process/tooling compensation.

The LOCAL_SMOOTH option features smoothing of a tool's local area mesh, which could become distorted because of a bad or coarse mesh of the original tool surface, a non-constant gap between tooling pairs (for example, flanging post and flanging steel), or a few compensation iterations. This option also requires using *SET_NODE_LIST_-SMOOTH.

The PART_CHANGE option allows for updating of the final compensated tool using the changed part or formed blank shape, thus eliminating the need for going through a new compensation iteration loop. This option is used together with *INCLUDE_COMPEN-SATION_UPDATED_BLANK_SHAPE, and *INCLUDE_COMPENSATION_UPDAT-ED_RIGID_TOOL.

The REFINE_RIGID option refines the rigid tool mesh and aligns the nodes along the user-provided trim curves. The required input will be the original tool mesh and trim curves. This option ensures subsequent compensation of the tool to extend all the way to the trim curves. Note this option does not physically change the shape of the tool, but the refined and realigned tool mesh at the trim curves will greatly improve the compensation convergence in the iterative process. This option only needs to be done once before the iterative springback compensation begins.

The FLANGE option defines flanging steel's moving direction and can be used in springback compensation of a flanging process.

PID	VX	VY	VZ				

This card is included if the option is <BLANK>, MULTI-STEPS, and LOCAL_SMOOTH.

Card 1a.1	1	2	3	4	5	6	7	8
Variable	METHOD	SL	SF	ELREF	PSIDP	UNDCT	ANGLE	NLINEAR
Type	I	F	F	I	F	F	F	I
Default	6	5.0	0.75	1	none	0	0.0	1

VARIABLE	DESCRIPTION
METHOD	There are several extrapolation methods for the addendum and binder outside of trim lines; see Compensation Methods Overview.
SL	The smooth level parameter controls the smoothness of the modified surfaces. A large value makes the surface smoother. Typically, the value ranges from 5 to 10. If springback is large, the transition region is expected to be large. However, by using a smaller value of SL, the region of transition can be reduced.
SF	Shape compensation scale factor. The value scales the springback amount of the blank and the scaled amount is used to compensate the tooling. GT.0: Compensate in the opposite direction of the springback; LT.0: Compensate in the punch moving direction (for undercut). This scale factor determines how much the shape deviation is compensated, and a favorable value can reduce the number of iterations. However, the right value is case dependent. Usually, SF is chosen between the range of 0.75 and 1.25.
ELREF	Element refinement option: EQ.1: Special element refinement is used with the tool elements (default); EQ.2: Special element refinement is turned off.
PSIDP	Define the part set ID for primary parts of the tooling. Properly choosing the parts for the primary side is important since it affects what kinds of modifications will be made to the tooling. Usually, only one side of the tool will be chosen as the primary side, and the modifications made to the other side (secondary side) depend solely on the changes in the primary side. This specification allows the two sides to be coupled while maintaining a constant (tool) gap between the two sides. If both sides are chosen to be primary, the gap between the two sides might change and become inhomogeneous. When using METHOD 7, the choice of primary side will affect the result when applied to three-piece draw models. At this time, when the punch and binder are chosen as the primary side, the binder region will not be changed. Otherwise, when the die is chosen as primary side, the binder will be changed since the changes extend to the edges of the primary tool.

VARIABLE	DESCRIPTION
UNDCT	Tool undercut treatment option: EQ.0: No check (default) EQ.1: Check and fix undercut.
ANGLE	An angle defining the undercut.
NLINEAR	Activate nonlinear extrapolation

This card is included if the option is <BLANK>.

Card 1a.2	1	2	3	4	5	6	7	8
Variable	TANGENT

VARIABLE	DESCRIPTION
MAXGAP	Maximum gap between the original part and changed part.

This card is used if the REFINE_RIGID option is used:

Card 1d.1	1	2	3	4	5	6	7	8
Variable	FILENAME1							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME1	A keyword file name of the rigid tool mesh to be refined. This should be the tooling mesh used in the forming or flanging simulation, before any compensation is done. The refined rigid tool mesh will be in the file rigid_refined.tmp. See the Option REFINE_RIGID: Tool Mesh Refinement for a Better Convergence below.

This card is included if the REFINE_RIGID option is used.

Card 1d.2	1	2	3	4	5	6	7	8
Variable	FILENAME2							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FILENAME2	A keyword file name with trim curves defined using *DEFINE_CURVE_TRIM_3D. The curves will be used to refine and realign the FILENAME1 to improve the convergence in the iterative compensation process. The refined rigid tool mesh will be in the file rigid_refined.tmp. See the Option REFINE_RIGID: Tool Mesh Refinement for a Better Convergence below.

This card is included if the FLANGE option is used. A maximum of two of this card may be inputted and the input ends with the next "*".

Card 1e	1	2	3	4	5	6	7	8
Variable	PID	VX	VY	VZ				
Type	I	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
PID	The part ID of the flanging steel to be compensated.

VARIABLE	DESCRIPTION
VX, VY, VZ	The vector components of the flanging steel's (PID) moving direction.

Compensation Methods Overview:

After trimming, only a limited part of the tool has direct relationship with the springback of the blank part. Modifications of the rigid tool outside the trimmed region involves extrapolation. Unfortunately, extrapolating is unstable and tends to generate non-smooth surfaces. To resolve this problem, seven smoothing algorithms are implemented. The most frequently used methods are methods 7, 8 and -8, while the others are used only occasionally.

Method 7

If the punch is chosen as the primary side, the binder will not be changed. Aside from the region inside the punch opening, the rest of the model is untouched. Smoothing has little effect on method 7. The smoothness of the modified tool depends on the magnitude of the springback and the size of the addendum region. This method is nonlinear and, therefore, necessitates an iterative solve.

Advantages: The binder will not be changed.

Disadvantages: The change will be limited inside the addendum region, and the modified surface may not be smooth if the springback magnitude is large and the transition is small.

Method 6

The smoothness and the transition region of the modified surface will depend on the springback magnitude and the smoothing factor. If the springback magnitude is large, the transition region will be increased automatically. On the other hand, the transition region will be smaller if the springback magnitude is small. At the same time, a larger smoothing factor will result in a smaller transition region. Like method 7, this too is non-linear.

Advantages: The smoothness of the modified surfaces can be controlled.

Disadvantages: It is impossible to limit the transition region, and the binder surface (and therefore, draw beads) could change if the spring back is large.

Method 3

Similar to Method 6, however, it is a linear method and no iteration is necessary.

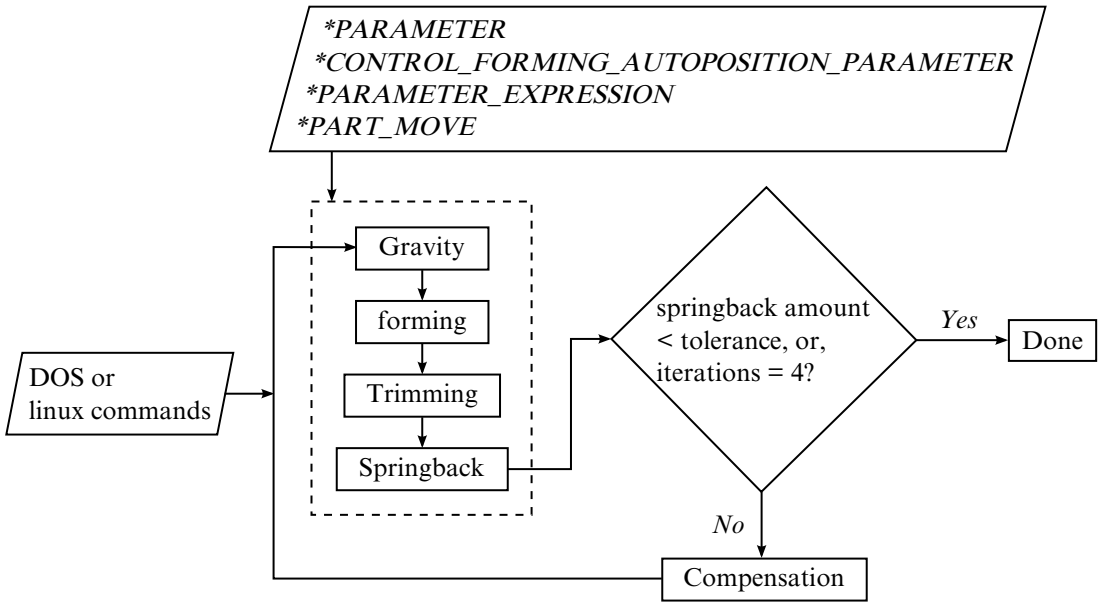

Figure 29-26. Iterative compensation flow chart

Method 8

This is an enhanced version of Method 6. It can account for addendum and binder changes. Usually, the upper tooling including addendum and binder (in an air draw) are included in the PSIDP definition.

Method -8

This method is a modification of Method 8. It is used for trim die nesting (from the drawn panel shape).

Methods 1, 2, 4, and 5

These methods are deprecated and may be removed in the future. They are included only for maintaining backwards compatibility.

Preventing Undercut:

When the draw wall is steep, it is likely that undercut will occur. Since undercut is not acceptable in real world die manufacturing, it must be prevented.

The compensation code can automatically detect undercut and issue a warning message. Additionally, LS-DYNA will write a list of undercut elements to a file called blankundercut.tmp so that the user can easily identify which elements may be problematic.

If the undercut is limited to only a few elements, it is possible to fix the problem manually.

Undercut can be reduced by compensating the springback only in the punch moving direction (by using a negative scale factor). This method is not 100% reliable and more robust solutions are being studied.

Iterative Springback Compensation:

Figure 29-26 illustrates the iterative springback compensation algorithm as applied to a typical stamping process. The first stamping process simulation is done following gravity → forming → trimming → springback (ITERATION 0). The stamping process simulation is set up using eZ-Setup in LS-PrePost. By using the parameterized automatic tool/blank positioning feature, the process simulation is fully automated (no user intervention required). Based on the calculated springback amount, tooling geometry is compensated through a compensation run. The stamping process simulation is conducted again, automatically, based on the new compensated tooling, followed by a second tooling compensation (ITERATION 1). Iterations 2, 3, and 4 follow the same pattern. The iteration process is repeated until the blank springback shape conforms to the target shape, or until it reaches 4 iterations (typically required to achieve part tolerance). With some shell scripting this iterative loop can be completed automatically. These tools allow the user to toggle between the single and double precision version of LS-DYNA.

The task of tracking the files involved in the iterative process can be daunting, especially in the advanced stage of the iterations. Figure 29-27 indicate what is written to storage during the process.

An input deck defining a springback compensation model is given below. The keyword file blank0.k includes node and element information of the blank shape before springback (after forming and trimming) with adaptive constraints (if exist). The keyword file spbk.k includes node and element information of the blank after springback, with adaptive constraints (if they exist). The blank shapes before and after springback (blank0.k and spbk.k) may be based on either the original die design (ITER0), or based on an intermediate compensated die design (say the n^{th} iteration).

The keyword file reference0.k is the blank shape before springback for iteration 0 (ITER0). This file is blank0.k and should *not* change from iteration to iteration. For iteration 0 the file reference1.k is also the same as blank0.k, but for iteration 1 reference1.k should be the disp.tmp generated from the compensation calculation during iteration 0 and so on and so forth for the subsequent iterations.

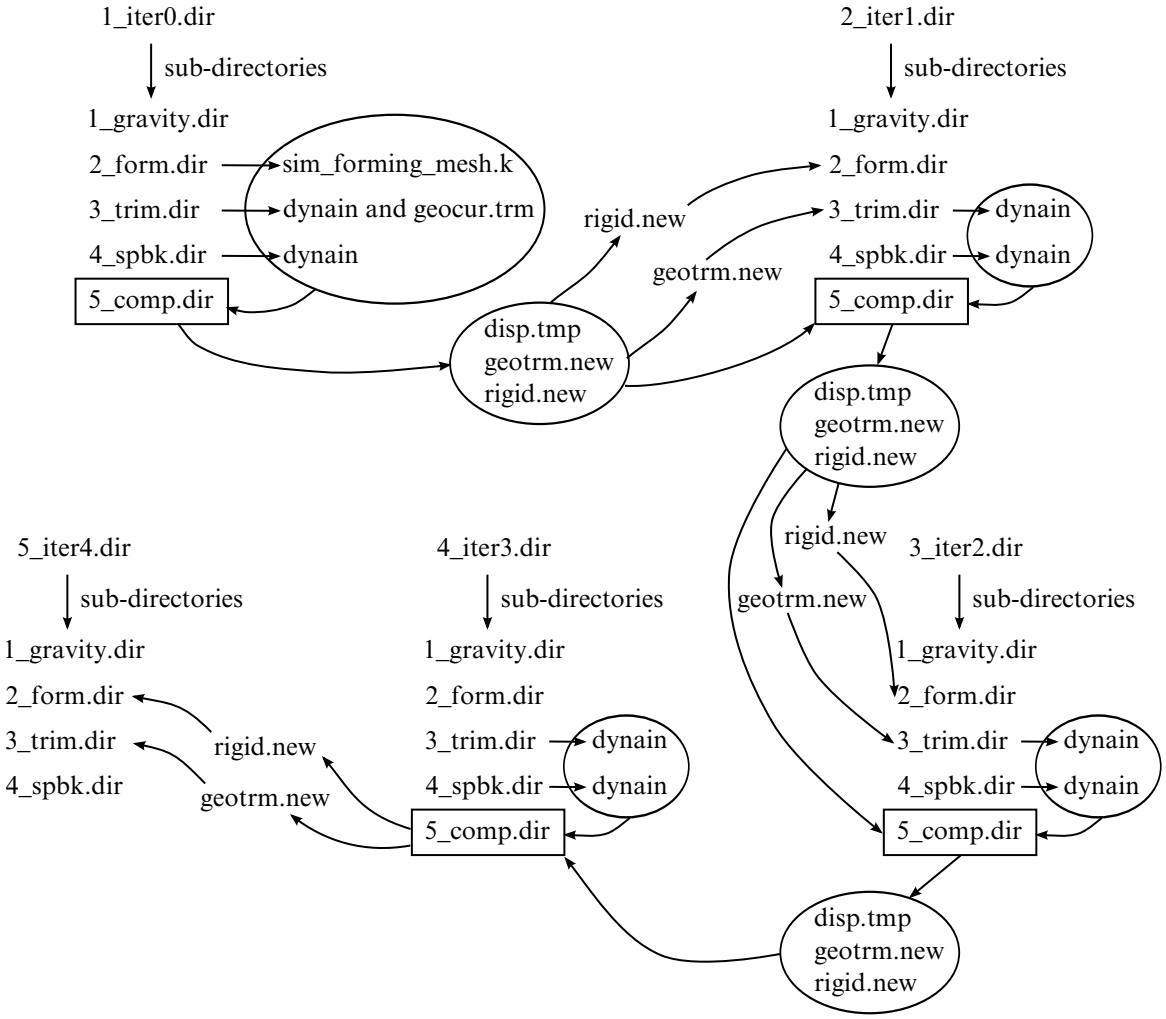

Figure 29-27. File structure for compensation

The keyword input tools.k must contain the mesh information for all of the stamping tools in their home positions. Compensated tools will be written to rigid.new with the original constant gap being maintained among the tools. During the baseline calculation, iteration 0, a keyword file called geocur.trm is generated during a LS-DYNA trimming simulation based on trimming curve input (usually in IGES format). During the compensation run of ITER1, geocur.trm is used to generate new trim curves which are output in geotrm.new. The new curves conform to the current compensated tools and are used for the next iteration. The new trim file, geotrm.new, is also in keyword format and contains a *DEFINE_CURVE_TRIM_3D card.

The example below models a three-piece air draw process. The upper die cavity (including binder) has a part ID 2, which is included in the part set ID 1 and is used for variable PSIDP. Method 8 will compensate all the tools included in file tools.k based on compensated shape for the upper cavity.

An NUMISHEET 2005 Example:

In Figure 29-28, the NUMISHEET 2005 cross member is compensated following the flow chart. In two iterations the springback is reduced from 13mm to 1.7mm. Further iterations will reduce the part deviation down to a specific design target. Typically, four iterations are needed.

Iterative Compensation Applied During Die Construction:

The blank shape after springback can be obtained from the actual experimental shape of the springback panel, if available. For example, in hard tool construction, the trimmed panel can be scanned using white light technology and the panel shape can be written to an STL file. The STL format can be easily converted to LS-DYNA keyword format and the trimmed panel can be used as a rigid tool onto which the baseline (ITER0) trimmed panel (deformable) can be "pushed" using element normal pressure, and using *CONTROL_IMPLICIT_FORMING type 1. In this scenario, the adaptive refinement is turned off to maintain the one-to-one correspondence of the elements and nodes information. An advantage of this method is that the springback shape used for compensation will be exactly the same as the actual panel springback; therefore, the best tooling compensation result is expected. An example of such is shown in Figures 29-29 and 29-30.

Compensation of Localized Regions:

Compensation of a localized tooling region is possible, with the keyword *INCLUDE_COMPENSATION_CURVE, by incorporating the following lines into the above example inputs:

```
*INCLUDE_COMPENSATION_CURVE
curves.k
```

The file curves.k defines the two enclosed "begin" and "end" curves using *DEFINE_-CURVE_COMPENSATION_CONSTRAINT_BEGIN/END. A more in depth explanation can be found in the corresponding keyword manual entries. In Figure 29-31, the NUMISHEET'05 decklid inner is compensated locally in the horizontal area above the backlite. Tangency of the compensated tool is maintained at the "End Curve" as shown in the section A-A. Also shown in Figure 29-32 includes color contours of part-separation distance throughout the iterations between compensated panel and the target design intent. Part tolerance is achieved in two iterations.

Accelerated Springback Compensation (ASC):

The option ACCELERATOR can be used in conjunction with *INCLUDE_COMPENSATION, with options ORIGINAL_DYNAIN and SPRINGBACK_INPUT to compensate springback with a faster convergence rate and a simplified user interface. A complete example is provided below. The example uses a spring back input file spbk.dyn, and a trimmed panel, with file name case20trimmed.dynain (including all stress and strain tensors and adaptive constraints). The variable ISTEPS is increased from 0 to 3, representing 3 compensation iterations. ISTEPS = 0 represents the baseline springback simulation (ITER0), while ISTEPS = 1, 2, 3 represent the compensation iterations. This feature requires the user to change only one variable (ISTEPS), and then submit the same input file to continue the next iteration.

Many scratch files, including a file named acceltmp.tmp, will be generated. *Do not delete them*. They are used to pass data between steps. A file, compensation.info, is generated and updated after each ISTEPS calculation. It contains iteration information, including maximum deviations in the x, y, and z directions. When the maximum deviation is within the tolerances specified in the TOLX, TOLY, and TOLZ fields, a message appears in the file indicating the compensation iterations have converged along with a message bootstrapping the next step. A file spbk.new is generated in the same directory and is used by the *INCLUDE_COMPENSATION_BLANK_AFTER_SPRINGBACK keyword with the scale factor for the tool compensation set to one. After the compensation, a verification calculation may be needed.

```
*KEYWORD
*INTERFACE_COMPENSATION_3D_ACCELERATOR
$    ISTEPS      TOLX      TOLY      TOLZ    OPTION
         3      0.20      0.20       0.2         1
*INCLUDE_COMPENSATION_ORIGINAL_DYNAIN
./case20trimmed.dynain
*INCLUDE_COMPENSATION_SPRING BACK_INPUT
./spbk.dyn
*END
```

Currently, mesh coarsening and checking are not supported in the accelerated mode. Also, the dynain file from the previous die process is not necessary.

An example of this feature is shown for a simple channel type of draw (one-half model) in Figure 29-33, which converged in three iterations; while four iterations were needed for the non-accelerated compensation.

Line Die Compensation:

The option MULTI_STEPS can be used together with *INCLUDE_COMPENSATION_-COMPENSATED_SHAPE_NEXT_STEP to enable compensation of tools for the next die process. An example is given below. In this example the target blank, named reference0.tmp, and the current tool named rigid.tmp come from the first die process. The disp.tmp file comes from the compensation in the second die process step. For example, a flanging die compensation can be a second die process step, preceded by a redraw die process as the first die process step.

```

Compensation of Trim Dies (Trim Die Nesting):

The trim die can be compensated using the drawn panel's springback shape when METHOD is set to -8. In the example below, which is also shown in Figure 29-34, the draw panel, state1.k, is taken as the blank before springback, and draw panel springback shape, state2.k, is taken as the blank after springback. The tool shape for the draw process, drawtool.k, is used as the current tool. After the simulation, LS-DYNA will create a compensated tool named rigid.new, which can be used for the trim die shape.

Local Smoothing of Tooling Mesh:

The option LOCAL_SMOOTH can be used, along with a few more keywords, to smooth and restore the distorted tooling mesh after iterative compensation. In the example below, the keyword *INCLUDE_COMPENSATION_ORIGINAL_RIGID_TOOL includes an original tool, rigid.tmp, which has a good and smooth mesh. The keyword *INCLUDE_COMPENSATION_3D_RIGID_TOOL includes a compensated tool, rigidnew.bad, which could have a distorted mesh arising from the reasons listed when describing this option in the introduction section of this keyword.

The last keyword *SET_NODE_LIST_SMOOTH defines a node set that includes a distorted local area in the distorted mesh. Each node set defines a region needing smoothing. The node set should not include any boundary nodes of the tooling parts, otherwise position of the tooling may be altered. Smoothed tooling is stored in a file called rigid.new. In this example method 7 is active, the variable ELREF is set to 2, and PSID is left as undefined. Note also the *INCLUDE keyword is *not* supported here. For example, *SET_NODE_LIST_SMOOTH must not be in a separate file that is included in the main input file.

```
*KEYWORD

         2
     56141     56142     56143     56144     56145     56146     56147     56148
...
*END
```

In an example shown in Figures 29-35 and 29-36, smoothing of the local mesh is performed in the draw bead area of the NUMISHEET 2005 cross member. In this case the die gap is not maintained throughout the tooling surface. Typically, this happens in the

draw bead regions when male beads have lower bending radii (missing upper radii) and female beads have only upper bending radii (missing lower radii). Two node sets are defined for local areas of left and right female draw beads (Figure 29-37), which needed smoothing. It is important to include in the node sets some of the nodes on the relatively flat portion of the binder immediately off the bend radii. The smoothed results are shown in Figure 29-38.

In another example, a corner of a flanging die on a fender outer is being smoothed. The mesh becomes distorted after a few compensation iterations, as shown in Figure 29-39. In Figure 29-40, the result of local smoothing is shown, and the improvement is remarkable.

Compensation with Symmetric Boundary Condition:

A keyword example is provided in the manual pages related to *INCLUDE_COMPENSATION.

Global Compensation Using the Original Tool Mesh:

For some tooling meshes, the compensated die surfaces will be distorted. The keyword option *INCLUDE_COMPENSATION_ORIGINAL_TOOL causes the compensation code to use the original tooling mesh (starting in the second compensation) to extrapolate the addendum and binder in the compensated tooling surfaces. This minimizes the accumulative error, compared with using the last compensated tooling mesh, and therefore is a preferred method.

A complete keyword example is included below. In it, part ID 3 (included in part set ID 1) is compensated after ITERATION 3 (ITER3), using method 8, with a scale factor of 0.5. The dynain files from the trimmed ITER3 is taken as the "BEFORE" state (see the BEFORE_SPRINGBACK option) and the dynain file from the springback calculation is taken as the "AFTER" state. The "DESIRED" blank shape is given by the dynain is from the trimmed ITER0 output. The "COMPENSATED_SHAPE" is taken from the disp.tmp file of the last compensation run. "CURRENT_TOOL" is also from last compensation iteration. The "ORIGINAL_TOOL", is taken from the tool mesh in ITER0. Updated trim curves geotrm.new are from the mapped trim lines of the last compensation.

It should be noted that, in an automatic compensation-loop calculation, as shown in the path of the input files, input files disp.tmp, rigid.new, and geotrm.new, which are the default file names of the previous compensation, should not be in the same directory as the current compensation run, as these files *will* be overwritten.

```

Updating Compensated Tool with Small Amount of Part Shape Change:

Often a part will have some small amount of shape change because of a product change. If the amount of shape change does not significantly alter the springback results, the compensated tools can be updated with the part mesh (inside the trim lines) or formed blank shape without going through another iterative compensation loop. This is accomplished using the PART_CHANGE option. Within the specified MAXGAP, the compensated tool shape can be updated. Changes to geometry involving sharp corners and transitions without fillets are not permissible. A complete keyword example is provided below, where a maximum gap of 5 mm is specified between the original shape and modified product shape. The updated part file name is updatepart.tmp and output file for the new rigid tool is newrigid.k.

```
*KEYWORD
*INTERFACE_COMPENSATION_3D_PART_CHANGE
$   MAXGAP
       5.0

*INCLUDE_COMPENSATION_UPDATED_BLANK_SHAPE
./updatedpart.tmp
*INCLUDE_COMPENSATION_UPDATED_RIGID_TOOL
$ file name to output the new rigid tools
./newrigid.k
*END
```

Option REFINE_RIGID: Tool Mesh Refinement for a Better Convergence:

The following keyword example refines the elements and aligns the nodes in the original tool mesh file rnominaltools.k at provided trim curves trimcurve106.k defined using the keyword *DEFINE_CURVE_TRIM_3D. The refined rigid tool mesh will be output as rigid_refined.tmp, which can be used to start the iterative springback compensation process. The aligned nodes will also be output in a file named bndnd0.tmp.

```
*KEYWORD
*INTERFACE_COMPENSATION_3D_REFINE_RIGID
Norminaltools.k
trimcurve106.k
*END
```

Maintain Tangency:

To maintain tangency between the addendum and binder (Method 7) in the draw die and tangential transitions immediately off the rigid tool at the trim curve area to the addendum, the variable TANGENT must be set to "1". In the keyword example below, the rigid_refined.tmp (from the option REFINE_RIGID) is used as both the current and the original tool. The aligned nodes file bndnd0.tmp is included under *INCLUDE_COMPENSATION_TRIM_NODE, which is used for tangency calculation. Note the variable TANGENT replaces the keyword *INCLUDE_COMPENSATION_TANGENT_CONSTRAINT.

Option FLANGE: Compensation of Flanging Process:

This option is developed specifically to compensate flanging tools for springback in a flanging process. A maximum of two cards can be input. The following keyword example defines flanging steels with PIDs 6 and 4 moving in the directions defined by the vectors [0.0,0.0, −1.0] and [0.0, −16.696, −5.674], respectively. The lower flanging post with PID2 is selected as the primary tool surface mesh and the flanging steels are compensated while maintaining the necessary tool gaps as in the original tool mesh iter0tools.k. Note in the compensation of flanging process the requirement on the even tool gap everywhere is removed, so flanging steels do not have to follow the flanging post, for example in the flanging steel radius area, etc.

```

*INTERFACE_COMPONENT_FILE

Purpose: Allow for the specification of the file where the component interface data should be written, and the optional use of a new binary format for that data.

Card 1	1	2	3	4	5	6	7	8
Variable	Filename							
Type	A80							
Default	none							

Optional Card.

Card 2	1	2	3	4	5	6	7	8
Variable	Format							
Type	I							
Default	2							

VARIABLE	DESCRIPTION
FNAME	Name of the file where the component data will be written
FORMAT	File format to use: EQ.1: Use old binary file format EQ.2: Use new LSDA file format

Remarks:

If Z = is used on the command line, this card will be ignored. If this card is in effect, the new LSDA file format is the default format to be used. The new format has certain advantages, and one possible drawback:

1. It allows for the use of the_TITLE modifier on all *INTERFACE_COMPONENT inputs, so that subsequent *INTERFACE_LINKING cards can refer to components by a user specified ID.

2. It is fully portable between machines with different precision and byte order.

3. It maintains the full precision of the coordinate vector. The internal coordinate vector has been in double precision for quite some time, even for single precision executables. The old binary format writes 32 bit data for single precision executables, losing some precision in the process.

4. Because of the maintained precision, the new format files will be significantly larger when running in single precision.

Of course, the new file format cannot be used for subsequent analysis with older versions of LS-DYNA, particularly those with a Product ID less than 50845. Executables which can read the new format for *INTERFACE_LINKING analysis will automatically detect whether the new or old format is in use.

***INTERFACE_COMPONENT**_*OPTION1_{OPTION2}*

Available values for OPTION1 include:

NODE

SEGMENT

SPH

OPTION2 only allows the value:

TITLE

Purpose: Create an interface for use in subsequent linking calculations. This command applies to the first analysis for storing interfaces in the interface file specified either by "Z=**isf1**" on the execution line or by the *INTERFACE_COMPONENT_FILE command. The output interval used to write data to the interface file is controlled by OPIFS on *CONTROL_OUTPUT. If OPIFS is not specified, the interval defaults to $1/10^{th}$ the value of DT specified in *DATABASE_BINARY_D3PLOT.

This capability allows the definition of interfaces that isolate critical components.

With the NODE and SEGMENT option, a database is created that records the motion of the interfaces. In later calculations the isolated components can be reanalyzed with arbitrarily refined meshes with the motion of their boundaries specified by the database created by this input. The interfaces defined here become the reference surfaces in the tied interface options.

With the SPH option, a database is created that records the FSI coupling forces of the interfaces. In later calculations the isolated components can be reanalyzed with arbitrarily refined meshes with external forces extracted from the database created by this input.

Each definition consists of a set of cards that define the interface. Interfaces may consists of a set of segments for later use with *INTERFACE_LINKING_SEGMENT, an ordered line of nodes for use with *INTERFACE_LINKING_EDGE, an unordered set of nodes for use with *INTERFACE_LINKING_NODE, or an unordered set of structure SPH particles for use with *INTERFACE_LINKING_FORCES.

Title Card. Additional card for TITLE keyword option.

NID	Node ID.

Remarks:

CID and NID are optional. If CID appears, the transformation matrix for this coordinate system is written to the linking file at each output state. If NID appears, the displacement of this node is also written to the file. This information is then available to be used by the *INTEFACE_LINKING_NODE_LOCAL. If either of these is non-zero, then the linking file will be written in the LSDA format, as the old format cannot support this optional output.

If the old style binary format is used for the linking file (see *INTERFACE_COMPONENT_FILE) then the ID values are ignored and all components are numbered according to their input order, starting from 1.

*INTERFACE_DE_HBOND

Purpose: Define the failure models for bonds linking various discrete element (DE) parts within one heterogeneous bond (*DEFINE_DE_HBOND).

Card 1	1	2	3	4	5	6	7	8
Variable	IID							
Type	I							
Default	none							

Bond Definition Cards. For each bond definition, include an additional card. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	PID1	PID2	PTYPE1	PTYPE2	FRMDL	FRGK	FRGS	DMG
Type	I	I	I	I	I	F	F	F
Default	none	none	none	none	1	none	none	1.0

VARIABLE	DESCRIPTION
IID	Interface ID. All interfaces should have a unique ID
PID1	First part ID.
PID2	Second part ID. PID1 and PID2 define the bonds that this fracture model is applied to. There are three combinations as Case a: PID1.EQ.0 This is the default model for all bonds, overriding the default model defined in Card 1.1 of *DEFINE_DE_HBOND. Case b: PID1.GT.0 and PID2.EQ.0 This model is applied to the bonds within part PID1, instead of the default model. Case c: PID1.GT.0 and PID2.GT.0

VARIABLE	DESCRIPTION
	This model is applied to the bonds between parts PID1 and PID2 only, but not to those within part PID1 or part PID2 (as in case b).
	Notes: 1. The default fracture model is applied to all parts that are not specified in case b. 2. The fracture model of the part with a smaller part id is applied to the bonds between two different parts if not specified in case c.
PTYPE1	First part type: EQ.0: DES part set EQ.1: DES part
PTYPE2	Second part type: EQ.0: DES part set EQ.1: DES part
FRMDL	Fracture model. (same as FRMDL in Card 1.1 of keyword *DEFINE_DE_HBOND.)
FRGK	Fracture energy release rate for volumetric deformation. (same as FRGK in Card 1.1 of keyword *DEFINE_DE_HBOND.)
FRGS	Fracture energy release rate for shear deformation. (same as FRGS in Card 1.1 of keyword *DEFINE_DE_HBOND.)
DMG	Continuous damage development. (same as DMG in Card 1.1 of keyword *DEFINE_DE_HBOND.)

INTERFACE_LINKING_DISCRETE_NODE_*OPTION

Available options include:

NODE

SET

Purpose: Link node(s) to an interface in an existing interface file. This link applies to all element types. The interface file is specified using *INTERFACE_LINKING_FILE or by including "L=**filename**" on the execution line.

With this command, nodes in a node set must be given in the same order as they appear in the interface file. This restriction does not apply to the more recent keyword *INTERFACE_LINKING_NODE_…

Card 1	1	2	3	4	5	6	7	8
Variable	NID/NSID	IFID						
Type	I	I						

VARIABLE	DESCRIPTION
NID	Node ID or Node set ID to be moved by interface file (see *NODE or *SET_NODE)
IFID	Interface ID in interface file

*INTERFACE_LINKING_EDGE

Purpose: Link a series of nodes to an interface in an existing interface force file. The interface file is specified using *INTERFACE_LINKING_FILE or by including "L=**filename**" on the execution line.

Card	1	2	3	4	5	6	7	8
Variable	NSID	IFID						
Type	I	I						

VARIABLE	DESCRIPTION
NSID	Node set ID to be moved by interface file.
IFID	Interface ID in interface file.

Remarks:

The set of nodes defined will be constrained to follow the movement of the interface IFID, which should correspond to a curve output on a previous analysis via *INTERFACE_-COMPONENT_NODE. The order of the nodes in the first analysis is important. The nodes, in the order specified in the first analysis, represent a curve. Each node in set NSID will be tied to the point on the curve nearest to its initial position, and then will be constrained to follow that point on the curve for the duration of the analysis. This option is intended to be used with beam or shell elements, as both translational and rotational degrees of freedom are constrained.

*INTERFACE_LINKING_FILE

Purpose: Allow for the specification of the file from which the component interface data should be read.

Card 1	1	2	3	4	5	6	7	8
Variable	Filename							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
FNAME	Name of the file from which the component data will be read

Remarks:

If L= is used on the command line, this card will be ignored. There is no option to specify the file format, as the file format is automatically detected.

*INTERFACE_LINKING_FORCES

Purpose: Link segments to an interface in an existing interface file. The interface file is specified using *INTERFACE_LINKING_FILE or by including "L=**filename**" on the execution line.

Segment Set ID Card. Include as many cards as desired. Input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	IFID						
Type	I	I						

VARIABLE	DESCRIPTION
SSID	Segment set on which to apply forces from interface file
IFID	Interface ID in interface file

Remarks:

The set of segments defined will receive external forces coming from the interface IFID, which should correspond to an interface output on a previous analysis using the *INTERFACE_COMPONENT_SPH keyword. Positions from the interface file will be projected to the closest element in the segment set, and forces will be interpolated to their corner nodes.

INTERFACE_LINKING_NODE_*OPTION

Available options include:

SET

LOCAL

SET_LOCAL

Purpose: Link nodes(s) to an interface in an existing interface file. This link applies to all element types. The interface file is specified using *INTERFACE_LINKING_FILE or by including "L=**filename**" on the execution line.

Node/Set ID Card. Include as many cards as desired. Input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NID/NSID	IFID	FX	FY	FZ			
Type	I	I	I	I	I			

VARIABLE	DESCRIPTION
NID	Node ID or Node set ID to be moved by interface file. See *NODE or *SET_NODE.
IFID	Interface ID in interface file
FX	ID of a *DEFINE_FUNCTION which determines the x direction displacement scale factor. See Remarks.
FY	ID of a *DEFINE_FUNCTION which determines the y direction displacement scale factor. See Remarks.
FZ	ID of a *DEFINE_FUNCTION which determines the z direction displacement scale factor. See Remarks.

Card 2. This card appears after Card 1 when the LOCAL keyword option is used.

Card 2	1	2	3	4	5	6	7	8
Variable	LCID	LNID	USEC	USEN				
Type	I	I	I	I				

VARIABLE	DESCRIPTION
LCID	Local coordinate system ID for transforming displacements.
LNID	Local node ID for transforming displacements
USEC	Flag to indicate the use of the coordinate system in the linking file during displacement transformation. See Remarks. EQ.0: Linking file coordinate system is ignored. EQ.1: Linking file coordinate system is used.
USEN	Flag to indicate the use of the node displacement in the linking file during displacement transformation. See Remarks. EQ.0: Node displacement is not used. EQ.1: Node displacement is used.

Remarks:

The set of nodes is constrained to follow the displacement of the interface having ID IFID in the linking file. Note that the linking file is usually generated by the *INTERFACE_-COMPONENT_NODE keyword in a previous analysis.

The order of the nodes is not important. Each node in set NID will be tied to the nearest node in IFID using a bucket sort during the initialization phase. Nodes not found are reported and subsequently not constrained. Translational degrees of freedom are constrained. If the constrained analysis has rotational degrees of freedom, then the rotation degrees of freedom will be likewise constrained and the linking file *must* include rotational degrees of freedom.

The displacements in the linking file can be scaled upon input so that

$$\mathbf{u}_{\text{constrained}} = \begin{bmatrix} f_{\text{FX}}(\dots) & 0 & 0 \\ 0 & f_{\text{FY}}(\dots) & 0 \\ 0 & 0 & f_{\text{FZ}}(\dots) \end{bmatrix} \mathbf{u}_{\text{linking file}}$$

where $f_{\mathrm{FX}}(\dots)$ is the *DEFINE_FUNCTION function having ID FX and so on. When a scaling function is not specified, the corresponding component is imported unscaled as if the scaling function had a constant value of unity. These functions may take either 0, 1, 3, or 4 input arguments. The functions FX, FY, and FZ may be different and they may take different numbers of arguments. The data passed into the scaling function depends on the number of arguments that the function takes and the possibilities can be broken down into four cases:

1. *0 variables*. A function taking no inputs is constant over space and time. LS-DYNA evaluates such a function at the start of the calculation and uses that value for the duration of the run.

2. *1 variables.* LS-DYNA passes in the simulation time at each step and the resulting value is applied to all nodes in the set.

3. *3 variables.* LS-DYNA passes in the *initial position* of each constrained node as an (x,y,z) triple at the start of the calculation and then uses the result for the duration of the run.

4. *4 variables*. LS-DYNA passes in the *current* simulation time and the *initial position* of each of the constrained nodes as an (x,y,z,t) tuple. This function is updated at each time step. Using scaling functions of 4 variables may result in a performance penalty as each function must be evaluated for every constrained node every cycle.

If time dependent scaling functions are used, then the constrained nodes must start with coordinates identical to the constraining nodes in the linking file.

The LOCAL option and the values of the LCID, LNID, USEC, USEN flags, which was designed in conjunction with Honda R&D Co., Ltd., allow for the interface displacements to be transformed in various ways. By default, the scale factors FX, FY, and FZ act on the nodal displacements in the global coordinate system of the constrained calculation. This may be undesirable depending on how the global coordinate system of the linked calculation is defined. The most general transformation rule is:

$$\mathbf{u}_{\mathrm{constrained}} = \mathbf{Q}_2 \begin{bmatrix} f_{\mathrm{FX}}(\dots) & 0 & 0 \\ 0 & f_{\mathrm{FY}}(\dots) & 0 \\ 0 & 0 & f_{\mathrm{FZ}}(\dots) \end{bmatrix} \mathbf{Q_1}(\mathbf{u}_{\mathrm{linked}} - \mathbf{c_1}) + \mathbf{c_2}$$

where,

$\mathbf{c}_1$ = The displacement of the NID node in the linking file
$\mathbf{c_2}$ = The displacement of node LNID
$\mathbf{Q}_1$ = Rotation into the local coordinates of the linking file
$\mathbf{Q}_2$ = Rotation into the local coordinate system; if unset the inverse of $\mathbf{Q}_1$

If USEC = 0, then $\mathbf{Q}_1$ is the identity rotation and any coordinate system in the linking file is ignored. If USEN = 0, then $\mathbf{c}_1$ is set to **0** and NID in the linking file is ignored.

*INTERFACE_LINKING_SEGMENT

Purpose: Link segments to an interface in an existing interface file. The interface file is specified using *INTERFACE_LINKING_FILE or by including "L=**filename**" on the execution line.

Segment Set ID Card. Include as many cards as desired. Input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	IFID						
Type	I	I						

VARIABLE	DESCRIPTION
SSID	Segment set to be moved by interface file
IFID	Interface ID in interface file

Remarks:

The set of segments defined will be constrained to follow the movement of the interface IFID, which should correspond to an interface output on a previous analysis using the *INTERFACE_COMPONENT_SEGMENT keyword. The behavior will be the same as if set SSID is the SURFA side of a *CONTACT_TIED_SURFACE_TO_SURFACE with IFID as the SURFB side. Translational movement will be constrained but not rotations.

*INTERFACE_SPG_1

Purpose: Indicate that the current analysis is the first stage of a two-stage SPG analysis. This keyword does not affect the results of the SPG analysis.

The two-stage SPG analysis feature is available beginning with R13.

This keyword does not have any data cards.

Remarks:

1. **Output File.** When this keyword is included, LS-DYNA generates an ASCII file named 1234spg at normal termination. This file contains information (stress, strain, total displacement, etc.) about the SPG nodes at the end of the calculation.

2. **Dynain File for Second Stage.** The second stage also requires a dynain file as input. Therefore, you need to also include *INTERFACE_SPRINGBACK_LSDY-NA in the first stage analysis to output this file. The part set for *INTERFACE_-SPRINGBACK_LSDYNA must include the SPG parts since the SPG coordinates at termination are needed.

*INTERFACE_SPG_2

Purpose: Indicate the current analysis is the second stage of a two-stage SPG analysis.

This keyword does not have any data cards.

The two-stage SPG analysis is only available for versions R13 and laters.

Remarks:

To perform a second stage analysis, the ASCII file 1234spg generated in the first stage calculation must be copied to the current folder and renamed as 1234spg0. The dynain file generated in the first stage calculation must also be included in the input deck for the second stage (see *INCLUDE_*{OPTION}*). The element connectivity and nodal coordinates for the second stage are taken from the dynain file.

***INTERFACE_SPRINGBACK**_*OPTION1_{OPTION2}*

Available options included for *OPTION1* are:

LSDYNA

NASTRAN

SEAMLESS

EXCLUDE (see Remark 9)

and for *OPTION2:*

<BLANK>

NOTHICKNESS (see Remark 1)

Purpose: This keyword causes LS-DYNA to, upon termination, write the final state of the system to an output file so that the results can be used as input for other subsequent calculations, such as trimming, springback, flanging, and hemming. Also, if a sense switch "swb", "swc", or "swd" is issued while the analysis is in progress, the current state will be written to an output file (see "SENSE SWITCH CONTROLS" in the Getting Started section for details). In addition to the analysis results, the output can optionally contain additional nodal constraints. The keyword name, which contains SPRINGBACK, is due to historical reasons as this feature is not limited to springback applications. All the options, except SEAMLESS, are used to control the output of the forming information.

With the SEAMLESS option, LS-DYNA will automatically run the springback analysis after the termination time of the explicit or implicit dynamic analysis. See Remarks for Seamless Springback for more details.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID	NSHV	FTYPE		FTENSR	NTHHSV	RFLAG	INTSTRN
Type	I	I	I		I	I	I	I

Irregular Optional Card. The keyword reader will interpret the card following Card 1 as optional Card 2 if the first column of the card is occupied by the string "OPTCARD." Otherwise, it is interpreted as the first Node Card; see below.

Card 2	1	2	3	4	5	6	7	8
Variable	OPTC	SLDO	NCYC	FSPLIT	NDFLAG	CFLAG	HFLAG	
Type	A	I	I	I	I	I	I	

Node Cards. Define a list of nodal points and constraints. For the SEAMLESS Option the constraints are used for the springback analysis. This input ends at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	NID	TC	RC					
Type	I	F	F					

VARIABLE	DESCRIPTION
PSID	Part set ID. See *SET_PART.
NSHV	Number of shell or solid history variables (beyond the six stresses and effective plastic strain) to be initialized in the interface file. For solids, one additional state variable (initial volume) is also written. If NSHV is nonzero, the element formulations, unit system, and constitutive models should not change between runs. If NHSV exceeds the number of integration point history variables required by the constitutive model, only the number required is written; therefore, if in doubt, set NHSV to a large number, such as 100.
FTYPE	File type (see Remark 6): EQ.0: ASCII EQ.1: Binary EQ.2: Both ASCII and binary. EQ.3: LSDA format (for LSDYNA option only)

VARIABLE	DESCRIPTION
	EQ.10: ASCII large format (see *INITIAL_STRESS_SHELL) EQ.11: Binary large format EQ.12: Both ASCII and binary large format
FTENSR	Flag for dumping tensor data from the element history variables into the dynain file. EQ.0: Don't dump tensor data from element history variables EQ.1: Dump any tensor data from element history variables into the dynain file in GLOBAL coordinate system. Currently, only Material 190 supports this option.
NTHHSV	Number of thermal history variables.
RFLAG	Flag to carry over reference quantities, such as the reference geometry for hyperelastic materials: EQ.0: Default, do not output. EQ.1: Output reference coordinates and nodal masses.
INTSTRN	Output of strains for shells; see also *INITIAL_STRAIN_SHELL. EQ.0: Only at the innermost and outermost integration points, EQ.1: At all through-thickness integration points.
SLDO	Output of solid element data as EQ.0: *ELEMENT_SOLID, or EQ.1: *ELEMENT_SOLID_ORTHO (only for anisotropic material).
NCYC	Number of process cycles this simulation corresponds to in the simulation of wear processes; see Remark 7.
FSPLIT	Flag for splitting of the dynain file (only for ASCII format): EQ.0: dynain file written in one piece. EQ.1: Output is divided into two files: dynain_geo including the geometry data and dynain_ini including initial stresses and strains.
NDFLAG	Flag to dump nodes into dynain file: EQ.0: Default, dump only SPH and element nodes

VARIABLE	DESCRIPTION
	EQ.1: Dump all nodes
CFLAG	Output contact state: EQ.0: Default, do not output. EQ.1: Output contact state, currently only Mortar segment pair information and selected tied contacts with restrictions; see Remark 8.
HFLAG	Output hourglass state, only valid for FTYPE = 3: EQ.0: Default, do not output. EQ.1: Output hourglass stresses for carrying over to the next simulation.
NID	Node ID, see *NODE.
TC	Translational Constraint: EQ.0: No constraints EQ.1: Constrained x displacement EQ.2: Constrained y displacement EQ.3: Constrained z displacement EQ.4: Constrained x and y displacements EQ.5: Constrained y and z displacements EQ.6: Constrained z and x displacements EQ.7: Constrained x, y, and z displacements
RC	Rotational constraint: EQ.0: No constraints EQ.1: Constrained x rotation EQ.2: Constrained y rotation EQ.3: Constrained z rotation EQ.4: Constrained x and y rotations EQ.5: Constrained y and z rotations EQ.6: Constrained z and x rotations EQ.7: Constrained x, y, and z rotations

Remarks:

1. **NOTHICKNESS Option.** The NOTHICKNESS option is available when the keyword's first option is either LSDYNA or NASTRAN. With the NOTHICKNESS option the shell element thickness is not output.

2. **Filenames.** The file name for the LSDYNA option is dynain and for NASTRAN is nastin.

3. **Trimming.** Trimming is available for the adaptive mesh, but it requires manual intervention. To trim an adaptive mesh, use the following procedure:

   a) Generate the file, dynain, using the keyword *INTERFACE_SPRINGBACK_LSDYNA.

   b) Prepare a new input deck including the dynain file.

   c) Add the keyword *ELEMENT_TRIM to this new deck.

   d) Add the keyword *DEFINE_CURVE_TRIM to this new deck.

   e) Run this new input deck with i=**input_file_name**. The adaptive constraints are eliminated by remeshing and the trimming is performed.

   f) In case this new trimmed mesh is needed, run a zero termination time job and output the file generated using the keyword, *INTERFACE_SPRINGBACK_LSDYNA.

4. **Temperature.** The file new_temp_ic.inc will be created for a thermal solution and a coupled thermal-mechanical solution. The file new_temp_ic.inc is a KEYWORD include file containing *new temperature initial conditions* for the nodes belonging to the PSID.

   a) For thermal user materials it is possible to dump thermal history variables. See the NTHHSV field.

5. **Velocity.** Nodal velocities from the final state are included in the dynain file when using the LSDA format (FTYPE = 3), or during a staged construction analysis (see *CONTROL_STAGED_CONSTRUCTION), but are otherwise not output.

6. **FTYPE.** The choice of format size in field FTYPE is only available for shell stresses and shell history data; see parameter LARGE on *INITIAL_STRESS_SHELL. For solid and beam elements, the large format is always written to dynain; that is LARGE is automatically set to 1 on *INITIAL_STRESS_SOLID and *INITIAL_STRESS_BEAM, respectively.

When you include a dynain file generated with a single precision executable in a subsequent double precision analysis, or vice versa, the dynain file should be in either ASCII or LSDA format. The binary file format is not compatible between single and double precision executables.

7. **NCYC.** When simulating wear processes, this represents the number of process cycles this particular simulation corresponds to and *INITIAL_CONTACT_-WEAR cards are generated accordingly in the dynain file (only ASCII format supported). Cards will only be generated for nodes in contact interfaces associated with a *CONTACT_ADD_WEAR, and having SAPR or SBPR set to 2 on the first card on *CONTACT. This wear data is in a subsequent simulation accounted for NCYC times when modifying the worn geometry, or alternatively processed in LS-PrePost.

8. **CFLAG.** Transferring contact state, particularly tied information, may be important for multistage simulations. Setting CFLAG to 1 will output Mortar contact segment pairs for sliding, tied, tiebreak, and tied weld options. The resulting dynain.lsda, which must use the LSDA format (FTYPE = 3), can be included in a subsequent simulation to restore the contact state. The LS-DYNA version or core count as wells as the contact type (for instance changing from tied weld to simple tied) may be changed between simulations if the contact ID and node IDs making up the segments remain unchanged. If parts or elements are removed between simulations and these happen to contain segments that are in the dynain.lsda file, these pairs will be simply ignored. This option provides a flexibility that is appealing for multistage processes. For sliding contact, typically the ignore and friction state is transferred. Concerning non-Mortar tied contacts, the contacts recommended along with the implicit accuracy option, IACC on *CONTROL_ACCURACY, are supported for implicit-implicit transitions and non-groupable option. More specifically, the supported contact formulations are

   *CONTACT_TIED_NODES_TO_SURFACE

   *CONTACT_TIED_NODES_TO_SURFACE_OFFSET

   *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET

   *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET

9. **EXCLUDE.** This option is used to limit what data will be output to the LSDYNA dynain file. The input format is completely different and consists of any number of keyword cards WITHOUT the leading *. These cards and their associated data will not be output. For example:

```
*INTERFACE_SPRINGBACK_EXCLUDE
BOUNDARY_SPC_NODE
CONSTRAINED_ADAPTIVITY
```

would output all the normal dynain data, except for the SPC and adaptive constraints. The currently recognized keywords that can be excluded are:

BOUNDARY_SLIDING_PLANE

BOUNDARY_SPC_NODE

CONSTRAINED_ADAPTIVITY

DEFINE_COORDINATE_NODES

DEFINE_COORDINATE_VECTOR

ELEMENT_BEAM

ELEMENT_SHELL

ELEMENT_SOLID

INITIAL_STRAIN_SHELL

INITIAL_STRAIN_SOLID

INITIAL_STRESS_BEAM

INITIAL_STRESS_SHELL

INITIAL_STRESS_SOLID

INITIAL_TEMPERATURE_NODE

INITIAL_VELOCITY_NODE

NODE

REFERENCE_GEOMETRY

Remarks for Seamless Springback:

When seamless springback is invoked, the solution automatically and seamlessly switches from explicit or implicit dynamic to implicit static mode at the termination time and continues to run the static springback analysis. Seamless springback can be activated in the original LS-DYNA input deck or later using a small restart input deck. In this way, the user can decide to continue a previous analysis by restarting to add the implicit springback phase. (Another alternative approach to springback simulation is to use the

keyword *INTERFACE_SPRINGBACK_LSDYNA to generate a dynain file after forming, and then perform a second simulation running LS-DYNA in fully implicit mode for springback. See Appendix P for a description of how to run an implicit analysis using LS-DYNA.)

The implicit springback phase begins when the forming simulation termination time ENDTIM is reached, as specified with the keyword *CONTROL_TERMINATION. Since the springback phase is static, its termination time can be chosen arbitrarily (unless material rate effects are included). The default choice is 2.0 × ENDTIM and can be changed using the *CONTROL_IMPLICIT_GENERAL keyword; see fields DT0 and NSBS.

Since the springback analysis is a static simulation, a minimum number of essential boundary conditions or Single Point Constraints (SPC's) can be input to prohibit rigid body motion of the part. These boundary conditions can be added for the springback phase using the input option on the *INTERFACE_SPRINGBACK_SEAMLESS keyword above.

If no boundary conditions are added with the SEAMLESS option, an eigenvalue computation is automatically performed using the Inertia Relief Option to find any rigid body modes and then automatically constrain them out of the springback simulation (see *CONTROL_IMPLICIT_INERTIA_RELIEF). This approach introduces no artificial deformation and is recommended for many simulations.

An “SPR” option is available for several *CONTROL_IMPLICIT keywords to further control the implicit springback phase. Generally, default settings can be used, in which case the SPR option for *CONTROL_IMPLICIT keywords is not necessary.

To obtain accurate springback solutions, a nonlinear springback analysis must be performed. In many simulations, this iterative equilibrium search will converge without difficulty. If the springback simulation is particularly difficult, either due to nonlinear deformation, nonlinear material response, or numerical precision errors, a multi-step springback simulation will be automatically invoked. In this approach, the springback deformation is divided into several smaller, more manageable steps.

Two specialized features in LS-DYNA are used to perform multi-step springback analyses. The addition and gradual removal of artificial springs is performed by the artificial stabilization feature. Simultaneously, the automatic time step control is used to guide the solution to the termination time as quickly as possible, and to persistently retry steps where the equilibrium search has failed. By default, both of these features are active during a seamless springback simulation. However, the default method attempts to solve the springback problem in a single step. If this is successful, the solution will terminate normally. If the single step springback analysis fails to converge, the step size will be reduced, and artificial stabilization will become active. Defaults for these features can be changed using the following keywords:

- *CONTROL_IMPLICIT_GENERAL,

- *CONTROL_IMPLICIT_AUTO, and
- *CONTROL_IMPLICIT_STABILIZATION.

*INTERFACE_SSI_{OPTION}_ID

Purpose: This card creates a tied-contact soil-structure interface for use in a transient analysis of a soil-structure system subjected to earthquake excitation. This card allows the analysis to start from a static state of the structure, as well as to read in ground motions recorded on the interface in an earlier analysis.

Available options are:

<BLANK>

OFFSET

CONSTRAINED_OFFSET

LS-DYNA implements the effective seismic input method [Bielak and Christiano (1984)] for modeling the interaction of a nonlinear structure with a linear soil foundation subjected to earthquake excitation. Note that any nonlinear portion of the soil near the structure may be incorporated with the structure into a larger generalized structure, but the soil is assumed to behave linearly beyond a certain distance from the structure.

The effective seismic input method couples the dynamic scattered motion in the soil, which is the difference between the motion in the presence of the structure and the free-field motion in its absence, with the total motion of the structure. This replaces the distant earthquake source with equivalent effective forces adjacent to the soil-structure interface and allows truncation of the large soil domain using a non-reflecting boundary (e.g. *MAT_PML_ELASTIC) to avoid unnecessary computation. These effective forces can be computed using the free-field ground motion at the soil-structure interface, thus avoiding deconvolution of the free-field motion down to depth.

Nonlinear behavior of the structure may be modeled by first carrying out a static analysis of the soil-structure system, and then carrying out the transient analysis with only the structure initialized to its static state. Because the transient analysis employs the dynamic scattered motion in the soil, the soil cannot have any static loads only it – only the structure is subjected to static forces. Consequently, the structure must be supported by the static reactions at the soil-structure interface. Additionally, the soil nodes at the interface must be initialized to be compatible with the initial static displacement of the structure. LS-DYNA will do these automatically if the soil-structure interface is identified appropriately in the static analysis and reproduced in the transient analysis.

Thus, soil-structure interaction analysis under earthquake excitation may be carried out in LS-DYNA as follows:

1. Carry out a static analysis of the soil-structure system (e.g. using dynamic relaxation; see *CONTROL_DYNAMIC_RELAXATION), with the soil-structure interface identified using *INTERFACE_SSI_STATIC_ID

Optionally, carry out a free-field analysis to record free-field motions on the future soil-structure interface, using either *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED, for surface-supported or embedded structures respectively.

2. Carry out the transient analysis as a full-deck restart job (see *RESTART), with only the structure initialized to its static stress state (see *STRESS_INITIALIZATION), and the same soil-structure interface identified using *INTERFACE_SSI_ID with the same ID as in static analysis:

   a) The structure mesh must be identical to the one used for static analysis.

   b) The soil mesh is expected to be different from the one used for static analysis, especially because non-reflecting boundary models may be used for transient analysis.

   c) The meshes for the structure and the soil need not match at the interface.

   d) Only the structure must be subjected to static loads, via *LOAD_BODY_PARTS

   e) The earthquake ground motion is specified using *LOAD_SEISMIC_SSI, and/or read from motions recorded from a previous analysis using *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card 2	1	2	3	4	5	6	7	8
Variable	STRID	SOILID	STRPR	SOILPR				
Type	I	I	I	I				
Default	none	none	0	0				

Optional card (superseded by LOAD_SEISMIC_SSI_AUX; see Remark 6)

Card 3	1	2	3	4	5	6	7	8
Variable	GMSET	SF	BIRTH	DEATH	MEMGM			
Type	I	F	F	F	I			
Default	none	1.	0.	10^{28}	2500000			

VARIABLE	DESCRIPTION
ID	Soil-structure interface ID. This is required and must be unique amongst all the contact interface IDs in the model.
HEADING	A descriptor for the given ID.
STRID	Segment set ID of base of structure at soil-structure interface.
SOILID	Segment set ID of soil at soil-structure interface.
STRPR	Include the structure side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: Structure side forces included. Note that for ncforc the forces for this side will be listed under surfa.
SOILPR	Include the soil side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: Soil side forces included. Note that for ncforc the forces for this side will be under surfb.
GMSET	Identifier for set of recorded motions from *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED
SF	Recorded motion scale factor.
BIRTH	Time at which specified recorded motion is activated.
DEATH	Time at which specified recorded motion is removed: EQ.0.0: Default set to 10^{28}
MEMGM	Size in words of buffer allocated to read in recorded motions

Remarks:

1. **Tied Contact Interface.** A tied contact interface (*CONTACT_TIED_SURFACE_TO_SURFACE) is created between the structure and the soil using the specified segment sets, with the soil segment set as the reference surface and the structure segment set as the tracked surface. Naturally, the two segment sets should not have merged nodes and can be non-matching in general. However, the area covered by the two surfaces should match.

2. **Keyword Options.** The options OFFSET and CONSTRAINED_OFFSET create the corresponding tied surface-to-surface contact interface.

3. **Interface ID.** The soil-structure interface ID is assigned as the ID of the generated contact interface.

4. **Soil Segment Set Orientation.** It is assumed that the soil segment set is oriented toward the structure.

5. **Multiple Soil-Structure Interfaces.** Multiple soil-structure interfaces are allowed, such as for bridge analysis.

6. **Obsolete Card.** Optional Card 3 has been superseded by *LOAD_SEISMIC_SSI_AUX, which allows for reading multiple ground motion files in the same model.

7. **Reading Recorded Motions.** The recorded motions are read in from a binary file named gmbin by default, but a different filename may be chosen using the option GMINP on the command line (see Getting Started, Execution Syntax).

8. **Recorded Motions.** If the motions from *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED were recorded on a segment set, then the free-field motions on each node in the soil segment set of the soil-structure interface are calculated from the nearest segment of the segment set used to record the motions. If, however, the motions were recorded on a node set, then the motions on the soil segment set nodes are found by interpolation as is done for *LOAD_SEISMIC_SSI.

***INTERFACE_SSI_AUX**_*{OPTION}*

Available options are:

<BLANK>

NODE

Purpose: This card records the motion at a free surface, or on a set of nodes on a free surface, for the purpose of using the recorded motion as a free-field motion in a subsequent interaction analysis using *INTERFACE_SSI. By default, this card records motions on a segment set defining a surface, but can record motions on a node set using the option NODE. Only one of *INTERFACE_SSI_AUX and *INTERFACE_SSI_AUX_EMBEDDED is to be used for a particular soil-structure interface.

Card 1	1	2	3	4	5	6	7	8
Variable	GMSET	SETID						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
GMSET	Identifier for this set of recorded motions to be referred to in *INTERFACE_SSI. Must be unique.
SETID	Segment set or node set ID where motions are to be recorded.

Remarks:

1. **Output File.** The motions on the specified segment set or node set is recorded in a binary file named gmbin by default, but a different filename may be chosen using option GMOUT on the command line (see Getting Started, Execution Syntax).

2. **Output Interval.** The output interval for the motions may be specified using the parameter GMDT on the *CONTROL_OUTPUT card, with the default value being one tenth of the output interval for d3plot states.

*INTERFACE_SSI_AUX_EMBEDDED_{OPTION1}_{OPTION2}

Purpose: This card creates a tied-contact interface and records the motions and contact forces. The recorded data can then be used as free-field motion and reactions in a subsequent soil-structure interaction analysis using *INTERFACE_SSI, where the structure is embedded in the soil after part of the soil has been excavated. Only one of *INTERFACE_SSI_AUX and *INTERFACE_SSI_AUX_EMBEDDED is to be used for a particular soil-structure interface.

Available options for *OPTION1* are:

<BLANK>

OFFSET

CONSTRAINED_OFFSET

OPTION2 allows an optional ID to be given:

ID

ID Card. Additional card for ID keyword option.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card 2	1	2	3	4	5	6	7	8
Variable	GMSET	STRID	SOILID	STRPR	SOILPR			
Type	I	I	I	I	I			
Default	none	none	none	0	0			

VARIABLE	DESCRIPTION
ID	Soil-structure interface ID. This is required and must be unique amongst all the contact interface IDs in the model.
HEADING	A descriptor for the given ID.

VARIABLE	DESCRIPTION
GMSET	Identifier for this set of recorded motions to be referred to in *INTERFACE_SSI. Must be unique.
STRID	Segment set ID at base of soil to be excavated
SOILID	Segment set ID at face of rest of the soil domain.
STRPR	Include the structure side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: Structure side forces included. Note that for ncforc the forces for this side will be listed under surfa.
SOILPR	Include the soil side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: Soil side forces included. Note that for ncforc the forces for this side will be listed under surfb.

Remarks:

1. **Output Binary File.** The motions on the specified segment set or node set is recorded in a binary file named gmbin by default, but a different filename may be chosen using the option GMOUT on the command line (see Getting Started, Execution Syntax).

2. **Output Interval.** The output interval for the motions may be specified using the parameter GMDT on the *CONTROL_OUTPUT card, with the default value being one tenth of the output interval for d3plot states.

*INTERFACE_SSI_STATIC_{OPTION}_ID

Purpose: This card creates a tied-contact soil-structure interface in order to record the static reactions at the base of the structure, which are to be used in a subsequent dynamic analysis of the soil-structure system subjected to earthquake excitation. This card is intended to be used with the initial static analysis of the structure subjected to gravity loads.

Available options are:

<BLANK>

OFFSET

CONSTRAINED_OFFSET

Card 1	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card 2	1	2	3	4	5	6	7	8
Variable	STRID	SOILID	STRPR	SOILPR				
Type	I	I	I	I				
Default	none	none	0	0				

VARIABLE	DESCRIPTION
ID	Soil-structure interface ID. This is required and must be unique amongst all the contact interface IDs in the model.
HEADING	A descriptor for the given ID.
STRID	Segment set ID of base of structure at soil-structure interface.
SOILID	Segment set ID of soil at soil-structure interface.

VARIABLE	DESCRIPTION
STRPR	Include the structure side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: Structure side forces included. Note that for ncforc the forces for this side will be listed under surfa.
SOILPR	Include the soil side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: Soil side forces included. Note that for ncforc the forces for this side will be listed under surfb.

Remarks:

See *INTERFACE_SSI_ID. The ID used for a particular interface in the static analysis must also be used for the same interface identified using *INTERFACE_SSI_ID during dynamic analysis.

*INTERFACE_THICKNESS_CHANGE_COMPENSATION

Purpose: Change the original tool gap between the upper and lower tools to variable gaps based on the formed blank thickness from a forming simulation. *This keyword must be used with *INCLUDE_COMPENSATION_CURRENT_TOOLS and *INCLUDE_COMPENSATION_BEFORE_SPRINGBACK.* This feature is useful for hot stamping simulations, where physical contacts are required between the upper/lower tools and the sheet blank to ensure a proper cooling rate. The rigid tools with the variable gaps will be output to the file rigid.new.

Compensation Card.

Card 1	1	2	3	4	5	6	7	8
Variable	IFLG	THK0						
Type	I	F						
Default	none	none						

VARIABLE	DESCRIPTION
IFLG	Activation flag; set to "1" to invoke the option.
THK0	Initial thickness of the sheet blank

Remarks:

1. **Overview.** This keyword causes LS-DYNA to modify the gap between tools due to the results of a forming simulation. *INCLUDE_COMPENSATION_CURRENT_TOOLS and *INCLUDE_COMPENSATION_BEFORE_SPRINGBACK are used to include the rigid tools and formed sheet blank files, respectively. The first file contains a set of upper and lower tools with the original gap. This gap is then modified to the formed blank thickness from a forming simulation provided in the second file, a dynain format file. The forming results from the dynain file must include the thicknesses of the formed sheet blank.

2. **Orientation of Surfaces.** For each tool, the surface normals must be consistent and must point towards the blank.

3. **Position.** The rigid tools and formed blank must be all in their punch home positions.

4. **Wrinkles.** To capture detailed tool gap change in case of wrinkles, the rigid body mesh size must be of the same order as the wrinkle wavelength.

Example:

A keyword example is provided below. The initial blank thickness is 1.2mm, the original tool is provided as rigid.inc, and the file drawn.dynain contains the formed blank with thickness information.

```
*KEYWORD
*INTERFACE_THICKNESS_CHANGE_COMPENSATION
$     IFLG      THK0
         1       1.2
*INCLUDE_COMPENSATION_CURRENT_TOOLS
rigid.inc
*INCLUDE_COMPENSATION_BEFORE_SPRINGBACK
drawn.dynain
```

Revision Information:

This feature was originally available in SMP (not available in MPP) Dev Revision 106357. Improvements are made in Dev Revision136166.

*INTERFACE_WELDLINE_DEVELOPMENT

Purpose: This keyword causes LS-DYNA to run a weld line development calculation instead of a finite element calculation. The input for this feature consists of (1) the formed blank from a completed metal forming simulation, (2) the corresponding initial blank, and (3) depending on which on desired whether the desired weld curve is on the formed or initial blank, the weld curve on the initial blank or on the final blank, respectively. Outputs include predicted final weld curve if input is the initial weld curve, or initial weld curve if input is the final welding curve; also nodes of any element edges that intersect the weld curve on the initial blank will be output to a file name affectednd_i.ibo and on the final blank to a file name affectednd_f.ibo.

Three additional keywords must be used together (and exclusively) with this keyword. They are: *INCLUDE_WD_INITIAL_BLANK, *INCLUDE_WD_FINAL_PART, and *INCLUDE_WD_WELDING_CURVE. See Remark 1 for a discussion of input order.

> **NOTE:** When this card is present, LS-DYNA *does not* proceed to the finite element simulation.

Development Parameter Card.

Card 1	1	2	3	4	5	6	7	8
Variable	IOPTION							
Type	I							
Default	1							

VARIABLE	DESCRIPTION
IOPTION	Welding curve development options: EQ.1: Calculate initial weld curve from final (given) weld curve, with output file name weldline.ibo, which will be on the initial blank mesh. EQ.-1: Calculate final weld curve from initial weld curve, with output file name weldline_f.ibo, which will be on the formed blank mesh.

Remarks:

1. **Input Order.** The input order of the keywords for a weld line development calculation is sensitive and must be in the order that follows:

```
*Keyword
*INTERFACE_WELDLINE_DEVELOPMENT
$  IOPTION
         1
*INCLUDE_WD_INITIAL_PART
$     filename
      initial.k
*INCLUDE_WD_FINAL_PART
$     filename
      final.k
*INCLUDE_WD_WELDING_CURVE
$     filename
      welding_curve.k
```

2. **Purpose of Weld Line Development Calculation.** For metal forming of tailor welded blanks, an initial straight weld line could become a curve on the formed part. The amount of deviation of the formed weld curve from its initial line depends on the part shape and forming conditions. Sometimes the formed weld curve is not desirable, thus a correction to the initial weld curve is needed. This keyword allows for determining the final weld curve given the initial weld curve and vice-versa, without performing another forming simulation.

3. **Mesh Adaptivity.** A mesh with adaptivity for the initial blank and final part is supported.

4. **Final (formed) Weld Curve.** The final formed weld curve should be projected onto the final blank mesh if it does not exactly lie on the mesh surface. This can be done with LS-PrePost4.2 via the menu option *GeoTol → Project → Project*, select *Closest Projection*, select *Project to Elements*, then define the destination mesh and source curves, and hit *Apply*. Sometimes the target curve may need enough points before projection; the points may be added via menu option *Curve → Spline → Method (Respace) → by number*. To write the curve out in *DEFINE_CURVE_TRIM_3D format, use *Curve → Convert → Method (To DEFINE_CURVE_TRIM) → To Key*, then write out the keyword using *FILE → Save Keyword*.

5. **Computed Weld Curve (and IGES).** Computed weld curves are written with a *DEFINE_CURVE_TRIM_3D keyword into a file called weldline.ibo (or, weldline_f.ibo, depending on IOPTION). The format of this file follows the keyword's specification. LS-PrePost4.0 can convert the computed curve to IGES; see the procedure in the manual pages for *INTERFACE_BLANKSIZE_DEVELOPMENT. After hitting Apply, the curves will show up in the graphics window, and *File → Save as → Save Geom as* can be used to write the curves out in IGES format.

Example:

As shown in Figure 29-41, given the initial (initialblank.k) and final blank (finalblank.k) configuration and a final formed weld curve (finalweldingcurve.k), the following input calculates a new initial weld curve on the initial blank. In this case, the final weld curve is specified as straight in the drawn panel.

```
*KEYWORD
*INTERFACE_WELDLINE_DEVELOPMENT
$OPTION
1
*INITIAL_BLANK
initialblank.k
*FINAL_PART
finalblank.k
*WELDING_CURVE
finalweldingcurve.k
*END
```

The output is the initial weld curve in the file weldline.ibo, Figure 29-41. Nodes of element edges that intersect the initial weld curve are output in affectednd_i.ibo; while nodes of element edges that intersect the final formed weld curve are output in affectednd_f.ibo, Figure 29-42.

To verify the predicted weld curve, the initial blank can be re-meshed according to the curve. A draw simulation can be performed again to confirm the final weld curve as straight, Figure 29-43.

Likewise, if given an initial weld curve (initialweldingcurve.k) and a final weld curve (weldline_f.ibo) can be calculated with the keyword inputs below:

```
*KEYWORD
*INTERFACE_WELDLINE_DEVELOPMENT
$OPTION
-1
*INITIAL_BLANK
initialblank.k
*FINAL_PART
finalblank.k
*WELDING_CURVE
initialweldingcurve.k
*END
```

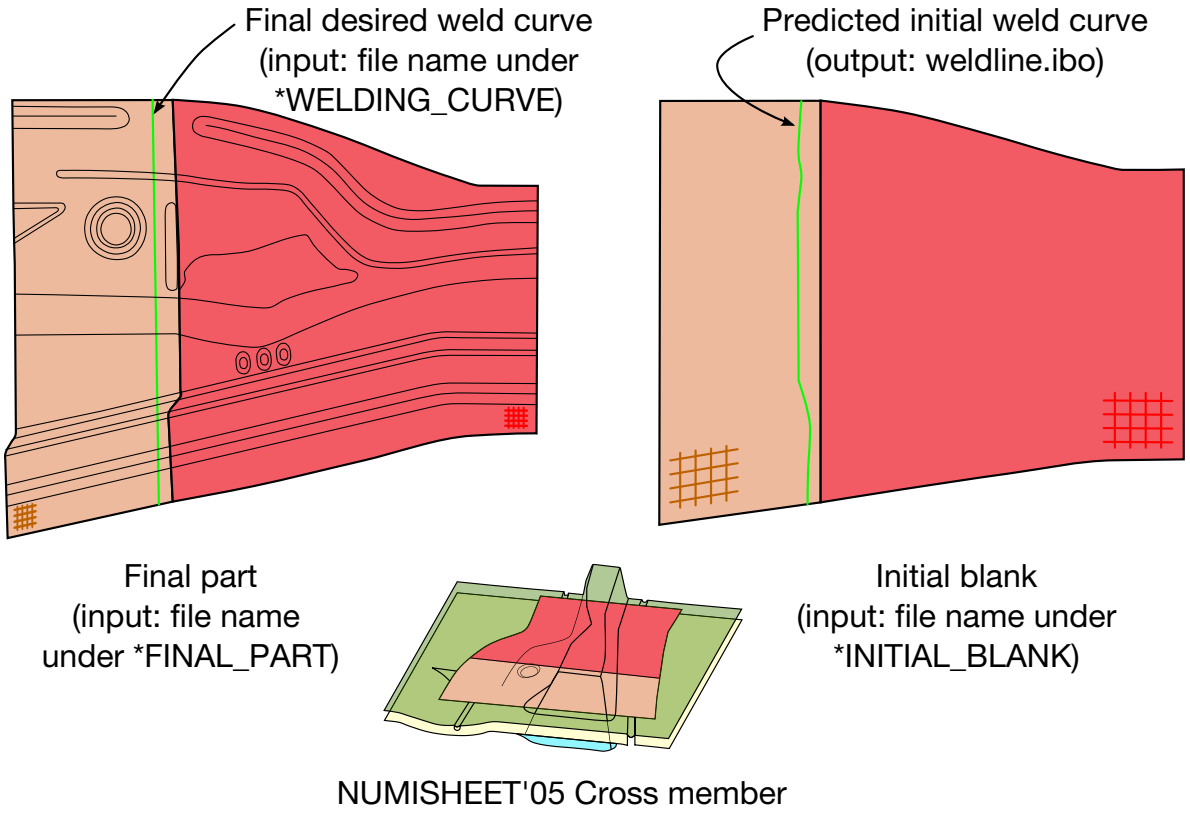

Figure 29-41. An example for a welding curve development.

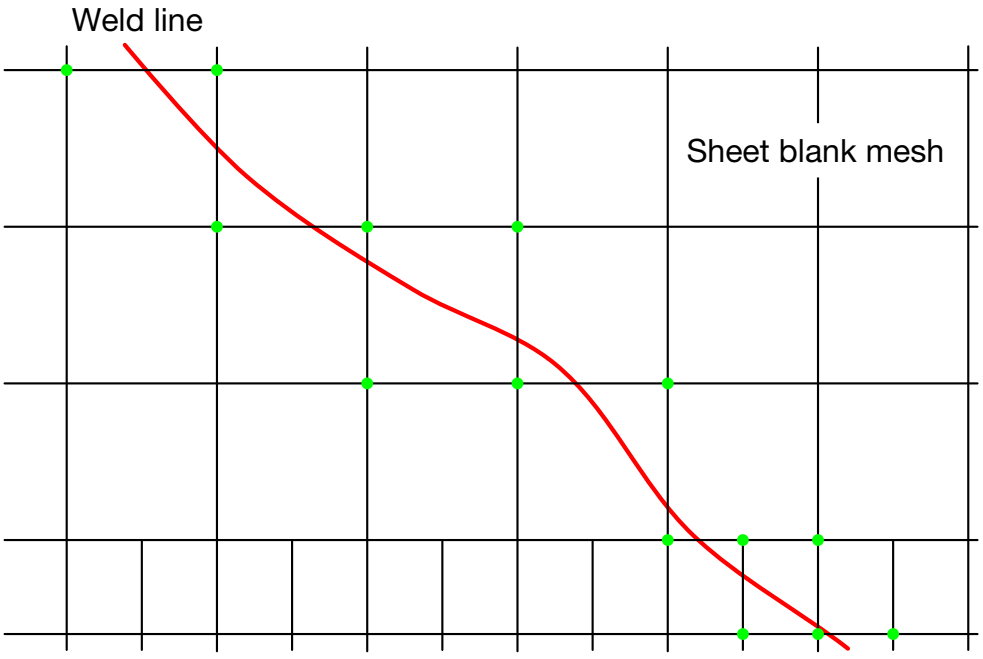

Figure 29-42. Nodes (in green) of element edges that intersect the weld curve are output in affectednd_i.ibo and affectednd_f.ibo, for initial and deformed mesh, respectively.

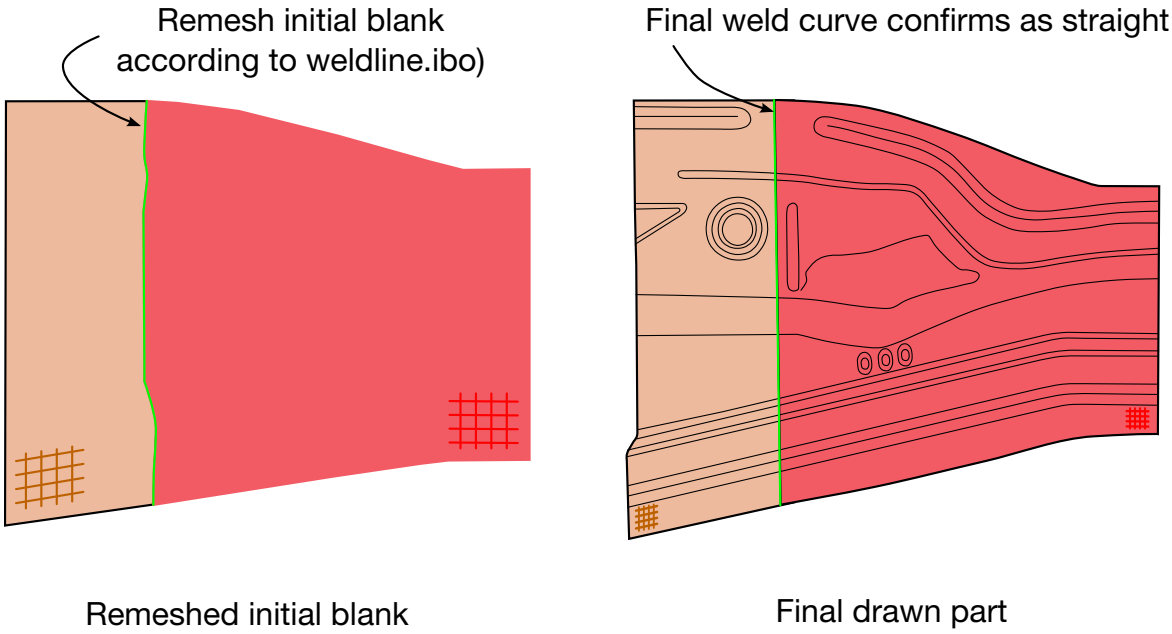

Figure 29-43. Verification run

Revision information:

1. IOPTION of "1": Revision 105189 in both double precision versions of SMP and MPP.
2. IOPTION of "-1": Revision 105727.
3. Output of nodes of element edges that intersect the weld curve: Revision 105727.
4. Later revisions may include improvements.

*KEYWORD

***KEYWORD**_*{OPTION} {memory} {memory2 = j} {NCPU = n}*

Available options include:

<BLANK>

ID

JOBID

Purpose: The keyword, *KEYWORD, flags LS-DYNA that the input deck is a keyword deck rather than the structured format, which has a strictly defined format. This must be the first card in the input file. Alternatively, by typing "keyword" on the execution line, keyword input formats are assumed and this beginning "*KEYWORD" line is not required.

There are 3 optional parameters that can be specified on the *KEYWORD line. If a number *{memory}* is specified, it defines the memory size in units of words to be allocated. For MPP, if the parameter {memory2 = *j*} is also given, *memory* defines the memory allocation in words for the first core and *j* defines the memory allocation in words for each of the remaining cores. Note that if the memory size is specified on the execution line, it will override the memory size specified on the *KEYWORD line.

If the parameter {NCPU = *n*} is specified it defines the number Shared Memory Parallel (SMP) threads of "*n*" to be used for each processor during the analysis. This applies to both SMP and HYBRID versions of LS-DYNA.

For the Distributed Memory Version (MPP), the number of CPUs is defined with the "mpirun –np *m*" command.

HYBRID is combination of SMP and MPP therefore the total number of cores used in this example will be *n x m* cores. Defining the number of CPUs on the execution line overrides what is specified on the *KEYWORD line and both override the number of CPUs specified by *CONTROL_PARALLEL. An example of the {memory} and {NCPU = *n*} options would be as follows:

```
*KEYWORD 120m memory2=10m NCPU=2
```

This *KEYWORD command is requesting 120 million words of memory, 10 million words of memory2 and 2 CPUs to be used for the analysis with the consistency flag (see CONST in *CONTROL_PARALLEL) turned off. To run with the consistency flag turned on (recommended), set NCPU to a negative value, e.g., "NCPU = -2" runs with 2 CPUs with the consistency flag turned on.

*KEYWORD

The ID and JOBID command line options are available to add a prefix to all output and scratch file names, i.e., not the input filenames. This allows multiple simulations in a directory since a different prefix prevents files from being overwritten. If the ID option is used, the prefix is constructed of three user specified strings separated by "_f" characters.

ID Card. Additional Card if the ID option is active.

Card 1	1	2	3	4	5	6	7	8
Variable	PROJECT		NUM		STAGE			
Type	A		A		A			
Default	none		none		none			

VARIABLE	DESCRIPTION
PROJECT	First part of the output file name prefix.
NUM	Second part of the output file name prefix.
STAGE	Third part of the output file name prefix.

By using the ID option of *KEYWORD, an output file name prefix may be specified as a combination of the variables PROJECT, NUM and STAGE as defined on Card 1 above. For example, if these variables were set literally to "PROJECT", "NUM", and "STAGE", the first d3plot would be named:

```
PROJECT_NUM_STAGE.d3plot
```

Alternatively, an output file name prefix can be assigned by including "jobid=" on the execution line. For example,

lsdyna i=**input.k** jobid=**PROJECT_NUM_STAGE**

A third way to define an output file name prefix is by using the JOBID option of the *KEYWORD command, in which case Card 1 is defined as shown below and the variable JBID acts as the output prefix.

JOBID Card. Additional card if the JOBID option is active.

Card 1	1	2	3	4	5	6	7	8
Variable	JBID							
Type	A							
Default	none							

*LOAD

The keyword *LOAD provides a way of defining applied forces. The keyword control cards in this section are defined in alphabetical order:

*LOAD_ACOUSTIC_SOURCE

*LOAD_ALE_CONVECTION

LOAD_BEAM_*OPTION

*LOAD_BLAST

*LOAD_BLAST_CLEARING

*LOAD_BLAST_ENHANCED

*LOAD_THERMAL_VARIABLE_BEAM

LOAD_THERMAL_VARIABLE_ELEMENT_*OPTION

*LOAD_THERMAL_VARIABLE_NODE

*LOAD_THERMAL_VARIABLE_SHELL

*LOAD_VOLUME_LOSS

*LOAD_ACOUSTIC_SOURCE

Purpose: Specify acoustic loading sources for *CONTROL_IMPLICIT_SSD_DIRECT and *CONTROL_ACOUSTIC_SPECTRAL analyses.

Card 1	1	2	3	4	5	6	7	8
Variable	NID/SSID	SRCTYP	LCID	DATA1	DATA2	DATA3	DATA4	DATA5
Type	I	I	I	F	F	F	F	F
Default	none	↓	0	1.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
NID	Node ID of the acoustic point source for SRCTYP = 1 and 5
SSID	Segment set ID of structural faces on the external fluid-structure boundary exposed to the acoustic wave source for SRCTYP = 11 and 12
SRCTYP	Acoustic source type: EQ.1: Harmonic nodal point source. DATA1, DATA2, and LCID define the harmonic nodal source strength $\dot{Q}$, the phase angle of the nodal source strength and frequency variation for a point source at node NID. EQ.5: Transient nodal point source. DATA1 and LCID define the transient nodal source strength ($\dot{Q}$) and temporal variation for a point source at node NID. EQ.11: Harmonic plane wave: DATA1 and LCID define the magnitude and frequency variation for a harmonic plane wave with direction cosines given in DATA2, DATA3, and DATA4. SSID is the segment set ID of the external structural (coupled) surface. EQ.12: Harmonic spherical wave. DATA1, DATA5, and LCID define the magnitude, reference radius and frequency variation for a harmonic spherical wave centered at coordinates x_0, y_0, and z_0 specified with DATA2, DATA3, and DATA4. SSID is the segment set ID of the external structural (coupled) surface.

VARIABLE	DESCRIPTION
LCID	Load curve ID of curve specifying the variation of the load with frequency or time. If LCID is undefined, then the loading is constant.
DATA1	SRCTYP.EQ.1: Magnitude of the harmonic nodal source strength, $\dot{Q}$ SRCTYP.EQ.5: Magnitude of the transient nodal source strength, $\dot{Q}$ SRCTYP.EQ.11: Pressure of the harmonic plane wave, P_0 SRCTYP.EQ.12: Pressure of the harmonic spherical wave, P_0, at r_0
DATA2	SRCTYP.EQ.1: Phase angle of the nodal source strength in radians SRCTYP.EQ.11: Direction cosine, α SRCTYP.EQ.12: x coordinate of center of spherical wave, x_0
DATA3	SRCTYP.EQ.11: Direction cosine, β SRCTYP.EQ.12: y coordinate of center of spherical wave, y_0
DATA4	SRCTYP.EQ.11: Direction cosine, γ SRCTYP.EQ.12: z coordinate of center of spherical wave, z_0
DATA5	For SRCTYP = 12, reference radius, r_0, where the pressure equals p_0

Remarks:

1. **Source Strength.** $\dot{Q}$ has dimensions of area times acceleration. In steady state analysis, it is related to Q_0 through

$$\dot{Q} = \omega Q_0 e^{i\left(\omega t + \frac{\pi}{2}\right)}$$

2. **External, Incident Wave Solutions.** With SRCTYP = 11 or 12, the SSD solution in the acoustic domain is for the scattered pressure.

3. **Incident Pressure and Particle Velocity.** For direct, steady state vibration acoustic scattering invoked with *CONTROL_IMPLICIT_SSD_DIRECT, the incident pressure and particle velocity applied depend on the source type.

a) For plane waves (SRCTYP = 11), they are given by:

$$P_{\text{inc}} = P_0 e^{-ik(\alpha x+\beta y+\gamma z)}$$
$$U_{\text{inc}} = \frac{P_0}{\rho_0 c_0} e^{-ik(\alpha x+\beta y+\gamma z)}$$

b) For spherical waves (SRCTYP = 12), they are given by:

$$P_{\text{inc}} = \frac{P_0 r_0}{r} e^{-ik(r-r_0)}$$
$$U_{\text{inc}} = \frac{P_0}{\rho_0 c_0}\left(\frac{r_0}{r}\right)\left(\frac{kr-i}{kr}\right) e^{-ik(r-r_0)}$$

*LOAD_ALE_CONVECTION_{OPTION}

Purpose: Define the convection thermal energy transfer from a hot ALE fluid to the surrounding Lagrangian structure (Remark 1). It is associated with a corresponding coupling card defining the interaction between the ALE fluid and the Lagrangian structure. It is only used when thermal energy transfer from the ALE fluid to the surrounding Lagrangian structure is significant. This is designed specifically for airbag deployment applications where the heat transfer from the inflator gas to the inflator compartment can significantly affect the inflation potential of the inflator.

Available options include:

<BLANK>

ID

To define an ID number for each convection heat transfer computation in an optional card preceding all other cards for this command. This ID number can be used to output the part temperature and temperature change as functions of time in the *DATABASE_FSI card. To do this, set CONVID in *DATABASE_FSI equal to this ID.

ID Card. Additional card for ID keyword option.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TITLE						
Type	I	A70						
Default	none	none						

Convection Card. Include as many cards as necessary. This input terminates at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	LAGPID	LAGT	LAGCP	H	LAGMAS			
Type	I	F	F	F	F			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
ID	ID number for each convection heat transfer computation
TITLE	A description of this convection heat transfer
LAGPID	Lagrangian structure PID from a corresponding coupling card which receives the thermal energy in the convection heat transfer
LAGT	Initial temperature of this Lagrangian structure part
LAGCP	Constant-pressure heat capacity of this Lagrangian structure part. It has a per-mass unit (for example, J/[kg*K]).
H	Convection heat transfer coefficient on this Lagrangian structure part surface. It is the amount of energy (J) transferred per unit area, per time, and per temperature difference. For example, its units may be J/[m^2*s*K].
LAGMAS	The mass of the Lagrangian structure part receiving the thermal energy. This is in absolute mass unit (for example, kg).

Remarks:

1. **Applications.** The only application of this card so far has been for the transfer of thermal energy from the ALE hot inflator gas to the surrounding Lagrangian structure (inflator canister and airbag-containing compartment) in an airbag deployment model.

2. **Model.** The heat transferred is taken out of the inflator gas thermal energy thus reducing its inflating potential. This is not a precise heat transfer modeling attempt. It is simply one mechanism for taking out excessive energy from the inflating potential of the hot inflator gas.

   The heat transfer formulation may roughly be represented as the following equation. Some representative units are shown just for clarity.

$$[\dot{Q}] = [\mathrm{H} \times A \times \Delta T] = \left(\frac{[\mathrm{E}]}{[L]^2[\mathrm{t}][\mathrm{T}]}\right) \times [\mathrm{L}]^2 \times [\mathrm{T}] = [\mathrm{Power}]$$

$$[\dot{Q}] = \left[\dot{M} C_p \left(T_{\mathrm{Lag\ New}} - T_{\mathrm{Lag\ Orig}}\right)\right] = \left(\frac{[\mathrm{M}]}{[t]}\right) \times \left(\frac{[\mathrm{E}]}{[\mathrm{M}][\mathrm{T}]}\right) \times [\mathrm{T}] = \frac{[\mathrm{E}]}{[\mathrm{t}]}$$

LOAD_BEAM_*OPTION

Available options include:

ELEMENT

SET

Purpose: Apply the distributed traction load along any local axis of a beam or a set of beams. The local axes are defined in Figure 31-1; see also *ELEMENT_BEAM.

Beam Cards. Include as many as necessary. This input stops at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	EID/ESID	DAL	LCID	SF				
Type	I	I	I	F				
Default	none	none	none	1.				

VARIABLE	DESCRIPTION
EID/ESID	Beam ID (EID) or beam set ID (ESID), see *ELEMENT_BEAM or *SET_BEAM.

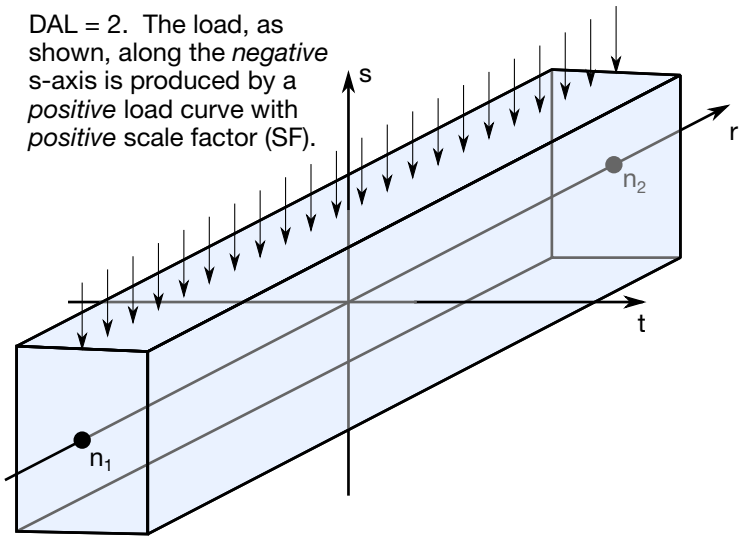

Figure 31-1. Applied traction loads are given in force per unit length. The *s* and *t*-directions are defined on the *ELEMENT_BEAM keyword.

VARIABLE	DESCRIPTION
DAL	Direction of applied load: EQ.1: parallel to *r*-axis of beam, EQ.2: parallel to *s*-axis of beam, EQ.3: parallel to *t*-axis of beam, EQ.4: parallel to global *X*-axis, EQ.5: parallel to global *Y*-axis, EQ.6: parallel to global *Z*-axis.
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). See Remark 1.
SF	Load curve scale factor. This is for a simple modification of the function values of the load curve.

Remark:

1. **LCID Function Arguments.** The function defined by LCID has 7 arguments: time, the 3 current coordinates, and the 3 reference coordinates. For example, the function (see *DEFINE_FUNCTION),

```
f(t,x,y,z,x0,y0,z0)= -10.*sqrt ( (x-x0)*(x-x0)+(y-y0)*(y-y0)+(z-z0)*(z-z0) ),
```

applies a force proportional to the distance from the initial coordinates.

*LOAD_BLAST

Purpose: Define an air blast function for the application of pressure loads from the detonation of conventional explosives. The implementation is based on a report by Randers-Pehrson and Bannister [1997] where it is mentioned that this model is adequate for use in engineering studies of vehicle responses due to the blast from land mines. This option determines the pressure values when used in conjunction with the keywords: *LOAD_SEGMENT, *LOAD_SEGMENT_SET, or *LOAD_SHELL.

Card 1	1	2	3	4	5	6	7	8
Variable	WGT	XBO	YBO	ZBO	TBO	IUNIT	ISURF	
Type	F	F	F	F	F	I	I	
Default	none	0.0	0.0	0.0	0.0	2	2	

Card 2	1	2	3	4	5	6	7	8
Variable	CFM	CFL	CFT	CFP	DEATH			
Type	F	F	F	F	F			
Default	0.0	0.0	0.0	0.0	0.0			

VARIABLE	DESCRIPTION
WGT	Equivalent mass of TNT.
XBO	x-coordinate of point of explosion.
YBO	y-coordinate of point of explosion.
ZBO	z-coordinate of point of explosion.
TBO	Time-zero of explosion.
IUNIT	Unit conversion flag. EQ.1: feet, pound-mass, seconds, psi EQ.2: meters, kilograms, seconds, pascals (default)

VARIABLE	DESCRIPTION
	EQ.3: inch, dozens of slugs, seconds, psi EQ.4: centimeters, grams, microseconds, megabars EQ.5: user conversions will be supplied (see Card 2)
ISURF	Type of burst. See Remark 2. EQ.1: surface burst. The blast is located on or very near the ground, which is modeled as a surface. See Remark 5. EQ.2: air burst. The blast is spherical (default).
CFM	Conversion factor: pounds per LS-DYNA mass unit.
CFL	Conversion factor: feet per LS-DYNA length units.
CFT	Conversion factor: milliseconds per LS-DYNA time unit.
CFP	Conversion factor: psi per LS-DYNA pressure unit
DEATH	Death time. Blast pressures are deactivated at this time.

Remarks:

1. **Load Curves.** A minimum of two load curves, even if unreferenced, must be present in the model. Even though this keyword does not use load curves, unless there are at least two *DEFINE_CURVE cards LS-DYNA will error terminate with *LOAD_BLAST. Note that one of the enhancements of *LOAD_BLAST_ENHANCED is that it does not require two (place holding) load curves.

2. **Orientation.** The target's segments must be consistently oriented so that the normal vector of the portion of the target having a direct line of sight to the blast points roughly towards the blast. For example, segments defining a structure being blasted from the outside should have outwardly oriented normal vectors, whereas a cavity containing a blast should have inwardly facing normal vectors.

3. **Equivalent Mass of TNT.** Several methods can be used to approximate the equivalent mass of TNT for a given explosive. The simplest involves scaling the mass by the ratio of the Chapman-Jouguet detonation velocities given the by:

$$M_{\mathrm{TNT}} = M_{\mathrm{e}} \frac{v_{\mathrm{e}}^2}{v_{\mathrm{TNT}}^2}$$

where M_{TNT} is the equivalent TNT mass and v_{TNT} is the Chapman-Jouguet (CJ) detonation velocity of TNT. M_{e} and v_{e} are, respectively, the mass and CJ velocity

of the explosive under consideration. LS-DYNA takes the density of "Standard" TNT to be 1.57 $\frac{\text{g}}{\text{cm}^3}$ and v_{TNT} to be 0.693 $\frac{\text{cm}}{\mu\text{s}}$.

4. **Limits of Model's Validity.** Define a scaled distance, Z, as follows:

$$Z = \frac{R}{M_{\text{e}}^{1/3}}$$

where R is the distance from the charge center to the target and M_{e} is the equivalent TNT mass (see Remark 3). The scaled distance determines the range of validity for these models. The spherical airburst model is valid for Z ranging from 0.37 ft/lbm$^{1/3}$ (0.147 m/kg$^{1/3}$) out to 100 ft/lb-m$^{1/3}$ (40 m/kg$^{1/3}$). The hemispherical surface burst is valid for Z ranging from 0.45 ft/lbm$^{1/3}$ (0.178 m/kg$^{1/3}$) out to 100 ft/lbm$^{1/3}$ (40 m/kg$^{1/3}$).

5. **Surface Burst Model.** The surface blast model is ideal for when a charge is located on or very near the ground. In this case the initial blast wave is immediately reflected and reinforced by the nearly rigid ground (the model accounts for yielding) to produce a hemispherical reflected wave from the point of the burst. This reflected wave merges with the initial incident wave producing overpressures which are greater than those produced by the initial wave alone. Target points equidistant from the burst point are loaded identically with the surface burst option.

6. **Single Charge Limitation.** This feature cannot model multiple blasts in one simulation. Use *LOAD_BLAST_ENHANCED for multiple charges.

7. **2D Analysis.** This feature cannot be used for 2D analysis. Instead, use *LOAD_BLAST_ENHANCED.

*LOAD_BLAST_CLEARING

Purpose: Define a surface to be cleared by a rarefaction wave which arises from the diffraction of a blast wave around the free edges of a target face. This feature works only with *LOAD_BLAST_ENHANCED. The implementation is based on a report by Hudson [1955].

Card 1	1	2	3	4	5	6	7	8
Variable	BID							
Type	I							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
BID	Blast source ID (see *LOAD_BLAST_ENHANCED)
N1 - N4	Node IDs of the corners of the surface

Remarks:

1. **Orientation.** The normal vector for the clear surface must nominally point toward the blast origin. The node numbering and normal convention are specified in Figure 31-2.

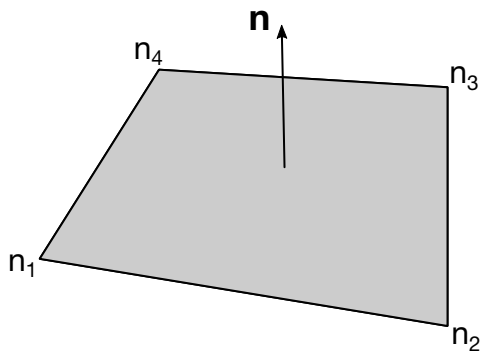

Figure 31-2. Nodal numbering for a cleared surface. Normal vector, **n**, points nominally toward the cleared surface.

*LOAD_BLAST_ENHANCED

Purpose: Define an air blast function for the application of pressure loads due the detonation of a conventional explosive. While similar to *LOAD_BLAST, this feature includes enhancements for treating ground-reflected waves, moving warheads and multiple blast sources. The loads are applied to facets defined with the keyword *LOAD_BLAST_SEGMENT. A database containing blast pressure history is also available (see *DATABASE_BINARY_BLSTFOR).

Card Summary:

Card Sets. Include as many sets of the following cards as necessary. This input terminates at the next keyword ("*") card.

Card 1. This card is required.

BID	M	XBO	YBO	ZBO	TBO	UNIT	BLAST

Card 2. This card is required.

CFM	CFL	CFT	CFP	NIDBO	DEATH	NEGPHS	

Card 3a. This card is included if BLAST = 3.

VEL	TEMP	RATIO	VID				

Card 3b. This card is included if BLAST = 4.

GNID	GVID				FLOOR		

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	BID	M	XBO	YBO	ZBO	TBO	UNIT	BLAST
Type	I	F	F	F	F	F	I	I
Default	none	0.0	0.0	0.0	0.0	0.0	2	2

VARIABLE	DESCRIPTION
BID	Blast ID. A unique number must be defined for each blast source (charge). Multiple charges may be defined, however, interaction of the waves in air is not considered. LT.-2: Blast ID that can be referenced by LCID in *LOAD_ERODING_PART_SET, allowing the pressure from the blast to be used by *LOAD_ERODING_PART_SET.
M	Equivalent mass of TNT (see Remark 1).
XBO	x-coordinate of charge center.
YBO	y-coordinate of charge center.
ZBO	z-coordinate of charge center.
TBO	Time of detonation. See Remark 3.
UNIT	Unit conversion flag. See Remark 4. EQ.1: pound-mass, foot, second, psi EQ.2: kilogram, meter, second, Pascal (default) EQ.3: dozen slugs (i.e., lbf-s2/in), inch, second, psi EQ.4: centimeters, grams, microseconds, Megabars EQ.5: user conversions will be supplied (see Card 2) EQ.6: kilogram, millimeter, millisecond, GPa EQ.7: metric ton, millimeter, second, MPa EQ.8: gram, millimeter, millisecond, MPa
BLAST	Type of blast source (see Remark 5). EQ.1: Hemispherical surface burst – charge is located on or very near the ground surface (see Remark 7) EQ.2: Spherical air burst (default) – no amplification of the initial shock wave due to interaction with the ground surface EQ.3: Air burst – moving non-spherical warhead EQ.4: Air burst with ground reflection – initial shock wave impinges on the ground surface and is reinforced by the reflected wave to produce a Mach front. See Remark 8.

Card 2	1	2	3	4	5	6	7	8
Variable	CFM	CFL	CFT	CFP	NIDBO	DEATH	NEGPHS	
Type	F	F	F	F	I	F	I	
Default	0.0	0.0	0.0	0.0	none	10^{20}	0	

VARIABLE	DESCRIPTION
CFM	Conversion factor - pounds per LS-DYNA mass unit.
CFL	Conversion factor - feet per LS-DYNA length units.
CFT	Conversion factor - milliseconds per LS-DYNA time unit.
CFP	Conversion factor - psi per LS-DYNA pressure unit.
NIDBO	Optional node ID representing the charge center. If nonzero, XBO, YBO, and ZBO are ignored.
DEATH	Death time. Blast pressures are deactivated at this time.
NEGPHS	Treatment of negative phase pressure and positive phase duration (see Remark 9): EQ.0: Negative phase dictated by the Friedlander equation EQ.1: Negative phase pressure ignored EQ.10: Positive phase duration in closer agreement with ConWep results (not recommended). EQ.11: Positive phase duration in closer agreement with ConWep results and negative phase pressure ignored (recommended for comparisons with ConWep).

Moving Non-Spherical Warhead Card. Additional Card for BLAST = 3.

Card 3a	1	2	3	4	5	6	7	8
Variable	VEL	TEMP	RATIO	VID				
Type	F	F	F	F				
Default	0.0	70.0	1.0	none				

VARIABLE	DESCRIPTION
VEL	Speed of warhead
TEMP	Ambient air temperature, Fahrenheit
RATIO	Aspect ratio of the non- spheroidal blast front. This is the longitudinal axis radius divided by the lateral axis radius. Shaped charge and EFP warheads typically have significant lateral blast resembling an oblate spheroid with RATIO < 1. Cylindrically cased explosives produce more blast in the longitudinal direction, so RATIO > 1, rendering a prolate spheroid blast front, is more appropriate.
VID	Vector ID representing the longitudinal axis of the warhead (see *DEFINE_VECTOR). This vector is parallel to the velocity vector when a non-zero velocity VEL is defined.

Spherical Air Burst with Ground Reflection Card. Additional card for BLAST = 4.

Card 3b	1	2	3	4	5	6	7	8
Variable	GNID	GVID				FLOOR		
Type	I	I				I		
Default	none	none				0		

VARIABLE	DESCRIPTION
GNID	ID of node residing on the ground surface

VARIABLE	DESCRIPTION
GVID	ID of vector representing the vertically upward direction, that is, normal to the ground surface (see *DEFINE_VECTOR).
FLOOR	Treatment subterranean segments. EQ.0: Subterranean segments are not affected by the blast. EQ.1: Blast pressure is applied to segments residing below the ground plane. The pressure is computed for the ground plane location regardless of the segment's depth below the plane.

Remarks:

1. **Equivalent Mass of TNT.** Several methods can be used to approximate the equivalent mass of TNT for a given explosive. The simplest involves scaling the mass by the ratio of the Chapman-Jouguet detonation velocities given by:

$$M_{\text{TNT}} = M_e \frac{v_e^2}{v_{\text{TNT}}^2}$$

where M_{TNT} is the equivalent TNT mass and v_{TNT} is the Chapman-Jouguet (CJ) detonation velocity of TNT. M_e and v_e are, respectively, the mass and CJ velocity of the explosive under consideration. LS-DYNA takes the density of "Standard" TNT to be $1.57\,\text{g/cm}^3$ and v_{TNT} to be $0.693\,\text{cm}/\mu\text{s}$.

2. **Orientation.** The target's segments must be consistently oriented so that the normal vector of the portion of the target having a direct line of sight to the blast points roughly towards the blast, unless pressure is to be applied to the leeward side of a structure. For example, segments defining a structure being blasted from the outside should have outwardly oriented normal vectors, whereas a cavity containing a blast should have inwardly facing normal vectors. The angle of incidence is zero when the segment normal points directly at the charge. Only incident pressure is applied to a segment when the angle of incidence is greater than 90 degrees.

3. **Detonation Time.** The blast time offset TBO can be used to adjust the detonation time of the charge relative to the start time of the LS-DYNA simulation. The detonation time is delayed when TBO is positive. More commonly, TBO is set negative so that the detonation occurs before time-zero of the LS-DYNA calculation. Time is, therefore, not wasted while "waiting" for the blast wave to reach the structure. The following message, written to the messag and d3hsp files as well as the screen, is useful for setting TBO:

```
Blast wave reaches structure at 2.7832E-01 milliseconds
```

For example, one might run LS-DYNA for one integration cycle and record the arrival time listed in the message above. Then TBO is set to a negative number slightly smaller in magnitude than the reported arrival time, for example TBO = -0.275 milliseconds. For this case, the blast wave would reach the structure shortly after the start of the simulation.

4. **Units.** Computation of blast pressure relies on an underlying method which uses base units of lbm-foot-millisecond-psi; note that this internal unit system is inconsistent. Calculations require that the system of units in which the LS-DYNA model is constructed must be converted to this internal set of units. Predefined and user-defined unit conversion factors are available (see the parameter UNIT) and these unit conversion factors are echoed back in the d3hsp file. Below is an example of user-defined (UNIT = 5) conversion factors for the gm-mm-millisecond-MPa unit system.

$$1 = \left[\frac{\text{CFM} \times \text{lb}}{\text{LS-DYNA mass unit}}\right] = \left[\underbrace{2.2 \times 10^{-3}}_{=\text{CFM}} \frac{\text{lbm}}{\text{gm}}\right]$$

$$1 = \left[\frac{\text{CFL} \times \text{ft}}{\text{LS-DYNA length unit}}\right] = \left[3.28 \times 10^{-3} \frac{\text{ft}}{\text{mm}}\right]$$

$$1 = \left[\frac{\text{CFT} \times \text{ms}}{\text{LS-DYNA time unit}}\right] = \left[1.0 \frac{\text{ms}}{\text{ms}}\right]$$

$$1 = \left[\frac{\text{CFP} \times \text{psi}}{\text{LS-DYNA pressure unit}}\right] = \left[145.0 \frac{\text{psi}}{\text{MPa}}\right]$$

5. **Limits of Model's Validity.** Define a scaled distance, Z, as follows:

$$Z = \frac{R}{M_{\text{TNT}}^{1/3}},$$

where R is the distance from the charge center to the target and M_{TNT} is the equivalent TNT mass (see Remark 1). The scaled distance determines the range of validity for these models. The spherical airburst model is valid for Z ranging from 0.37 ft/lbm$^{1/3}$ (0.147 m/kg$^{1/3}$) out to 100 ft/lbm$^{1/3}$ (40 m/kg$^{1/3}$). The hemispherical surface burst is valid for Z ranging from 0.45 ft/lbm$^{1/3}$ (0.178 m/kg$^{1/3}$) out to 100 ft/lbm$^{1/3}$ (40 m/kg$^{1/3}$).

For the spherical air burst with ground reflection (BLAST = 4), the same scaled distance can be used to determine validity, except R is now the height of the charge center above the ground. This model is valid for Z ranging from 1.0 ft/lbm$^{1/3}$ (0.397 m/kg$^{1/3}$) out to 7.0 ft/lbm$^{1/3}$ (2.78 m/kg$^{1/3}$)

6. **Axisymmetric Analyses.** Blast loads can be used in 2D axisymmetric analyses. Repeat the second node for the third and fourth nodes of the segment definition in *LOAD_BLAST_SEGMENT and *LOAD_BLAST_SEGMENT_SET.

7. **Surface Burst Model.** The surface blast model is ideal for when a charge is located on or very near the ground. In this case the initial blast wave is

immediately reflected and reinforced by the nearly rigid ground (the model accounts for yielding) to produce a hemispherical reflected wave from the point of the burst. This reflected wave merges with the initial incident wave producing overpressures which are greater than those produced by the initial wave alone. Target points equidistant from the burst point are loaded identically with the surface burst option.

8. **BLSTFOR Components.** The BLSTFOR file (see *DATABASE_BINARY_BLSTFOR) contains blast pressures, blast wind velocity, air density, and wave index. The "wave index", relevant only for BLAST = 4, denotes the nature of the blast pressure applied to the segment, such that,

   EQ.-1: below the ground plane

   EQ.0: no blast pressure

   EQ.1: primary incident wave

   EQ.2: detached ground-reflected wave

   EQ.3: Mach stem region

9. **ConWep.** ConWep is neither embedded in nor coupled with LS-DYNA. The *LOAD_BLAST_ENHANCED feature is based on the work of Randers-Pehrson and Bannister. NEGPHS = 11 gives positive phase duration in close agreement with ConWep, and it zeroes out the negative phase pressure, as in ConWep. NEGPHS = 10 should not be used for analysis because it presents a significant negative phase pressure; it is included only to illustrate this unwanted effect. *LOAD_BLAST_ENHANCED combines incident and reflected pressure according to the work of Randers-Pehrson and Bannister while ConWep computes reflected pressure in a different manner.

10. **Internally Used Values for Ambient Air Pressure and Density.** The following values for ambient air pressure and density are used internally:

$$p = 101.325 \text{ kPa}$$
$$\rho = 1.225 \text{ kg/m}^3$$

These values come into play only when the blast load is coupled to ALE air (see ALEPID in LOAD_BLAST_SEGMENT). Accordingly, the initial density of the air should be set (in *MAT) as well as pressure (through *EOS). Those values should reflect the unit system selected with UNIT in *LOAD_BLAST_ENHANCED.

*LOAD_BLAST_SEGMENT

Purpose: Apply blast pressure loading over a triangular or quadrilateral segment for 3D geometry or line segment for 2D geometry (see *LOAD_BLAST_ENHANCED).

Segment Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	BID	N1	N2	N3	N4	ALEPID	SFNRB	SCALEP
Type	I	I	I	I	I	I	F	F
Default	none	none	none	none	none	none	0.	1.

VARIABLE	DESCRIPTION
BID	Blast source ID (see *LOAD_BLAST_ENHANCED).
N1	Node ID.
N2	Node ID.
N3	Node ID. For line segments on two-dimensional geometries set N3 = N2.
N4	Node ID. For line segments on two-dimensional geometries set N4 = N3 = N2 or for triangular segments in three diemensions set N4 = N3.
ALEPID	Part ID of ALE ambient part underlying this segment to be loaded by this blast (see *PART and *SECTION_SOLID, AET = 5). This applies only when the blast load is coupled to an ALE air domain.
SFNRB	Scale factor for the ambient element non-reflecting boundary condition. Shocks waves reflected back to the ambient elements can be attenuated with this feature. A value of 1.0 works well for most situations. The feature is disabled when a value of zero is specified
SCALEP	Pressure scale factor.

*LOAD_BLAST_SEGMENT_SET

Purpose: Apply blast pressure loading over each segment in a segment set (see *LOAD_-BLAST_ENHANCED).

Segment Set Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	BID	SSID	ALEPID	SFNRB	SCALEP			
Type	I	I	I	F	F			
Default	none	none	↓	0.	1.			

VARIABLE	DESCRIPTION
BID	Blast source ID (see *LOAD_BLAST_ENHANCED).
SSID	Segment set ID (see *SET_SEGMENT).
ALEPID	Part ID of ALE ambient part underlying this segment to be loaded by this blast (see *PART and *SECTION_SOLID, AET = 5). This applies *only* when the blast load is coupled to an ALE air domain.
SFNRB	Scale factor for the ambient element non-reflecting boundary condition. Shocks waves reflected back to the ambient elements can be attenuated with this feature. A value of 1.0 works well for most situations.
SCALEP	Pressure scale factor.

Remarks:

1. **Triangular Segments.** Triangular segments are defined by setting N4 = N3.

2. **Line Segments.** Line segments for two-dimensional geometries are defined by setting N4 = N3 = N2.

***LOAD_BODY**_*OPTION*

Available options include for base accelerations:

X

Y

Z

for angular velocities:

RX

RY

RZ

for loading in any direction, specified by vector components (see About Keyword Option VECTOR):

VECTOR

and to specify a part set:

PARTS

Purpose: Define body force loads due to a prescribed base acceleration or angular velocity using global axes directions. This option applies nodal forces only: it cannot be used to prescribe translational or rotational motion. By default, these body forces do not take into account non-physical mass added via mass scaling, see DT2MS on *CONTROL_TIMESTEP. However, if in addition EMSCL > 0 on *CONTROL_TIMESTEP, then EMSCL ×100% of the added mass contributes to the gravity load.

NOTE: This data applies to all nodes in the complete problem unless a part subset is specified via the *LOAD_BODY_PARTS keyword.

If a part subset with *LOAD_BODY_PARTS, then all nodal points belonging to the subset will have body forces applied.

NOTE: Only one *LOAD_BODY_PARTS card is permitted per deck. To specify, for instance, one body load on one part and another body load on another part use *LOAD_BODY_GENERALIZED instead.

Card Summary:

Card 1a.1. This card is included if and only if the keyword option is X, Y, Z, RX, RY, RZ, or VECTOR.

LCID	SF	LCIDDR	XC	YC	ZC	CID	

Card 1a.2. This card is included if and only if the VECTOR keyword option is used.

V1	V2	V3					

Card 1b. This card is included if and only if the PARTS keyword option is used.

PSID							

Data Cards:

For options X, Y, Z, RX, RY, RZ and VECTOR.

Card 1a.1	1	2	3	4	5	6	7	8
Variable	LCID	SF	LCIDDR	XC	YC	ZC	CID	
Type	I	F	I	F	F	F	I	
Default	none	1.	↓	0.	0.	0.	global	

VARIABLE	DESCRIPTION
LCID	Load curve ID specifying loading, see *DEFINE_CURVE. See Remark 1.
SF	Load curve scale factor. Applies to both LCID and LCIDDR.
LCIDDR	Load curve ID for dynamic relaxation phase (optional). This is needed when dynamic relaxation is defined and a different load curve to LCID is required during the dynamic relaxation phase. Note if LCID is undefined, then no body load will be applied during dynamic relaxation regardless of the value LCIDDR. See *CONTROL_DYNAMIC_RELAXATION. See Remark 1.
XC	x-center of rotation, define for angular velocities.
YC	y-center of rotation, define for angular velocities.

VARIABLE	DESCRIPTION
ZC	z-center of rotation, define for angular velocities.
CID	Coordinate system ID to define acceleration in local coordinate system. The accelerations (LCID) are with respect to CID. EQ.0: Global

For option VECTOR.

Card 1a.2	1	2	3	4	5	6	7	8
Variable	V1	V2	V3					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
V1, V2, V3	Components of vector **V**

For option PARTS.

Card 1b	1	2	3	4	5	6	7	8
Variable	PSID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PSID	Part set ID

Remarks:

1. **Base Accelerations.** Translational base accelerations allow body force loads to be imposed on a structure. Conceptually, base acceleration may be thought of as accelerating the coordinate system in the direction specified, and, thus, the

inertial loads acting on the model are of opposite sign. For example, if a cylinder were fixed to the *yz*-plane and extended in the positive *x*-direction, then a positive *x*-direction base acceleration would tend to shorten the cylinder, i.e., create forces acting in the negative *x*-direction.

Base accelerations are frequently used to impose gravitational loads during dynamic relaxation to initialize the stresses and displacements. During the analysis, in this latter case, the body forces loads are held constant to simulate gravitational loads. When imposing loads during dynamic relaxation, the load curve should slowly ramp up to avoid the excitation of a high frequency response.

2. **Angular Velocity.** Body force loads due to the angular velocity about an axis are calculated with respect to the deformed configuration and act radially outward from the axis of rotation. Torsional effects which arise from changes in angular velocity are neglected with this option. The angular velocity is assumed to have the units of radians per unit time.

3. **Body Force Density.** The body force density is given at a point **P** of the body by:

$$\mathbf{b} = \rho[\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r})] \ ,$$

where ρ is the mass density, $\boldsymbol{\omega}$ is the angular velocity vector, and **r** is a position vector from the origin to point **P**. Although the angular velocity may vary with time, the effects of angular acceleration are not included.

4. **Transient Deformation.** Angular velocities are useful for studying transient deformation of spinning three-dimensional objects. Typical applications have included stress initialization during dynamic relaxation where the initial rotational velocities are assigned at the completion of the initialization, and this option ceases to be active.

Example:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$  *LOAD_BODY_Z
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  Add gravity such that it acts in the negative Z-direction.
$  Use units of mm/ms2.  Since gravity is constant, the load
$  curve is set as a constant equal to 1.  If the simulation
$  is to exceed 1000 ms, then the load curve needs to be
$  extended.
$
$$$  Note: Positive body load acts in the negative direction.
$
*LOAD_BODY_Z

```

About Keyword Option VECTOR:

The vector **V** defines the direction of the body force. Body forces act in the negative direction of the vector **V**.

In the example shown in Figure 31-3, a rectangular sheet metal blank is loaded with gravity which causes it to be deformed by a fixed rigid ball. Given the global coordinate system shown, if the part set ID of the blank is 1, the keywords responsible for specifying the body force (in units of mm, second, tonne and Newton) in positive direction of $(1.0, 1.0, 1.0)$ will be as follows,

```
*LOAD_BODY_PARTS
1
*LOAD_BODY_VECTOR
101, 9810.0
-1.0, -1.0, -1.0
*DEFINE_CURVE
101
0.0, 1.0
10.0, 1.0
```

It is note that straight lines represent a cube with each edge length of 500.0 mm.

Revision Information:

The VECTOR keyword option is available in LS-DYNA R5 Revision 59290 and later releases.

LOAD_BODY_GENERALIZED_*OPTION

Available options include:

SET_NODE

SET_PART

Purpose: Define body force loads due to a prescribed base acceleration or a prescribed angular motion over a subset of the complete problem. The subset is defined by using nodes or parts. Warning: Nodes, which belong to rigid bodies, should not be specified. Rigid bodies must be included within the part sets definitions.

The body forces defined using this command do not take into account non-physical mass added via mass scaling; see *CONTROL_TIMESTEP.

Card Sets. Include as many sets of Cards 1 and 2 as necessary. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	N1/SID	N2	LCID	DRLCID	XC	YC	ZC	
Type	I	I	I	I	F	F	F	
Default	none	none	none	0	0.	0.	0.	

Card 2	1	2	3	4	5	6	7	8
Variable	AX	AY	AZ	OMX	OMY	OMZ	CID	ANGTYP
Type	F	F	F	F	F	F	I	A
Default	0.	0.	0.	0.	0.	0.	global	CENT
Remarks	1, 2	1, 2	1, 2	3, 4, 5	3, 4, 5	3, 4, 5		3

VARIABLE	DESCRIPTION
N1/SID	Beginning node ID for body force load or the node or part set ID.

VARIABLE	DESCRIPTION
N2	Ending node ID for body force load. Set to zero if a set ID is defined.
LCID	Load curve ID; see *DEFINE_CURVE.
DRLCID	Load curve ID for dynamic relaxation phase. Only necessary if dynamic relaxation is defined. See *CONTROL_DYNAMIC_RELAXATION.
XC	x-center of rotation. Define only for angular motion.
YC	y-center of rotation. Define only for angular motion.
ZC	z-center of rotation. Define only for angular motion.
AX	Scale factor for acceleration in x-direction
AY	Scale factor for acceleration in y-direction
AZ	Scale factor for acceleration in z-direction
OMX	Scale factor for x-angular velocity or acceleration
OMY	Scale factor for y-angular velocity or acceleration
OMZ	Scale factor for z-angular velocity or acceleration
CID	Coordinate system ID to define acceleration in the local coordinate system. The coordinate (XC, YC, ZC) is defined with respect to the local coordinate system if CID is nonzero. The accelerations, LCID and their scale factors are with respect to CID. EQ.0: global
ANGTYP	Type of body loads due to angular motion: EQ.CENT: body load from centrifugal acceleration, $\rho[\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r})]$. EQ.CORI: body load from Coriolis-type acceleration, $2\rho(\boldsymbol{\omega} \times \mathbf{v})$. EQ.ROTA: body load from rotational acceleration, $\rho(\boldsymbol{\alpha} \times \mathbf{r})$,

VARIABLE	DESCRIPTION
	where $\boldsymbol{\omega}$ is the angular velocity, $\boldsymbol{\alpha}$ is the angular acceleration, **r** is the position vector relative to center of rotation and **v** is the velocity vector

Remarks:

1. **Base Accelerations.** Translational base accelerations allow body forces loads to be imposed on a structure. Conceptually, base acceleration may be thought of as accelerating the coordinate system in the direction specified, and, thus, the inertial loads acting on the model are of opposite sign. For example, if a cylinder were fixed to the *yz*-plane and extended in the positive *x*-direction, then a positive *x*-direction base acceleration would tend to shorten the cylinder, that is, create forces acting in the negative *x*-direction.

2. **Gravitational Loads.** Base accelerations are frequently used to impose gravitational loads during dynamic relaxation to initialize the stresses and displacements. During the analysis, in this latter case, the body forces loads are held constant to simulate gravitational loads. When imposing loads during dynamic relaxation, the load curve should slowly ramp up to avoid the excitation of a high frequency response.

3. **Angular Motion.** Body force loads due to the angular motion about an axis are calculated with respect to the deformed configuration. When ANGYP = CENT or CORI, torsional effects which arise from changes in angular velocity are neglected. Such torsional effects can be taken into account by setting ANGTYP = ROTA. The angular velocity is assumed to have the units of radians per unit time, accordingly angular acceleration has the units of radians/time^2.

4. **Body Force Density.** With ANGTYP = CENT, the body force density at a point **P** of the body (similar to *LOAD_BODY) is given by:

$$\mathbf{b} = \rho[\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r})] \ ,$$

   where ρ is the mass density, $\boldsymbol{\omega}$ is the angular velocity vector, and **r** is a position vector from the origin to point **P**.

   One of the enhancements in *LOAD_BODY_GENERALIZED, compared to *LOAD_BODY, is that it provides additional options ANGTYP = CORI and ANGTYP = ROTA to include Coriolis and Euler forces, respectively.

5. **Transient Deformation.** Angular velocities are useful for studying transient deformation of spinning three-dimensional objects. Typical applications have included stress initialization during dynamic relaxation where the initial

rotational velocities are assigned at the completion of the initialization, and this option ceases to be active.

*LOAD_BODY_POROUS

Purpose: Define the effects of porosity on the flow with body-force-like loads applied to the ALE element nodes. Ergun porous flow assumptions are used. This only applies to non-deformable (constant-porosity), fully saturated porous media. This model only works with a non-zero and constant viscosity fluid defined using either *MAT_NULL or *MAT_ALE_VISCOUS card.

Card Sets. Include as many sets of Cards 1 and 2 as necessary. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	SIDTYP	AX	AY	AZ	BX	BY	BZ
Type	I	I	F	F	F	F	F	F
Default	none	0	0.0	0.0	0.0	0.0	0.0	0.0

Card 2	1	2	3	4	5	6	7	8
Variable	AOPT							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
SID	Set ID of the ALE fluid part subjected to porous flow condition.
SIDTYP	Set ID type of the SID above: EQ.0: Part set ID (default) EQ.1: Part ID
AX, AY, AZ	Viscous coefficients for viscous terms in global x, y, and z directions (see Remark 1). If $A_x \neq 0.0$ and $A_y = A_z = 0.0$, then an isotropic viscous permeability condition is assumed for the porous medium.

VARIABLE	DESCRIPTION
BX, BY, BZ	Inertial coefficients for inertia terms in global x, y, and z directions (see Remarks 1 and 2). If $B_x \neq 0.0$, and $B_y = B_z = 0.0$, then an isotropic inertial permeability condition is assumed for the porous medium.
AOPT	Material axis option: EQ.0: Inactive EQ.1: The forces are applied in a local system attached to the ALE solid (see CTYPE = 12 and DIREC = 1 in *CONSTRAINED_LAGRANGE_IN_SOLID).

Remarks:

1. **Ergun Porous Flow Model.** Consider the basic general Ergun equation for porous flow in one direction:

$$\frac{\Delta P}{\Delta L} = \frac{\mu}{k_1} V_s + \frac{\rho}{k_2} {V_s}^2 \ ,$$

where

ρ = Fluid Density
μ = Fluid dynamic vicosity
$V_s = \dfrac{4Q}{\pi D^2}$ = Superficial fluid velocity
Q = Overall volume flow rate $\left(\dfrac{\mathrm{m}^3}{\mathrm{s}}\right)$
D = Porous channel characteristic width (perpendicular to ΔL)
$k_1 = \dfrac{\varepsilon^3 {d_p}^2}{150(1-\varepsilon)^2}$ = Permeability parameter
$k_2 = \dfrac{\varepsilon^3 d_p}{1.75(1-\varepsilon)}$ = Passability parameter
ε = Porosity= $\dfrac{\text{total pore volume}}{\text{total media volume}}$
d_p = Effective particle diameter

The above equation can be generalized into 3 dimensional flows where each component may be written as

$$-\frac{dP}{dx_i} = A_i \mu V_i + B_i \rho |V_i| V_i$$

where $i = 1,2,3$ refers to the global coordinate directions (no summation intended for repeated indices), μ is the constant dynamic viscosity, ρ is the fluid density,

V_i is the fluid velocity components, A_i is analogous to k_1 above, and B_i is analogous to k_2 above. A matrix version can be defined by ALE elements with *DEFINE_POROUS_ALE.

2. **Inertia Coefficients.** If $B_i = 0$, the equation is reduced to simple Darcy Law for porous flow (may be good for sand-like flow). For coarse grain (rocks) media, the inertia term will be important, so you need to input these coefficients.

*LOAD_BRODE

Purpose: Define Brode function for application of pressure loads due to explosion; see Brode [1970]. See also *LOAD_SEGMENT, *LOAD_SEGMENT_SET, or *LOAD_SHELL.

Card 1	1	2	3	4	5	6	7	8
Variable	YLD	BHT	XBO	YBO	ZBO	TBO	TALC	SFLC
Type	F	F	F	F	F	F	I	I
Default	0.0	0.0	0.0	0.0	0.0	0.0	0	0

Card 2	1	2	3	4	5	6	7	8
Variable	CFL	CFT	CFP					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
YLD	Yield, *W*, (Kt, equivalent tons of TNT). This parameter is constant yield unless SFLC is defined. In that case it becomes a parameter for calculating the variable yield where it will be referenced as YLD. See Remark 1.
BHT	Height of burst.
XBO	*x*-coordinates of Brode origin.
YBO	*y*-coordinates of Brode origin.
ZBO	*z*-coordinates of Brode origin.
TBO	Time offset of Brode origin.
TALC	Load curve number giving time of arrival as a function of range relative to Brode origin (space, time). See *DEFINE_CURVE and Remark 1.

VARIABLE	DESCRIPTION
SFLC	Load curve number giving yield scaling, W_s, as a function of scaled time. Scaled time is time relative to the Brode origin, t_B, divided by $\text{YLD}^{1/3}$, that is, $t_B/\text{YLD}^{1/3}$. See *DEFINE_CURVE and Remark 1.
CFL	Conversion factor - kft to LS-DYNA length units.
CFT	Conversion factor - milliseconds to LS-DYNA time units.
CFP	Conversion factor - psi to LS-DYNA pressure units.

Remarks:

1. **Yield Parameter.** If the curves, TALC and SFLC, are defined, a variable yield as opposed to a constant yield is assumed. *Both* load curves must be specified for the variable yield option. If this option is used, the shock time of arrival is found from the time of arrival curve. The yield used in the Brode formulas is computed by taking the yield scaling value, W_s, at the current scaled time ($t_B/\text{YLD}^{1/3}$) and multiplying W_s by the constant yield input in field YLD, that is,

$$W\Big|_{t_B} = W_s\Big|_{t_B/\text{YLD}^{1/3}} \times \text{YLD} \ .$$

*LOAD_DENSITY_DEPTH

Purpose: Define density versus depth for gravity loading. This option has been occasionally used for analyzing underground and submerged structures where the gravitational preload is important. The purpose of this option is to initialize the hydrostatic pressure field at the integration points in the element. See also GRAV in *PART.

This card should be only defined once in the input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID	GC	DIR	LCID				
Type	I	F	I	I				
Default	0	0.0	1	none				
Remarks	1,2			3				

VARIABLE	DESCRIPTION
PSID	Part set ID, see *SET_PART. If a PSID of zero is defined, then all parts are initialized.
GC	Gravitational acceleration value.
DIR	Direction of loading: EQ.1: global x, EQ.2: global y, EQ.3: global z.
LCID	Load curve ID defining density as a function of depth; see *DEFINE_CURVE.

Remarks:

1. **Hydrostatic Pressure.** Density as a function of depth curves are used to initialize hydrostatic pressure due to gravity acting on an overburden material. The hydrostatic pressure acting at a material point at depth, d, is given by:

$$p = -\int_{d}^{d_{\text{surface}}} \rho(z) g dz \ ,$$

where p is pressure, d_{surface}, is the depth of the surface of the material to be initialized (usually zero), $\rho(z)$ is the mass density at depth z, and g is the acceleration of gravity. This integral is evaluated for each integration point. Depth may be measured along any of the global coordinate axes, and the sign convention of the global coordinate system should be respected. The sign convention of gravity also follows that of the global coordinate system. For example, if the positive z-axis points "up", then gravitational acceleration should be input as a negative number.

2. **Limitations.** For this option there is a limit of 12 parts that can be defined by PSID, unless all parts are initialized.

3. **Depth LCID.** Depth is the ordinate of the curve and is input as a descending x, y, or z coordinate value. Density is the abscissa of the curve and must vary (increase) with depth, that is, an infinite slope is not allowed.

*LOAD_ERODING_PART_SET

Purpose: Apply a pressure load to the exposed surface composed of solid elements that may erode.

Card Sets. Include as many sets of Cards 1 and 2 as necessary. This input terminates at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	ID	LCID	SF	AT	PSID	BOXID	MEM	ALPHA
Type	I	I	F	F	I	I	I	F
Default	none	none	1.0	0.0	none	0	50	80

Card 2	1	2	3	4	5	6	7	8
Variable	IFLAG	X	Y	Z	BETA			
Type	I	F	F	F	F			
Default	0	0.0	0.0	0.0	90			

VARIABLE	DESCRIPTION
ID	ID number.
LCID	Load curve ID defining pressure as a function of time; see *DEFINE_CURVE. LT.0: Pressure determined from certain *LOAD keywords. See Remark 1.
SF	Scale factor.
AT	Arrival time.
PSID	Part set ID; see *SET_PART.

VARIABLE	DESCRIPTION
BOXID	Box ID; see *DEFINE_BOX. Any segment that would otherwise be loaded but whose centroid falls outside of this box is not loaded.
MEM	Extra memory, in percent, to be allocated above the initial memory for storing the new load segments exposed by the erosion.
ALPHA	The maximum angle (in degrees) permitted between the normal of a segment at its centroid and the average normal at its nodes. This angle is used to eliminate interior segments.
IFLAG	Flag for choosing a subset of the exposed surface that is oriented towards a blast or other loading source. The vector from the center of the element to the source location must be within an angle of BETA of the surface normal. If IFLAG > 0, then the subset is chosen, otherwise if IFLAG = 0, the entire surface is loaded.
X, Y, Z	Optional source location.
BETA	Maximum permitted angle (in degrees) between the surface normal and the vector to the source. The exposed segment is not loaded if the calculated angle is greater than BETA.

Remarks:

1. **Special Values Input for LCID.** If LCID is input as:

   a) -1, then the Brode function is used to determine the pressure for the segments; see *LOAD_BRODE.

   b) -2, then an empirical air blast function is used to determine the pressure for the segments; see *LOAD_BLAST.

   c) An integer < -2, then LCID references BID from *LOAD_BLAST_ENHANCED and the air blast function specified with the referenced *LOAD_BLAST_ENHANCED instantiation is used to determine the pressure for the segments.

2. **Load Curve Multipliers.** The load curve multipliers may be used to increase or decrease the pressure. The time value is not scaled.

3. **Activation Time.** The activation time, AT, is the time during the solution that the pressure begins to act. Until this time, the pressure is ignored. The function value of the load curves will be evaluated at the offset time given by the difference of the solution time and AT, that is solution time − AT.

4. **Requirements.** For proper evolution of the loaded surface, it is a requirement that DTMIN in *CONTROL_TERMINATION be greater than zero and ERODE in *CONTROL_TIMESTEP be set to 1.

*LOAD_EXPANSION_PRESSURE_{OPTION}

To define an ID for the pressure loading, the following option is available:

ID

Purpose: Apply a uniform pressure to a section of a chamber that can vary in size due to a moving edge. For instance, this keyword can be used to apply pressure to a cylinder on one side of a moving piston. See Figure 31-4.

ID Card. Additional card needed for the ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	Heading						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	LCID	SF	AT				
Type	I	I	F	F				
Default	none	none	1.0	0.0				

Card 2	1	2	3	4	5	6	7	8
Variable	NSID	XN	YN	ZN				
Type	I	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
ID	Loading ID
Heading	Description of the loading

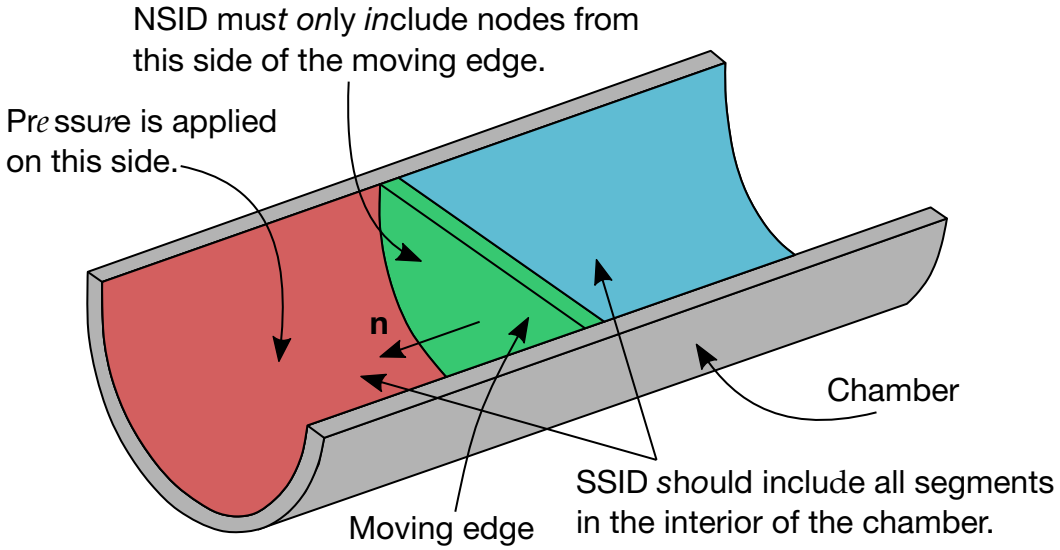

Figure 31-4. Schematic view of half a chamber (cut for clarity). Pressure is applied through this keyword to the red region but not the blue region of the chamber. The normal of the moving edge (in green) must point toward the part of the chamber where the pressure is applied.

VARIABLE	DESCRIPTION
SSID	Segment set ID which specifies the interior of the chamber. As the edge moves, the pressure is applied or could be applied to these segments.
LCID	Load curve ID that defines the pressure as a function of time
SF	Load curve scale factor
AT	Activation time which is the time at which the pressure begins to be applied. Before this time, pressure will not be applied to the chamber. See Remark 2.
NSID	Node set ID that defines the moving edge/plane of the dynamic chamber. Note that this node set must include at least 3 nodes to define a plane. See Remark 1.
XN	*X* component of the initial outward normal of the moving plane/edge. See Remark 1.
YN	*Y* component of the initial outward normal of the moving plane/edge
ZN	*Z* component of the initial outward normal of the moving plane/edge

Remarks:

1. **Moving Plane/Edge.** NSID defines the position of the moving plane/edge. It must include enough nodes (at least 3) on the side facing where the pressure is applied to define a plane. Note that the moving plane/edge is not loaded with this keyword. It should be loaded with the same load curve, LCID, as this keyword using *LOAD_SEGMENT_SET.

   The reference normal direction of the plane/edge defined by XN, YN, and ZN should point toward the part of the chamber where the pressure is applied. At each time step, the normal direction of the edge is found by applying the right-hand rule to the node set in the order of the nodes in the set. Note that for a non-flat edge, the normal can be an average or estimate.

2. **Activation Time.** The activation time, AT, is the time during the solution that the pressure begins to act. Until this time, the pressure is ignored. The function value of the load curves will be evaluated at the offset time given by the difference of the solution time and AT, that is, solution time − AT.

***LOAD_FACE_UVW**_*{OPTION}*

Available options include:

SET

Purpose: Apply a uniform pressure load on a parametric face or a set of parametric faces.

Face/Face Set Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	FID	LCID	SF	AT				
Type	I	I	F	F				
Default	none	none	1.0	0.0				

VARIABLE	DESCRIPTION
FID	Parametric face ID or parametric face set ID for the SET keyword option; see *IGA_FACE_UVW and *SET_IGA_FACE_UVW (see Remark 1)
LCID	Load curve ID (see *DEFINE_CURVE). The load curve must provide pressure as a function of time.
SF	Load curve scale factor
AT	Arrival or birth time for pressure

Remarks:

1. **Parametric Control Points.** The coordinates of the control points in *IGA_2D_NURBS_UVW referenced in *IGA_FACE_UVW are defined in the parametric space of *IGA_3D_NURBS_XYZ. The parametric plane defined by this *IGA_2D_NURBS_UVW must be parallel to one of the parametric *r*-*s*, *s*-*t*, or *t*-*r* planes (u, v, or w must be constant). General cases are currently not supported.

*LOAD_FACE_XYZ_{OPTION}

Available options include:

SET

Purpose: Apply a uniform pressure load on a physical face or a set of physical faces.

Face/Face Set Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	FXYZID	LCID	SF	AT				
Type	I	I	F	F				
Default	none	none	1.0	0.0				

VARIABLE	DESCRIPTION
FXYZID	Physical face ID or physical face set ID for the SET keyword option; see *IGA_FACE_XYZ and *SET_IGA_FACE_XYZ (see Remark 2)
LCID	Load curve ID (see *DEFINE_CURVE). The load curve must provide pressure as a function of time.
SF	Load curve scale factor
AT	Arrival or birth time for pressure

Remarks:

2. **Pressure Load on Partial Areas.** When an instantiation of *IGA_SHELL references this FXYZID, the pressure load will be applied on all elements of this physical face (full area). If you want to apply a pressure load on a certain area of this physical face, you need to define another *IGA_FACE_XYZ for this area and reference this face on *LOAD_FACE_XYZ. This additional *IGA_FACE_XYZ references the same *IGA_2D_NURBS_XYZ of the physical face. It also has its own *IGA_1D_BREP that selects the partial area on the current physical face. No additional *IGA_SHELL is needed since the shell elements have been defined by the current *IGA_SHELL.

***LOAD_GRAVITY_PART**_*{OPTION}*

Available options are:

<BLANK>

SET

Purpose: Define gravity for individual parts. This feature is intended for use with *LOAD_STIFFEN_PART to simulate staged construction. This keyword is available for solids, shells and thick shells as well as beam element types 1, 2, 3, 4, 5, 6, 9, 11, 12 and 13.

Part Cards. Include this card as many times as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	DOF	LC	ACCEL	LCDR	STGA	STGR	
Type	I	I	I	F	I	I	I	
Default	none	none	1.0	0	none	0	0	

VARIABLE	DESCRIPTION
PID/PSID	Part ID (or Part Set ID for the SET option) for application of gravity load
DOF	Direction: enter 1, 2 or 3 for x, y or z
LC	Load curve defining factor as a function of time (or zero if STGA, STGR are defined). See Remark 1.
ACCEL	Acceleration (will be multiplied by factor from curve)
LCDR	Load curve defining as a function of time during dynamic relaxation
STGA	Construction stage at which part is added (optional)
STGR	Construction stage at which part is removed (optional)

Remarks:

1. **Defining Gravity Load.** There are 3 options for defining how the gravity load on a part varies with time.

   a) Curve LC gives factor as a function of time. This overrides the other methods if LC is non-zero. A constant factor of 1.0 is assumed if LC is not specified.

   b) STGA, STGR refer to stages at which part is added and removed – the stages are defined in *DEFINE_CONSTRUCTION_STAGES. If STGA is zero, the gravity load starts at time zero. If not, it ramps up from the small factor FACT (on *CONTROL_STAGED_CONSTRUCTION) up to full value over the ramp time ATR at the start of stage STGA (see *DEFINE_CONSTRUCTION_STAGES). If STGR is zero, the gravity load continues until the end of the analysis. If not, it ramps down from full value to FACT over the ramp time ATR at the start of stage STGR.

   c) *DEFINE_STAGED_CONSTRUCTION_PART can be used instead of *LOAD_GRAVITY_PART to define this loading. During initialization, a *LOAD_GRAVITY_PART card will be created and the effect is the same as using the STGA, STGR method described above; ACCEL is then taken from *CONTROL_STAGED_CONSTRUCTION.

2. **Mass Loading.** This feature calculates the loading from the mass of the elements of the referenced parts only (density × volume). This mass does not include any attached lumped mass elements. Only solid, beam, shell and thick shell elements can be loaded.

*LOAD_HEAT_CONTROLLER

Purpose: Used to define a thermostat control function. The thermostat controls the heat generation within a material by monitoring a remote nodal temperature. Control can be specified as on-off, proportional, integral, or proportional with integral.

Sensor Node Cards. Include up to 20 cards. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NODE	PID	LOAD	TSET	TYPE	GP	GI	
Type	I	I	F	F	I	F	F	
Default	none	none	none	none	none	none	none	

VARIABLE	DESCRIPTION
NODE	Sensor is located at this node number.
PID	Part ID assigned to the elements modeling the heater or cooler being controlled.
LOAD	Heater output q_0. [typical units: W/m^3]
TSET	Controller set point temperature at the location identified by NODE.
TYPE	Type of control function. EQ.1: on-off EQ.2: proportional + integral
GP	Proportional gain.
GI	Integral gain.

Remarks:

The thermostat control function is

$$\dot{q}''' = \dot{q}_0''' \left[G_P (T_{\text{set}} - T_{\text{node}}) + G_I \int_{t=0}^{t} (T_{\text{set}} - T_{\text{node}})\, dt \right]$$

*LOAD_HEAT_EXOTHERMIC_REACTION

Purpose: Define node sets with heat generation coming from battery abuse thermal models. This keyword is intended for thermal runaway studies.

Card Summary:

Card 1. This card is required.

HSID	STYPE	NSID	BT	DT	TMIN	TMAX	TOFF

Card 2a. This card is included if STYPE = 0 or 1.

CSEI0	ASEI	EASEI	MSEI	HSEI	WC		RU

Card 2b. This card is included if STYPE = 2.

ALPHA0	ASEI	EASEI	MSEI	HSEI	WC	P	RU

Card 3a. This card is included if STYPE = 0 or 1.

CNE0	ANE	EANE	MNE	HNE	WCNE	TSEI0	TSEIR

Card 3b. This card is included if STYPE = 2.

N							

Card 4. This card is included if STYPE = 0 or 1.

ALPHA0	APE	EAPE	MPEP1	HPE	WPE	MPEP2	

Card 5. This card is included if STYPE = 0 or 1.

CE0	AE	EAE	ME	HE	WE		

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	HSID	STYPE	NSID	BT	DT	TMIN	TMAX	TOFF
Type	I	I	I	F	F	F	F	F
Default	none	none	none.	0.	10^{16}	0.	10^{16}	0.

VARIABLE	DESCRIPTION
HSID	Heat source ID
STYPE	Heat source model type: EQ.0.or.1: Heat source defined by NREL's 4-Equation model. See Remark 1. EQ.2: Heat source defined by 1-Equation model. See Remark 2.
NSID	Node set ID
BT/DT	Birth and death times for application of heat source term
TMIN/TMAX	Minimum and maximum temperature before heat source activation is triggered
TOFF	Option offset for temperature used in heat source calculation

Solid Electrolyte Interface (SEI) decomposition reaction. This card is included if STYPE = 0 or 1. See Remark 1.

Card 2a	1	2	3	4	5	6	7	8
Variable	CSEI0	ASEI	EASEI	MSEI	HSEI	WC		RU
Type	F	F	F	F	F	F		F
Default	0.	0.	0.	0.	0.	0.		8.314

VARIABLE	DESCRIPTION
CSEI0	Initial concentration of Solid Electrolyte Interphase (SEI)
ASEI	SEI decomposition frequency factor, A_{sei}
EASEI	SEI decomposition activation energy, $E_{a,\text{sei}}$
MSEI	Reaction order for c_{sei}, m_{sei}
HSEI	SEI decomposition heat release, H_{sei}
WC	Specific carbon content in jellyroll, W_c

VARIABLE	DESCRIPTION
RU	Reaction constant. R_u

1-Equation Model Card. This card is included if STYPE = 2. See Remark 2.

Card 2b	1	2	3	4	5	6	7	8
Variable	ALPHA0	ASEI	EASEI	MSEI	HSEI	WC	P	RU
Type	F	F	F	F	F	F	F	F
Default	0.	0.	0.	0.	0.	0.	0.	8.314

VARIABLE	DESCRIPTION
ALPHA0	Initial concentration of α
ASEI	SEI decomposition frequency factor, A_{sei}
EASEI	SEI decomposition activation energy, $E_{a,\text{sei}}$
MSEI	Reaction order for c_{sei}, m_{sei}
HSEI	SEI decomposition heat release, H_{sei}
WC	Specific carbon content in jellyroll, W_c
P	Reaction order of $\log(1-\alpha)$
RU	Reaction constant, R_u

Negative solvent reaction. This card is included if STYPE = 0 or 1. See Remark 1.

Card 3a	1	2	3	4	5	6	7	8
Variable	CNE0/N	ANE	EANE	MNE	HNE	WCNE	TSEI0	TSEIR
Type	F	F	F	F	F	F	F	F
Default	0.	0.	0.	0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
CNE0	Initial concentration value of NE
ANE	Negative solvent frequency factor, A_{ne}
EANE	Negative solvent activation energy, $E_{a,ne}$
MNE	Reaction order forc_{neg}, $m_{ne,n}$
HNE	Negative solvent heat release, H_{ne}
WCNE	Specific carbon content in jellyroll, W_{cne}
TSEI0	Initial value of t_{sei}
TSEIR	Reference t_{sei} value, $t_{sei,ref}$

Second 1-Equation Model Card. This card is included if STYPE = 2. See Remark 2.

Card 3b	1	2	3	4	5	6	7	8
Variable	N							
Type	F							
Default	0.							

VARIABLE	DESCRIPTION
N	$(1-\alpha)$ reaction order, n

Positive Solvent Reaction Card. This card is included if STYPE = 0 or 1. See Remark 1.

Card 4	1	2	3	4	5	6	7	8
Variable	ALPHA0	APE	EAPE	MPEP1	HPE	WPE	MPEP2	
Type	F	F	F	F	F	F	F	
Default	0.	0.	0.	0.	0.	0.	0.	

VARIABLE	DESCRIPTION
ALPHA0	Initial value of α
APE	Positive solvent frequency factor, A_{pe}
EAPE	Positive solvent activation energy, $E_{a,\text{pe}}$
MPEP1	Reaction order for α, $m_{\text{pe,p1}}$
HPE	Positive solvent heat release, H_{pe}
WPE	Specific positive active content, W_p
MPEP2	Reaction order for $(1-\alpha)$, $m_{\text{pe,p2}}$

Electrolyte Decomposition Reaction Card. This card is included if STYPE = 0 or 1. See Remark 1.

Card 5	1	2	3	4	5	6	7	8
Variable	CE0	AE	EAE	ME	HE	WE		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
CE0	Initial concentration value of CE (c_e)
AE	Electrolyte decomposition frequency factor, A_e
EAE	Electrolyte activation energy, $E_{a,e}$
ME	Reaction order for CE, m_e
HE	Electrolyte decomposition heat release, H_e
WE	Specific electrolyte content, W_e

Remarks:

1. **NREL's 4-Equation model.** When this model is selected, the total heat generation can be modelled as four exothermic reactions:

$$S_{\text{abuse\_chem}} = S_{\text{sei}} + S_{\text{ne}} + S_{\text{pe}} + S_{\text{ele}}$$

These reactions are the solid electrolyte interface (SEI) decomposition reaction, the negative solvent reaction, the positive solvent reaction, and the electrolyte decomposition reaction. The models for these reactions are described below. See Hatchard et al 2001 and Kim et al 2007 for details about this model. The equations here are taken from Kim et al 2007.

a) SEI decomposition reaction:

$$\begin{aligned} R_{\text{sei}}(T, c_{\text{sei}}) &= A_{\text{sei}} \times \exp\left(-\frac{E_{a,\text{sei}}}{R_u T}\right) \times c_{\text{sei}}^{m_{\text{sei}}} \\ S_{\text{sei}} &= H_{\text{sei}} \times W_c \times R_{\text{sei}} \\ \frac{dc_{\text{sei}}}{dt} &= -R_{\text{sei}} \end{aligned}$$

Here A_{sei}, $E_{a,\text{sei}}$, m_{sei}, H_{sei}, and W_c are model constants input on Card 2.

b) Negative solvent reaction:

$$\begin{aligned} R_{\text{ne}}(T, c_{\text{neg}}, t_{\text{sei}}) &= A_{\text{ne}} \times \exp\left(-\frac{t_{\text{sei}}}{t_{\text{sei,ref}}}\right) \times c_{\text{neg}}^{m_{\text{ne},n}} \times \exp\left(-\frac{E_{a,\text{ne}}}{R_u T}\right) \\ S_{\text{ne}} &= H_{\text{ne}} \times W_{\text{cne}} \times R_{\text{ne}} \\ \frac{dc_{\text{neg}}}{dt} &= -R_{\text{ne}} \\ \frac{dt_{\text{sei}}}{dt} &= R_{\text{ne}} \end{aligned}$$

Here A_{ne}, $m_{\text{ne,n}}$, $E_{a,\text{ne}}$, H_{ne}, W_{cne}, and $t_{\text{sei,ref}}$ are model constants input on Cards 2 and 3.

c) Positive solvent reaction:

$$\begin{aligned} R_{\text{pe}}(t, \alpha) &= A_{\text{pe}} \times \alpha^{m_{\text{pe,p1}}} \times (1-\alpha)^{m_{\text{pe,p2}}} \times \exp\left(-\frac{E_{a,\text{pe}}}{R_u T}\right) \\ S_{\text{pe}} &= H_{\text{pe}} \times W_p \times R_{\text{pe}} \\ \frac{d\alpha}{dt} &= R_{\text{pe}} \end{aligned}$$

Here A_{pe}, $m_{\text{pe,p1}}$, $m_{\text{pe,p2}}$, $E_{a,\text{pe}}$, H_{pe}, and W_p are model constants

d) Electrolyte decomposition reaction:

$$R_e(T, c_e) = A_e \times \exp\left(-\frac{E_{a,e}}{R_u T}\right) \times c_e^{m_e}$$
$$S_{\text{ele}} = H_e \times W_e \times R_e$$
$$\frac{dc_e}{dt} = -R_e$$

Here A_e, $E_{a,e}$, m_e, H_e, and W_e are model constants

2. **1-Equation reaction model.** Total heat generation due to thermal abuse can be modeled as one exothermic reaction (MacNeil and Dahn 2001):

$$R(T, \alpha) = A_{\text{sei}} \times \alpha^{m_{\text{sei}}} \times (1-\alpha)^n \times (-\ln(1-\alpha))^p \times \exp\left(-\frac{E_{a,\text{sei}}}{R_u T}\right)$$
$$S = H_{\text{sei}} \times W_c \times R$$
$$\frac{d\alpha}{dt} = R$$

Here A_{sei}, m_{sei}, n, p, $E_{a,\text{sei}}$, R_u, H_{sei}, and W_c are input parameters.

LOAD_HEAT_GENERATION_*OPTION

Available options include:

SOLID

SET_SOLID

SHELL

SET_SHELL

Purpose: Define elements or element sets with heat generation.

Generation Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	LCID	MULT	WBLCID	CBLCID	TBLCID		
Type	I	I	F	I	I	I		
Default	none	none	0.	0	0	0		

VARIABLE	DESCRIPTION
SID	Element ID or element set ID, see *ELEMENT_SOLID, *SET_SOLID, *ELEMENT_SHELL, and *SET_SHELL, respectively.
LCID	Volumetric heat generation rate, $\dot{q}'''$, specification. SI units are W/m^3. This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 1). When the reference is to a curve, LCID has the following interpretation: GT.0: $\dot{q}'''$ is defined by a curve consisting of (time, $\dot{q}'''$) data pairs. EQ.0: $\dot{q}'''$ is a constant defined by the value MULT. LT.0: $\dot{q}'''$ is defined by a curve consisting of (temperature, $\dot{q}'''$) data pairs. Enter |-LCID| on the DEFINE_CURVE keyword.
MULT	Volumetric heat generation, $\dot{q}'''$, curve multiplier.

VARIABLE	DESCRIPTION
WBLCID	Load curve ID defining the blood perfusion rate [e.g., kg/m^3 sec] as a function of time.
CBLCID	Load curve ID defining the blood specific heat [e.g., J/kg C] as a function of the blood temperature.
TBLCID	Load curve ID defining the blood temperature [e.g., C] as a function of time.

Remarks:

1. **Volumetric Heat Generation Rate Function.** If LCID references a *DEFINE_FUNCTION, the volumetric heat generation rate can be a function of element centroid coordinates, element centroid velocity components, the element integration point temperature, and solution time, that is, "f(x, y, z, vx, vy, vz, temp, time)."

2. **Blood Heat Transfer to Tissue Rate.** Rate of heat transfer from blood to tissue is $W_b C_b (T_b - T)$ [units: J/m^3 sec].

*LOAD_MASK

Purpose: Apply a distributed pressure load over a three-dimensional shell part. The pressure is applied to a subset of elements that are within a fixed global box and lie either outside or inside of a closed curve in space which is projected onto the surface.

Card Sets. Include as many sets of Cards 1 and 2 as necessary. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	LCID	VID1	OFF	BOXID	LCIDM	VID2	INOUT
Type	I	I	I	F	I	I	I	I
Default	none	none	0	0.	↓	0	none	0

Card 2	1	2	3	4	5	6	7	8
Variable	ICYCLE							
Type	I							
Default	200							

VARIABLE	DESCRIPTION
PID	Part ID (PID). This part must consist of three-dimensional shell elements. To use this option with solid elements the surface of the solid elements must be covered with null shells. See *MAT_NULL.
LCID	Curve ID defining the pressure time history, see *DEFINE_-CURVE.
VID1	Vector ID normal to the surface on which the applied pressure acts. Positive pressure acts in a direction that is in the opposite direction. This vector may be used if the surface on which the pressure acts is relatively flat. EQ.0: the pressure load depends on the orientation of the shell elements as shown in Figure 31-12.

VARIABLE	DESCRIPTION
OFF	Pressure loads will be discontinued if $\|\text{VID1} \cdot \mathbf{n}_{\text{shell}}\| < \text{OFF}$, where $\mathbf{n}_{\text{shell}}$ is the normal vector to the shell element.
BOXID	Only elements inside the box with part ID, PID, are considered. If no ID is given, all elements of PID, are included. When the active list of elements is updated, elements outside the box will no longer have pressure applied, that is, the current configuration is always used.
LCIDM	Curve ID defining the mask. This curve defines (x,y) pairs of points in a local coordinate system defined by the vector ID, VID2. Generally, the curve should form a closed loop, that is, the first point is identical to the last point, and the curve should be flagged as a DATTYP = 1 curve in the *DEFINE_CURVE section. If no curve ID is given, all elements of PID are included with the exception of those deleted by the box. The mask works like the trimming option; see DEFINE_CURVE_TRIM and Figure 17-23.
VID2	Vector ID used to project the masking curve onto the surface of part ID, PID. The origin of this vector determines the origin of the local system that the coordinates of the PID are transformed into prior to determining the pressure distribution in the local system. This vector must be defined if LCIDM is nonzero. See Figure 17-23.
INOUT	Flag for applying pressure to elements inside or outside of projected curve: EQ.0: elements whose center falls inside the projected curve are considered. EQ.1: elements whose center falls outside the projected curve are considered.
ICYCLE	Number of time steps between updating the list of active elements. The list update can be quite expensive and should be done at a reasonable interval. The default is not appropriate for all problems.

*LOAD_MOTION_NODE

Purpose: Apply a concentrated nodal force or moment to a node based on the motion of another node.

Node Cards. Include as many cards as desired. This input ends at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	NODE1	DOF1	LCID	SF	CID1	NODE2	DOF2	CID2
Type	I	I	I	F	I	I	I	I
Default	none	none	none	1.	global	none	none	global

VARIABLE	DESCRIPTION
NODE1	Node ID for the concentrated force.
DOF1	Applicable degrees-of-freedom: EQ.1: x-direction of load action, EQ.2: y-direction of load action, EQ.3: z-direction of load action, EQ.4: moment about the x-axis, EQ.5: moment about the y-axis, EQ.6: moment about the z-axis.
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). The applied force is a function of the applicable degree-of-freedom of NODE2.
SF	Load curve scale factor.
CID1	Coordinate system ID (optional). See Remark 1.
NODE2	Node ID for calculating the force.

VARIABLE	DESCRIPTION
DOF2	Applicable degrees-of-freedom: EQ.1: x-coordinate EQ.2: y-coordinate, EQ.3: z-coordinate, EQ.4: x-translational displacement, EQ.5: y-translational displacement, EQ.6: z-translational displacement, EQ.7: rotational displacement about the x-axis, EQ.8: rotational displacement about the y-axis, EQ.9: rotational displacement about the z-axis. EQ.10: x-translational velocity, EQ.11: y-translational velocity, EQ.12: z-translational velocity, EQ.13: rotational velocity about the x-axis, EQ.14: rotational velocity about the y-axis, EQ.15: rotational velocity about the z-axis.
CID2	Coordinate system ID (optional); see Remark 1.

Remarks:

1. **Coordinate System.** The global coordinate system is the default. The local coordinate system IDs are defined in the *DEFINE_COORDINATE_SYSTEM section.

*LOAD_MOVING_PRESSURE

Purpose: Apply moving pressure loads to a surface. The pressure loads approximate a jet of high velocity fluid impinging on the surface. Multiple surfaces may be defined each acted on by a set of nozzles.

Card 1	1	2	3	4	5	6	7	8
Variable	LOADID							
Type	I							
Default	none							

Nozzle Cards. Define the following cards for each nozzle. Include as many cards as desired. This input ends at the first card with the second field (NODE2) ≤ 3.

Card 2	1	2	3	4	5	6	7	8
Variable	NODE1	NODE2	LCID	CUTOFF	LCIDT	LCIDD	IDIR	LSFLG
Type	I	I	I	F	I	I	I	I
Default	none	none	none	none	0	0	0	0

The following card defines the surface where the nozzles act.

Card 3	1	2	3	4	5	6	7	8
Variable	ID	IDTYPE	NIP					
Type	I	I	I					
Default	none	none	3x3					

VARIABLE	DESCRIPTION
LOADID	Loading ID
NODE1	Node located at the origin of the nozzle

VARIABLE	DESCRIPTION
NODE2	Node located at the head of the nozzle
LCID	Load curve or function ID (see *DEFINE_FUNCTION) defining pressure as a function of radial distance from the center of the jet
CUTOFF	Outer radius of jet. The pressure acting outside this radius is set to zero.
LCIDT	Load curve or function ID (see *DEFINE_FUNCTION), which scales the pressure as a function of time. If a load curve isn't specified, the scale factor defaults to 1.0.
LCIDD	Load curve or function ID (see *DEFINE_FUNCTION), which scales the pressure as a function of distance from the nozzle. If a load curve isn't specified, the scale factor defaults to 1.0.
IDIR	Direction of the pressure applied to the segments (see Remark 1): EQ.0: The normal direction of the segments EQ.1: The direction from the nozzle (NODE1) to the segments EQ.2: The direction from NODE1 to NODE2 EQ.3: Pressure is in the direction from NODE1 to NODE2 but only the normal component is applied on the segments.
LSFLG	Line-of-sight flag: EQ.0: See Remark 2. EQ.1: Pressure is applied on the first-hit segments from the nozzle.
ID	Segment set ID, shell element set ID, shell part set ID, or shell part ID. See IDTYPE below.
IDTYPE	Value that determines the meaning of variable ID. If segments to be loaded are located on solid elements or on thick shell elements, IDTYPE must be set to 0. EQ.0: ID is a segment set ID. EQ.1: ID is a shell set ID. EQ.2: ID is a shell part set ID. EQ.3: ID is a shell part ID.

VARIABLE	DESCRIPTION
NIP	Number of integration points in segment used to compute pressure loads

Remarks:

1. **Pressure Direction.** Pressure directions for different cases of IDIR are illustrated in Figure 31-5. The magnitude of the pressure, p, is determined by the curves given in LCID, LCIDT and LCIDD.

2. **Line of Sight.** When LSFLG = 0, this feature is turned off and the originally implemented algorithm of *LOAD_MOVING_PRESSURE is performed. With this algorithm, pressure is applied differently depending on if MPP or SMP is used. In SMP, it works well for non-disjoint and single-layer surfaces. Examples of applying pressure in SMP are demonstrated in Figure 31-6. For continuous surfaces, the pressure is applied to all segments inside the cylinder defined by the CUTOFF radius. However, with disjoint surfaces, the pressure is only applied to the surface which is cut by the line through NODE1 and NODE2. For the cases with multiple layers, the algorithm does not work consistently and may apply the pressure to the bottom layer as illustrated in Figure 31-6. In MPP, pressure will be applied to all segments inside the cylinder (see Figure 31-7). Note that, in the multiple-layer case, the pressure is applied on all layers.

   When LSFLG = 1, the line-of-sight feature is turned on and the pressure is applied to the first-hit segments (from the nozzle). LS-DYNA will check all the potential segments inside the cylinder to find these segments. Note that this cylinder is defined by the CUTOFF radius, so specifying this radius by a value larger than the effective radius defined by the curve in LCID will unnecessarily increase the computational time. For example, if the curve in LCID is in the range of 0 to 100 with non-zero values only from 0 to 5, the CUTOFF radius should be 5. With this feature, the pressure is applied in the same way in both SMP and MPP (see Figure 31-8).

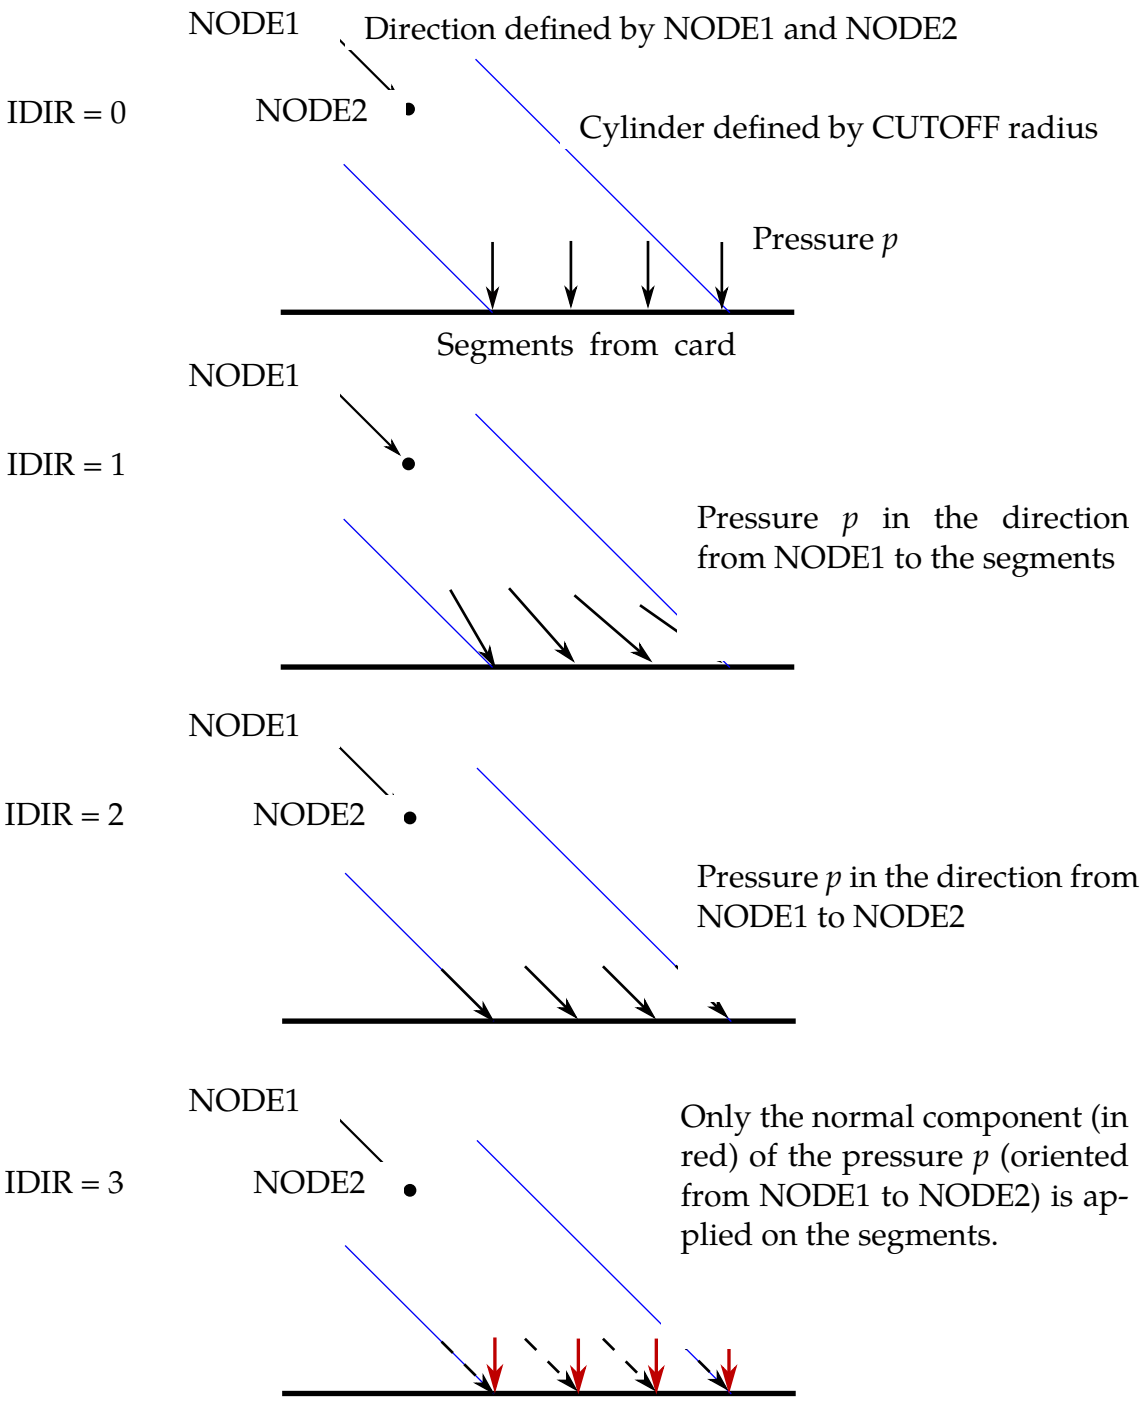

Figure 31-5. Pressure directions for different values of IDIR.

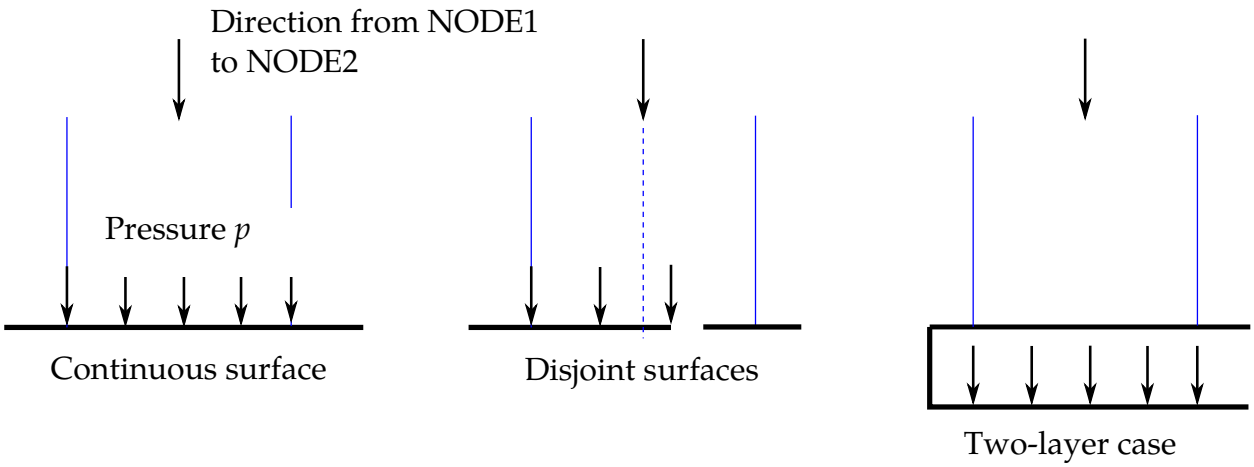

Figure 31-6. Applying pressure in SMP when LSFLG = 0

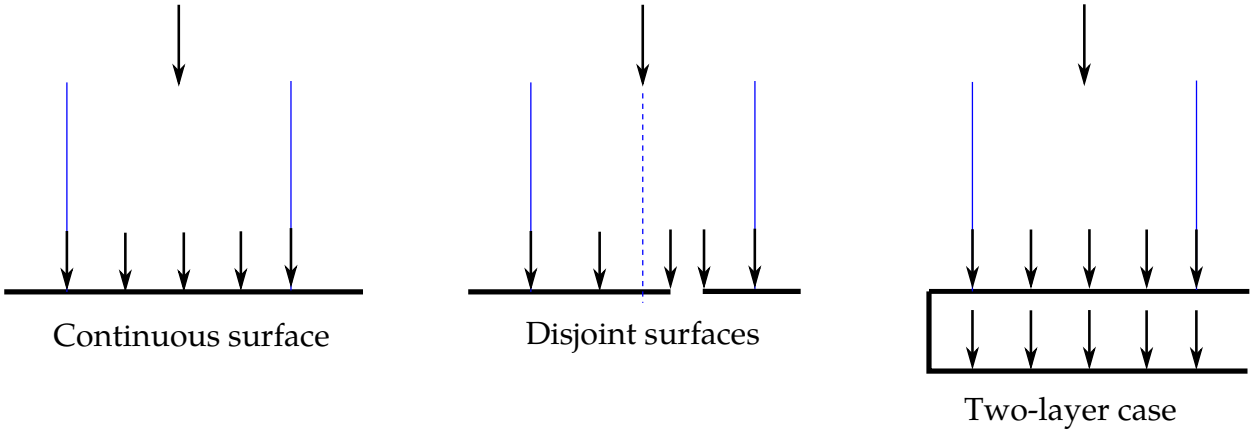

Figure 31-7. Applying pressure in MPP when LSFLG = 0

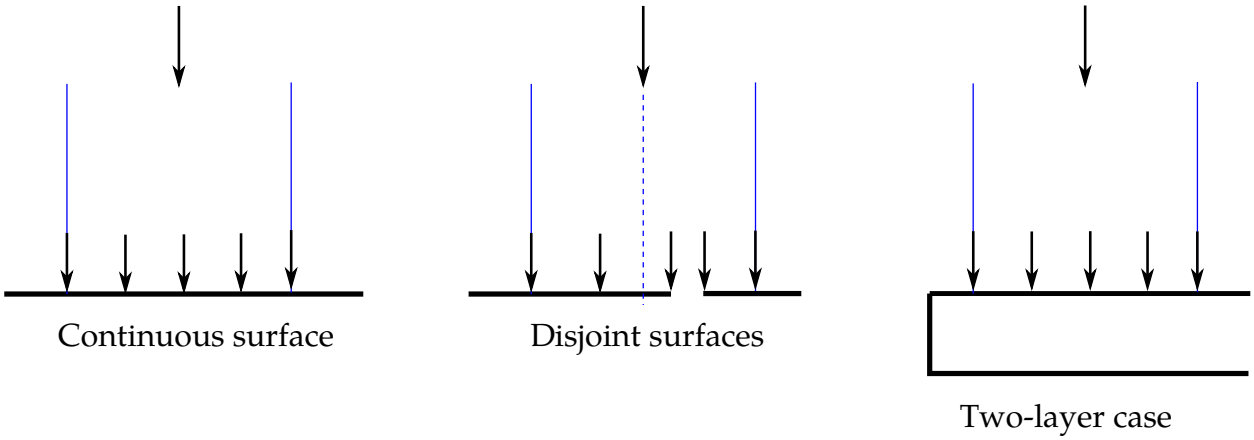

Figure 31-8. Applying pressure in SMP/MPP when LSFLG = 1

LOAD_NODE_*OPTION

Available options include:

POINT

SET

SET_ONCE

For SET_ONCE, the load function (LCID) is only evaluated once. The value is stored and applied to the rest of run.

Purpose: Apply a concentrated nodal force to a node or each node in a set of nodes.

Node/Node Set Cards. Include as many of this card for the SET and POINT keyword options or sets of this card with the next card for the SET_ONCE keyword option. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NID/NSID	DOF	LCID	SF	CID	M1	M2	M3
Type	I	I	I	F	I	I	I	I
Default	none	none	none	1.	global	↓	↓	↓

VARIABLE	DESCRIPTION
NID/NSID	Node ID (POINT keyword option) or nodal set ID (SET or SET_ONCE keyword option); see *SET_NODE.
DOF	Applicable degrees-of-freedom: EQ.1: x-direction of load action, EQ.2: y-direction of load action, EQ.3: z-direction of load action, EQ.4: Follower force (see Remark 2), EQ.5: Moment about the x-axis (see Remark 4), EQ.6: Moment about the y-axis axis (see Remark 4), EQ.7: Moment about the z-axis axis (see Remark 4), EQ.8: Follower moment (see Remarks 2 and 4).

VARIABLE	DESCRIPTION
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION and Remark 5 below). For SET_ONCE, LCID must refer to a function ID. In this case, the function is only evaluated once. The value is stored and applied for the rest of the run.
SF	Load curve scale factor. For SET_ONCE, this field is ignored.
CID	Coordinate system ID (optional); see Remark 1.
M1	Node 1 ID. Only necessary if DOF = 4 or 8; see Remark 2 below.
M2	Node 2 ID. Only necessary if DOF = 4 or 8; see Remark 2 below.
M3	Node 3 ID. Only necessary if DOF = 4 or 8; see Remark 2 below.

SET_ONCE Scale Factor Card. Include this card in a set with the previous card for the SET_ONCE keyword option. Include as many sets as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	LCIDSF							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
LCIDSF	Load curve ID giving a scale factor as a function of time which scales the stored value.

Remarks:

1. **Coordinate Systems.** The global coordinate system is the default. If CID is nonzero, the local coordinate is defined using *DEFINE_COORDINATE_*OPTION*, and furthermore, if *DEFINE_COORDINATE_NODES is used with FLAG=1 to define the local coordinate system, the local coordinate system and thus the direction of the applied load is updated with time; otherwise the

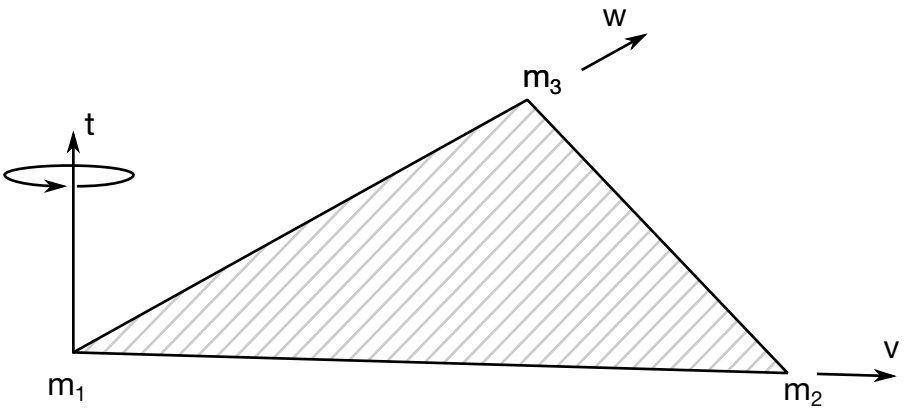

Figure 31-9. Nodes M1, M2, and M3 define a plane. A positive follower force acts in the positive *t*-direction of that plane, that is, along the normal vector of the plane. A positive follower moment puts a counterclockwise torque about the normal vector. The normal vector is found by the cross product $\mathbf{t} = \mathbf{v} \times \mathbf{w}$ where **v** and **w** are vectors as shown.

direction of the load is static. An alternative way to update the direction of the load is to use the follower forces option (see next remark).

2. **Follower Forces.** The current position of nodes M1, M2, and M3 are used to control the direction of a follower force. A positive follower force acts normal to the plane defined by these nodes, and a positive follower moment puts a counterclockwise torque about the *t*-axis. These actions are depicted in Figure 31-9. An alternative way to define the force direction is by setting M3 to any non-positive value, in which case the follower force is in the M1 to M2 direction.

3. **Axisymmetric Elements with Area and Volume Weighting.** For shell formulations 14 and 15, the axisymmetric solid elements with area and volume weighting, respectively, the specified nodal load is per unit length (type14) and per radian (type 15).

4. **Moments.** Moments can only be applied to nodes that have rotational degrees of freedom. Element type and formulation determine the degrees of freedom for a node. For example, the nodes of solid formulation 1 have only 3 translational degrees of freedom and no rotational degrees of freedom.

5. ***DEFINE_FUNCTION for LCID.** The function defined by LCID has 8 arguments: time (float), the 3 current coordinates (float), the 3 reference coordinates (float) and the number of nodes in the node set (int). A function that applies a force proportional to the distance from the initial coordinates would be:

```
f(t,x,y,z,x0,y0,z0,nnodes)= -10.*sqrt ( (x-x0)*(x-x0)+(y-y0)*(y-y0)+(z-z0)*(z-z0) )
```

Example:

*LOAD_NURBS_SHELL_{OPTION}

The following option is available to define an ID for the load applied to a NURBS shell patch:

ID

If the ID is defined, an additional card is required.

Purpose: Apply a load over a NURBS shell patch.

Card Summary:

Card ID. This card is included if and only if the ID option is used.

ID	HEADING

Card 1. This card is required.

PTID	LCID	SF	AT	DT	LTYPE	REGDEF	

Card 1.1. This card is included if and only if LTYPE = "TRACT".

CID	V1	V2	V3				

Card 2a. This card included if and only if LTYPE = "PRESS" or "TRACT" and REGDEF = "RS". Define as many cards as needed.

RMIN	SMIN	RMAX	SMAX				

Card 2b. This card is included if and only if LTYPE = "PRESS" or "TRACT" and REGDEF = "NBEW". Define as many cards as needed.

NE1	NE2	NE3	NE4	NE5	NE6	NE7	NE8

Card 2c. This card is included if and only if LTYPE = "PRESS" or "TRACT" and REGDEF = "NBEP". Define as many cards as needed.

NT1	NT2	NT3	NT4	NTE			

Card 2d. This card is included if and only if LTYPE = "CRV," "CRVS," "CRVT," or "CRVN" and REGDEF = "RS". Define as many cards as needed.

R1	S1	R2	S2				

Card 2e. This card is included if and only if LTYPE = "CRV," "CRVS," "CRVT," or "CRVN" and REGDEF = "NBEP". Define as many cards as needed.

NC1	NC2	NCE					

Data Cards:

ID Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
ID	Loading ID
HEADING	A description of the loading.

Card 1	1	2	3	4	5	6	7	8
Variable	PTID	LCID	SF	AT	DT	LTYPE	REGDEF	
Type	I	I	F	F	F	A10	A10	
Default	none	none	1.	0.	10^{16}	PRESS	RS	

VARIABLE	DESCRIPTION
SSID	NURBS shell patch ID; see *ELEMENT_SHELL_NURBS_PATCH.
LCID	Load curve ID
SF	Load curve scale factor
AT	Arrival/birth time for load.
DT	Death time for load.

VARIABLE	DESCRIPTION
LTYPE	Load type. Default = "PRESS".
	EQ.CRV: Loading is applied on a curve on a NURBS patch, along (V1,V2,V3) of CID coordinate system. The loading dimension is force per unit length along the curve.
	EQ.CRVS: Loading, force per unit length, is applied on a curve on the surface of a NURBS patch, along the local shear direction, CS direction, in Figure 31-10.
	EQ.CRVT: Loading, force per unit length, is applied on a curve on the surface of a NURBS patch, along the local transverse direction, CT direction, in Figure 31-10.
	EQ.CRVN: Loading, force per unit length, is applied on a curve on the surface of a NURBS patch, along the local normal direction, CN direction, in Figure 31-10.
	EQ.PRESS: Surface traction is applied on a region on a NURBS patch, along the opposite direction to the NURBS patch surface normal. The loading unit is force per unit area of the region.
	EQ.TRACT: Surface traction, force per unit area, is applied on a region on a NURBS patch, along (V1,V2,V3) of the coordinate system CID.
REGDEF	The method of defining the region of a NURBS shell patch on which the loading is applied. Default = "RS".
	When LTYPE = "PRESS" or "TRACT":
	EQ.RS: The extreme values of the univariate knot vector in local *r* and *s*-directions are used to define the traction application region; see RK*i* and SK*i* of *ELEMENT_SHELL_NURBS_PATCH. When not defined, the whole NURBS shell patch is subject to the traction.
	EQ.NBEW: The traction loading is applied to the whole NURBS-element which is identified by an interior node on the surface of the NURBS-element, such as NE1 through NE4 in Figure 31-10.
	EQ.NBEP: The traction loading is applied to part of a NURBS-element which is identified by four nodes on the surface of the NURBS-element, such as NT1 through NT4 in Figure 31-10.
	When LTYPE = "CRV," "CRVS," "CRVT," or "CRVN":

VARIABLE	DESCRIPTION
	EQ.RS: The values of (RK, SK) of the starting point and the ending point of a curve. NC1 and NC2 in Figure 31-10, on the surface of the NURBs shell patch are used to define the curve loading application region.
	EQ.NBEP: The curve loading is applied to a curve on a NURBS-element which is identified by two nodes on the surface of the NURBS-element, NC1 and NC2 in Figure 31-10.

"TRACT" Coordinate Card. Include this card if LTYPE = "TRACT." This card defines the traction load's coordinate system and loading direction.

Card 1.1	1	2	3	4	5	6	7	8
Variable	CID	V1	V2	V3				
Type	I	F	F	F				
Default	0	none	none	none				

VARIABLE	DESCRIPTION
CID	Coordinate system ID, only applicable when LTYPE = "TRACT".
V1, V2, V3	Vector direction cosines defining the direction of the traction loading.

Region definition card for surface traction loading using when LTYPE = "PRESS" or "TRACT" and REGDEF = "RS". Define as many cards as needed.

Card 2a	1	2	3	4	5	6	7	8
Variable	RMIN	SMIN	RMAX	SMAX				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
RMIN, SMIN, RMAX, SMAX	The minimum and maximum values of the univariate knot vector in local *r* and *s*-directions of the area on which the pressure loading is applied. See *ELEMENT_SHELL_NURBS_PATCH for details.

Region definition card when LTYPE = "PRESS" or LTYPE = "TRACT" and REGDEF = "NBEW". Define as many cards as needed.

Card 2b	1	2	3	4	5	6	7	8
Variable	NE1	NE2	NE3	NE4	NE5	NE6	NE7	NE8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
NE*i*	An interior node on the surface of the NURBS element on which the traction loading is applied.

Region definition card when LTYPE = "PRESS" or LTYPE = "TRACT" and REGDEF = "NBEP". Define as many cards as needed.

Card 2c	1	2	3	4	5	6	7	8
Variable	NT1	NT2	NT3	NT4	NTE			
Type	I	I	I	I	I			
Default	none	none	none	none	see below			

VARIABLE	DESCRIPTION
NT*i*	Nodes defining an area on the surface of a NURBS element where loading is applied. Using nodes shared with other NURBS elements, such as node NB in Figure 31-10, as NT*i* is not recommended.

VARIABLE	DESCRIPTION
NTE	Optional node used to identify the NURBS element on which the load application area defined by the NT*i*'s is located. NTE is *only* needed when *all* NT*i*'s are shared with other NURBS elements. If not defined, node NT1 has to be owned exclusively by the NURBS element containing the load application region.

Region definition card for curve loading when LTYPE = "CRV", "CRVS", "CRVT", or "CRVN" and REGDEF = "RS". Define as many cards as needed.

Card 2d	1	2	3	4	5	6	7	8
Variable	R1	S1	R2	S2				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
R1, S1, R2, S2	The univariate knot vector in local *r* and *s*-directions of the starting and ending points of the curve on which the curve loading is applied. An example would be the knot vector for nodes NC1 and NC2 as shown in Figure 31-10.

Region definition card for curve loading when LTYPE = "CRV", "CRVS", "CRVT", or "CRVN" and REGDEF = "NBEP". Define as many cards as needed.

Card 2e	1	2	3	4	5	6	7	8
Variable	NC1	NC2	NCE					
Type	I	I	I					
Default	none	none	see below					

VARIABLE	DESCRIPTION
NC*i*	Nodes defining a curve on the surface of a NURBS element where loading is applied. Using nodes shared with other NURBS elements, such as node NB in Figure 31-10, as NC*i* is not recommended.
NCE	Optional node used to identify the NURBS element on which the load application curve defined by the NT*i*'s is located. NCE is *only* needed when *both* NC*i*'s are shared with other NURBS elements. If not defined, node NC1 has to be owned exclusively by the NURBS element containing the load application curve.

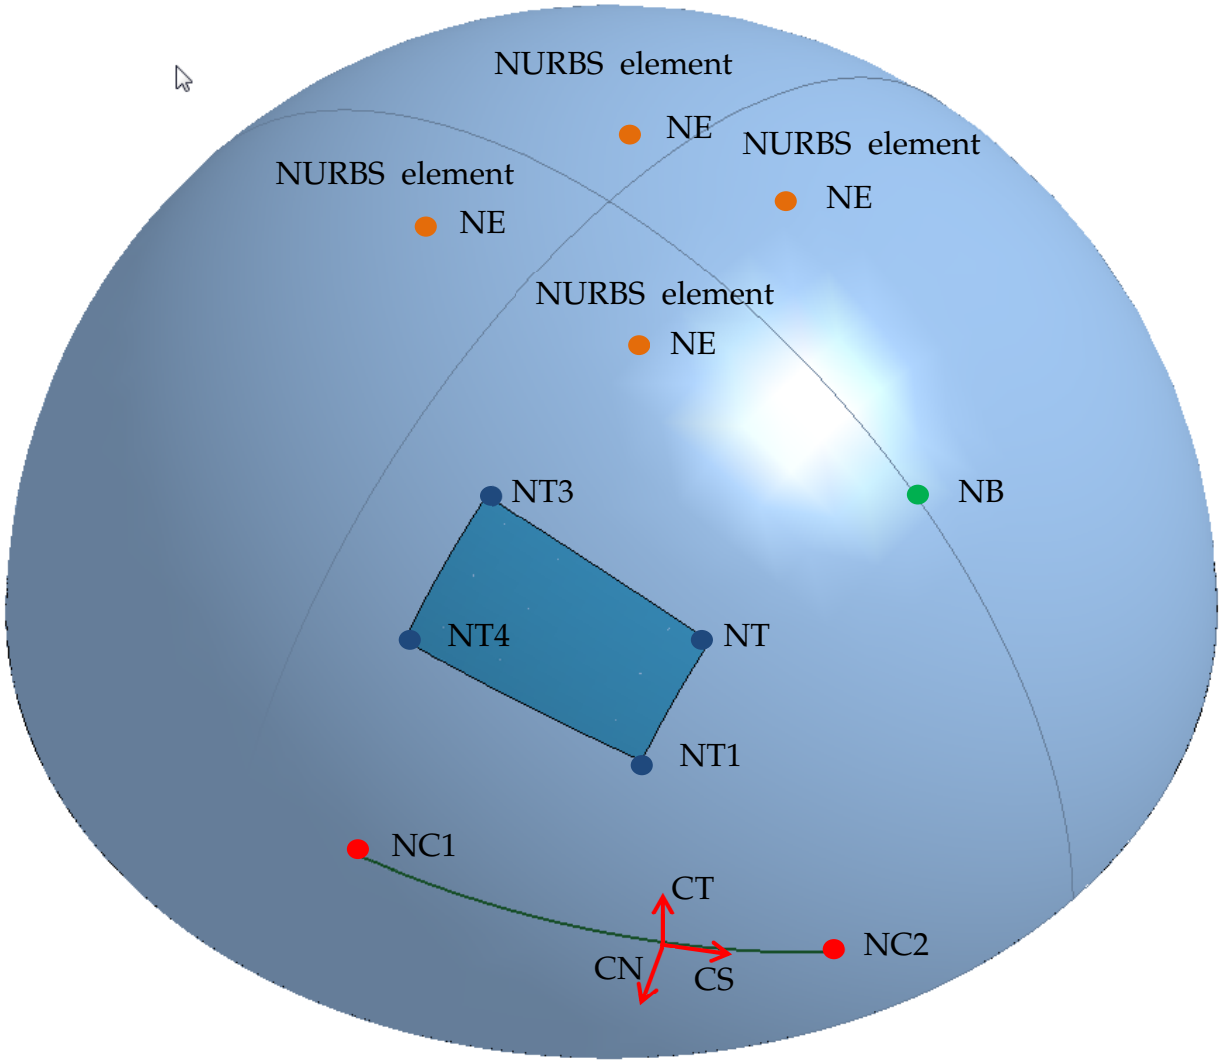

Figure 31-10. NURBS shell patch with four NURBS shell elements.

***LOAD_POINT_UVW**_*{OPTION}*

Available options include:

SET

Purpose: Apply a concentrated force to a parametric point or each parametric point in a set of parametric points.

Point/Point Set Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	DOF	LCID	SF				
Type	I	I	I	F				
Default	none	none	none	1.				

VARIABLE	DESCRIPTION
PID	Parametric point ID or parametric point set ID for the SET keyword option; see *IGA_POINT_UVW and *SET_IGA_POINT_UVW
DOF	Applicable degrees-of-freedom: EQ.1: x-direction of load action, EQ.2: y-direction of load action, EQ.3: z-direction of load action, EQ.5: Moment about the x-axis, EQ.6: Moment about the y-axis axis, EQ.7: Moment about the z-axis axis.
LCID	Load curve ID (see *DEFINE_CURVE)
SF	Load curve scale factor

*LOAD_PYRO_ACTUATOR

Purpose: Calculate forces from a pyrotechnic actuator between nodes/segments. The main application in mind is active hood lifters for pedestrian protection. The keyword models the expansion/contraction of the gas chamber in a piston actuator using a mass flow curve, the chamber cross section area, and cylinder length determined by the nodes/segments. It uses the same gas law as *AIRBAG_SIMPLE_AIRBAG_MODEL but does not require modeling the chamber/piston. You can access chamber solution data by including *DATABASE_PYRO in the input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	ID1	ID2	CSA	VOL	PRS	DENS	ATIME
Type	I	I	I	F	F	F	F	F

Card 2	1	2	3	4	5	6	7	8
Variable	MCID	CV	CP	TEMP				
Type	F	F	F					

VARIABLE	DESCRIPTION
ID	Unique ID for actuator
ID1	Node or segment set where forces act on one side of the chamber (see Remarks): GT.0: Node ID LT.0: |ID1| is a segment set ID.
ID2	Node or segment set where forces act on the other side of the chamber (see Remarks): GT.0: Node ID LT.0: |ID2| is a segment set ID.
CSA	Chamber cross section area
VOL	GT.0: Initial chamber volume

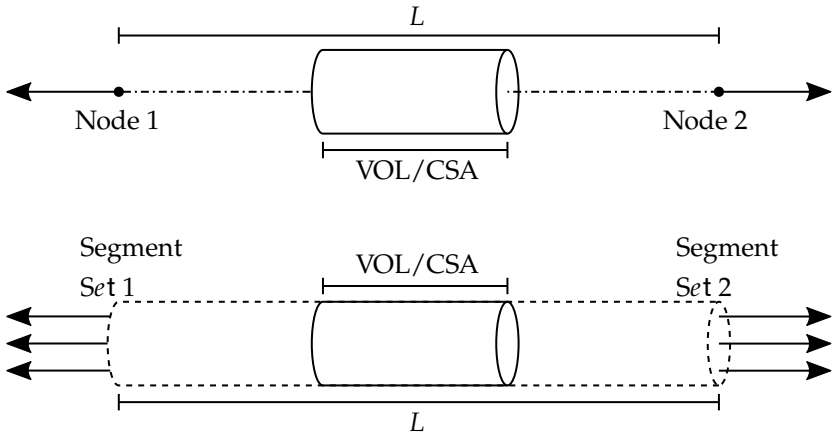

Figure 31-11. Model of a chamber between nodes or segments. For VOL > 0.0, the initial chamber length is VOL/CSA which may be shorter or longer than the node/set distance *L*.

VARIABLE	DESCRIPTION
	EQ.0: Initial chamber volume given by distance between ID1 and ID2. See Remarks and Figure 31-11.
PRS	Ambient pressure
DENS	Ambient gas density
ATIME	Activation time
MCID	Mass flow curve ID (mass flow as function of time)
CV	Specific heat capacity at constant pressure
CP	Specific heat capacity at constant volume
TEMP	Gas generator temperature

Remarks:

This feature calculates axial forces resulting from pressure in a (cylindric) chamber of varying length. ID1 and ID2 can be segment sets or single nodes upon which the forces act. Before the activation time, ATIME,

$$p(t) = \text{PRS} \ .$$

Starting at the activation time, LS-DYNA solves the following pressure ODE:

$$\dot{p}(t) = \frac{\gamma}{V(t)}\left(R \times \text{TEMP} \times \text{MCID}(t) - p(t)\dot{V}(t)\right) \ .$$

where

$$R = \mathrm{CP} - \mathrm{CV}, \qquad \gamma = \frac{\mathrm{CP}}{\mathrm{CV}} \ .$$

The chamber volume is given by

$$V(t) = \begin{cases} \big(L(t) - L(\mathrm{ATIME})\big) \times \mathrm{CSA} + \mathrm{VOL}, & \mathrm{VOL} > 0, \\ L(t) \times \mathrm{CSA}, & \mathrm{VOL} = 0, \end{cases}$$

where the length, $L(t)$, is the current distance between the nodes/sets ID1 and ID2. Note that for VOL > 0.0, the actual chamber length may be shorter or longer than the distance between ID1 and ID2. For VOL $= 0$, ID1 and ID2 mark the endpoints of the chamber. If ID1 and ID2 are nodes, the initial length must be greater than 0 to calculate the direction of the forces on the nodes. We assume the segment sets are planar, parallel, and form the two ends of a chamber. The forces are applied in the direction of the segment normal vectors.

*LOAD_PZE

Purpose: Apply a concentrated or distributed electric charge over a set of segments or nodes with piezoelectric properties.

Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SETID	LCID	SF	SETYP				
Type	I	I	F	A				
Default	none	0	none	NSET				

VARIABLE	DESCRIPTION
SETID	Set ID; see *SET_SEGMENT or *SET_NODE.
LCID	Load curve gives concentrated charge (in electric charge units) or distributed electric charge (in unit of electric charge per unit area) vs. time.
SF	Scale factor on curve or constant electric charge if LCID = 0.
SETYP	Type of SETID EQ.NSET: SETID is a node set. EQ.SEGSET: SETID is a segment set.

***LOAD_REMOVE_PART**_*{OPTION}*

Available options include:

<BLANK>

SET

Purpose: Delete the elements of a part in a staged construction simulation. Shock effects are prevented by gradually reducing the stresses prior to deletion. This feature is available for solid, shell, thick shell and beam elements.

Part Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	TIME0	TIME1	STGR				
Type	I	F	F	I				
Default	none	0.	0.	0				

VARIABLE	DESCRIPTION
PID	Part ID (or Part Set ID for the SET keyword option) for deletion
TIME0	Time at which stress reduction starts
TIME1	Time at which stresses become zero and elements are deleted
STGR	Construction stage at which the part is removed (optional)

Remarks:

There are 3 methods to define the part removal time:

1. TIME0 and TIME1 override all the other methods if non-zero.

2. STGR refers to the stage at which the part is removed; the stages are defined in *DEFINE_CONSTRUCTION_STAGES. This method is equivalent to setting TIME0 and TIME1 equal to the start and end of the ramp time at the beginning of stage STGR.

3. *DEFINE_STAGED_CONSTRUCTION_PART can be used instead of *LOAD_-REMOVE_PART to achieve the same effect.

*LOAD_RIGID_BODY

Purpose: Apply a concentrated nodal force to a rigid body. The force is applied at the center of mass or a moment is applied around a global axis. As an option, local axes can be defined for force or moment directions.

Rigid Body Cards. Include as many Rigid Body Cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	DOF	LCID	SF	CID	M1	M2	M3
Type	I	I	I	F	I	I	I	I
Default	none	none	none	1.	global	0	0	0

VARIABLE	DESCRIPTION
PID	Part ID of the rigid body; see *PART_*OPTION*.
DOF	Applicable degrees-of-freedom: EQ.1: *x*-direction of load action, EQ.2: *y*-direction of load action, EQ.3: *z*-direction of load action, EQ.4: follower force; see Remark 2, EQ.5: moment about the *x*-axis, EQ.6: moment about the *y*-axis, EQ.7: moment about the *z*-axis. EQ.8: follower moment; see Remark 2.
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION and Remark 3). GT.0: force as a function of time. LT.0: force as a function of the absolute value of the rigid body displacement. This option only applies to load curves.
SF	Load curve scale factor

VARIABLE	DESCRIPTION
CID	Coordinate system ID. See Remark 1.
M1	Node 1 ID. Only necessary if DOF = 4 or 8; see Remark 2.
M2	Node 2 ID. Only necessary if DOF = 4 or 8; see Remark 2.
M3	Node 3 ID. Only necessary if DOF = 4 or 8; see Remark 2.

Remarks:

1. **Coordinate System.** The global coordinate system is the default. The local coordinate system ID's are defined in the *DEFINE_COORDINATE_SYSTEM section. This local axis is fixed in inertial space, i.e., it does not move with the rigid body.

2. **Follower Force and Moments.** Nodes M_1, M_2, and M_3 must be defined for a follower force or moment. The follower force acts normal to the plane defined by these nodes as depicted in Figure 31-9. The positive *t*-direction is found by the cross product $\mathbf{t} = \mathbf{v} \times \mathbf{w}$ where **v** and **w** are vectors as shown. The follower force is applied at the center of mass. A positive follower moment puts a counterclockwise torque about the *t*-axis. An alternative way to define the force direction is by setting M_3 to any non-positive value, in which case the follower force is in the M_1 to M_2 direction.

3. **Force Function.** When LCID defines a function, the function has seven arguments: time, the 3 current coordinates for the center of mass, and the 3 reference coordinates. A function that applies a force proportional to the distance from the initial coordinates would be

```
f(t,x,y,z,x0,y0,z0)= -10.*sqrt ( (x-x0)*(x-x0)+(y-y0)*(y-y0)+(z-z0)*(z-z0) ).
```

Example:

```

*LOAD_SEGMENT_{OPTION}

To define an ID for the segment loading, the following option is available:

ID

If the ID is defined, an additional card is required.

Purpose: Apply the distributed pressure load over one triangular or quadrilateral segment defined by four, six, or eight nodes, or in the case of two-dimensional geometries, over one two-noded line segment. The pressure and node numbering convention are specified in Figure 31-12. To apply a uniform pressure, see Remark 5.

ID Card. Additional card for the ID keyword option.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card 2	1	2	3	4	5	6	7	8
Variable	LCID	SF	AT	N1	N2	N3	N4	N5
Type	I	F	F	I	I	I	I	I
Default	none	1.	0.	none	none	none	none	none

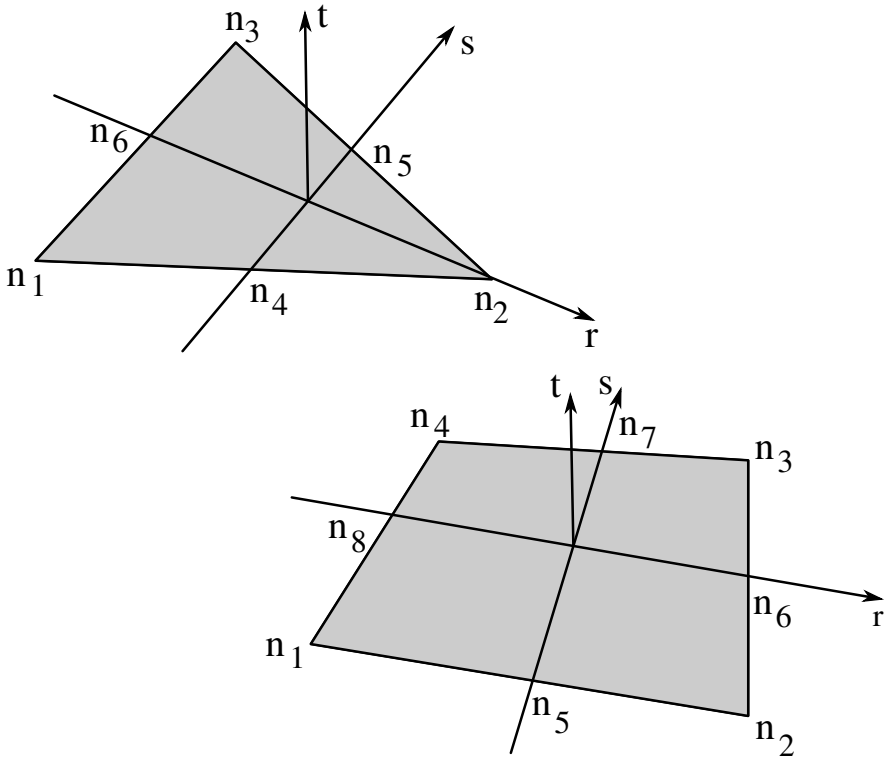

Figure 31-12. Nodal numbering for pressure segments in three-dimensional geometries. Positive pressure acts in the negative **t**-direction.

Additional card for when N5 ≠ 0.

Card 3	1	2	3	4	5	6	7	8
Variable	N6	N7	N8					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
ID	Loading ID
HEADING	A description of the loading.
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). See Remark 1.
SF	Load curve scale factor. See Remark 2.

VARIABLE	DESCRIPTION
AT	Arrival time for pressure or birth time of pressure. See Remark 3.
N1	Node ID
N2	Node ID
N3	Node ID. See Remark 4.
N4	Node ID. See Remark 4.
N5	Mid-side node ID, if applicable. See Figure 31-12.
N6	Mid-side node ID, if applicable. See Figure 31-12.
N7	Mid-side node ID, if applicable. See Figure 31-12.
N8	Mid-side node ID, if applicable. See Figure 31-12.

Remarks:

1. **Empirical Functions for Pressure.** If LCID is input as -1, then the Brode function is used to determine the pressure for the segments; see *LOAD_BRODE. If LCID is input as -2, then an empirical airblast function is used to determine the pressure for the segments; see *LOAD_BLAST.

2. **Load Curve Multipliers.** The load curve multipliers may be used to increase or decrease the pressure. The time value is not scaled.

3. **Activation Time.** The activation time, AT, is the time during the solution that the pressure begins to act. Until this time, the pressure is ignored. The function value of the load curves will be evaluated at the offset time given by the difference of the solution time and AT, that is, solution time − AT.

4. **Triangular Segments and Two-Dimensional Geometries.** Triangular segments without mid-side nodes are defined by setting N4 = N3. Segments for two-dimensional geometries are defined by two nodes, N1 and N2. Leave N3 and N4 as zero or set both equal to N2. A positive pressure acts on the segment in the $\hat{\mathbf{z}} \times (\text{N1} - \text{N2})$ direction where $\hat{\mathbf{z}}$ is the unit vector in the z-direction and (N1 − N2) is the vector from N1 to N2.

5. **Uniform Pressure.** To apply a uniform pressure to type 17 tetrathedral elements, 4 triangular segments should be defined for each loaded face of an element. Three of the segments should each have one corner node and the two

adjacent mid-side nodes. The 4th segment should be made from the 3 mid-side nodes.

To apply a uniform pressure to type 16 tetrahedral elements or type 24 triangular shell elements, one 6 node segment may be defined for each loaded face. However, LS-DYNA will accept and properly treat "any" other segment definition. In other words, if the preprocessor happens to create *one* 3-noded segment corresponding to local node numbering convention {1,2,3,3} in Figure 31-12, or permutations thereof, then this will internally be detected as a 6-noded segment and the nodal forces will be consistently distributed over the 6 involved nodes. Likewise, if four 3-noded segments corresponding to local node numbering conventions {1,4,6,6}, {2,5,4,4}, {3,6,5,5} and {4,5,6,6}, or permutations thereof, are created, then these will be detected to belong to the same 6-noded segment and again result in the correct nodal forces. The difference between the two latter approaches is that using four "sub-segments" will provide four different normal directions **t** instead of just one, and for curved faces this will provide a more accurate representation of the pressure load.

To apply a uniform pressure to type 23 hexahedral elements or type 23 quadrilateral shell elements, one 8 node segment may be defined for each loaded face. However, LS-DYNA will accept and properly treat a segment excluding the 4 mid side nodes. In other words, if the preprocessor happens to create just one 4-noded segment corresponding to local node numbering convention {1,2,3,4} in Figure 31-12, or permutations thereof, then this will internally be detected as a 8-noded segment and the nodal forces will be consistently distributed over the 8 involved nodes.

To apply a uniform pressure to type 24 hexahedral elements, either one 4 node segment corresponding to the numbering convention {1,2,3,4} in Figure 31-12, or permutations thereof, may be defined for each loaded face. But LS-DYNA will also accept and properly treat *four* 4 node segments corresponding to {1,5,9,8}, {2,6,9,5}, {3,7,9,6} and {4,8,9,7}, where local node number 9 is located in the center of the face. The difference between these two approaches is that using four "sub-segments" will provide four different normal directions **t** instead of just one, and for curved faces this will provide a more accurate representation of the pressure load.

6. **Example.** The partial input deck below applies pressure to a solid block, using this keyword. The function defined by LCID has 10 arguments: time, the 3 current coordinates, the 3 reference coordinates, and the 3 velocities. A function that applies a pressure proportional to the distance from the initial coordinates with damping in the x-direction would be, for example,

```
f(t,x,y,z,x0,y0,z0,vx,vy,vz)= 10.*sqrt ( (x-x0)*(x-x0)+(y-y0)*(y-y0)+(z-z0)*(z-z0) )+2.*vx
```

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$   *LOAD_SEGMENT
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  A block of solid elements is pressed down onto a plane as it moves along
$  that plane.  This pressure is defined using the *LOAD_SEGMENT keyword.
$
$  The pressure is applied to the top of the block.  This top is defined
$  by the faces on top of the appropriate solid elements.  The faces are
$  defined with segments.  For example, nodes 97, 106, 107 & 98 define
$  a top face on one of the solids (and thus, one of the faces to apply the
$  pressure too).  This "face" is referred to as a single segment.
$
$  The load is defined with load curve number 1.  The curve starts at zero,
$  ramps to 100 in 0.01 time units and then remains constant.  However,
$  the curve is then scaled by sclo = 2.5.  Thus, raising the load to 250.
$  Note that the load is NOT scaled in the *LOAD_SEGMENT keyword, but
$  could be using the sf variable.
$

*LOAD_SEGMENT_CONTACT_MASK

Purpose: Mask the pressure from a *LOAD_SEGMENT_SET when the pressure segments are in contact with another material. For non-Mortar contact, this keyword is currently only supported in the MPP version, while Mortar contact is supported in all versions. Note that the Heading Card is required.

Heading Card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Load Set Card.

Card 2	1	2	3	4	5	6	7	8
Variable	LSID	P1	P2	CID1	CID2	CID3	CID4	CID5
Type	I	F	F	I	I	I	I	I

Optional Cards. Include as many cards as desired. This data ends at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	CID6	CID7	CID8	CID9	CID10	CID11N	CID12	CID13
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
LSID	Load set ID to mask, which must match a *LOAD_SEGMENT_SET. See Remark 2.
P1	Lower pressure limit. When the surface pressure due to contact is below P1, no masking is done and the full load defined in *LOAD_SEGMENT_SET is applied. For pressures between P1 and P2 see Remark 1.

VARIABLE	DESCRIPTION
P2	Upper pressure limit. When the surface pressure due to contact is above P2, no load is applied due to the *LOAD_SEGMENT_SET. For pressures between P1 and P2 see Remark 1.
CID*n*	The IDs of contacts that can mask the pressure loads. The specified contact definitions must all be of the same type. Furthermore, only non-automatic SURFACE_TO_SURFACE (two way) and AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK contacts are supported. For TIEBREAK contacts, pressure is masked until the tie fails. Once the tie fails, the full pressure will be applied for the remainder of the simulation. The values P1 and P2 are ignored. For other contact types, the contact forces, along with the nodal contact surface areas, are used to compute the contact pressure at each node to determine any masking effect.

Remarks:

1. **Intermediate Pressures.** If the contact pressure, p_{contact} is between P1 and P2, the pressure load is scaled by a factor of

$$f = \frac{\text{P2} - p_{\text{contact}}}{P2 - P1}.$$

   P1 may be set equal to P2 if desired.

2. **LSID.** The LSID values must be unique. Having two instances of this referencing the same*LOAD_SEGMENT_SET *is not supported*. However, a contact ID *may* appear in two different instances of this keyword.

3. **IDOF on *SECTION_SHELL.** When IDOF = 3 on *SECTION_SHELL, the shell thickness strain is governed by the stress from contact and pressure loads. If IDOF = 3 *and* the masking contact is of Mortar type, the masking will not apply for the thickness strain. Other contact types do not have this limitation.

*LOAD_SEGMENT_FILE

Purpose: To define *time-varying* distributed pressure loads over triangular or quadrilateral segments defined by four, six, or eight nodes using *a binary file*.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							

Card 2 is required but may be left blank.

Card 2	1	2	3	4	5	6	7	8
Variable	LCID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
FILENAME	Filename of binary database containing segment pressures as a function of time. There are three sections in this database.
LCID	Optional load curve ID defining segment pressure scale factor as a function of time.

Remarks:

Each database is assumed to be written with a block size equal to a multiple of 512 words, with each block containing 1 or more states. If the data does not complete the last block, it is padded with zeros. The code will open and read the next family file if it detects a phony word or EOF. If the IO returns a zero length read, the code assumes end of IO and stops reading.

Linear interpolation is used if the IO can find the current time between two states. Therefore, the given database can have more states than simulation time steps.

Linear extrapolation will only be used when the IO reaches the end of the database. The last two states will be used and the warning message "MSG_SOL+1323" will be issued to the d3hsp and messag files.

Section	Words	Description
Control Section 64 words	10	Title
	1	NSEG: The absolute value, |NSEG|, specifies the number of segments contained within the file. If NSEG < 0, then the file contains mid-side nodes.
Segment Data 4 words	1	N1: Node ID.
	1	N2: Node ID.
	1	N3: Node ID. Repeat N2 for two-dimensional geometries.
	1	N4: Node ID. Repeat N2 for two-dimensional geometries or repeat N3 for 3-node triangular segments.
Mid-side Nodes 4 Words. Omitted unless NSEG < 0.	1	N5: Optional mid-side node ID.
	1	N6: Optional mid-side node ID.
	1	N7: Optional mid-side node ID.
	1	N8: Optional mid-side node ID.
⋮	4 or 8	⋮
NSEGth segment data	4 or 8	Last set of segment data

	⋮	⋮
	1	Pressure of last segment
⋮	1	⋮
	NSEG	⋮

*LOAD_SEGMENT_FSILNK

Purpose: Apply distributed pressure loads from a previous ALE analysis to a specified segment set in the current analysis. This capability trades some of the model's accuracy for a large reduction in model size.

> NOTE: The deck for the "previous" run must include a *DATABASE_BINARY_FSILNK card to activate the creation of the fsilink file. Either the *LOAD_SEGMENT_FSILNK card (this card) or the *DATABASE_BINARY_FSILNK card may be in an input deck, *but not both*.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							

Card 2	1	2	3	4	5	6	7	8
Variable	NINT	LCID						
Type	I	I						
Default	none	0						

Coupling ID Cards. Read in NINT coupling IDs. Repeat this card as many times as necessary to input all NINT values.

Card 3	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
FILENAME	Filename of the interface linking file.
NINT	Number of couplings for which the previous run provides pressure data.
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). The curve referred to by LCID provides a scale factor as a function of time. The pressure data that is read in from the fsilnk file is scaled according to this value.
ID*i*	These must match COUPIDs from the *CONSTRAINED_LAGRANGE_IN_SOLID card from the previous runs. These IDs specify which of the first run's couplings are propagated into this run through pressure data read from the fsilnk file.

The algorithm:

This feature provides a method for using pressure time history data from *CONSTRAINED_LAGRANGE_IN_SOLID Lagrangian-to-ALE couplings in one calculation as pressure data for the same segment in subsequent calculations. The time range covered by the subsequent calculation *must* overlap the time range of the initial calculation.

First calculation: Write out pressure data.

1. Add a *DATABASE_BINARY_FSILNK card to the first run.

2. Specify filename for the fsilnk file by adding a command line argument to ls-dyna.

   ls-dyna … fsilnk=**fsi_filename** …

   Without a *DATABASE_BINARY_FSILNK card this command line argument will have no effect.

Format of fsilnk File:

WRITE: Job title (character*80 TITLE)
WRITE: Number of interfaces (integer NINTF)

For *i* = 1 to NINTF {

  WRITE: Number of segments in the i^{th} interface (integer NSEG[*i*])

  For *j* = 1 to NSEG[*i*] {

```
            WRITE: Connectivities of j^th segment in the i^th interface (integer*4)
        }
}
For n = 1 to number of time steps {
        WRITE: time value for the n^th time step (real)
        For i = 1 to NINTF
            For j = 1 to NSEG[i] {
                WRITE: Pressure for the j^th segment of the i^th interface (real)
            }
        }
}
```

Subsequent calculations: Read fsilnk File.

Include this keyword, *LOAD_SEGMENT_FSILNK, and be careful to remove the *DATABASE_BINARY_FSILNK keyword. Specify the name of the fsilnk file from the previous run on *LOAD_SEGMENT_FSILNK's first data card.

Then, at each time step, the pressure of the specified coupling IDs is set on the Lagrangian-mesh side from data in the fsilnk file. For times outside of the fsilnk file's range LS-DYNA extrapolates.

1. If current time is before the 1st fsilnk time, then pressure is set to 0.
2. If the current time is in the range of times in the fsilnk file, then the pressure is linearly interpolated from the data at the two time states in the fsilnk file bracketing the current time.
3. If the current time is after the last fsilnk time, then the pressure is set to the fsilnk pressure at last time step.

*LOAD_SEGMENT_NONUNIFORM_{OPTION}

To define an ID for the non-uniform segment loading the following option is available:

ID

If the ID option is used, an additional card is required.

Purpose: Apply a distributed load over one triangular or quadrilateral segment defined by three, four, six, or eight nodes. The loading and node numbering convention follows Figure 31-9.

ID Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card Sets. Each segment is specified by a set of the following 3 cards. Include as many sets as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	SF	AT	DT	CID	V1	V2	V3
Type	I	F	F	F	I	F	F	F
Default	none	1.	0.	1.E+16	0	none	none	none

Card 2	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	N5	N6	N7	N8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

Card 3	1	2	3	4	5	6	7	8
Variable	P1	P2	P3	P4	P5	P6	P7	P8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
ID	Loading ID
HEADING	A description of the loading.
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). For a load curve ID the load curve must provide pressure as a function of time. For a function ID, the function is expected to have seven arguments: current time minus the birth time, the current x, y, and z coordinates, and the initial x, y, and z coordinates. LT.0: Applies to 3, 4, 6 and 8-noded segments. With this option the load becomes a follower load, meaning that the direction of the load is constant with respect to the local segment coordinate system.
SF	Load curve scale factor
AT	Arrival / birth time for the traction load.
DT	Death time for the traction load
CID	Coordinate system ID
V1, V2, V3	Vector direction cosines relative to coordinate system CID defining the direction of the traction loading. Note that for LCID < 0 this vector rotates with the geometry of the segment.
N1	Node ID
N2	Node ID
N3	Node ID. Repeat N2 for two-dimensional geometries.

VARIABLE	DESCRIPTION
N4	Node ID. Repeat N2 for two-dimensional geometries or repeat N3 for 3-node triangular segments.
N5	Optional mid-side node ID (see Figure 31-12).
N6	Optional mid-side node ID (see Figure 31-12).
N7	Optional mid-side node ID (see Figure 31-12).
N8	Optional mid-side node ID (see Figure 31-12).
P1	Scale factor at node ID, N1.
P2	Scale factor at node ID, N2.
P3	Scale factor at node ID, N3.
P4	Scale factor at node ID, N4.
P5	Scale factor at node ID, N5.
P6	Scale factor at node ID, N6.
P7	Scale factor at node ID, N7.
P8	Scale factor at node ID, N8.

***LOAD_SEGMENT_SET** *{OPTION}*

To define an ID for the segment loading, the following option is available:

ID

If the ID is defined, an additional card is required.

Purpose: Apply the distributed pressure load over each segment in a segment set. See *LOAD_SEGMENT for a description of the pressure sign convention and remarks on higher order segment definitions.

ID Card. Additional card for the ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Segment Set Cards. Include as many segment set cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	LCID	SF	AT				
Type	I	I	F	F				
Default	none	none	1.	0.				
Remarks		1	2	3				

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT.
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). For a load curve ID the load curve must provide pressure as a function of time. For a function ID the function is expected to have seven arguments: current time minus the birth time, the current x, y, and z coordinates, and the initial x, y, and z coordinates.

VARIABLE	DESCRIPTION
SF	Load curve scale factor
AT	Arrival time for pressure or birth time of pressure.

Remarks:

1. **Pressure Functions.** If LCID is input as -1, then the Brode function is used to determine pressure for the segment set; also see *LOAD_BRODE. If LCID is input as -2, then an empirical airblast function is used to determine the pressure for the segments; see *LOAD_BLAST.

2. **Load Curve Multipliers.** The load curve multipliers may be used to increase or decrease the pressure. The time value is not scaled.

3. **Activation Time.** The activation time, AT, is the time during the solution that the pressure begins to act. Until this time, the pressure is ignored. The function value of the load curves will be evaluated at the offset time given by the difference of the solution time and AT, that is, (solution time-AT).

*LOAD_SEGMENT_SET_ANGLE

Purpose: Apply a traction load over a segment set that is dependent on the orientation of a vector. An example application is applying a pressure to a cylinder as a function of the crank angle in an automobile engine. The pressure and node numbering convention follows Figure 31-12.

Card Sets. Include as many sets of Cards 1 and 2 as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	IDSS	LCID	SCALE	IOPTP	IOPTD		
Type	I	I	I	F	I	I		
Default	none	none	none	1.	0	0		

Card 2	1	2	3	4	5	6	7	8
Variable	N1	N2	NA	NI				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
ID	Loading ID
IDSS	Segment set ID.
LCID	Load curve or function ID defining the traction as a function of the angle. If IOPTP, defined below, is 0, define the abscissa between 0 and 2π radians or 0 and 360 degrees depending on IOPTD.
SCALE	Scale factor on value of the load curve or function.
IOPTP	Flag for periodicity of load curve LCID:

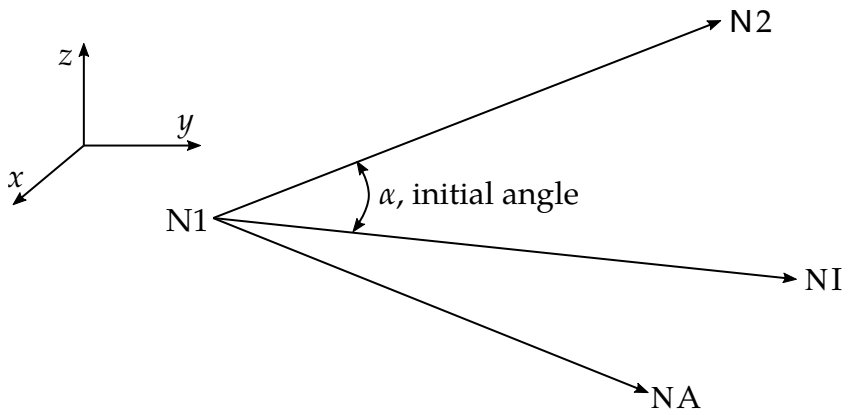

Figure 31-13. Orientation of rotating vector

VARIABLE	DESCRIPTION
	EQ.0: Requires the load curve to be defined between 0 and 2π. This is useful, for example, for modeling an engine that is running at a steady state since each rotation will experience the same loading. EQ.1: Load curve defined over the full range of angles for modeling a transient response. A different response is, therefore, permitted on the second and subsequent revolutions.
IOPTD	Flag for specifying angle units of the load curve LCID: EQ.0: Load curve or function argument is in radians. EQ.1: Load curve or function argument is in degrees.
N1	The node specifying the tail of the rotating vector. See Figure 31-13.
N2	The node specifying the head of the rotating vector. See Figure 31-13.
NA	The node specifying the head of the vector defining the axis of rotation. The node N1 specifies the tail. See Figure 31-13.
NI	The node specifying the orientation of the vector at an angle of zero. If the initial angle is zero, NI should be equal to N2. See Figure 31-13.

*LOAD_SEGMENT_SET_NONUNIFORM_{OPTION}

To define an ID for the non-uniform segment loading the following option is available:

ID

If the ID is defined, an additional card is required.

Purpose: Apply the traction load over one triangular or quadrilateral segment defined by three or four nodes. The pressure and node numbering convention follows Figure 31-12.

ID Card. Additional card for ID keyword option.

Optional	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card Sets. Include as many pairs of Cards 1 and 2 as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	LCID	SF	AT	DT	ELTYPE		
Type	I	I	F	F	F	A		
Default	none	none	1.	0.	10^{16}	↓		

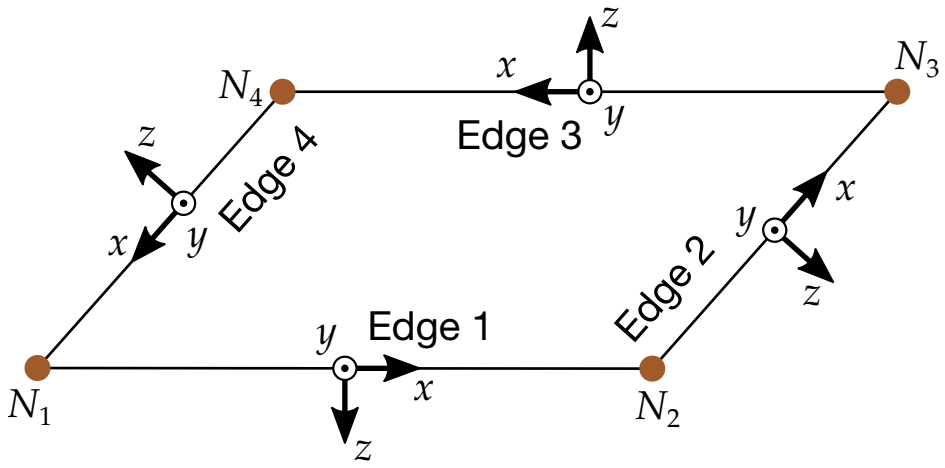

Figure 31-14. Local coordinates system for edge load.

Card 2	1	2	3	4	5	6	7	8
Variable	CID	V1	V2	V3				
Type	I	F	F	F				
Default	0	none	none	none				

VARIABLE	DESCRIPTION
ID	Loading ID
HEADING	A description of the loading.
SSID	Segment set ID.
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). The seven arguments for the function are current time minus the birth time, the current x, y, and z coordinates, and the initial x, y, and z coordinates. LT.0: Applies to 3, 4, 6 and 8-noded segment sets. With this option the load becomes a follower load, meaning that the direction of the load is constant with respect to the local segment coordinate system. The local coordinate system for edge load, see ELTYPE, is shown in Figure 31-14.
SF	Load curve scale factor
AT	Arrival/birth time for pressure.

VARIABLE	DESCRIPTION
DT	Death time for pressure.
ELTYPE	Optional edge loading type. If left blank, pressure on the segment will be applied. EQ.EF1: Distributed force per unit length along edge 1, Figure 31-14. EQ.EF2: Distributed force per unit length along edge 2, Figure 31-14. EQ.EF3: Distributed force per unit length along edge 3, Figure 31-14. EQ.EF4: Distributed force per unit length along edge 4, Figure 31-14.
CID	Coordinate system ID
V1, V2, V3	Vector direction cosines relative to the coordinate system CID defining the direction of the traction loading. Note that for LCID < 0 this vector rotates with the geometry of the segment.

LOAD_SEISMIC_SSI_*OPTION1_{OPTION2}

Available options for *OPTION1* include:

NODE

SET

POINT

DECONV

OPTION2 allows an optional ID to be given:

ID

Purpose: Apply earthquake load due to free-field earthquake ground motion at certain locations — defined by either nodes or coordinates — on a soil-structure interface, for use in earthquake soil-structure interaction analysis. The specified motions are used to compute a set of effective forces in the soil elements adjacent to the soil-structure interface, according to the effective seismic input–domain reduction method [Bielak and Christiano (1984)].

Card Summary:

Card Sets. Include as many sets of the following cards (depending on the keyword options) as needed. This input ends at the next keyword ("*") card.

Card ID. This card is included if ID keyword option is used.

ID	HEADING

Card 1a. This card is included if the NODE or SET keyword option is used.

SSID	TYPEID	GMX	GMY	GMZ			

Card 1b. This card is included if the POINT or DECONV keyword option is used.

SSID	XP	YP	ZP	GMX	GMY	GMZ

Card 2. This card is required.

SF	CID	BIRTH	DEATH	ISG	IGM	PSET	VDIR

Data Card Definitions:

ID Card. Additional card for the ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
ID	Optional ID. This ID does not need to be unique.
HEADING	An optional descriptor for the given ID.

Node and set Cards. Card 1 for keyword options NODE and SET:

Card 1a	1	2	3	4	5	6	7	8
Variable	SSID	TYPEID	GMX	GMY	GMZ			
Type	I	I	I	I	I			
Default	none	none	none	none	none			

Point Cards. Card 1 for keyword options POINT and DECONV.

Card 1b	1	2	3	4	5	6	7	8	9	10
Variable	SSID	XP		YP		ZP		GMX	GMY	GMZ
Type	I	F		F		F		I	I	I
Default	none	0.		0.		0.		none	none	none

VARIABLE	DESCRIPTION
SSID	Soil-structure interface ID.
TYPEID	Node ID (NID in *NODE) or nodal set ID (SID in *SET_NODE).

VARIABLE	DESCRIPTION
XP	x coordinate of ground motion location.
YP	y coordinate of ground motion location.
ZP	z coordinate of ground motion location.
GMX	Acceleration load curve or ground motion ID for motion in the (local) x-direction.
GMY	Acceleration load curve or ground motion ID for motion in the (local) y-direction.
GMZ	Acceleration load curve or ground motion ID for motion in the (local) z-direction.

Card 2	1	2	3	4	5	6	7	8
Variable	SF	CID	BIRTH	DEATH	ISG	IGM	PSET	VDIR
Type	F	I	F	F	I	I	I	I
Default	1.	0	0.	10^{28}	0	0	none	3

VARIABLE	DESCRIPTION
SF	Ground motion scale factor.
CID	Coordinate system ID; see *DEFINE_COORDINATE_SYSTEM.
BIRTH	Time at which specified ground motion is activated.
DEATH	Time at which specified ground motion is removed: EQ.0.0: default set to 10^{28}
ISG	Definition of soil-structure interface: EQ.0: SSID is the ID for the soil-structure interface defined by *INTERFACE_SSI_ID for a non-matching mesh between soil and structure. For the DECONV keyword option, ISG = 0 additionally flags that the free-field within motion is computed at depth.

VARIABLE	DESCRIPTION
	EQ.1: SSID is the ID of the segment set on the soil side of the soil-structure interface. This segment set should be oriented toward the structure. For the DECONV, ISG = 1 additionally flags that the free-field outcrop motion is computed at depth.
IGM	Specification of ground motions GMX, GMY, GMZ: EQ.0: Ground motions are specified as acceleration load curves. See *DEFINE_CURVE EQ.1: Both ground accelerations and velocities specified using *DEFINE_GROUND_MOTION.
PSET	Soil part set through which ground motion travels (DECONV option only)
VDIR	Vertical direction (local if CID ≠ 0) for ground motion propagation (DECONV option only): EQ.-1: -x-direction EQ.-2: -y-direction EQ.-3: -z-direction EQ.1: x-direction EQ.2: y-direction EQ.3: z-direction

Remarks:

1. **Ground Motion at Soil-Structure Interface.** The ground motion at any node on a soil-structure interface is computed as follows:

   a) If the node coincides with a location where ground motion is specified, that ground motion is used for that node.

   b) If the node does not coincide with a location where ground motion is specified, the ground motion at that node along a particular degree-of-freedom is taken as a weighted average of all the ground motions specified on the interface along that degree-of-freedom, where the weights are inversely proportional to the distance of the node from the ground motion location.

2. **Multiple Ground Motions.** Multiple ground motions specified at the same location are added together to obtain the resultant ground motion at that location.

3. **Spatially-Uniform Ground Motion.** Spatially-uniform ground motion may be specified on a soil-structure interface by specifying the ground motion at only one location on that interface. Specifying the ground motion at more than one point on a soil-structure interface results in spatially-varying ground motion on that interface.

4. **Deconvolution input.** The DECONV option provides a simplified ground motion input for a soil-structure interface that goes below the flat, top surface of the soil. The free-field ground motion is specified at the top of the soil, and the corresponding motion at the interface nodes at depth are computed assuming the free-field motion propagates only vertically. ISG = 0 flags that the within motion is computed while ISG = 1 flags that the outcrop motion is computed. Currently, this keyword option is available only when the soil domain is modeled with either *MAT_ELASTIC or *MAT_BIOT_HYSTERETIC. Other materials can be supported upon request.

***LOAD_SEISMIC_SSI_AUX**_*{OPTION}*

OPTION allows an optional ID to be given:

ID

Purpose: Apply earthquake load due to free-field earthquake ground motion on a soil-structure interface, where the free-field motions were recorded from a previous analysis using *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED. The specified motions are used to compute a set of effective forces in the soil elements adjacent to the soil-structure interface, according to the effective seismic input–domain reduction method [Bielak and Christiano (1984)].

This card supersedes the optional Card 3 in *INTERFACE_SSI

Card Sets. Include as many pairs of Cards 1 and 2 as necessary. This input ends at the next keyword ("*") card. If the ID keyword option is used, include a separate ID card for each pair.

ID Card. Additional card for the ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70

Type	I	I	F	F	F	I	I	
Default	none	none	1.	0.	10^{28}	0	2500000	

VARIABLE	DESCRIPTION
ID	Optional ID. This ID does not need to be unique.
HEADING	An optional descriptor for the given ID
FILENAME	Name of binary file containing recorded motions
SSID	Soil-structure interface ID
GMSET	Identifier for set of recorded motions; see *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED
SF	Recorded motion scale factor
BIRTH	Time at which specified recorded motion is activated
DEATH	Time at which specified recorded motion is removed. EQ.0.0: Set to the default, 10^{28}
ISG	Definition of soil-structure interface: EQ.0: SSID is an ID for the soil-structure interface defined by *INTERFACE_SSI_ID for a non-matching mesh between soil and structure. EQ.1: SSID is the ID of the segment set on the soil side of the soil-structure interface. This segment set should be oriented toward the structure.
MEMGM	Size in words of buffer allocated to read in recorded motions

Remarks:

1. **Binary File for Recorded Motions.** The free-field motions are read in from a binary file created in a previous run using *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED.

2. **Multiple Ground Motion Inputs.** Multiple ground motion files can be specified at the same interface. All the ground motions are added together to obtain the resultant free-field motion at that interface.

3. **Interface Geometry Match.** It is assumed that the nodes of the soil-structure interface lie on the surface of the interface used in the previous run to record the ground motion.

***LOAD_SHELL**_OPTION1_{OPTION2}

Available options for *OPTION1* include:

ELEMENT

SET

Available options for *OPTION2* include:

ID

If the ID is defined, an additional card is required.

Purpose: Apply the distributed pressure load over a single shell element or a shell element set. The numbering of the shell nodal connectivities must follow the right hand rule with positive pressure acting in the negative *t*-direction. See Figure 31-12. This option applies to the three-dimensional shell elements only.

ID Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Shell Cards. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID/ESID	LCID	SF	AT				
Type	I	I	F	F				
Default	none	none	1.	0.				

VARIABLE	DESCRIPTION
EID/ESID	Shell ID (EID) or shell set ID (ESID), see *ELEMENT_SHELL or *SET_SHELL.

VARIABLE	DESCRIPTION
LCID	Load curve ID, see *DEFINE_CURVE. EQ.-1: Brode function; see *LOAD_BRODE. EQ.-2: ConWep function; see *LOAD_BLAST.
SF	Load curve scale factor. See Remark 1.
AT	Arrival time for pressure or birth time of pressure.

Remarks:

1. **Multipliers.** The load curve multipliers may be used to increase or decrease the pressure. The time value is not scaled.

Example:

```

$$$

*LOAD_SPCFORC

Purpose: When used in a full-deck restart run, this card will apply the SPC constraint forces from the initial run on the corresponding degrees of freedom in the current run. This is useful when modeling unbounded domains using a non-reflecting boundary while incorporating static stresses computed in the initial run: the fixed constraints on the outer boundary in the initial static analysis are removed in the transient analysis and replaced by equivalent static forces.

While *BOUNDARY_NON_REFLECTING acts similarly if dynamic relaxation is used for the static analysis, this approach works for any method used to preload the model.

No parameters are necessary for this card.

*LOAD_SSA

Purpose: The Sub-Sea Analysis (SSA) capability allows a simple and efficient way of loading the structure to account for the effects of the primary shock wave and the subsequent bubble oscillations of an underwater explosion. It achieves its efficiency by approximating the pressure scattered by air and water-backed plates and the pressure transmitted through a water-back plate. The loading incorporates the plane wave approximation for direct shock response and the virtual mass approximation for bubble response. *LOAD_SSA does not implement a doubly asymptotic approximation of transient fluid-structure interaction.

Card 1	1	2	3	4	5	6	7	8
Variable	VS	DS	REFL	ZB	ZSURF	FPSID	PSID	NPTS
Type	F	F	I	F	F	I	I	I
Default	none	none	0	0.	0.	0	0	1

Card Sets. Include as many pairs of Cards 2 and 3 as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	A	ALPHA	GAMMA	KTHETA	KAPPA			
Type	F	F	F	F	F			
Default	none	none	none	none	none			

Card 3	1	2	3	4	5	6	7	8
Variable	XS	YS	ZS	W	TDELY	RAD	CZ	
Type	F	F	F	F	F	F	F	
Default	none	none	none	none	none	none	none	

VARIABLE	DESCRIPTION
VS	Sound speed in fluid
DS	Density of fluid
REFL	Consider reflections from sea floor. EQ.0: off EQ.1: on
ZB	Z coordinate of sea floor if REFL = 1, otherwise, not used.
ZSURF	Z coordinate of sea surface
FPSID	Part set ID of parts subject to flood control. See Remark 2. Use the *SET_PART_COLUMN option where the parameters A1 and A2 must be defined as follows: Parameter A1: Flooding status: EQ.1.0: Fluid on both sides. EQ.2.0: Fluid outside, air inside. EQ.3.0: Air outside, fluid inside. EQ.4.0: Material or part is ignored. Parameter A2: Tubular outer diameter of beam elements. For shell elements this input must be greater than zero for loading.
PSID	Part set IDs of parts defining the wet surface. The elements defining these parts must have their outward normals pointing into the fluid. See Figure 31-15. EQ.0: all parts are included. GT.0: the part set ID.
NPTS	Number of integration points for computing pressure (1 or 4)
A	Shock pressure parameter
ALPHA	α, shock pressure parameter
GAMMA	γ, time constant parameter
KTHETA	K_θ, time constant parameter
KAPPA	κ, ratio of specific heat capacities

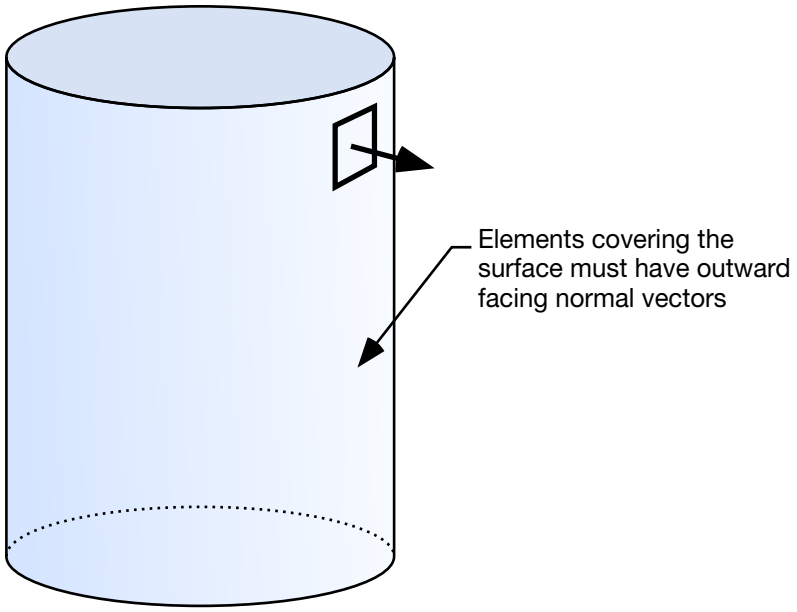

Figure 31-15. The shell elements interacting with the fluid must be numbered such that their outward normal vector points into the fluid media.

VARIABLE	DESCRIPTION
XS	*X* coordinate of charge
YS	*Y* coordinate of charge
ZS	*Z* coordinate of charge
W	Weight of charge
TDELY	Time delay before charge detonates
RAD	Charge radius
CZ	Charge depth

Remarks:

1. **Units.** SSA assumes the model is in MKS units. If it is in another system of units, *CONTROL_COUPLING should be used to account for the conversion.

2. **Flooding Status.** The "flooding status" is instrumental in determining how the model parts are loaded. If A1 = 1.0, the front of the plate as defined by the outward normal is exposed to the incident pressure. The back of the plate is not exposed to the incident pressure but feels a transmitted pressure that resists

plate motion. If A1 = 2.0, then the plate has fluid on the outside as determined by the outward normal. It is exposed to the incident pressure and feels the scattered pressure. No loading is applied to the back side. If A1 = 3.0, then air is on the front of the plate and water is on the back. Neither the front nor the back of the plate is exposed to the incident pressure, but the motion of the plate is resisted by pressure generated on the back of the plate when it moves. Transmitted pressures are assumed not to strike another plate.

3. **Pressure History of Primary Shockwave.** The pressure history of the primary shockwave at a point in space through which a detonation wave passes is given as:

$$P(t) = P_m e^{\frac{-t}{\theta}}$$

where P_m and the time constant θ below are functions of the type and weight W of the explosive charge and the distance Q from the charge.

$$P_{peak} = A\left[\frac{W^{1/3}}{Q}\right]^{\alpha}$$

$$\theta = K_\theta W^{1/3}\left[\frac{W^{1/3}}{Q}\right]^{\gamma}$$

where A, α, γ, and K_θ are constants for the explosive being used.

4. **Model Orientation.** The positive global Z-direction points vertically upward, from the sea floor to water surface. The finite element model must be oriented accordingly.

*LOAD_STEADY_STATE_ROLLING

Purpose: Steady state rolling analysis is a generalization of *LOAD_BODY, allowing the user to apply body loads to part sets due to translational and rotational accelerations in a manner that is more general than the *LOAD_BODY capability. *LOAD_STEADY_-STATE_ROLLING may be invoked multiple times as long as no part has the command applied more than once. Furthermore, the command may be applied to arbitrary meshes, that is, axisymmetric meshes are not required.

Card Sets. Include as many sets consisting of the following four cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	PSID						
Type	I	I						
Default	none	none						

Card 2	1	2	3	4	5	6	7	8
Variable	N1	N2	LCD1	LCD1R				
Type	I	I	I	I				
Default	0	0	0	LCD1				

Card 3	1	2	3	4	5	6	7	8
Variable	N3	N4	LCD2	LCD2R				
Type 4	I	I	I	I				
Default	0	0	0	LCD2				

Card 4	1	2	3	4	5	6	7	8
Variable	N5	N6	LCD3	LCD3R				
Type	I	I	I	I				
Default	0	0	0	LCD3				

VARIABLE	DESCRIPTION
ID	ID
PSID	Part set ID
N1	Node 1 defining rotational axis
N2	Node 2 defining rotational axis
LCD1	Load curve defining angular velocity around rotational axis.
LCD1R	Optional load curve defining angular velocity around rotational axis for dynamic relaxation. LCD1 is used during dynamic relaxation if LCD1R is not defined.
N3	Node 3 defining turning axis
N4	Node 4 defining turning axis
LCD2	Load curve defining angular velocity around turning axis.
LCD2R	Optional load curve defining angular velocity around turning axis for dynamic relaxation. LCD2 is used during dynamic relaxation if LCD2R is not defined.
N5	Node 5 defining translational direction
N6	Node 6 defining translational direction
LCD3	Load curve defining translational velocity in translational direction.
LCD3R	Optional load curve defining translational velocity in translational direction. LCD3 is used during dynamic relaxation if LCD3R is not defined.

Remarks:

1. **Model.** The steady state rolling capability adds inertial body loads in terms of a moving reference defined by the user input. The current coordinates are defined in terms of the displacement, u, and the moving reference frame, Y,

$$x_{SSR} = u + Y \quad \dot{x}_{SSR} = \dot{u} + \dot{Y} \quad \ddot{x}_{SSR} = \ddot{u} + \ddot{Y}$$
$$Y = R(\omega_2 t)[R(\omega_1 t)(X - X_O) - X_C] + Y_T(t)$$

where R is the rotation matrix obtained by integrating the appropriate angular velocity, the magnitude of the angular velocities ω_1 and ω_2 are defined by load curves LCD1 and LCD2 respectively, and the directions are defined by the current coordinates of the node pairs N1-N2 and N3-N4. The velocity corresponding to the translational term, $Y_T(t)$, is defined in magnitude by LCD3 and in direction by the node pair N5-N6. The initial coordinates of the nodes are X, X_O is the initial coordinate vector of node N1 and X_C is the initial coordinate vector of node N3. If data defining an angular velocity is not specified, the velocity is defaulted to zero, and R is the identity matrix. In a similar manner, if the translational velocity is not specified, it is defaulted to zero.

2. **Restrictions.** This capability is useful for initializing the stresses and velocity of tires during dynamic relaxation and rolling processes in manufacturing. It is available for solid formulations 1, 2, 10, 13, and 15, and for shell formulations 2, 4, 5, 6, 16, 25, 26, and 27. It is *not* available for beams and tshells. It is available for implicit and explicit simulations, but it is *not* available for eigenvalue problems. To invoke this keyword for dynamic relaxation, specify that the load curves are used during dynamic relaxation (SIDR = 1 or 2 on *DEFINE_CURVE). At the end of the dynamic relaxation, the velocities of the parts with this load are set to $\dot{x}_{SSR}$ while the remaining parts are initialized according to the input file.

3. **Convergence and Stability.** Users must ensure that the appropriate load curves are turned on during the relaxation process, and if implicit dynamic relaxation is used, that sufficient constraints are applied during the initialization to remove any rigid body motion and that they are removed at the end of the dynamic relaxation. The implicit iteration convergence rate is often improved by adding the geometric stiffness matrix using *CONTROL_IMPLICIT_GENERAL. A consistent tangent matrix is available by using *CONTROL_IMPLICIT_-GENERAL, and while it improves the convergence rate with problems with small strains, it is often unstable for problems with large strains. The *CONTROL_STEADY_STATE_ROLLING options should be used to ramp up the frictional forces to obtain smooth solutions and good convergence rates.

4. **Angular Velocity and Hoop Strain.** To obtain the free-rolling angular velocity, the tire should be first inflated, then brought into contact with the road while the frictional force is ramped up with a load curve and a large value of SCL_K

specified in *CONTROL_STEADY_STATE_ROLLING. The angular velocity of the tire is then slowly varied over a range that covers the free rolling velocity. The free rolling velocity is obtained when either the frictional force in the direction of rolling or the moment about the tire axis is near zero. For a tire with an initial radius of R and a translational velocity of V, the approximate value for the free rolling value of the rolling velocity is

$$\omega = \frac{V}{(1+\varepsilon)R} \ ,$$

where ε is the hoop strain of the rolling tire. For a first guess, the hoop strain can be set to 0.0, and the rolling velocity will be within 10% of the actual value. After the first calculation, a smaller range bracketing the free rolling velocity should be used in a second calculation to refine the free rolling velocity. An accurate value of the free rolling velocity is necessary for subsequent analyses, such as varying the slip angle of the tire.

5. **Slip Angle.** A time varying slip angle can be specified by moving one of the nodes defining the direction vector of the translational velocity. To check that the stiffness scale factor in *CONTROL_STEADY_STATE_ROLLING is high enough, a complete cycle from a zero slip angle to a maximum value, then back to zero, should be performed. If the loading and unloading values are reasonably close, then the stiffness scale factor is adequate.

***LOAD_STIFFEN_PART** *{OPTION}*

Available options include:

<BLANK>

SET

Purpose: Staged construction. Available for solid, shell, thick shell, and beam elements. See also *DEFINE_STAGED_CONSTRUCTION_PART, which provides an alternative, simpler input method for the same capability.

Construction Cards. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	LC	(blank)	STGA	STGR			
Type	I	I		I	I			
Default	none	0		0	0			

VARIABLE	DESCRIPTION
PID	Part ID (or Part Set ID for the SET keyword option)
LC	Load curve defining factor as a function of time. See Remark 5.
STGA	Construction stage at which part is added (optional)
STGR	Construction stage at which part is removed (optional)

Remarks:

1. **Removing and Adding Parts.** For parts that are initially present but are removed during the analysis (for example, soil that is excavated), the stiffness factor starts at 1.0. Before the part is deleted, the stiffness factor should ramp down to a small value, such as 10^{-6}, over a duration long enough to avoid introducing shock or dynamic effects. The elements of a part introduced during the construction, such as retaining walls, are initially present in the model; however, the factor for this part is initially set to a low value, such as 10^{-6}. The stiffness factor increases to 1.0 when the part is added. A factor that increases from 10^{-6} to 1.0

and then reduces back to 10^{-6} can be used for temporary retaining walls, props, etc.

2. **Increasing and Decreasing Factor.** When the factor is increasing, it applies *only* to the stiffness and strength of the material in response to *subsequent* strain increments, not to any existing stresses. When the factor is decreasing, it applies to existing stresses as well as to the stiffness and strength.

3. **Compatible Material Models.** This feature works with all material models when used only to *reduce* the stiffness (e.g. parts that are excavated, not parts that are added during construction). When used to *increase* the stiffness from an initial low value, this feature works for most material types but not for hyperelastic types as well as certain others. There is no error check at present to detect STIFFEN_PART being used with an inappropriate material model. Symptoms of resulting problems would include non-physically large stresses when a part stiffens due to the accumulated strains in the "dormant" material since the start of the analysis.

4. **Gravity Factor.** This feature is generally used with *LOAD_GRAVITY_PART. The same curve is often used for the stiffness factor and the gravity factor.

5. **Factor Curve.** There are 3 methods for defining the factor as a function of time:

   a) LC overrides STGA and STGR if LC is non-zero.

   b) STGA and STGR refer to stages at which the part is added and removed: the stages are defined in *DEFINE_CONSTRUCTION_STAGES. If STGA is zero, the part has full stiffness at time zero. If not, it starts with a value equal to FACT (on *CONTROL_STAGED_CONSTRUCTION) and increases immediately to 1.0 at the start of stage STGA. If STGR is zero, the stiffness factor continues at 1.0 until the end of the analysis. If not, it ramps down from 1.0 to FACT over the ramp time at the start of stage STGR.

   c) *DEFINE_STAGED_CONSTRUCTION_PART can be used instead of *LOAD_STIFFEN_PART to define this loading. During initialization, a *LOAD_STIFFEN_PART card will be created, and the effect is the same as using the STGA and STGR method described above. In many cases using *DEFINE_STAGED_CONSTRUCTION_PART is more convenient than this keyword.

*LOAD_SUPERPLASTIC_FORMING

Purpose: Perform superplastic forming (SPF) analysis. This option can be applied to 2D and 3D solid elements and to 3D shell elements, and has been implemented for both explicit and implicit analyses. The pressure loading controlled by the load curve ID given below is scaled to maintain a constant maximal strain rate or other target value.

This option must be used with material model 64, *MAT_RATE_SENSITIVE_POWER-LAW_PLASTICITY, for strain rate sensitive, powerlaw plasticity. For the output of data, see *DATABASE_SUPERPLASTIC_FORMING. Mass scaling is recommended in SPF applications.

New options to compute the target value with various averaging techniques and autojump options to control the simulation are implemented. Strain-rate speedup is also available. See Remarks 5, 6, and 7 for details.

Card Sets. Include as many sets consisting of the following four cards as desired. This input ends at the next keyword ("*") card.

Remarks				7	7	8		

VARIABLE	DESCRIPTION
LCP1	Load curve number for Phase I pressure loading; see *DEFINE_CURVE. The scaled version of this curve as calculated by LS-DYNA is output to curve1. See Remark 3.
CSP1	Contact surface number to determine completion of Phase I.
NCP1	Percent of nodes in contact to terminate Phase I; see *CONTACT_*OPTION*.
LCP2	Load curve number for Phase II pressure loading (reverse); see *DEFINE_CURVE. The scaled version of this curve as calculated by LS-DYNA is output to curve2. See Remark 3.
CSP2	Contact surface to determine completion of Phase II; see *CONTACT_OPTION.
NCP2	Percent of nodes in contact to terminate Phase II.

VARIABLE	DESCRIPTION
PCTS1	Percentage of nodes-in-contact to active autojump in Phase I forming.
PCTS2	Percentage of nodes-in-contact to active autojump in Phase II forming.
ERATE	Desired target value. If it's strain rate, this is the time derivative of the logarithmic strain.
SCMIN	Minimum allowable value for load curve scale factor. To maintain the target value, the pressure curve is scaled. In the case of a snap through buckling the pressure may be removed completely. By putting a value here the pressure will continue to act but at a value given by this scale factor multiplying the pressure curve.
SCMAX	Maximum allowable value for load curve scale factor. Generally, it is a good idea to put a value here to keep the pressure from going to unreasonable values after full contact has been attained. When full contact is achieved the strain rates will approach zero and pressure will go to infinity unless it is limited or the calculation terminates.
NCYL	Number of cycles for monotonic pressure after reversal.
NTGT	Type of the target (controlling) variable: EQ.1: strain rate. EQ.2: effective stress.
LEVEL	Criterion to compute averaged maximum of controlling variable: EQ.0: no average used. GE.1: averaging over neighbors of element with peak value of the controlling variable. This parameter determines the level of neighbor search. EQ.-1: averaging over elements within selective range of peak controlling variable.
TSRCH	Time interval to conduct neighbors search.
AT	Time when SPF Phase I simulation starts.
TPEAK	Additional run time to terminate simulation when maximum pressure is reached.

VARIABLE	DESCRIPTION
TNEG	Additional run time to terminate simulation when percentage change of nodes-in-contact is zero or negative.
TOSC	Additional run time to terminate simulation when percentage change of nodes-in-contact oscillates within a specific value.
POSC	Percentage change to define the oscillation of percentage of nodes-in-contact.
PDROP	Drop in percentage of nodes-in-contact from the maximum to terminate simulation after the specified termination percentage has been reached.
STR	Autojump option or strike-through time (period of time without autojump check): EQ.0: no autojump EQ.-1: autojump controlled by peak pressure EQ.-2: autojump controlled by percentage of nodes in contact EQ.-3: autojump controlled by both above GT.0: strike-through time, then same as STR = -3
THRES	Threshold percentage that gives the threshold value above which elements are considered for average.
LOWER	Lower percentile of elements above the threshold value to be included for average.
UPPER	Upper percentile of elements above the threshold value to be included for average.
RILIM	Maximum percentage change for pressure increment.
RDLIM	Maximum percentage change for pressure decrement.
TFACT	Strain rate speedup factor.
NTFCT	Number of computing cycles to ramp up speedup.
BOX	Box ID or Box Set ID. See Remark 8. GT.0: Box ID; see *DEFINE_BOX. LT.0: |BOX| is box set ID; see *SET_BOX.

Remarks:

1. **Second Phase.** Optionally, a second phase can be defined. In this second phase a *unique* set of pressure segments must be defined whose pressure is controlled by LCP2. During the first phase, the pressure segments of LCP2 are inactive, and likewise, during the second phase the pressure segments of the first phase are inactive. When shell elements are used, the complete set of pressure segments can be repeated in the input with a sign reversal used on the load curve. When solid elements are used, the pressure segments for each phase, in general, must be unique.

2. **NCYCL.** This is an ad hoc parameter which should probably not be used.

3. **Output Files.** There are three output files pressure, curve1, and curve2 from the SPF simulation, and they may be plotted using ASCII → superpl in LS-PrePost. The file curve2 is created only if the second phase is active. The time interval for writing out these files is controlled by *DATABASE_SUPERPLASTIC_FORMING. The files curve1 and curve2 contain the adjusted pressure histories calculated by SPF solver. The file pressure contains time histories of scaling factor, maximal target value, averaged target value, and percentage of contact.

4. **Contact.** The constraint method contact, *CONTACT_CONSTRAINT_NODES_TO_SURFACE, is recommended for superplastic forming simulations since the penalty methods are not as reliable when mass scaling is applied. Generally, in superplastic simulations mass scaling is used to enable the calculation to be carried out in real time.

5. **Averaging Algorithms.** In order to reduce the oscillation in pressure, the maximal target value used to adjust the pressure load is calculated by a special averaging algorithm. There are two options available:

   a) *Averaging over neighbors of element with maximum target value*: In this method, the element that has the maximum strain rate or other controlling variable is stored in each cycle of the computation. The elements close to the element with the maximum value are searched and stored in an array. The averaged maximal target value is computed over the neighboring elements. The user can input an integer number to control the level of neighbor search, which will affect the total number of elements for average. Because the neighbor search is time consuming, the user can input a time interval to limit the occurrence of searching. The neighbor search is conducted only when the simulation time reaches the specified time or the element with maximum target value falls out of the array of neighbors.

   b) *Averaging over elements within selective range of target value:* In this method, all elements that have target value above a threshold value (a threshold

percentage of maximum target value) are sorted according to their target value, and the elements between the user specified lower percentile and upper percentile are selected to compute the average of the maximal target value.

6. **Autojump.** The SPF simulation can be controlled by various autojump options. When autojump conditions are met, the SPF simulation will be either terminated or continued from phase I to phase II simulation. The autojump check can be held inactive by setting a strikethrough time. In this case the SPF simulation will continue for that period of time and only be interrupted when the percentage of nodes-in-contact reaches 100% for a specified time. The available autojump conditions are:

   a) *Peak pressure is reached and stays for certain time:* The peak pressure is determined by the maximum allowable scale factor and the load curve. The simulation will continue for a user specified time before termination.

   b) *User specified percentage of nodes-in-contact is reached:* The simulation will be terminated or continued to Phase II automatically if one of the following conditions is met:

      i) If the change of the percentage of nodes-in-contact is zero or negative for a specified time.

      ii) If the percentage of nodes-in-contact oscillates in a specified range for a specified time.

      iii) If the percentage of nodes-in-contact drops more than a specified value from the maximum value recorded.

      iv) If the percentage of nodes-in-contact reaches a user specified stop value.

7. **Computation Time.** In order to speed up the simulation of the superplastic forming process, we scale down the computation time. By doing this we increase the strain rate allowed in the SPF process, resulting in reduced simulation time. However, caution should be utilized with this speedup as it may affect the accuracy of the results. We recommend no or small strain rate speedup for simulations with complex geometry or tight angles.

8. **Critical Regions.** If the user knows the area(s) in the workpiece that are critical in the SPF process, he can use the box option to limit the region(s) where the elements are checked for computing the average of the maximal target value.

*LOAD_SURFACE_STRESS_{OPTION}

Available options include:

<BLANK>

SET

Purpose: This keyword modifies the behavior of shell elements causing them to pass pressure-type loads to material models 37 and 125 (see Remarks 1 and 2); shells usually omit such effects.

With this keyword, LS-DYNA calculates segment pressures from contact and applied pressure loads on both the upper and lower surfaces of the shell and applies them as negative local *z*-stresses during the simulation. It is found in some cases this capability can improve the accuracy of metal forming simulations.

Card Sets. Include as many sets consisting of the following three cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID							
Type	I							

Card 2	1	2	3	4	5	6	7	8
Variable	LSCID1	LSCID2	LSCID3	LSCID4	LSCID5	LSCID6	LSCID7	LSCID8
Type	I	I	I	I	I	I	I	I

Card 3	1	2	3	4	5	6	7	8
Variable	USCID1	USCID2	USCID3	USCID4	USCID5	USCID6	USCID7	USCID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
PID/PSID	Part ID or, if option SET is active, part set ID.
LSCID*n*	Lower surface contact IDs. Up to eight IDs can be defined. These contacts definitions contribute to the pressure acting on the lower surface of the shell. If the pressure on the lower surface is due to applied pressure loads, specify a value -1 instead of a contact ID. Only one of the LSCID*n* may be set to -1. Lower surface of a part is on the opposite side of the shell element normals, which must be made consistent (in LS-PrePost).
USCID*n*	Upper surface contact IDs. Up to eight IDs can be defined. These contacts definitions contribute to the pressure acting on the upper surface of the shell. If the pressure on the upper surface is due to applied pressure loads, specify a value of -1 instead of a contact ID. Only one of the USCID*n* may be set to -1. Upper surface of a part is on the same side of the shell element normals, which must be made consistent (in LS-PrePost).

Remarks:

1. **MAT_TRANSVERSLY_ANISOTROPIC_ELASTIC_PLASTIC (37).** This keyword can be used with *MAT_037 when ETAN is set to a negative value (see *MAT_037 manual pages), which triggers normal stresses (local *z*-stresses) resulting either from sliding contact or applied pressure to be considered in the shell formulation. The normal stresses can be significant in male die radius and corners in forming of Advanced High Strength Steels (AHSS). The negative local *z*-stresses are written to the d3plot files after Revision 97158 and can be plotted in LS-PrePost by selecting *z*-stress under *FCOMP* → *Stress* and select *local* under *FCOMP*.

2. **MAT_KINEMATIC_HARDENING_TRANSVERSLY_ANISOTROPIC (125).** This keyword can also be used in a simulation with *MAT_125 to account for the normal stresses (see *MAT_125 manual pages). For this material inserting this keyword *anywhere* in the input deck will invoke the shell normal stress calculation.

***LOAD_THERMAL**_*OPTION*

Available options include:

BINOUT

CONSTANT

CONSTANT_ELEMENT_*OPTION*

CONSTANT_NODE

D3PLOT

LOAD_CURVE

RSW

TOPAZ

VARIABLE

VARIABLE_ELEMENT_*OPTION*

VARIABLE_NODE

VARIABLE_SHELL_*OPTION*

Purpose: To define nodal temperatures that thermally load the structure. Nodal temperatures defined by the *LOAD_THERMAL_*OPTION* method are all applied in a structural only analysis. They are ignored in a thermal only or coupled thermal/structural analysis, see *CONTROL_THERMAL_*OPTION*.

All the *LOAD_THERMAL options cannot be used in conjunction with each other. Only those of the same thermal load type, as defined below in column 2, may be used together.

*LOAD_THERMAL_CONSTANT	- Thermal load type 1
*LOAD_THERMAL_ELEMENT	- Thermal load type 1
*LOAD_THERMAL_CONSTANT_NODE	- Thermal load type 1
*LOAD_THERMAL_LOAD_CURVE	- Thermal load type 2
*LOAD_THERMAL_TOPAZ	- Thermal load type 3
*LOAD_THERMAL_VARIABLE	- Thermal load type 4
*LOAD_THERMAL_VARIABLE_ELEMENT	- Thermal load type 4

*LOAD_THERMAL_VARIABLE_NODE - Thermal load type 4

*LOAD_THERMAL_VARIABLE_SHELL - Thermal load type 4

*LOAD_THERMAL_BINOUT

Purpose: Nodal temperatures computed in one or more prior simulations are used to load a mechanical-only analysis. Each of the prior simulations can either be a thermal-only or coupled thermal/structural analysis. The temperatures are read from the TPRINT section in the binary database binout or any other file containing the necessary information in LSDA-format. The data is mapped based on the nodal IDs.

Card 1	1	2	3	4	5	6	7	8
Variable	DEFTEMP							
Type	F							
Default	0.							

Card Sets. Include as many sets consisting of the following two cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							

Card 2	1	2	3	4	5	6	7	8
Variable	STARTT	TSF	TMPOFF					
Type	F	F	F					
Default	0.	1.	0.					

VARIABLE	DESCRIPTION
DEFTEMP	Default temperature applied to nodes that do not have temperature information provided in the binout file(s)
FILENAME	Name of the file that contains the temperature information

VARIABLE	DESCRIPTION
STARTT	Start time, t_{start}, for the temperature mapping. Until this time the nodal temperature for the first step provided in the file is used.
TSF	Time scale factor, α_t, which represents the speed-up factor of the mechanical analysis to the previous thermal analysis
TMPOFF	Temperature offset that is added to the temperature data in the specified LSDA input file.

Remarks:

1. **Overview of Keyword.** This feature provides a method for using temperature data from a previous thermal-only or even as coupled thermal/structural analysis as an external thermal load for a mechanical-only simulation. For any node of the mechanical model, the algorithm searches for temperature data in the given files. This search is based on the nodal ID. If no information is found, the default temperature is assumed. Therefore, the algorithm requires only a partial overlap of the meshes.

2. **Thermal and Mechanical Simulation Time.** Each of the thermal results can be applied starting at different simulation times, t_{start}, of the mechanical run. Furthermore, the algorithm allows running an artificially accelerated mechanical analysis. It takes into account possibly different acceleration factors, α_t, for each of the thermal runs. Those factors are equivalent to the parameter TSF as given in the keyword *CONTROL_THERMAL_SOLVER. As a result, a time, t_{th}, in the thermal run corresponds to

$$t_{\text{mech}} = t_{\text{start}} + \frac{t_{\text{th}}}{\alpha_t} \ .$$

3. **Temperature Information File.** With this keyword, binary LSDA files must be specified as input. The files should provide the same information as the TPRINT section in the binary database binout. More details for this output are defined in *DATABASE_*OPTION*.

*LOAD_THERMAL_CONSTANT

Purpose: Define the constant temperature that is applied to a given nodal set. The reference temperature state is assumed to be a null state with this option. A nodal temperature state, read in and held constant throughout the analysis, dynamically loads the structure. Thus, the temperature defined can also be seen as a relative temperature to a surrounding or initial temperature.

Card Sets. Include as many sets consisting of the following two cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	NSIDEX	BOXID					
Type	I	I	I					
Default	{all}	0	0					

Card 2	1	2	3	4	5	6	7	8
Variable	T	TE						
Type	F	F						
Default	0.	0.						

VARIABLE	DESCRIPTION
NSID	Nodal set ID containing nodes for initial temperature EQ.0: all nodes are included
NSIDEX	Nodal set ID containing nodes that are exempted from the imposed temperature (optional).
BOXID	All nodes in box which belong to NSID are initialized. Others are excluded (optional).
T	Temperature

VARIABLE	DESCRIPTION
TE	Temperature of exempted nodes (optional)

LOAD_THERMAL_CONSTANT_ELEMENT_*OPTION

Available options include:

BEAM

SHELL

SOLID

TSHELL

Purpose: Define a uniform element temperature that remains constant for the duration of the calculation. The reference temperature state is assumed to be a null state. An element temperature, read in and held constant throughout the analysis, dynamically loads the structure. The defined temperature can also be seen as a relative temperature to a surrounding or initial temperature.

Element Cards. Include as many cards in this format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	EID	T						
Type	I	F						
Default	none	0.						

VARIABLE	DESCRIPTION
EID	Element ID
T	Temperature, see Remark 1.

Remarks:

1. **Reference Temperature.** The temperature range for the constitutive constants in the thermal materials must include the reference temperature of zero. If not, termination will occur with a temperature out-of-range error immediately after the execution phase is entered.

*LOAD_THERMAL_CONSTANT_NODE

Purpose: Define nodal temperature that remains constant for the duration of the calculation. The reference temperature state is assumed to be a null state with this option. A nodal temperature state, read in and held constant throughout the analysis, dynamically loads the structure. Thus, the temperature defined can also be seen as a relative temperature to a surrounding or initial temperature.

Node Cards. Include as many cards in this format as desired. This input ends at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	NID	T						
Type	I	F						
Default	none	0.						

VARIABLE	DESCRIPTION
NID	Node ID
T	Temperature, see Remark 1.

Remarks:

1. **Reference Temperature.** The temperature range for the constitutive constants in the thermal materials must include the reference temperature of zero. If not, termination will occur with a temperature out-of-range error immediately after the execution phase is entered.

*LOAD_THERMAL_D3PLOT

Purpose: Temperatures computed in a prior thermal-only analysis are used to load a mechanical-only analysis. The rootname of the d3plot database from the thermal-only analysis is specified on the execution line of the mechanical-only analysis using T = tpf, where tpf is that rootname, such as T = d3plot.

Warnings:

1. If using a double precision LS-DYNA executable in making the two runs, do not write the d3plot data using 32ieee format in the thermal-only run, that is, the environment variable LSTC_BINARY must not be set.

2. The rootnames of the d3plot databases from the two runs must not conflict. Such conflict can be avoided, for example, by using jobid = *jobname* on the execution line of the second (mechanical-only) run.

*LOAD_THERMAL_LOAD_CURVE

Purpose: Nodal temperatures will be uniform throughout the model and will vary according to a load curve. The temperature at time = 0 becomes the reference temperature for the thermal material. The reference temperature is obtained from the optional curve for dynamic relaxation if this curve is used. The load curve option for dynamic relaxation is useful for initializing preloads.

Thermal Load Curve Cards. Include as many cards in this format as desired. This input ends at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	LCID	LCIDDR						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
LCID	Load curve ID, see *DEFINE_CURVE, to define temperature as a function of time.
LCIDDR	An optional load curve ID, see *DEFINE_CURVE, to define temperature as a function of time during the dynamic relaxation phase.

*LOAD_THERMAL_RSW

Purpose: Define thermal loading conditions within an ellipsoidal region of the solid or shell structure for structural-only simulation. Temperatures are prescribed to nodes found in a region defined by this keyword. The load condition is tailored to represent the so-called weld nuggets evolving during resistive spot welding (RSW) processes and surrounding heat affected zones. For any node that is not part of a spot weld region, a default temperature is assumed.

Card Summary:

Card 1. This card is required.

DEFTEMP							

Card 2. Include as many sets of Cards 2 through 4 as needed (Card 4 is only included in the set if OPTION = 1). This input ends at the next keyword ("*") card.

SID	OPTION	NID1	NID2	TDEATH	TBIRTH	LOC	GEOUP

Card 3. Include in set with Card 2.

DIST	H1	H2	R	TEMPC	TEMPB	LCIDT	

Card 4. Include in set with Cards 2 and 3 if OPTION = 1 on Card 2.

HZ1	HZ2	RZ	TEMPZB				

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	DEFTEMP							
Type	F							
Default	0.							

VARIABLE	DESCRIPTION
DEFTEMP	Default temperature outside the nuggets and heat affected zones

Include as many sets of Cards 2 through 4 as needed (Card 4 is only included in the set if OPTION = 1). This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	SID	OPTION	NID1	NID2	TDEATH	TBIRTH	LOC	GEOUP
Type	I	I	I	I	F	F	I	I
Default	none	0	none	none	10^{20}	0.	0	0

VARIABLE	DESCRIPTION
SID	Node set ID; see *SET_NODE_*OPTION*. Nodes in the set will be checked to see if they are in the nugget or heat affected zone. If they are, the load will be applied. The load will not be applied to nodes in these regions if they are not included in the set.
OPTION	Option for heat affected zone around the weld nugget: EQ.0: No heat affected zone EQ.1: Ellipsoidal region considered
NID1	Node defining the tail of the orientation vector (axis of rotation of the ellipsoidal region) and the base for positioning of the nugget. See Remarks 1 and 2.
NID2	Node defining the head of the orientation vector (axis of rotation of the ellipsoidal region). See Remarks 1 and 2.
TDEATH	Deactivation time for temperature boundary condition. At this point in time, the temperature constraint is removed.
TBIRTH	Activation time for temperature boundary condition. Before this point in time, the temperature constraint is ignored.
LOC	Application of surface for thermal shell elements; see parameter, THSHEL, in the *CONTROL_SHELL input: EQ.-1: Lower surface of thermal shell element EQ.0: Middle surface of thermal shell element EQ.1: Upper surface of thermal shell element

VARIABLE	DESCRIPTION
GEOUP	Number of times the geometry of the spot weld is updated between TBIRTH and TDEATH EQ.0: Update geometry every time step

Geometry and Temperature Card. Include in set with Card 2.

Card 3	1	2	3	4	5	6	7	8
Variable	DIST	H1	H2	R	TEMPC	TEMPB	LCIDT	
Type	F	F	F	F	F	F	I	
Default	0.	0.	0.	0.	0.	0.	none	

VARIABLE	DESCRIPTION
DIST	Position of center of nugget on the axis of rotation. Parameter defines the distance to NID1 along the orientation vector. See Remark 1.
H1	Half width h_1 of nugget in the lower half, meaning in direction to NID1. See Remark 2.
H2	Half width h_2 of nugget in the upper half, meaning in direction to NID2. See Remark 2.
R	Radius r_{weld} of the nugget in surface normal to orientation vector. See Remark 2.
TEMPC	Base temperature at the center of the nugget. See Remark 3.
TEMPB	Base temperature at the boundary of the nugget. See Remark 3.
LCIDT	|LCIDT| refers to the load curve ID prescribing the temperature evolution in the nugget as a function of time. The abscissa of the load curve will be normalized between the birth and death times of the boundary condition. GT.0: The ordinate values of the load curve scale the respective base temperature of a particular point. EQ.0: No temperature evolution. Base temperatures are used.

VARIABLE	DESCRIPTION
	LT.0: The ordinate values of the load curve are used to define a linear combination between the temperature at the birth time and the base temperature of a particular point. Load curve ordinate values should range between 0.0 and 1.0. We recommend LCIDT < 0 to ensure a smooth temperature evolution.
	See Remark 3.

Heat Affected Zone Card. Include in set with Cards 2 and 3 if OPTION = 1 on Card 2.

Card 4	1	2	3	4	5	6	7	8
Variable	HZ1	HZ2	RZ	TEMPZB				
Type	R	F	F	R				
Default	0.	0.	0.	0.				

VARIABLE	DESCRIPTION
HZ1	Half width h_{z1} of heat affected zone in the lower half, meaning in direction to NID1. See Remark 4.
HZ2	Half width h_{z2} of heat affected zone in the upper half, meaning in direction to NID1. See Remark 4.
RZ	Radius r_{haz} of the heat affected zone in surface normal to orientation vector. See Remark 4.
TEMPBZ	Base temperature at the boundary of the heat affected zone. See Remark 4.

Remarks:

1. **Positioning.** The position of the center of the nugget is defined starting from a base node (NID1). It is then translated by a distance DIST along the orientation vector **v** of the nugget. Vector **v** points from NID1 to NID2. See Figure 31-16.

2. **Geometry of the nugget.** Orientation vector **v** defines the axis of rotational symmetry for the ellipsoidal region, which reflects the weld nugget. The radius around this axis is defined by r_{weld}. The nugget consists of two half ellipsoids

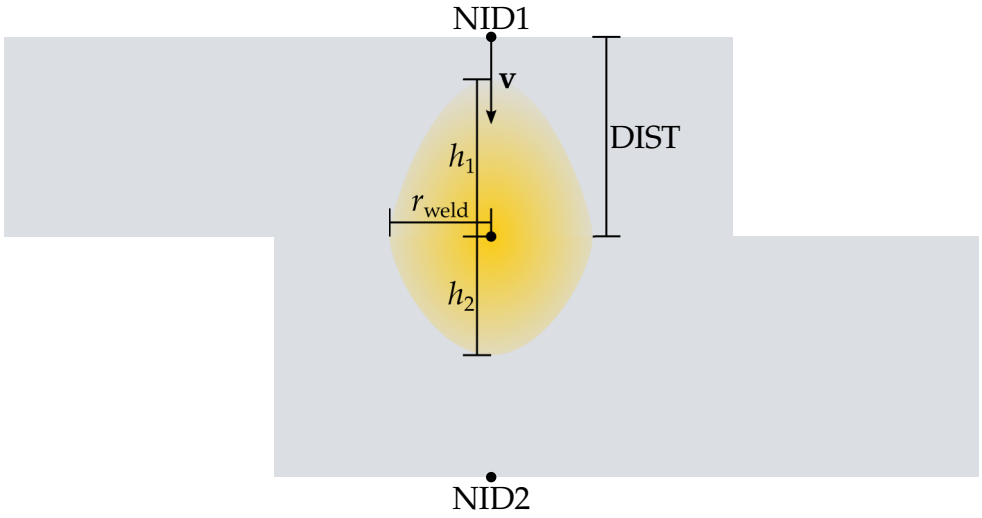

Figure 31-16. Example of geometry for OPTION = 0

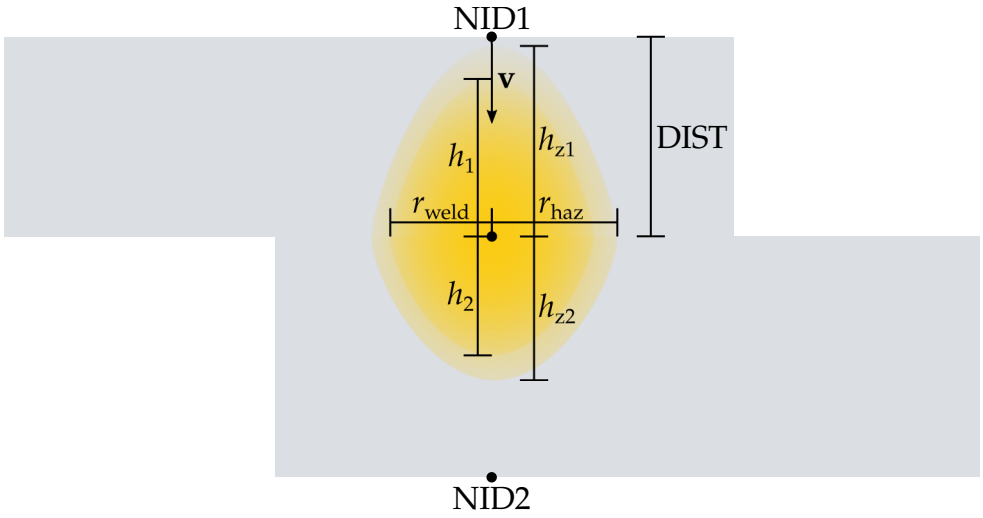

Figure 31-17. Example of geometry with OPTION = 1 (heat affected zone)

of possibly different height. The lower half, i.e. the half between NID1 and the center, has a height of h_1, wheras the upper half has a height of h_2. See Figure 31-16.

3. **Prescribing temperature values.** You can prescribe the base temperatures at the boundary and the center of the nugget with TEMPC and TEMPB, respectively. In between LS-DYNA calculates the base temperature in the nugget, $T_{\mathrm{nug},b}(x,y,z)$, with a quadratic interpolation.

   For this loading condition, you must provide activation and deactivation times, t_{ac} and t_{deac}, respectively. With LCIDT, you can specify the temperatures as a function, $\theta(\tilde{t})$, of the normalized time, $\tilde{t} = (t - t_{\mathrm{ac}})/(t_{\mathrm{deac}} - t_{\mathrm{ac}})$, within this time span. For positive values of field LCIDT, a simple scaling is applied:

$$T_{\mathrm{nug}}(x,y,z,t) = T_{\mathrm{nug},b}(x,y,z) \times \theta(\tilde{t}(t)) \quad .$$

For negative values of LCIDT, a smooth evolution of the temperature from the birth time is ensured, so we recommend this type of load curve. The temperature is given by:

$$T_{\text{nug}}(x,y,z,t) = T_{\text{ac}}(x,y,z) + \Big(T_{\text{nug},b}(x,y,z) - T_{\text{ac}}(x,y,z)\Big) \times \theta(\tilde{t}) \ .$$

Here T_{ac} corresponds to the temperature of a particular point right before the birth time.

4. **Heat affected zone.** With input field OPTION set to 1, the prescribed load expands to a heat affected zone that has the same general shape definition as the weld nugget described in Remark 2. The dimensions are here given by r_{haz}, h_{z1}, and h_{z2}. See Figure 31-17.

   You can prescribe the base temperature value at the boundary of the heat affected zone. LS-DYNA finds the base temperature in the heat affected zone, $T_{\text{HAZ},b}(x,y,z)$ with a linear interpolation between the base boundary temperature of the nugget and the base boundary temperature of the heat affected zone. The load curve LCIDT governs the temperature evolution of the heat affected zone as described in Remark 3.

*LOAD_THERMAL_TOPAZ

Purpose: Nodal temperatures will be read in from the TOPAZ3D database. This file is defined on the execution line by the specification: T=**tpf**, where **tpf** is a binary database file (such as T3PLOT).

*LOAD_THERMAL_VARIABLE

Purpose: Define nodal temperature using node set(s) and temperature as a function of time curve(s).

Card Sets. Include as many sets consisting of the following two cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	NSIDEX	BOXID					
Type	I	I	I					
Default	{all}	{∅}	0					

Card 2	1	2	3	4	5	6	7	8
Variable	TS	TB	LCID	TSE	TBE	LCIDE	LCIDR	LCIDEDR
Type	F	F	I	F	F	I	I	I
Default	0.	0.	none	0.	0.	↓	none	↓
Remark	1	1	1	1	1			

VARIABLE	DESCRIPTION
NSID	Nodal set ID containing nodes (see *SET_NODE_*OPTION*): EQ.0: all nodes are included.
NSIDEX	Nodal set ID containing nodes that are exempted (optional), (see *SET_NODE_OPTION).
BOXID	All nodes in box which belong to NSID are initialized. Others are excluded.
TS	Scaled temperature.
TB	Base temperature.

VARIABLE	DESCRIPTION
LCID	Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION and Remark 2) that multiplies the scaled temperature.
TSE	Scaled temperature of the exempted nodes (optional).
TBE	Base temperature of the exempted nodes (optional).
LCIDE	Load curve ID that multiplies the scaled temperature of the exempted nodes (optional), (see *DEFINE_CURVE).
LCIDR	Load curve ID that multiplies the scaled temperature during the dynamic relaxation phase
LCIDEDR	Load curve ID that multiplies the scaled temperature of the exempted nodes (optional) during the dynamic relaxation phase.

Remarks:

1. **Temperature Model.** The total temperature is defined as

$$T = \mathrm{TB} + \mathrm{TS} \times f(t) \ ,$$

where $f(t)$ is the current value of the load curve, TS is the scaled temperature, and TB is the base temperature. The initial temperature and thus the reference temperature for a thermal loading is consistently defined by $T_0 = \mathrm{TB} + \mathrm{TS} \times f(0)$.

2. ***DEFINE_FUNCTION for LCID.** If LCID references a function ID, then the following function arguments are allowed: $f(x0, y0, z0, x, y, z, t)$, where $x0$, $y0$ and $z0$ are the original coordinates; x, y and z are the current coordinates; and t is the solution time

3. **Thermal Strain.** The rate of thermal strain is based on the rate of temperature change. In other words, the thermal load arises from change in total temperature. Furthermore, the calculation of the thermal strain from the coefficient of thermal expansion depends on the material model, and some material models, e.g., *MAT_255, may offer multiple options. Temperature-dependent material properties are based on the total temperature.

*LOAD_THERMAL_VARIABLE_BEAM_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Define a known temperature time history as a function of the section coordinates for Hughes-Liu beam elements. To set the temperature for the whole element see *LOAD_THERMAL_VARIABLE_ELEMENT_BEAM.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	EID/SID	IPOLAR					
Type	I	I	I					
Default	none	none	0					

Temperature Cards. Include as many cards in the following format as desired. See Remarks 2 and 3. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	TBASE	TSCALE	TCURVE	TCURDR	SCOOR	TCOOR		
Type	F	F	I	I	F	F		
Default	0.	1.0	0	TCURVE	none	none		

VARIABLE	DESCRIPTION
ID	Load case ID
EID/SID	Beam ID or beam set ID
IPOLAR	Flag to use polar coordinates instead of rectangular coordinates. GT.0: The coordinates SCOOR and TCOOR are given in polar coordinates. See Remark 3.
TBASE	Base temperature

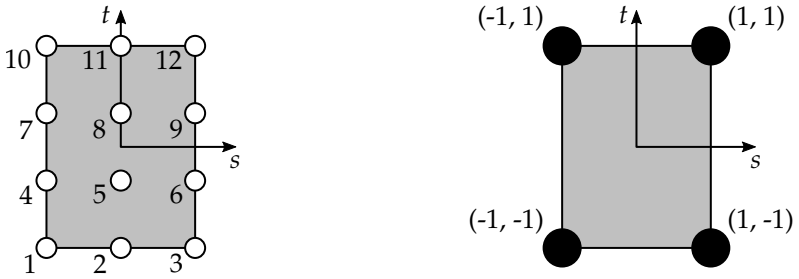

Figure 0-1. Figure illustrating point ordering.

VARIABLE	DESCRIPTION
TSCALE	Constant scale factor applied to temperature from curve
TCURVE	Curve ID for temperature as a function of time
TCURDR	Curve ID for temperature as a function of time used during dynamic relaxation
SCOOR	Normalized coordinate in local s-direction (-1.0 to +1.0)
TCOOR	Normalized coordinate in local t-direction (-1.0 to +1.0)

Remarks:

1. **Temperature Curve.** The temperature T is defined as:

$$T = TBASE + TSCALE \times f(t)$$

where $f(t)$ is the current ordinate value of the curve. If the curve is undefined, then T = TBASE at all times.

2. **Cross Section Coordinates.** At least four points (four Card 2's) must be defined in a rectangular grid since each edge can have a different temperature history. The required order of the points is as shown in Figure 0-1. First, define the bottom row of points (most negative t), left to right in order of increasing s. Then increment t to define the next row of points, left-to-right in order of increasing s, and so on. The s-t axes are in the plane of the beam cross-section with the s-axis in the plane of nodes N1, N2, N3 defined in *ELEMENT_BEAM.

3. **Polar Cross Section Coordinates.** For this option only two points (two Card 2's) must be defined for the center and edge of the section because the temperature changes are assumed to only be in the radial direction. For the polar option, SCOOR is the non-dimensional radius R/R_0 where R_0 is the outer radius of the section; and TCOOR is defined as θ/π, where θ is the angle in radians from the s-axis and ranges from $-\pi$ to π.

4. **Integration Point Temperatures.** Temperatures will be assigned to the integration points by linear interpolation from the points defined using this command.

LOAD_THERMAL_VARIABLE_ELEMENT_*OPTION

Available options include:

BEAM

SHELL

SOLID

TSHELL

Purpose: Define element temperature that is variable during the calculation. The reference temperature state is assumed to be the temperature at time = 0.0 with this option.

Element Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	EID	TS	TB	LCID				
Type	I	F	F	I				
Default	none	0.	0.	none				

VARIABLE	DESCRIPTION
EID	Element ID
TS	Scaled temperature
TB	Base temperature
LCID	Load curve ID defining a scale factor that multiplies the scaled temperature as a function of time (see *DEFINE_CURVE).

Remarks:

1. The temperature is defined as:

$$T = \mathrm{TB} + \mathrm{TS} \times f(t)$$

where $f(t)$ is the current value of the load curve, TS is the scaled temperature, and TB is the base temperature

*LOAD_THERMAL_VARIABLE_NODE

Purpose: Define nodal temperature that is variable during the calculation. A nodal temperature state read in and varied according to the load curve dynamically loads the structure.

Node Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	NID	TS	TB	LCID				
Type	I	F	F	I				
Default	none	0.	0.	none				

VARIABLE	DESCRIPTION
NID	Node ID
TS	Scaled temperature
TB	Base temperature
LCID	Load curve ID that multiplies the scaled temperature, (see *DEFINE_CURVE).

Remarks:

1. The temperature is defined as:

$$T = \mathrm{TB} + \mathrm{TS} \times f(t)$$

where $f(t)$ is the current value of the load curve, TS is the scaled temperature, and TB is the base temperature. The initial temperature and thus the reference temperature for a thermal loading is consistently defined by $T_0 = \mathrm{TB} + \mathrm{TS} \times f(0)$.

*LOAD_THERMAL_VARIABLE_SHELL_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Define a known temperature time history as a function of the through-thickness coordinate for the shell elements.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	EID/SID						
Type	I	I						
Default	none	none						

Temperature Cards. Include as many cards of this type as desired. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	TBASE	TSCALE	TCURVE	TCURDR	ZCO			
Type	F	F	I	I	F			
Default	0.0	1.0	Rem 1	TCURVE	none			

VARIABLE	DESCRIPTION
ID	Load case ID
EID/SID	Shell ID or shell set ID
TBASE	Base temperature
TSCALE	Constant scale factor applied to temperature from curve
TCURVE	Curve ID for temperature as a function of time

VARIABLE	DESCRIPTION
TCURDR	Curve ID for temperature as a function of time used during dynamic relaxation
ZCO	Normalized through-thickness coordinate (-1.0 to +1.0). See Remarks 2 and 3.

Remarks:

1. **Temperature Definition.** The temperature T is defined as:

$$T = \text{TBASE} + \text{TSCALE} \times f(t) ,$$

where $f(t)$ is the current ordinate value of the curve. If the curve is undefined, then T = TBASE at all times.

2. **Through-Thickness Coordinate.** Through-thickness points must be defined in order of increasing ZCO (-1.0 to +1.0). ZCO = +1.0 is the top surface of the element, that is, the element surface in the positive outward normal vector direction from the mid-plane.

3. **Shell Temperature Distribution.** At least two points (two Card 2's) must be defined. Temperatures will be assigned in the through-thickness direction by linear interpolation from the points defined using this command. If the element has multiple in-plane integration points, the same temperature distribution is used at each in-plane integration point.

4. **LOAD_THERMAL_NODE.** If a shell's temperature distribution is defined using this card, any values defined by *LOAD_THERMAL_NODE are ignored for that shell.

*LOAD_VOLUME_LOSS

Purpose: To represent the effect of tunneling on surrounding structures, it is common to assume that a pre-defined fraction (e.g., 2%) of the volume occupied by the tunnel is lost during the construction process. This feature is available for solid elements only.

Part Set Cards. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

Card	1	2	3	4	5	6	7	8
Variable	PSID	COORD	LCUR	FX	FY	FZ	PMIN	FACTOR
Type	I	I	I	F	F	F	F	F
Default	none	global	0	1	1	1	-10^{20}	.01

VARIABLE	DESCRIPTION
PSID	Part Set ID
COORD	Coordinate System ID (default - global coordinate system)
LCUR	Curve ID containing volume fraction lost as a function of time
FX	Fraction of strain occurring in *x*-direction
FY	Fraction of strain occurring in *y*-direction
FZ	Fraction of strain occurring in *z*-direction
PMIN	(Leave blank)
FACTOR	Feedback factor

Remarks:

1. **Volume Loss Algorithm.** Volume loss is modeled by a process similar to thermal contraction: if the material is unrestrained, it will shrink while remaining unstressed; if restrained, stresses will become more tensile. Typically, the material surrounding the tunnel offers partial restraint; the volume loss algorithm adjusts the applied "thermal" strains to attempt to achieve the desired volume loss. Optionally, FX, FY and FZ may be defined: these will be treated as ratios

for the x, y and z strains; this feature can be used to prevent contraction parallel to the tunnel axis.

2. **Output.** The total volume of all the parts in the part set is monitored and output at the time-history interval (on *DATABASE_BINARY_D3THDT) to a file named vloss_output. This file contains lines of data (*time, volume1, volume2, volume3…*) where *volume1* is the total volume of elements controlled by the first *LOAD_VOLUME_LOSS card, *volume2* is the total volume of elements controlled by the second *LOAD_VOLUME_LOSS card, etc.

3. **Material Models.** This feature works only with material types that use incremental strains to compute stresses. Thus, hyperelastic materials (e.g. MAT_027) are excluded, as are certain foam material types (e.g. MAT_083).

4. **Feedback Factor.** The feedback factor (see FACTOR field) controls how strongly the algorithm tries to impose the desired change of volumetric strain. The default value is recommended. If the volumetric response appears noisy or unstable, it may be necessary to reduce FACTOR. Alternatively, if the actual volumetric strain changes much more slowly than the input curve, it may be necessary to increase FACTOR.

*MODULE

The keyword *MODULE provides a way to load user compiled libraries at runtime, to support user defined capabilities such as material models, equations of state, element formulations, etc. The following keywords implement this capability:

*MODULE_LOAD

*MODULE_PATH

*MODULE_USE

*MODULE_LOAD

Purpose: Load a dynamic library for user subroutines.

Card Sets. Repeat as many sets of data cards as desired (Cards 1 and 2) to load multiple libraries. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	MDLID		TITLE					
Type	A20		A60					
Default	none		none					

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	none							

VARIABLE	DESCRIPTION
MDLID	Module identification. A unique string label must be specified.
TITLE	Description of the module
FILENAME	File name of the library to be loaded, 80 characters maximum. If the file name has no path component, LS-DYNA will search in all directories specified in *MODULE_PATH first. If not found and the file name starts with "+" (a plus sign), LS-DYNA will continue to search all directories specified in the system environment variable LD_LIBRARY_PATH.

Remarks:

1. **Library Restrictions.** The MODULE capability described here and in *MODULE_USE is still under development and is considered experimental. As such,

it is currently only supported in specially compiled executables on Linux systems for pure MPP.

2. **Execution Line Option.** If only one dynamic library is loaded and no rules are required (*MODULE_USE), this dynamic library can be specified through the execution line option "module=*dll*". The system environment variable LD_LIBRARY_PATH is also used for searching the dynamic library if the file name starts with "+". This execution line option provides the support to the classic user subroutine subroutines without modifying the input deck.

MODULE_PATH_*{OPTION}

Available options:

<BLANK>

RELATIVE

LS-DYNA's default behavior is to search for modules in the current working directory. If a module file is not found and the filename has no path component, LS-DYNA will search in all directories specified on the cards following a *MODULE_PATH keyword. Multiple paths can be specified using one *MODULE_PATH keyword card, that is,

```
*MODULE_PATH
Directory_path1
Directory_path2
Directory_path3
```

Directory paths are read until the next keyword ("*") card is encountered. A directory path can have up to 236 characters. See Remark 2.

When the RELATIVE option is used, all directories are relative to the location of the input file. For example, if "i=/home/test/problems/input.k" is given on the command line, and the input contains

```
*MODULE_PATH_RELATIVE
lib
../lib
```

then the two directories /home/test/problems/lib and /home/test/lib will be searched for module files.

Remarks:

1. **Input Format.** Filenames and pathnames are limited to 236 characters spread over up to three 80 character lines. When 2 or 3 lines are needed to specify the filename or pathname, end the preceding line with "␣+" (space followed by a plus sign) to signal that a continuation line follows. Note that the "␣+" combination is, itself, part of the 80 character line; hence the maximum number of allowed characters is 78 + 78 + 80 = 236.

*MODULE_USE

Purpose: Define the rules for mapping the user subroutines loaded in dynamic libraries to the model. The rules can be applied to:

*MAT_USER_DEFINED_MATERIAL_MODELS	(MAT 41 - 50)
*MAT_THERMAL_USER_DEFINED	(MAT T11 - T15)
*EOS_USER_DEFINED	(EOS 21 – 30)
*SECTION_SOLID	(ELFORM 101 - 105)
*SECTION_SHELL	(ELFORM 101- 105)
*USER_INTERFACE_FRICTION	
*CONTACT_..._MORTAR_TIED_WELD	(TEMP.LT.0)

as well as other subroutines in the LS-DYNA user-subroutine package.

LS-DYNA requires that subroutines in modules (see *MODULE_LOAD) be named as if they were part of the traditional user-subroutine framework. Each module, however, can contain a complete set of those subroutines. It is, therefore, possible to import from different modules the same subroutines of the same name several times. Each module is, essentially, an independent copy of the traditional user-subroutine framework. This keyword, *MODULE_USE, deals with namespace conflicts by defining how each subroutine in the module is presented to the other keywords.

The rules defined in *MODULE_USE are applied to only one dynamic library.

Card 1	1	2	3	4	5	6	7	8
Variable	MDLID							
Type	A20							
Default	none							

Rule Cards. Card 2 defines the rules for the module specified in Card 1. Include one instance of this card for each subroutine to be mapped. If two rules conflict, new rules override existing rules. Input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	TYPE		PARAM1		PARAM2			
Type	A20		A20		A20			
Default	none		blank		blank			

VARIABLE	DESCRIPTION
MDLID	Module identification defined in *MODULE_LOAD
TYPE	Rule type. See TYPE definitions below.
PARAM1	Type-dependent parameter
PARAM2	Type-dependent parameter.

User-Defined Materials:

TYPE	DESCRIPTION
UMAT	Implements the user-material type PARAM1 in the model via a possibly different type PARAM2 in the dynamic library. Types in the extended range from 1001 to 2000 can be used as material types in the model. For example, if PARAM1 = 1001 and PARAM2 = 42, then model material 1001 will use subroutine `umat42` from this library. If PARAM1 is blank and PARAM2 is not, then all user materials in the model will use the indicated subroutine from this library. If PARAM2 is blank and PARAM1 is not, the material type PARAM1 in the model will use the traditional subroutine from this library. For example, if PARAM1 = 43 and PARAM2 is blank, material type 43 in the model will use the subroutine `umat43` from this library.

TYPE	DESCRIPTION
	If PARAM1 and PARAM2 are blank, then all user-defined materials in the model will use the traditional subroutines from this library (41 → `umat41`, 42 → `umat42`, etc.).
MATID	Implements the user material having ID = PARAM1 via a possibly different material type PARAM2 in the dynamic library. PARAM2 may be blank if the material type defined in the model is the same as the one in the dynamic library. PARAM1 can be a numerical ID or label of the material as defined in the model. Materials beyond user material models can be overloaded.

Thermal User-Defined Materials:

TYPE	DESCRIPTION
TUMAT	Implements the user thermal material type PARAM1 in the model (PARAM1 = 11-15) via type PARAM2 in the dynamic library. See type UMAT for the default rules.
TMATID	Implements the user thermal material having ID = PARAM1 via thermal material type PARAM2 in the dynamic library. PARAM2 may be blank if the material type defined in the model is the same as the one in the dynamic library. PARAM1 can be a numerical ID or label of the thermal material as defined in the model. Materials beyond user material models can be overloaded.

User-Defined EOS:

TYPE	DESCRIPTION
UEOS	Implements the user EOS model PARAM1 in the model (PARAM1 = 21-30) via EOS model PARAM2 in the dynamic library. See type UMAT for the default rules.

User-Defined Elements:

TYPE	DESCRIPTION
UELEM	Implements the user element type PARAM1 in the model (PARAM1 = 101-105) via element type PARAM2 in the dynamic library. See type UMAT for the default rules.
SECTIONID	Implements the user element type with section ID = PARAM1 via element type PARAM2 in the dynamic library. PARAM2 may be blank if the element type defined in the model is the same as the one in the dynamic library.

> **Note**: Solid element types are mapped to subroutine `usrsld`, and shell element types are mapped to subroutine `usrshl`. These interfaces are documented in the Fortran user-subroutine files.

Other User Subroutines:

If TYPE = UTIL, the model uses the following subroutines implemented in the dynamic library. LS-DYNA ignores any subroutines with the same name in other dynamic libraries, if they exist.

PARAM1	DESCRIPTION
UMATFAIL	matusr_24 matusr_103
UFRICTION	usrfrc mortar_usrfrc mortar_usrtie

UCOU-PLE2OTHER	couple2other_boxminmax couple2other_comm couple2other_dt couple2other_extra couple2other_getf couple2other_givex couple2other_reader chkusercomm usercomm usercomm1

PARAM1	DESCRIPTION
UOUTPUT	ushout

Remarks:

1. **Omitting *MODULE_USE.** To simplify the development of user-defined materials via modules, the *MODULE_USE keyword can be omitted in one case. If only a single module library will be used and no remapping of material types is desired, then a *MODULE_LOAD keyword may appear with a single library and no other *MODULE keywords. In this case, all the user-defined subroutines in this library will be used in the usual way. For example, if the library contains `umat41` and `umat43`, those routines will be used for all materials of type 41 and 43, respectively. The *MODULE_USE keyword describing this library may be omitted.

EXAMPLES:

The following examples demonstrate the input for the MODULE keywords:

*MODULE_PATH

*MODULE_LOAD

*MODULE_USE

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  Using *MODULE_PATH to define additional directories where

```

*NODE

The keywords defined in this section include:

NODE_*{OPTION}

*NODE_MERGE_SET

*NODE_MERGE_TOLERANCE

*NODE_RIGID_SURFACE

NODE_SCALAR_*{OPTION}

*NODE_THICKNESS

*NODE_TO_TARGET_VECTOR

*NODE_TRANSFORM

***NODE**_*{OPTION}*

Available options include:

<BLANK>

MERGE

Purpose: Define a node and its coordinates in the global coordinate system. Also, the boundary conditions in global directions can be specified. Generally, nodes are assigned to elements; however, exceptions are possible (see Remark 2 below). The nodal point ID must be unique relative to other nodes defined in the *NODE section.

The MERGE option is usually applied to boundary nodes on disjoint parts and only applies to nodes defined when the merge option is invoked. With this option, nodes with identical coordinates are replaced during the input phase by the first node encountered that shares the coordinate. During the merging process a tolerance is used to determine whether a node should be merged. This tolerance can be defined using the keyword *NODE_MERGE_TOLERANCE keyword, which is recommended over the default value. See the *NODE_MERGE_TOLERANCE input description in the next section.

Node Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	NID	X		Y		Z		TC	RC	
Type	I	F		F		F		I	I	
Default	none	0.		0.		0.		0	0	
Remarks								1	1	

VARIABLE	DESCRIPTION
NID	Node number
X	*x* coordinate
Y	*y* coordinate
Z	*z* coordinate

VARIABLE	DESCRIPTION
TC	Translational Constraint: EQ.0: no constraints, EQ.1: constrained x displacement, EQ.2: constrained y displacement, EQ.3: constrained z displacement, EQ.4: constrained x and y displacements, EQ.5: constrained y and z displacements, EQ.6: constrained z and x displacements, EQ.7: constrained x, y, and z displacements.
RC	Rotational constraint: EQ.0: no constraints, EQ.1: constrained x rotation, EQ.2: constrained y rotation, EQ.3: constrained z rotation, EQ.4: constrained x and y rotations, EQ.5: constrained y and z rotations, EQ.6: constrained z and x rotations, EQ.7: constrained x, y, and z rotations.

Remarks:

1. **Boundary Conditions.** Boundary conditions can also be defined on nodal points in a local (or global) system by using the keyword *BOUNDARY_SPC. For other possibilities also see the *CONSTRAINED keyword section of the manual. No attempt should be made to apply boundary conditions to nodes belonging to rigid bodies (see *MAT_RIGID for application of rigid body constraints).

2. **Massless Nodes.** A node without an element or a mass attached to it will be assigned a very small amount of mass and rotary inertia. Generally, massless nodes should not cause any problems but in rare cases may create stability problems if these massless nodes interact with the structure. Warning messages are printed when massless nodes are found. Also, massless nodes are used with rigid bodies to place joints, see *CONSTRAINED_EXTRA_NODES_*OPTION* and *CONSTRAINED_NODAL_RIGID_BODY.

*NODE_MERGE_SET

Purpose: The MERGE_SET option is applied to a set of boundary nodes on disjoint part. With this option, nodes with identical coordinates that are members of any node set ID defined by this keyword are replaced during the input phase by one node within the set or sets. Of the nodes sharing the same coordinates, the node chosen is the one with the smallest ID. During the merging process a tolerance is used to determine whether a node should be merged. This tolerance can be defined using the keyword *NODE_MERGE_-TOLERANCE keyword, which is recommended over the default value. See the *NODE_-MERGE_TOLERANCE input description in the next section. Only nodes contained within the specified sets will be merged. Nodes contained within the set are defined by the *NODE keyword. With this option, the keyword *NODE_MERGE is not needed.

Node Set Cards. Include as many cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
NSID	Node set ID containing list of nodes to be considered for merging.

*NODE_MERGE_TOLERANCE

Purpose: Define a tolerance that determines whether a node listed in *NODE_MERGE should be merged.

Card 1	1	2	3	4	5	6	7	8
Variable	T0LR							
Type	F							
Default	Rem 1							

VARIABLE	DESCRIPTION
TOLR	Physical distance used to determine whether to merge a nodal pair of nearby nodes.

Remarks:

1. **Default Tolerance.** If the tolerance, TOLR, is undefined or if it is defaulted to zero, a value is computed as:

$$\text{TOLR} = 10^{-5} \cdot \frac{\text{XMAX} + \text{YMAX} + \text{ZMAX} - \text{XMIN} - \text{YMIN} - \text{ZMIN}}{3 \times \sqrt[3]{\text{NUMNP}}},$$

where XMIN, XMAX, YMIN, YMAX, ZMIN, and ZMAX represent the minimum and maximum values of the (x, y, z) nodal point coordinates in the global coordinate system, and NUMNP is the number of nodal points.

*NODE_RIGID_SURFACE

Purpose: Define a rigid node and its coordinates in the global coordinate system. These nodes are used to define rigid road surfaces, and they have no degrees of freedom. The nodal points are used in the definition of the segments that define the rigid surface. See *CONTACT_RIGID_SURFACE. The nodal point ID must be unique relative to other nodes defined in the *NODE section.

Node Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	NID	X		Y		Z				
Type	I	F		F		F				
Default	none	0.		0.		0.				

VARIABLE	DESCRIPTION
NID	Node number
X	*x* coordinate
Y	*y* coordinate
Z	*z* coordinate

***NODE_SCALAR**_{OPTION}_

Available options include:

<BLANK>

VALUE

Purpose: Define a scalar nodal point which has a specified number of degrees-of-freedom. The scalar point ID must be unique relative to other nodes defined in the *NODE section.

Node Card. Card 1 for no keyword option (option set to <BLANK>). Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1a	1	2	3	4	5	6	7	8	9	10
Variable	NID	NDOF								
Type	I	I								
Default	none	0								

Node Card. Card 1 for the VALUE keyword option. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1b	1	2	3	4	5	6	7	8	9	10
Variable	NID	X1		X2		X3		NDOF		
Type	I	F		F		F		I		
Default	none	0.0		0.0		0.0		0		

VARIABLE	DESCRIPTION
NID	Scalar node ID
NDOF	Number of degrees-of-freedom: EQ.0: Fully constrained EQ.1: One degree-of-freedom

VARIABLE	DESCRIPTION
	EQ.2: Two degrees-of-freedom
	EQ.3: Three degrees-of-freedom
X*i*	Initial value of i^{th} degree of freedom

***NODE_THICKNESS**_{OPTION1}_{OPTION2}

For OPTION1 the available options include:

<BLANK>

SET

For OPTION2 the available options include:

<BLANK>

GENERATE

Purpose: Define nodal thickness that overrides nodal thickness otherwise determined via *SECTION_SHELL, *PART_COMPOSITE, or *ELEMENT_SHELL_THICKNESS. The option GENERATE generates a linear thickness distribution between a starting node (or node set) and a ending node (or node set).

Card 1	1	2	3	4	5	6	7	8
Variable	ID1	THK	ID2	INC				
Type	I	F	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
ID1	Node ID, or node set ID if SET option is active. If GENERATE option is active, ID1 serves as the starting node (or node set).
THK	Thickness at node ID1, or node set ID1 if SET option is active (ignored if GENERATE option is active).
ID2	Ending node (or node set) if GENERATE option is active.
INC	Increment in node numbers if GENERATE option is active.

Remarks:

When the GENERATE option is active, both the starting and ending nodes (or node sets) must have a nodal thickness as defined by *NODE_THICKNESS or NODE_THICK-

NESS_SET. The sample commands shown below create a linear thickness distribution between node set 100 and node set 200.

```
*SET_NODE_LIST
100
1, 15, 39
*SET_NODE_LIST
200
7, 21, 45
*NODE_THICKNESS_SET
$ assign thickness of 2.0 to node 1, 15 and 39
100, 2.0
*NODE_THICKNESS_SET
$ assign thickness of 5.0 to node 7, 21 and 45
200, 5.0
*NODE_THICKNESS_SET_GENERATE
$ assign thickness of 3. (= 2.+1.) to node 3 (=1+2), 17 (=15+2) and 41 (=39+2)
$ assign thickness of 4. (= 2.+2.) to node 5 (=1+4), 19 (=15+4) and 43 (=39+4)
100,, 200, 2
```

*NODE_TO_TARGET_VECTOR

Purpose: When the input contains a *CONTROL_FORMING_BESTFIT_VECTOR card, LS-DYNA writes as output a keyword file named bestfit.out. Unlike most keyword cards, which are read by LS-DYNA to define a model, LS-DYNA's keyword reader ignores this card. This card and its associated data cards are a kind of output for the user's benefit (or for post-processing).

Recall that the *CONTROL_FORMING_BESTFIT_VECTOR keyword (mentioned above) rigidly moves a part to best fit a target, such as a scanned part. For each node of the best fit part LS-DYNA writes a data card (Card 1, below) consisting of the components of the vector that is the shortest distance from the node to the target.

Node Cards. As many cards as needed are output in the following format. This output ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	NID	XDELTA		YDELTA		ZDELTA				
Type	I	F		F		F				
Default	none	0.		0.		0.				

VARIABLE	DESCRIPTION
NID	Node ID on a part best fitted to the target.
XDELTA	x-component of the shortest vector from the node to the target
YDELTA	y-component of the shortest vector from the node to the target.
ZDELTA	z-component of the shortest vector from the node to the target.

Revision Information:

The keyword is available starting from revision 112655.

*NODE_TRANSFORM

Purpose: Perform a transformation on a node set based on a transformation defined by the keyword *DEFINE_TRANSFORMATION.

Transformation Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	TRSID	NSID	IMMED					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
TRSID	The ID of the transformation defined under *DEFINE_TRANSFORMATION.
NSID	Node set ID of the set of nodes to be subject to the transformation.
IMMED	Optional flag for transformation processing: EQ.0: Node transformation is performed after all input cards are read through. It is more efficient, and the definition sequence of *NODE_TRANSFORM and its NSID is irrelevant, meaning the referred NSID doesn't have to be defined prior to *NODE_TRANSFORM. However, if nodes in NSID are used in, for instance, POS6N of *DEFINE_TRANSFORMATION, the original coordinates, not the transformed coordinates, will be used to define the transformation matrix. EQ.1: Node transformation is performed immediately after *NODE_TRANSFORM is read. The referred NSID and its nodes must be defined prior to *NODE_TRANSFORM.

*PARAMETER

The *PARAMETER family of commands assign numerical values or expressions to named parameters. The parameter names can be used subsequently in the input in place of numerical values.

PARAMETER_*OPTION

*PARAMETER_DUPLICATION

*PARAMETER_EXPRESSION

*PARAMETER_TYPE

***PARAMETER**_*{OPTION}*_*{OPTION}*_*{OPTION}*

The available options are

<BLANK>

LOCAL (see Remark 5)

MUTABLE (see Remark 6)

NOECHO (see Remark 7)

The keyword name may include any combination of the above keyword options in any order.

Purpose: Define the numerical values of parameter names referenced throughout the input file. The parameter definitions, if used, should be placed at the beginning of the input file following *KEYWORD or at the beginning of an include file if the LOCAL option is specified.

Parameter Cards. Include as many cards as necessary.

Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
PRMR*n*	PRMR*n* sets both the n^{th} parameter and its storage type. $\text{PRMR} = \texttt{T}\underbrace{\texttt{xxxxxxxxx}}_{\text{9 character name}}$ The first character, "T", is decoded as follows: T.EQ."R": Parameter is a real number T.EQ."I": Parameter is an integer T.EQ."C": Parameter is a character

VARIABLE	DESCRIPTION
	The remaining 9 characters specify the name of the parameter. A parameter name of "time" (case insensitive) is disallowed. Appendix U lists reserved names. Parameter names can only include numbers, letters, and "_". The first character in a name cannot be a number. For example, to define a shell thickness named, "SHLTHK", the input "RSHLTHK", "R␣␣␣SHLTHK", or "R␣␣SHLTHK␣" are all equivalent 10 character strings ("␣" is space). For instructions regarding how to use the variable "SHLTHK," see Remark 1.
VAL*n*	Define the value of the n^{th} parameter as either a real or integer number, or a character string consistent with preceding definition for PRMR*n*.

Remarks:

1. **Syntax for Using Parameters.** Parameters can be referenced anywhere in the input by placing an "&" immediately preceding the parameter name. If a minus sign "-" is placed directly before "&", i.e., "-&", with no space the sign of the numerical value will be switched.

2. **Including Character Parameters in Larger Strings.** A character parameter can be included as part of a larger string. The included character parameter should start with '&' and end with '^'. The ending character '^' will be replaced by '_' in the resultant larger string. For example, a string definition of "&TORSO^lower arm" will result in "P101_lower arm" if parameter "TORSO" is defined as "C" type with a value of "P101".

   Note that prior to R12.1, specifying an include file name with a character parameter in a larger string did not work properly. LS-DYNA added erroneous spaces to the name. For instance,

```
*PARAMETER
C TST              01
*INCLUDE
file_&TST^.k
```

   led to an error termination in earlier versions since LS-DYNA interpreted the name as "file_01 ␣␣.k" ("␣" is a space).

3. **Comma-Delimited Format for Character Parameters**. Note that prior to R12.1, the comma-delimited input format for character parameters did not work correctly. You should use the fixed format for prior LS-DYNA versions.

4. **Reserved Variable Names.** See Appendix U for a list of variable names reserved internally by LS-DYNA.

5. **LOCAL Option.** *PARAMETER_LOCAL behaves like the *PARAMETER keyword with one difference. A parameter defined by *PARAMETER without the LOCAL option is visible and available at any later point in the input processing. Parameters defined with the LOCAL versions disappear when the input parser finishes reading the file in which they appear. LOCAL variables can temporarily mask non-LOCAL variables.

   For example, suppose you have the following input files:

   main.k:
```
*PARAMETER
R  VAL1    1.0
*PARAMETER
R  VAL2    2.0
*PARAMETER
R  VAL3    3.0
*CONTROL_TERMINATION
   &VAL1
*INCLUDE
file1
```

   file1:
```
*PARAMETER
R  VAL1    10.0
*PARAMETER_LOCAL
R  VAL2    20.0
*PARAMETER_LOCAL
R  VAL4    40.0
*INCLUDE
file2
⋮
```

   Then, inside file2 we will see VAL1 = 10.0, VAL2 = 20.0, VAL3 = 3.0 and VAL4 = 40.0. In main.k, after returning from file1, we will see VAL1 = 10.0, VAL2 = 2.0, and VAL3 = 3.0. VAL4 will not exist. This allows for include files that can set all their own parameters without clobbering the parameters in the rest of the input.

6. **MUTABLE Option for Redefining.** The MUTABLE option indicates that an integer or real parameter may be redefined at some later point in the input processing (it is ignored for character parameters). Redefinition is allowed regardless of the setting of *PARAMETER_DUPLICATION. The MUTABLE qualifier must appear for the first definition of the parameter. It is not required for any later redefinition.

7. **NOECHO Option.** The NOECHO keyword option tells LS-DYNA to not echo the defined parameters to the d3hsp file. This feature is useful for indicating which parameters in an encrypted file should not be echoed.

*PARAMETER_DUPLICATION

Purpose: The purpose is to control how the code behaves if a duplicate parameter definition is found in the input. This command must appear in the keyword deck before all *PARAMETER definitions.

Card 1	1	2	3	4	5	6	7	8
Variable	DFLAG							
Type	I							
Default	1							

VARIABLE	DESCRIPTION
DFLAG	Flag to control treatment of duplicate parameter definitions: EQ.1: issue a warning and ignore the new definition (default) EQ.2: issue a warning and accept the new definition EQ.3: issue an error and ignore (terminates at end of input) EQ.4: accept silently EQ.5: ignore silently

Remarks:

1. **LOCAL and non-LOCAL Variables.** A LOCAL variable appearing in a file, which masks a non-LOCAL parameter, won't trigger these actions; however, a LOCAL that masks another LOCAL or a non-LOCAL that masks a non-LOCAL will.

2. **Multiple Cards.** Only one *PARAMETER_DUPLICATION card is allowed. If more than one is found, a warning is issued and any after the first are ignored.

***PARAMETER_EXPRESSION**_*{OPTION}_{OPTION}_{OPTION}*

The available options are

<BLANK>

LOCAL

MUTABLE (see Remark 3)

NOECHO (see Remark 4)

The keyword name may include any combination of the above keyword options in any order.

Purpose: Define the numerical values of parameter names referenced throughout the input file. Like the *PARAMETER keyword, but allows for general algebraic expressions, not simply fixed values. The LOCAL option allows for include files to contain their own unique expressions without clobbering the expressions in the rest of the input. See the *PARAMETER keyword.

Parameter Cards. Include as many cards as necessary.

Card 1	1	2	3	4	5	6	7	8
Variable	PRMR1	EXPRESSION1						
Type	A	A						
Default	none	none						

VARIABLE	DESCRIPTION
PRMR*n*	Define the *n*th parameter in a field of 10. Within this field the first character must be either an "R" for a real number, "I" for an integer, or "C" for a character string. Lower or upper case for "I/C/R" is okay. Following the type designation, define the name of the parameter using up to, but not exceeding nine characters. For example, when defining a shell thickness named, "SHLTHK", both inputs "RSHLTHK" or "R SHLTHK" can be used and placed anywhere in the field of 10. When referencing SHLTHK in the input file, see Remark 1 below.
EXPRESSION*n*	General expression which is evaluated, having the result stored in PRMR*n*. The following functions are available:

VARIABLE	DESCRIPTION
	sin, cos, tan, csc, sec, ctn, asin, acos, atan, atan2, sinh, cosh, tanh, asinh, acosh, atanh, min, max, sqrt, mod, abs, sign, int, aint, nint, anint, float, exp, log, log10, float, pi, and general arithmetic expressions involving +, -, *, /, and **. The standard rules regarding operator precedence are obeyed, and nested parentheses are allowed. The expression can reference previously defined parameters (with or without the leading &). The expression can be continued on multiple lines simply by leaving the first 10 characters of the continuation line blank. For type "C" parameters, the expression is not evaluated in any sense, just stored as a string.

Remarks:

1. **Referencing Parameters.** Parameters can be referenced anywhere in the input by placing an "&" immediately preceding the parameter name. Expressions can be included in the input when placed between brackets "<>" as long as the total line length does not exceed 80 columns and fields are comma-delimited. For example, this…

```
*parameter
rterm, 0.2, istates,  80
*parameter_expression
rplot,term/(states-30)
*DATABASE_BINARY_D3PLOT
&plot
```

is equivalent to

```
*parameter
rterm, 0.2, istates,  80
*DATABASE_BINARY_D3PLOT
<term/(states-30)>,
```

2. **Expression Properties.** Properties used when evaluating the expressions are listed below.

   a) The integer and real properties of constants and parameters are honored when evaluating expressions. So 2/5 becomes 0, but 2.0/5 becomes 0.4.

b) The sign, atan2, min, max, and mod functions all take two arguments. The others all take only 1. The mod function supports integers only and any real arguments will be rounded.

c) Functions that use an angle as their argument, e.g., sin or cos, assume the angle is in radians.

d) The unary minus has higher precedence than exponentiation, that is, the formula -3**2 will be interpreted as $(-3)^2 = 9$.

3. **Redefining Parameters.** The MUTABLE option indicates that an integer or real parameter may be redefined at some later point in the input processing (it is ignored for character parameters). Redefinition is allowed regardless of the setting of *PARAMETER_DUPLICATION. The MUTABLE qualifier must appear for the first definition of the parameter. It is not required for any later redefinition.

4. **NOECHO Option.** The NOECHO keyword option tells LS-DYNA to not echo the defined parameters to the d3hsp file. This feature is useful for indicating which parameters in an encrypted file should not be echoed.

*PARAMETER_TYPE

*PARAMETER_TYPE is a variation on the *PARAMETER keyword command. In addition to its basic function of associating a parameter name (PRMR) with a numerical value (VAL), the *PARAMETER_TYPE command also includes information (PRTYP) about how the parameter is used by LS-DYNA, such as a Part ID or as a segment set ID.

*PARAMETER_TYPE is useful only when (1) the parameter is used to represent an integer ID number, and (2) LS-PrePost is used to combine two or more models (keyword decks) into a larger model.

Only by knowing how the parameter is used by LS-DYNA is LS-PrePost able to increment the parameter value by the proper "offset" when LS-PrePost combines two or more input decks together into a larger deck. These offsets are necessary so that IDs of a certain type, such as Part IDs, are not duplicated in the assembled model. Figure 34-1 (b) shows the offset input dialog box of LS-PrePost where offset values for specific ID types are assigned.

Background:

This command is designed to support workflows involving models that are built up from discrete subassemblies created by independent workgroups. As the subassembly models evolve through the design process, Part IDs, material IDs, etc. in the models may change with each design iteration; therefore, it is advantageous to parameterize those IDs. In this way, though the parameter values may change, the parameter names remain the same. When the subassembly models are combined by LS-PrePost to create a larger model of an assembly or of a complete system, for instance, an aircraft engine model, parameter values assigned using *PARAMETER_TYPE are incremented by the proper ID offset value as prescribed when LS-PrePost imports each keyword file.

Card Format:

Parameter Cards. For each parameter with type information, include an additional card. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PRMR	VAL	PRTYP					
Type	A	I	A					
Default	none	none	none					

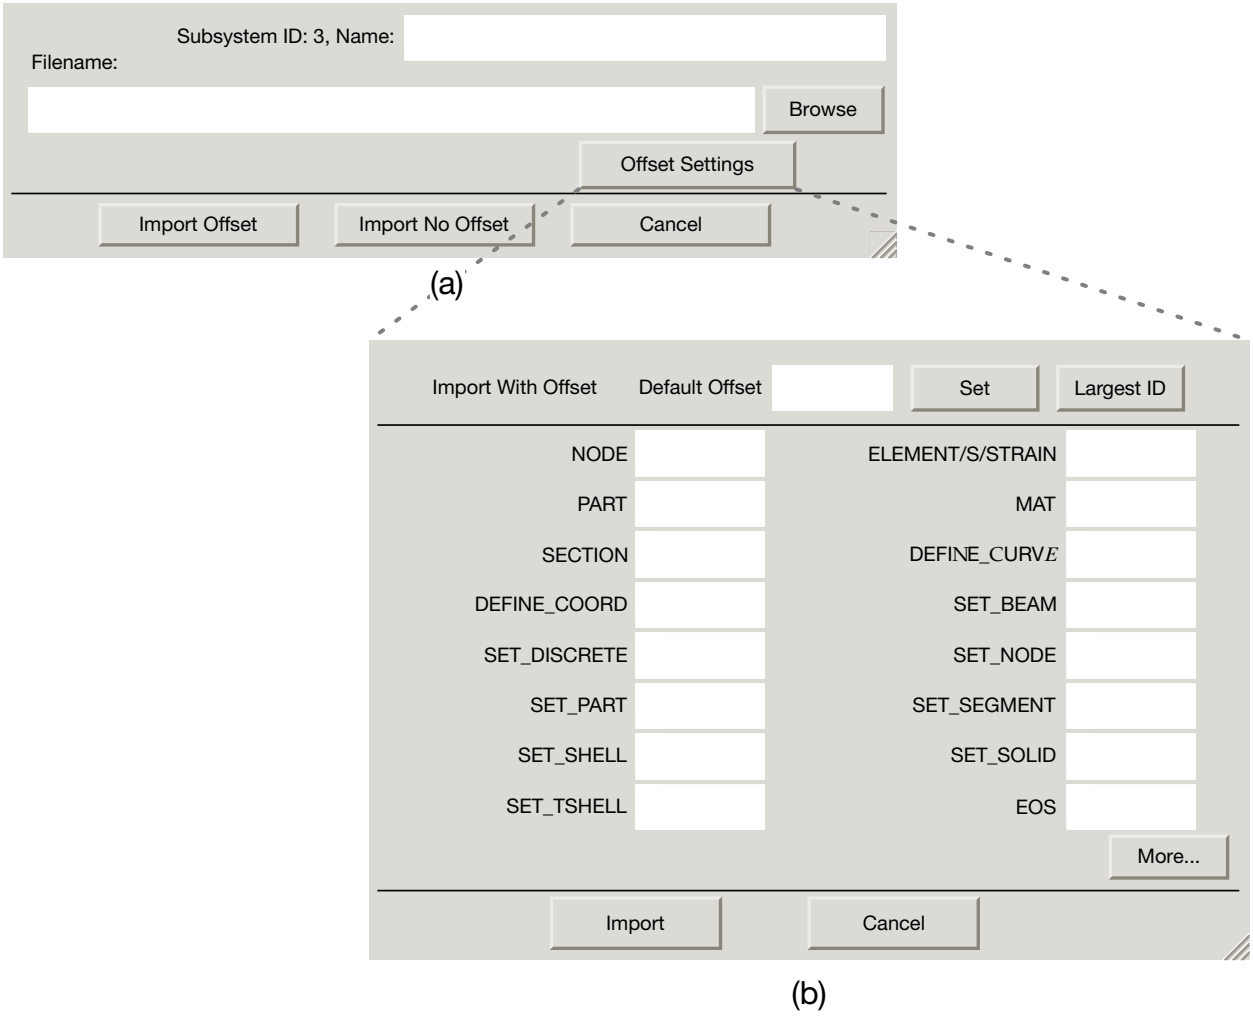

Figure 34-1. (a) the *file* → *import* → *keyword dialog box*; (b) the LS-PrePost dialog that takes the offset as a function of ID type.

VARIABLE	DESCRIPTION
PRMR	PRMR must be in the following format $\text{PRMR} = \texttt{I}\underbrace{\texttt{xxxxxxxxx}}_{\text{9 character name}}$ The first character is the type indicator and must be set to "I" for integer. The remaining 9 characters specify the name of the parameter. For example, to define a part ID "WHLPID", the input "IWHLPID", "I␣␣␣WHLPID", or "I␣␣WHLPID␣" are all equivalent 10 character strings ("␣" is space). For instructions regarding how to use the variable "WHLPID" see Remark 1.

VARIABLE	DESCRIPTION
VAL	Define the value of the parameter. The VAL field must contain an integer.
PRTYP	Describes, for the benefit of LS-PrePost only, how the parameter PRMR is used by LS-DYNA. PRTYP is ignored by LS-DYNA. For example, if VAL represents a Part ID, then PRTYP should be set to "PID". Knowing how the parameter is used by LS-DYNA, LS-PrePost can apply the appropriate offset to VAL when input decks are combined using LS-PrePost. EQ.NID: Node ID, EQ.NSID: Node set ID, EQ.PID: Part ID, EQ.PSID: Part set ID, EQ.MID: Material ID, EQ.EOSID: Equation of state ID, EQ.BEAMID: Beam element ID, EQ.BEAMSID: Beam element set ID, EQ.SHELLID: Shell element ID, EQ.SHELLSID: Shell element set ID, EQ.SOLIDID: Solid element ID, EQ.SOLIDSID: Solid element set ID, EQ.TSHELLID: Tshell element ID, EQ.TSHELLSID: Tshell element set ID, EQ.SSID: Segment set ID

Remarks:

1. **Referencing Parameters.** Parameters can be referenced anywhere in the input by placing an "&" at the first column of its field followed by the name of the parameter without blanks. For example, if PRMR is set to "I␣␣WHLPID␣", then the appropriate reference is "&WHLPID".

   Example:

```
*PARAMETER_TYPE
I WHLPID  100       PID
I WHLMID  300       MID
```

```
*PART
Wheel
&WHLPID,200,&WHLMID
```

2. **LS-PrePost.** *PARAMETER_TYPE is only supported by LS-PrePost 4.1 or later.

3. **Use Limitations.** Combining *INCLUDE_TRANSFORM with *PARAMETER_-TYPE is unsupported. This will introduce conflicting parameter offset values, and offset values specified in *INCLUDE_TRANSFORM will override offset values associated with *PARAMETER_TYPE.

*PART

The following keywords are used in this section:

PART_*{OPTION1}_{OPTION2}_{OPTION3}_{OPTION4}_{OPTION5}_{OPTION6}

*PART_ADAPTIVE_FAILURE

*PART_ANNEAL

PART_COMPOSITE_*{OPTION}

*PART_DUPLICATE

*PART_MODES

*PART_MOVE

*PART_SENSOR

*PART_STACKED_ELEMENTS

***PART**_*{OPTION1}_{OPTION2}_{OPTION3}_{OPTION4}_{OPTION5}_{OPTION6}*

For *OPTION1* the available options are

ATTACHMENT_NODES

For *OPTION5* the available options are

<BLANK>

AVERAGED

For *OPTION6* the available options are

<BLANK>

FIELD

Options 1, 2, 3, 4, 5 and 6 may be specified in any order on the *PART card.

Purpose: Define parts, that is, combine material information, section properties, hourglass type, thermal properties, and a flag for part adaptivity.

The INERTIA option allows the inertial properties and initial conditions to be defined rather than calculated from the finite element mesh. This applies to rigid bodies, see *MAT_RIGID, only.

The REPOSITION option applies to deformable materials and is used to reposition deformable materials attached to rigid dummy components whose motion is controlled by either CAL3D or MADYMO. At the beginning of the calculation each component controlled by CAL3D/MADYMO is automatically repositioned to be consistent with the CAL3D/MADYMO input. However, deformable materials attached to these components will not be repositioned unless this option is used.

The CONTACT option allows part-based contact parameters to be used with the automatic contact types a3, 4, a5, b5, a10, 13, a13, 15 and 26, that is

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE,

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR,

*CONTACT_SINGLE_SURFACE,

*CONTACT_AUTOMATIC_NODES_TO_SURFACE,

*CONTACT_AUTOMATIC_BEAMS_TO_SURFACE,

*CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE,

*CONTACT_AUTOMATIC_SINGLE_SURFACE,

*CONTACT_AUTOMATIC_SINGLE_SURFACE_MORTAR,

*CONTACT_AIRBAG_SINGLE_SURFACE,

*CONTACT_ERODING_SINGLE_SURFACE,

*CONTACT_AUTOMATIC_GENERAL.

The default values to use for these contact parameters can be specified on the *CONTACT input section card.

The PRINT option allows user control over whether output data is written into the ASCII files matsum and rbdout. See *DATABASE_ASCII.

The AVERAGED option may be applied *only* to parts consisting of a single (non-branching) line of truss elements. The average strain and strain rate over the length of the truss elements in the *part* is calculated, and the resulting average axial force is applied to all the elements in the part. Truss elements in an averaged part form one long continuous "macro-element." The time step size for an AVERAGED part is based on the total length of the assembled trusses, rather than on the shortest truss.

Effectively, the truss elements of an AVERAGED part behave as a string under uniform tension. In an AVERAGED part there are no internal forces acting to keep the nodes

separated, and other force contributions from the surrounding system *must* play that role. Therefore, the nodes connected to the truss elements should be attached to other structural members. This model is prototypically used for modeling cables in mechanical actuators. The AVERAGED option can be activated for all material types, which are available for truss elements.

The FIELD option allows you to define spatially varying properties for the current part. The field card determines a unique correlation between properties of the current part and the corresponding fields of data. Field data are specified in the physical space on sets of points; see *DEFINE_FIELD and *DEFINE_POINT_CLOUD. The FIELD option currently allows you to define spatially varying baseline orientation vectors for non-isotropic materials. It is currently supported only for isogeometric shell and solid elements defined with *IGA keywords.

Card Summary:

Card Sets. Repeat as many sets of data cards as desired (Card 1 through 10 depending on options). This input ends at the next keyword ("*") card.

Card 1. This card is required.

HEADING	

Card 2. This card is required.

PID	SECID	MID	EOSID	HGID	GRAV	ADPOPT	TMID

Card 3. This card is included if the INERTIA option is used.

XC	YC	ZC	TM	IRCS	NODEID		

Card 4. This card is included if the INERTIA option is used.

IXX	IXY	IXZ	IYY	IYZ	IZZ		

Card 5. This card is included if the INERTIA option is used.

VTX	VTY	VTZ	VRX	VRY	VRZ		

Card 6. This card is included if the INERTIA option is used. It is optional unless IRCS = 1.

XL	YL	ZL	XLIP	YLIP	ZLIP	CID	

Card 7. This card is included if the REPOSITION option is used.

CMSN	MDEP	MOVOPT					

Card 8. This card is included if the CONTACT option is used.

FS	FD	DC	VC	OPTT	SFT	SSF	CPARM8

Card 9. This card is included if the PRINT option is used.

PRBF							

Card 10. This card is included if the ATTACHMENT_NODES option is used.

ANSID							

Card 11. This card is included if the FIELD option is used.

FIDBO							

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	HEADING							
Type	A							

VARIABLE	DESCRIPTION
HEADING	Heading for the part

Card 2	1	2	3	4	5	6	7	8
Variable	PID	SECID	MID	EOSID	HGID	GRAV	ADPOPT	TMID
Type	I/A	I/A	I/A	I/A	I/A	I	I	I/A
Default	none	none	none	0	0	0	0	0

VARIABLE	DESCRIPTION
PID	Part identification. A unique number or label must be specified.

VARIABLE	DESCRIPTION
SECID	Section identification defined in a *SECTION keyword. See Remark 7.
MID	Material identification defined in the *MAT section. See Remark 7.
EOSID	Equation of state identification defined in the *EOS section. Nonzero only for solid elements using an equation of state to compute pressure. See Remark 7.
HGID	Hourglass/bulk viscosity identification defined in the *HOURGLASS Section. See Remark 7. EQ.0: Default values are used.
GRAV	Flag to turn on gravity initialization according to *LOAD_DENSITY_DEPTH. EQ.0: Part will be initialized only if included in the part set PSID in *LOAD_DENSITY_DEPTH. EQ.1: Part will be initialized irrespective of PSID in *LOAD_DENSITY_DEPTH.
ADPOPT	Indicate if this part is adapted or not. (See also *CONTROL_ADAPTIVE): LT.0: *r*-adaptive remeshing for 2D solids, |ADPOPT| gives the load curve ID that defines the element size as a function of time. EQ.0: Adaptive remeshing is inactive for this part ID. EQ.1: *h*-adaptive for 3D shells and for shell/solid/shell sandwich composites. EQ.2: *r*-adaptive remeshing for 2D solids, 3D tetrahedrons and 3D EFG. EQ.3: Axisymmetric *r*-adaptive remeshing for 3D solid (see Remark 6). EQ.9: Passive *h*-adaptive for 3D shells. The elements in this part will not be split unless their neighboring elements in other parts need to be split more than one level.
TMID	Thermal material property identification defined in the *MAT_THERMAL Section. Thermal properties must be specified for all solid, shell, and thick shell parts if a thermal or coupled thermal

VARIABLE	DESCRIPTION
	structural/analysis is being performed. Discrete elements are not considered in thermal analyses. See Remark 7.

Inertia Card 1. Additional Card for the INERTIA option. See Remarks 2, 3, and 4.

Card 3	1	2	3	4	5	6	7	8
Variable	XC	YC	ZC	TM	IRCS	NODEID		
Type	F	F	F	F	I	I		

VARIABLE	DESCRIPTION
XC	Global x-coordinate of center of mass. If nodal point, NODEID, is defined XC, YC, and ZC are ignored and the coordinates of the nodal point, NODEID, are taken as the center of mass.
YC	Global y-coordinate of center of mass
ZC	Global z-coordinate of center of mass
TM	Translational mass
IRCS	Flag for inertia tensor reference coordinate system: EQ.0: Global inertia tensor EQ.1: Local inertia tensor is given in a system defined by the orientation vectors.
NODEID	Nodal point defining the CG of the rigid body. This node should be, but is not required to be, included as an extra node for the rigid body. If this node is free, its motion will not be updated to correspond with the rigid body after the calculation begins.

Inertia Card 2. Additional Card for the INERTIA option.

Card 4	1	2	3	4	5	6	7	8
Variable	IXX	IXY	IXZ	IYY	IYZ	IZZ		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
IXX	I_{xx}, xx component of inertia tensor (see Remark 4)
IXY	I_{xy}, xy component of inertia tensor (see Remark 4)
IXZ	I_{xz}, xz component of inertia tensor (see Remark 4)
IYY	I_{yy}, yy component of inertia tensor (see Remark 4)
IYZ	I_{yz}, yz component of inertia tensor (see Remark 4)
IZZ	I_{zz}, zz component of inertia tensor (see Remark 4)

Inertia Card 3. Additional Card for the INERTIA option.

Card 5	1	2	3	4	5	6	7	8
Variable	VTX	VTY	VTZ	VRX	VRY	VRZ		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
VTX	Initial translational velocity of rigid body in global x-direction (see Remark 5)
VTY	Initial translational velocity of rigid body in global y-direction (see Remark 5)
VTZ	Initial translational velocity of rigid body in global z-direction (see Remark 5)
VRX	Initial rotational velocity of rigid body about global x-axis (see Remark 5)
VRY	Initial rotational velocity of rigid body about global y-axis (see Remark 5)
VRZ	Initial rotational velocity of rigid body about global z-axis (see Remark 5)

Inertial Coordinate System Card. Optional card required for IRCS = 1 with INERTIA option. Define two local vectors or a local coordinate system ID.

Card 6	1	2	3	4	5	6	7	8
Variable	XL	YL	ZL	XLIP	YLIP	ZLIP	CID	
Type	F	F	F	F	F	F	I	
Remark	1	1	1	1	1	1		

VARIABLE	DESCRIPTION
XL	x-coordinate of local x-axis. Origin lies at (0,0,0).
YL	y-coordinate of local x-axis
ZL	z-coordinate of local x-axis
XLIP	x-coordinate of vector in local x-y plane
YLIP	y-coordinate of vector in local x-y plane
ZLIP	z-coordinate of vector in local x-y plane
CID	Local coordinate system ID, see *DEFINE_COORDINATE_… With this option leave fields 1 - 6 blank.

Reposition Card. An additional Card is for the REPOSITION option.

Card 7	1	2	3	4	5	6	7	8
Variable	CMSN	MDEP	MOVOPT					
Type	I	I	I					

VARIABLE	DESCRIPTION
CMSN	CAL3D segment number / MADYMO system number. See the numbering in the corresponding program.
MDEP	MADYMO ellipse/plane number: GT.0: Ellipse number

VARIABLE	DESCRIPTION
	EQ.0: Default LT.0: Absolute value is plane number.
MOVOPT	Flag to deactivate moving for merged rigid bodies, see *CONSTRAINED_RIGID_BODIES. This option allows a merged rigid body to be fixed in space while the nodes and elements of the generated CAL3D / MADYMO parts are repositioned: EQ.0: Merged rigid body is repositioned. EQ.1: Merged rigid body is not repositioned.

Contact Card. Additional Card is required for the CONTACT option.

Card 8	1	2	3	4	5	6	7	8
Variable	FS	FD	DC	VC	OPTT	SFT	SSF	CPARM8
Type	F	F	F	F	F	F	F	F

NOTE: If FS, FD, DC, and VC are specified they will not be used unless FS is set to a negative value (-1.0) in the *CONTACT section. These frictional coefficients apply only to contact types:

SINGLE_SURFACE,
AIRBAG_SINGLE_SURFACE,
AUTOMATIC_GENERAL,
AUTOMATIC_SINGLE_SURFACE,
AUTOMATIC_SINGLE_SURFACE_MORTAR,
AUTOMATIC_NODES_TO_...,
AUTOMATIC_SURFACE_...,
AUTOMATIC_SURFACE_..._MORTAR,
AUTOMATIC_ONE_WAY_...,
ERODING_SINGLE_SURFACE

Default values are input via *CONTROL_CONTACT input.

VARIABLE	DESCRIPTION
FS	Static coefficient of friction. The functional coefficient is assumed to be dependent on the relative velocity $v_{\text{rel}}$of the surfaces in contact, $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\times\lvert v_{\text{rel}}\rvert}.$$ For mortar contact $\mu_c = \text{FS}$, that is, dynamic effects are ignored.
FD	Dynamic coefficient of friction. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\times\lvert v_{\text{rel}}\rvert}.$$ For mortar contact $\mu_c = \text{FS}$, that is, dynamic effects are ignored.
DC	Exponential decay coefficient. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\times\lvert v_{\text{rel}}\rvert}.$$ For mortar contact $\mu_c = \text{FS}$ (dynamical effects are ignored).
VC	Coefficient for viscous friction. This is necessary to limit the friction force to a maximum. A limiting force is computed by $$F_{\text{lim}} = \text{VC} \times A_{\text{cont}},$$ where A_{cont} is the area of the segment contacted by the node in contact. The suggested value for VC is to use the yield stress in shear VC $= \sigma_0/\sqrt{3}$ where σ_0 is the yield stress of the contacted material.
OPTT	Optional contact thickness. For SOFT = 2, it applies to solids, shells and beams. For SOFT = 0 and 1 and for Mortar contacts, it applies to shells and beams only. However, for the MPP version only, OPTT does affect the contact behavior of solid elements for SOFT = 0 and 1 but *not* by changing the contact thickness. In the case of MPP with SOFT = 0 and 1 for solids, OPTT overrides the thickness of the solid elements used for the calculation of the contact penetration release (see Table 11-2) but does *not* affect the contact thickness. This is *not* available in SMP.
SFT	Optional thickness scale factor for PART ID in automatic contact (scales true thickness). This option applies only to contact with shell elements. True thickness is the element thickness of the shell elements.

VARIABLE	DESCRIPTION
SSF	Scale factor on default tracked surface penalty stiffness for this part ID whenever it appears in the contact definition. If zero, SSF is taken as unity.
CPARM8	Flag to exclude beam-to-beam contact from the same PID for CONTACT_AUTOMATIC_GENERAL. This applies only to MPP. Global default may be set using CPARM8 on *CONTACT_…_MPP Optional Card. EQ.0: Flag is not set (default). EQ.1: Flag is set. EQ.2: Flag is set. CPARM8 = 2 has the additional effect of permitting contact treatment of spot weld (type 9) beams in AUTOMATIC_GENERAL contacts; spot weld beams are otherwise disregarded entirely by AUTOMATIC_GENERAL contacts.

Print Card. An additional card is required for the PRINT option. This option applies to rigid bodies and provides a way to turn off ASCII output in files rbdout and matsum.

Card 9	1	2	3	4	5	6	7	8
Variable	PRBF							
Type	I							

VARIABLE	DESCRIPTION
PRBF	Print flag for rbdout and matsum files. EQ.0: Default is taken from the keyword *CONTROL_OUTPUT. EQ.1: Write data into rbdout file only. EQ.2: Write data into matsum file only. EQ.3: Do not write data into rbdout and matsum.

Attachment Nodes Card. Additional card required for the ATTACHMENT_NODES option. See Remark 8.

Card 10	1	2	3	4	5	6	7	8
Variable	ANSID							
Type	I							

VARIABLE	DESCRIPTION
ANSID	Attachment node set ID. See Remark 8. This option should be used very cautiously and applies only to rigid bodies. The attachment point nodes are updated each cycle whereas other nodes in the rigid body are updated only in the output databases. All loads seen by the rigid body must be applied through this nodal subset or directly to the center of gravity of the rigid body. If the rigid body is in contact, this set must include all interacting nodes. EQ.0: All nodal updates are skipped for this rigid body. The null option can be used if the rigid body is fixed in space or if the rigid body does not interact with other parts, for example, the rigid body is only used for some visual purpose.

Field Card. An additional Card is required for the FIELD option.

Card 11	1	2	3	4	5	6	7	8
Variable	FIDBO							
Type	I							

VARIABLE	DESCRIPTION
FIDBO	Field ID for baseline orientation vectors for the material referenced by MID. See Remark 9.

Remarks:

1. **Local Inertia Tensor Coordinate System.** The local Cartesian coordinate system is defined as described in *DEFINE_COORDINATE_VECTOR. The local *z*-

axis vector is the vector cross product of the *x*-axis and the in-plane vector. The local *y*-axis vector is finally computed as the vector cross product of the *z*-axis vector and the *x*-axis vector. The local coordinate system defined by CID has the advantage that the local system can be defined by nodes in the rigid body which makes repositioning of the rigid body in a pre-processor much easier since the local system moves with the nodal points.

2. **Inertia Option and Shared Rigid/Deformable Nodes.** When specifying mass properties for a rigid body using the inertia option, the mass contributions of deformable bodies to nodes which are shared by the rigid body should be considered as part of the rigid body.

3. **Inertia Option Lacks Default Values.** If the inertia option is used, all mass and inertia properties of the body *must* be specified. *There are no default values.*

4. **Inertia Tensor Characteristics.** The inertia terms are always with respect to the center of mass of the rigid body. The reference coordinate system defines the orientation of the axes, not the origin. Note that the off-diagonal terms of the inertia tensor are opposite in sign from the products of inertia.

5. **Initial Velocity Card for Rigid Bodies.** The initial velocity of the rigid body may be overwritten by the *INITIAL_VELOCITY card.

6. **Axisymmetric Remeshing.** Axisymmetric remeshing is specially for 3D orbital forming. The adaptive part using this option needs to meet the following requirements for both geometry and discretization:

   a) The geometry is (quasi-) symmetric with respect to the local *z*-axis, which in turn must be parallel to the global *z*-axis. See CID in *CONTROL_REMESHING.

   b) A set of 2D cross-sections with uniform angular interval around *z*-axis are discretized by mixed triangular and quadrilateral elements in a similar pattern.

   c) A set of circular lines around the *z*-axis pass through the nodes of the cross-sections and form orbital pentahedrons and hexahedrons.

7. **Allowed ID Values.** The variables SECID, MID, EOSID, HGID, and TMID in *PART, and in *SECTION, *MAT, *EOS, *HOURGLASS, and *MAT_THERMAL, respectively, may be input as a 10-character alphanumeric variable (20-characters if long format is used), such as "HS Steel", or as a 10-digit integer (20-digit integer if long format is used) that may not exceed the limit of a 4-byte integer (2,147,483,647) if a single precision executable is used. If any of the aforementioned variables are non-numeric, the LS-DYNA execution line should include "plabel=y" for proper (but unfortunately slower) input processing.

8. **Attachment Nodes Option.** All nodes are treated as attachment nodes if this option is not used. Attachment nodes apply to rigid bodies only. The motion of these nodes, which must belong to the rigid body, are updated each cycle. Other nodes in the rigid body are updated only for output purposes. Include all nodes in the attachment node set which interact with the structure through joints, contact, merged nodes, applied nodal point loads, and applied pressure. Include all nodes in the attachment node set if their displacements, accelerations, and velocities are to be written into an ASCII output file. Body force loads are applied to the center of gravity of the rigid body.

9. **Spatially Varying Baseline Orientation Vectors.** This FIELD option is active only for material models that allow the specification of baseline orientation vectors with parameter AOPT in the keyword *MAT. If vectors are specified with this FIELD option, then the baseline orientation vectors associated with the parameter AOPT are disregarded for the current part.

   For shells, three values per point are required, so NV should be set to 3 in *DEFINE_FIELD. These values correspond to the components of the baseline orientation vector, which are automatically interpolated at the integration points. The interpolated vector is projected to the reference surface of the shell. The first material axis coincides with the projected vector unless an additional rotation, with respect to the element's normal vector, is specified. The rotation angle between the projected baseline orientation vector and the first material axis can be defined with the material orientation angle cards on *SECTION_IGA_SHELL by setting ICOMP equal to 1.

   For solids, six values per point are required, so NV should be set to 6 in *DEFINE_FIELD. The first three per-point values define the first baseline orientation vector $\mathbf{a}$, while the last three per-point values define the vector $\mathbf{d}$. The components of these vectors are automatically interpolated at the integration points. The interpolated vectors $\mathbf{a}_I$ and $\mathbf{d}_I$ are used to compute the material axes: $\mathbf{a}_{\text{mat}} = \mathbf{a}_I$, $\mathbf{c}_{\text{mat}} = \mathbf{a}_{\text{mat}} \times \mathbf{d}_I$ and $\mathbf{b}_{\text{mat}} = \mathbf{c}_{\text{mat}} \times \mathbf{a}_{\text{mat}}$, where the symbol × denotes the cross product between two vectors.

*PART_ADAPTIVE_FAILURE

Purpose: This option applies to two-dimensional adaptivity and allows a part that is singly connected to be split into two parts.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	T	TERM					
Type	I	F	I					

VARIABLE	DESCRIPTION
PID	Part ID
T	Thickness. When the thickness of the part reaches this minimum value, the part is split into two parts. *The value for T should be on the order of the element thickness of a typical element.*
TERM	Control adaptivity after the part separates: EQ.0: continue to adapt part (default) EQ.1: remove only this part from the adaptivity. Other parts will continue to adapt as normal. If there are no remaining parts to be adapted, adaptivity is disabled EQ.2: adaptivity is disabled for all parts.

*PART_ANNEAL

Available options include:

<BLANK>

SET

Purpose: To initialize the stress states at integration points within a specified part to zero at a given time during the calculation. This option is valid for parts that use constitutive models where the stress is incrementally updated. This option applies to the Hughes-Liu beam elements, the integrated shell elements, thick shell elements, and solid elements. In addition to the stress tensor components, the effective plastic strain is also set to zero.

Part Cards. Include as many parts cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	TIME						
Type	I	F						
Default	none	none						

VARIABLE	DESCRIPTION
PID/PSID	Part ID or part set ID if the SET option is active.
TIME	Time when the stress states are reinitialized.

*PART_COMPOSITE_{OPTION}

Available options include:

<BLANK>

CONTACT

TSHELL

LONG

IGA_SHELL

Purpose: The following input provides a simplified method of defining a composite material model for shell elements and thick shell (TSHELL) elements that eliminates the need for user defined integration rules and part IDs for each composite layer. When *PART_COMPOSITE is used, a section definition, *SECTION_SHELL or *SECTION_TSHELL, and integration rule definition, *INTEGRATION_SHELL, are unnecessary. Using *PART_COMPOSITE, the user specifies layer thicknesses, and integration points reside at the mid-points of layers (trapezoidal rule), if not otherwise defined through IRPL on irregular optional Card 2 (see Remark 6). So, while *PART_COMPOSITE is more straightforward than *INTEGRATION_SHELL, it does not offer the same generality as *INTEGRATION_SHELL in terms of defining an arbitrary integration rule.

The material ID, thickness, material angle and thermal material ID for each through-thickness layer of a composite shell or thick shell are provided in the input for this command. The total number of layers is determined by the number of entries on these cards.

Unless the *ELEMENT_SHELL_THICKNESS card is set, the thickness is assumed to be constant on each shell element. The thickness, then, is given by summing the THICK*i* values from Card 5a/b below over the layers *i*. When the *ELEMENT_SHELL_THICKNESS card is included, the THICK*i* values are scaled to fit the nodal thickness values assigned using the *ELEMENT_SHELL_THICKNESS keyword. For thick shells, the total thickness is obtained from the positions of the nodes on the top and bottom surfaces. In this case, the THICK*i* are also scaled to conform to the geometry defined by the element's nodes.

For a more general method of defining composite shells and thick shells, see *ELEMENT_SHELL_COMPOSITE and *ELEMENT_TSHELL_COMPOSITE. These commands permit unique layer stack-ups for each element without requiring a unique part ID for each element.

With *PART_COMPOSITE, two layers with 4 constants each are provided in each Layer Properties Card. With the LONG option, namely *PART_COMPOSITE_LONG, for each

layer there is one Layer Properties Card. The LONG option can also be used with *PART_COMPOSITE_TSHELL.

To maintain a direct association of through-thickness integration point numbers with physical plies in the case where plies span over more than one part ID, see Remark 5.

The CONTACT option allows part-based contact parameters to be used with the automatic contact types a3, 4, a5, a10, 13, a13, 15 and 26, which are listed under the *PART definition above.

The IGA_SHELL option allows *PART_COMPOSITE to be used with IGA shells. The part ID specified in *IGA_SHELL can reference the part ID in *PART_COMPOSITE.

Card Summary:

Card 1. This card is required.

HEADING	

Card 2. The keyword reader will interpret the card following Card 1 as optional Card 2 if the first column of the card is occupied by the string "OPTCARD." Otherwise, it is interpreted as Card 3a, 3b, or 3c.

OPTC	IRPL						

Card 3a. This card is included for all keyword options other than TSHELL or IGA_SHELL.

PID	ELFORM	SHRF	NLOC	MAREA	HGID	ADPOPT	THSHEL

Card 3b. This card is included if the TSHELL option is used.

PID	ELFORM	SHRF			HGID		TSHEAR

Card 3c. This card is included if the IGA_SHELL option is used.

PID	ELFORM	SHRF	NLOC		IRL		

Card 4. This card is included if the CONTACT option is used.

FS	FD	DC	VC	OPTT	SFT	SSF	

Card 5a. This card is included if the LONG option is not used. This card provides the layer data. Include as many cards as necessary. This input ends at the next keyword ("*") card.

MID1	THICK1	B1	TMID1	MID2	THICK2	B2	TMID2

Card 5b. This card is included if the LONG option is used. This card provides the layer data. Include as many cards as necessary. This input ends at the next keyword ("*") card.

MID1	THICK1	B1	TMID1	PLYID1	SHRFAC1		

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	HEADING							
Type	A							

VARIABLE	DESCRIPTION
HEADING	Heading for the part

Irregular Optional Card. The keyword reader will interpret the card following Card 1 as optional Card 2 if the first column of the card is occupied by the string "OPTCARD." Otherwise, it is interpreted as Card 3 (a, b or c); see below.

Card 2	1	2	3	4	5	6	7	8
Variable	OPTC	IRPL						
Type	A	I						

VARIABLE	DESCRIPTION
OPTC	Include string "OPTCARD" to activate this card.
IRPL	Through thickness integration rule per layer (see Remark 6) EQ.103: 3-point Simpson

Thin Shell Card. The following card is required for thin shell composites that are not IGA. Omit this card if the TSHELL option or the IGA_SHELL option is used.

Card 3a	1	2	3	4	5	6	7	8
Variable	PID	ELFORM	SHRF	NLOC	MAREA	HGID	ADPOPT	THSHEL
Type	I	I	F	F	F	I	I	I
Default	none	none	1.0	0.0	0.0	0	0	0

VARIABLE	DESCRIPTION
PID	Part ID
ELFORM	Element formulation options for thin shells: EQ.1: Hughes-Liu, EQ.2: Belytschko-Tsay, EQ.3: BCIZ triangular shell, EQ.4: C^0 triangular shell, EQ.6: S/R Hughes-Liu, EQ.7: S/R co-rotational Hughes-Liu, EQ.8: Belytschko-Leviathan shell, EQ.9: Fully integrated Belytschko-Tsay membrane, EQ.10: Belytschko-Wong-Chiang, EQ.11: Fast (co-rotational) Hughes-Liu, EQ.16: Fully integrated shell element (very fast), EQ.-16: Fully integrated shell element modified for higher accuracy, EQ.17: Fully integrated DKT, triangular shell element, EQ.18: Fully integrated linear DK quadrilateral/triangular shell, EQ.20: Fully integrated linear assumed strain C0 shell, EQ.21: Fully integrated linear assumed strain C0 shell (5 DOF), EQ.23: 8-node quadratic quadrilateral shell (see IRQUAD in *CONTROL_SHELL),

VARIABLE	DESCRIPTION
	EQ.24: 6-node quadratic triangular shell, EQ.25: Belytschko-Tsay shell with thickness stretch, EQ.26: Fully integrated shell with thickness stretch, EQ.27: C0 triangular shell with thickness stretch, EQ.30: Fast fully integrated element with 2 in-plane integration points based on ELFORM 16 EQ.41: Mesh-free (EFG) shell local approach (more suitable for crashworthiness analysis), EQ.42: Mesh-free (EFG) shell global approach (more suitable for metal forming analysis), EQ.101: User defined shell, EQ.102: User defined shell, EQ.103: User defined shell, EQ.104: User defined shell, EQ.105: User defined shell.
SHRF	Shear correction factor which scales the transverse shear stress.
NLOC	Location of reference surface, available for thin shells only. If nonzero, the offset distance from the plane of the nodal points to the reference surface of the shell in the direction of the shell normal vector is a value: $\text{offset} = -0.50 \times \text{NLOC} \times (\text{average shell thickness})$. This offset is not considered in the contact subroutines unless CNTCO is set to 1 in *CONTROL_SHELL. Alternatively, the offset can be specified by using the OFFSET option in the *ELEMENT_SHELL input section. EQ.1.0: Top surface, EQ.0.0: Mid-surface (default), EQ.-1.0: Bottom surface.
MAREA	Non-structural mass per unit area. This is additional mass which comes from materials such as carpeting. This mass is not directly included in the time step calculation.

VARIABLE	DESCRIPTION
HGID	Hourglass/bulk viscosity identification defined in the *HOURGLASS Section: EQ.0: Default values are used.
ADPOPT	Indicate if this part is adapted or not. Also see, *CONTROL_ADAPTIVITY: EQ.0: No adaptivity, EQ.1: *h*-adaptive for 3-D thin shells.
THSHEL	Thermal shell formulation EQ.0: Default is governed by THSHEL on *CONTROL_SHELL EQ.1: Thick thermal shell EQ.2: Thin thermal shell

Thick Shell Card. This is an additional card for the TSHELL option.

Card 3b	1	2	3	4	5	6	7	8
Variable	PID	ELFORM	SHRF			HGID		TSHEAR
Type	I	I	F			I		I
Default	none	none	1.0			0		0

VARIABLE	DESCRIPTION
PID	Part ID
ELFORM	Element formulation options for thick shells: EQ.1: One point reduced integration, EQ.2: Selective reduced 2 × 2 in plane integration, EQ.3: Assumed strain 2 × 2 in plane integration, EQ.5: Assumed strain reduced integration with brick materials EQ.6: Assumed strain reduced integration with shell materials EQ.7: Assumed strain 2 × 2 in plane integration

VARIABLE	DESCRIPTION
SHRF	Shear correction factor which scales the transverse shear stress.
HGID	Hourglass/bulk viscosity identification defined in the *HOURGLASS Section: EQ.0: Default values are used.
TSHEAR	Flag for transverse shear stress distribution (see Remarks 3 and 4): EQ.0: Parabolic, EQ.1: Constant through thickness.

IGA Shell Card. The following card is required for the IGA_SHELL option.

Card 3c	1	2	3	4	5	6	7	8
Variable	PID	ELFORM	SHRF	NLOC		IRL		
Type	I	I	F	F		I		
Default	none	0	1.0	0.0		0		

VARIABLE	DESCRIPTION
PID	Part ID
ELFORM	Element formulation options for IGA shells: EQ.0: Reissner-Mindlin with fibers at the control points EQ.1: Kirchhoff-Love with fibers at the control points EQ.2: Kirchhoff-Love with fibers at the integration points EQ.3: Reissner-Mindlin with fibers at the integration points EQ.5: Shell with thickness stretch based on the ELFORM = 0 EQ.6: Shell with thickness stretch based on ELFORM = 3
SHRF	Shear correction factor which scales the transverse shear stress.
NLOC	Location of reference surface; see the definition of NLOC in *SECTION_IGA_SHELL for more details.

VARIABLE	DESCRIPTION
IRL	Lamina integration rule: EQ.0: Reduced Gauss-Legendre EQ.1: Gauss-Legendre EQ.2: Patchwise reduced Gauss-Legendre (for biquadratic NURBS only)

Contact Card. Additional card is required for the CONTACT option.

Card 4	1	2	3	4	5	6	7	8
Variable	FS	FD	DC	VC	OPTT	SFT	SSF	
Type	F	F	F	F	F	F	F	

NOTE: If FS, FD, DC, and VC are specified they will not be used unless FS is set to a negative value (-1.0) in the *CONTACT section. These frictional coefficients apply only to contact types:

SINGLE_SURFACE,
AUTOMATIC_GENERAL,
AUTOMATIC_SINGLE_SURFACE,
AUTOMATIC_NODES_TO_...,
AUTOMATIC_SURFACE_...,
AUTOMATIC_ONE_WAY_...,
ERODING_SINGLE_SURFACE

Default values are input via *CONTROL_CONTACT input.

VARIABLE	DESCRIPTION
FS	Static coefficient of friction. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact as $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\times\lvert v_{\text{rel}}\rvert}.$$
FD	Dynamic coefficient of friction. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact as

VARIABLE	DESCRIPTION
	$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\times\lvert v_{\text{rel}}\rvert}$.
DC	Exponential decay coefficient. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact as $\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\times\lvert v_{\text{rel}}\rvert}$.
VC	Coefficient for viscous friction. This is necessary to limit the friction force to a maximum. A limiting force is computed $F_{\text{lim}} = \text{VC} \times A_{\text{cont}}$. A_{cont} being the area of the segment contacted by the node in contact. The suggested value for VC is to use the yield stress in shear VC $= \sigma_o/\sqrt{3}$ where σ_0 is the yield stress of the contacted material.
OPTT	Optional contact thickness. This applies to shells only.
SFT	Optional thickness scale factor for PART ID in automatic contact (scales true thickness). This option applies only to contact with shell elements. True thickness is the element thickness of the shell elements.
SSF	Scale factor on default tracked surface penalty stiffness for this part ID whenever it appears in the contact definition. If zero, SSF is taken as unity.

Layer Data Cards without Long Option. The material ID, thickness, and material angle for each through-thickness layer of a composite shell are provided below (up to two layers per card). The layer data should be given sequentially starting with the bottommost layer. The total number of layers is determined by the number of entries on these cards. Include as many cards as necessary. The next keyword ("*") card terminates this input.

Card 5a	1	2	3	4	5	6	7	8
Variable	MID1	THICK1	B1	TMID1	MID2	THICK2	B2	TMID2
Type	I	F	F	I	I	F	F	I

Layer Data Cards for Long Option. The material ID, thickness, and material angle for each through-thickness layer of a composite shell are provided below (one layer per card). The layer data should be given sequentially starting with the bottommost layer. The total number of layers is determined by the number of entries on these cards. Include as many cards as necessary. The next keyword ("*") card terminates this input.

Card 5b	1	2	3	4	5	6	7	8
Variable	MID1	THICK1	B1	TMID1	PLYID1	SHRFAC1		
Type	I	F	F	I	I	F		

VARIABLE	DESCRIPTION
MID*i*	Material ID of layer *i*, see *MAT_… Section.
THICK*i*	Thickness of layer *i*.
B*i*	Material angle of layer *i*. This material angle applies only to material types 21, 22, 23, 33, 33_96, 34, 36, 40, 41-50, 54, 55, 58, 59, 103, 103_P, 104, 108, 116, 122, 133, 135, 135_PLC, 136, 157, 158, 190, 219, 226, 233, 234, 235, 242, 243, 261, 262, 278, and 293.
TMID*i*	Thermal material ID of layer *i*
PLYID*i*	Ply ID of layer *i* (for post-processing purposes)
SHRFAC*i*	Transverse shear stress scale factor

Remarks:

1. **Orthotropic Materials.** In cases where there is more than one orthotropic material model referenced by *PART_COMPOSITE, the orthotropic material orientation parameters (AOPT, BETA, and associated vectors) from the material model of the first orthotropic integration point apply to all the orthotropic integration points. AOPT, BETA, etc. input for materials of subsequent integration points are ignored. B*i*, not to be confused with BETA, is applied into account for each integration point.

2. **SHRF Field and Zero Traction Condition.** Thick shell formulations 1, 2, and 3, and all shell formulations, except for BCIZ and DK elements, are based on first order shear deformation theory that yields constant transverse shear strains which violates the condition of zero traction on the top and bottom surfaces of the shell. For these elements, setting SHRF = 0.83333 will compensate for this

error and result in the correct transverse shear deformation, so long as all layers have the same transverse stiffness. SHRF is not used by thick shell forms 3, 5, or 7 except for materials 33, 36, 133, 135, and 243.

3. **Thick Shell 5 or 6 and Shear Stress.** When thick shell formulation 5 and 6 are used, LS-DYNA will use either a parabolic transverse shear stress distribution when TSHEAR = 0 or a constant shear stress distribution when TSHEAR = 1. The parabolic option is recommended when elements are used in a single layer to model a plate or beam. The constant option may be better when elements are stacked so there are two or more elements through the thickness.

4. **Laminated Shear Stress Theory to Minimize Discontinuities.** For composites that have a transverse shear stiffness that varies by layer, laminated shell theory, activated by LAMSHT on *CONTROL_SHELL, will correct the transverse shear stress to minimize stress discontinuities between layers and at the bottom and top surfaces by imposing a parabolic transverse shear stress. SHRF should be set to the default value of 1.0 when the shear stress distribution is parabolic. If thick shells are stacked so that there is more than one element through the thickness of a plate or beam model, setting TSHEAR = 1 will cause a constant shear stress distribution which may be more accurate than parabolic. The TSHEAR parameter is available for all thick shell forms when laminated shell theory is active. Alternatively, a scale factor can be defined for transverse shear stress in each layer of shell or thick shell composites using the SHRFAC parameter. The inputted SHRFAC values are normalized so that overall shear stiffness is unaffected by the distribution. Therefore, only the ratio of parameter values is significant.

5. **Assignment of Zero Thickness to Layers.** The ability to assign zero thickness layers in the stacking sequence allows the number of layers to remain constant even as the number of physical plies varies from part to part and eases post-processing since a particular layer corresponds to a physical ply. Such a capability is important when one or more of the physical plies are not continuous across a composite structure. To represent a missing ply in *PART_COMPOSITE, set THICK*i* to 0.0 for the corresponding layer and additionally, set either MID = -1 or, if the LONG option is used, set PLYID to any nonzero value.

   When the number of physical plies varies from element to element in a part, one can assign zero thickness to integration points in exactly the same manner as described above but on an element-by-element basis using *ELEMENT_SHELL_COMPOSITE(_LONG) or *ELEMENT_TSHELL_COMPOSITE.

   When post-processing the results using LS-PrePost version 4.5, read both the keyword deck and d3plot database into the code and then select *Option* →*N/A gray fringe*. Then, when viewing fringe plots for a particular integration point

(*FriComp* → *IPt* → *intpt#*), the element will be grayed out if the selected integration point is missing (or has zero thickness) in that element.

6. **Through Thickness Integration Rule per Layer.** If not otherwise stated, each layer will be numerically integrated with a one-point trapezoidal rule which should be sufficient for most composite layups and which will be the recommended setting. However, by adding an irregular optional card 1a, the user may define other through thickness integration rules that should be applied for the numerical integration of an individual ply. So far, a 3-point Simpson integration per layer is supported, where the integration points are located at the bottom, the middle and the top of each individual layer. If IRPL is set to an unknown integration rule, the standard default one-point integration will be used.

*PART_DUPLICATE_{OPTION}

The available *OPTION* is:

<BLANK>

NULL_OVERLAY

NULL_OVERLAY is used to generate null shells for contact. See Remark 5.

Purpose: To provide a method of duplicating parts or part sets without the need to use the *INCLUDE_TRANSFORM option.

Duplication Cards. This format is used when the keyword option is left <BLANK>. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

Card 1a	1	2	3	4	5	6	7	8
Variable	PTYPE	TYPEID	IDPOFF	IDEOFF	IDNOFF	TRANID	BOXID	ZMIN
Type	A	I	I	I	I	I	I	F
Default	none	none	0	0	0	0	0	0.0

Null Duplication Cards. This format is used when the keyword option is set to NULL_-OVERLAY. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

Card 1b	1	2	3	4	5	6	7	8
Variable	PTYPE	TYPEID	IDPOFF	IDEOFF	DENSITY	E	PR	
Type	A	I	I	I	F	F	F	
Default	none	none	0	0	0	0	0	

VARIABLE	DESCRIPTION
PTYPE	Type of entity to duplicate: EQ.PART: Duplicate a single part EQ.PSET: Duplicate a part set

VARIABLE	DESCRIPTION
TYPEID	ID of part or part set to be duplicated
IDPOFF	ID offset of newly created parts
IDEOFF	ID offset of newly created elements
IDNOFF	ID offset of newly created nodes
TRANID	ID of *DEFINE_TRANSFORMATION to transform the existing nodes in a part or part set; see Remark 4.
BOXID	Optional *DEFINE_BOX ID used to define the boundary of the transformed configuration; see Remark 6.
ZMIN	Minimum value of the Z-coordinate of the transformed part or part set if set to a value other than zero. This field applies to all transformations except for SCALE.
DENSITY	Density
E	Young's modulus
PR	Poisson's ratio

Remarks:

1. **Parts with Common Nodes.** All parts sharing common nodes must be grouped in a *PART_SET and duplicated in a single *PART_DUPLICATE command so that the newly duplicated parts still share common nodes.

2. **Allowed Elements.** The following elements which need a *PART to complete their definition can be duplicated by using this command: *ELEMENT_SOLID, *ELEMENT_DISCRETE, *ELEMENT_SHELL, *ELEMENT_TSHELL, *ELEMET_BEAM, and *ELEMENT_SEATBELT.

3. **Constraints.** This command only duplicates definition of nodes, elements and parts, not the associated constraints. For example, TC and RC defined in *NODE will not be passed to the newly created nodes.

4. **Transformation.** When IDNOFF = IDPOFF = IDEOFF = 0, the existing part, or part set, will be transformed as indicated by TRANID; no new node or elements will be created.

5. **Null Elements.** The NULL_OVERLAY option may be used to generate 3 and 4-node null shell elements from the 6- and 8-node quadratic elements for use in contact. No additional nodes are generated.

6. **Boundary Box.** The XMIN, XMAX, YMIN, YMAX, ZMIN, and ZMAX of *DEFINE_BOX define the boundary of the transformed configuration. If any node falls out of the box boundary after transformation, TRANID, is applied, an additional rigid body translation will be applied automatically to the whole part(s) to assure no box boundary violation.

Example:

The following partial keyword example will rotate a part set 45° about the global Y-axis, passing through the global origin. The minimum coordinate of any nodes in the part set after the transformation will be 431.0 mm.

```

Revision Information:

The variable ZMIN is available starting in Dev 138833.

*PART_MODES

Purpose: Treat a part defined with *MAT_RIGID as a linearized flexible body (LFB) whereby deformations are calculated from mode shapes. Unlike superelements (*ELEMENT_DIRECT_MATRIX_INPUT), linearized flexible bodies are accurate for systems undergoing large displacements and large rotations.

The deformations are modeled using the modes shapes obtained experimentally or in a finite element analysis, e.g., NASTRAN .pch file or a LS-DYNA d3eigv or d3mode file. These files may contain a combination of normal modes, constraint modes, and attachment modes. For stress recovery in linearized flexible bodies, use of linear element formulations is recommended. A lump mass matrix is assumed in the implementation. See also *CONTROL_RIGID.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	NMFB	FORM	ANSID	FORMAT	KMFLAG	NUPDF	SIGREC
Type	I	I	I	I	I	I	I	

Card 2	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	C							
Default	none							

Kept Mode Cards. Additional card KMFLAG = 1. Use as many cards as necessary to specify the NMFB kept modes. After NMFB modes are defined no further input is expected.

Card 3	1	2	3	4	5	6	7	8
Variable	MODE1	MODE2	MODE3	MODE4	MODE5	MODE6	MODE7	MODE8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

Optional Modal Damping Cards. This input ends at the next keyword ("*") card.

Card 4	1	2	3	4	5	6	7	8
Variable	MSTART	MSTOP	DAMPF					
Type	I	I	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
PID	Part identification. This part must be a rigid body. See Remark 4.
NMFB	Number of kept modes in linearized flexible body. The number of modes in the file, FILENAME, must equal or exceed NMFB. If KMFLAG = 0, the first NMFB modes in the file are used.
FORM	Linearized flexible body formulation. See Remark 6 below. EQ.0: Exact EQ.1: Fast EQ.2: General formulation (default) EQ.3: General formulation without rigid body mode orthogonalization
ANSID	Attachment node set ID (optional).
FORMAT	Input format of modal information:

VARIABLE	DESCRIPTION
	EQ.0: NASTRAN .pch file.
	EQ.1: (not supported)
	EQ.2: NASTRAN .pch file (LS-DYNA binary version). The binary version of this file is automatically created if a NASTRAN .pch file is read. The name of the binary file is the name of the NASTRAN .pch file but with .bin appended. The binary file is smaller and can be read much faster.
	EQ.3: LS-DYNA d3eigv binary eigenvalue database (see *CONTROL_IMPLICIT_EIGENVALUE).
	EQ.4: LS-DYNA d3mode binary constraint/attachment mode database (see *CONTROL_IMPLICIT_MODE).
KMFLAG	Kept mode flag. Selects method for identifying modes to keep. This flag is not supported for FORMAT = 4 (d3mode).
	EQ.0: The first NMFB modes in the file, FILENAME, are used.
	EQ.1: Define NMFB kept modes with additional input.
NUPDF	Nodal update flag. If active, an attachment node set, ANSID, must be defined.
	EQ.0: All nodes of the rigid part are updated each cycle.
	EQ.1: Only attachment nodes are fully updated. All nodes in the body are output based on the rigid body motion without the addition of the modal displacements. For maximum benefit an attachment node set can also be defined with the PART_ATTACHMENT_NODES option. The same attachment node set ID should be used here.
SIGREC	Stress recovery flag:
	EQ.0: Do not recover stress.
	EQ.1: Recover stress.
	EQ.2: Recover stress and then set the recovery stress as initial stress when switching to a deformable body using *DEFORMABLE_TO_RIGID_AUTOMATIC. (shell formulations 16, 18, 20, and 21 and solid formulation 2).

VARIABLE	DESCRIPTION
	EQ.3: Recover stress based on shell formulation 21, and then set the recovery stress as initial stress for shell formulation 16 when switching to a deformable body using *DEFORMABLE_TO_RIGID_AUTOMATIC (shell formulation 16 only).
FILENAME	The path and name of a file which contains the modes for this rigid body.
MODEn	Keep normal mode, MODEn.
MSTART	First mode for damping, $(1 \leq \text{MSTART} \leq \text{NMFB})$.
MSTOP	Last mode for damping, MSTOP, $(1 \leq \text{MSTOP} \leq \text{NMFB})$. All modes between MSTART and MSTOP inclusive are subject to the same modal damping coefficient, DAMPF.
DAMPF	Modal damping coefficient, ζ. See Remark 5.

Remarks:

1. **Shared Nodes and Interconnections.** Currently, linearized flexible bodies cannot share nodes with other linearized flexible bodies or rigid bodies; however, interconnections to other linearized flexible bodies or to rigid bodies can use the penalty joint option. The linearized flexible bodies are not implemented with the Lagrange multiplier joint option (see LMF in *CONTROL_RIGID).

2. **Normal Modes File Format.** The format of the file which contains the normal modes follows the file formats of NASTRAN output for modal information.

3. **Mode Set.** The mode set typically combines both normal modes and attachment modes. The eigenvalues for the attachment modes are computed from the stiffness and mass matrices.

4. **PID.** The part ID specified must be either a single rigid body or a lead rigid body (see *CONSTRAINED_RIGID_BODIES) which can be made up of many rigid parts.

5. **Modal Damping.** The modal damping is defined by the modal damping coefficient ζ, where a value of 1.0 equals critical damping. For a one degree of freedom model system, the relationship between the damping and the damping coefficient is $c = 2\zeta\omega_n m$, where c is the damping, m is the mass, and ω_n is the natural frequency, $\sqrt{k/m}$.

6. **Linearized Flexible Body Formulations.** There are four linearized flexible body formulations. The first is a formulation that contains all the terms of the linearized flexible body equations, and its cost grows approximately as the square of the number of modes. The second formulation ignores most of the second order terms appearing in the exact equations and its cost grows linearly with the number of modes. If the angular velocities are small and if the deflections are small with respect to the geometry of the system, the cost savings of the second formulation may make it more attractive than the first method.

   Please note that the first two formulations are only applicable when the modes are eigenmodes computed for the free-free problem, that is, the 6 rigid body modes are included. The third formulation, the default, is a more general formulation which allows more general mode shapes. The fourth formulation does not orthogonalize the modes with respect to the rigid body modes and may allow boundary conditions to be imposed more simply in some cases than the third formulation. This last formulation is selected regardless of user input if attachment modes are used.

*PART_MOVE

Purpose: Translate a part by an incremental displacement in either a local or global coordinate system or by a distance along a defined vector. This option currently applies to parts defined by either shell or solid elements. All nodal points of the given part ID are moved. Care must be observed since parts that share boundary nodes with the part being moved must also be moved to avoid severe mesh distortions – the variable IFSET can be used to handle the situation.

Part/Part Set Move Cards. Include as many of following cards as desired. This input ends at the next keyword ("*") cards.

Card 1	1	2	3	4	5	6	7	8	9	10
Variable	PID	XMOV		YMOV		ZMOV		CID	IFSET	
Type	I	F		F		F		I	I	
Default	none	0.0		0.0		0.0		0	0	

VARIABLE	DESCRIPTION
PID	Part or part set identification number.
XMOV	Move shell/solid part ID, PID, in the x-direction by the incremental distance, XMOV. Ignored if CID < 0.
YMOV	Move shell/solid part ID, PID, in the y-direction by the incremental distance, YMOV. Ignored if CID < 0.
ZMOV	Move shell/solid part ID, PID, in the z-direction by the incremental distance, ZMOV. CID.LT.0: ZMOV is the distance the part is translated along CID.
CID	Coordinate system ID to define incremental displacement or vector ID to define the direction for the translation. GT.0: Local coordinate system ID. All displacements, XMOV, YMOV, and ZMOV, are with respect to CID. EQ.0: Global coordinate system. All displacements, XMOV, YMOV, and ZMOV, are with respect to the global coordinate system.

VARIABLE	DESCRIPTION
	LT.0: |CID| is a vector ID for a vector that points in the direction of the part translation. XMOV and YMOV are ignored in this case.
IFSET	Indicate if part set ID is used in PID definition. EQ.0: Part ID is used. EQ.1: Part set ID is used.

Remarks:

1. **Multiple Parts.** IFSET addresses the movement of multiple parts that share common boundary nodes, such as tailor-welded blanks. This field allows for all parts in a part set to move simultaneously.

2. **Draw Beads.** Draw beads can be modeled as beam elements that move the same distance and direction as either the die or punch, depending on the draw types.

3. **Supported Keywords.** Keywords *SET_PART_COLLECT and *SET_PART_-ADD are supported.

Example:

The example partial deck given below automatically positions all tools in a toggle draw of a decklid inner, with a tailor welded blank consisting of PID 1 and PID5, as shown in Figure 35-1. The keyword *CONTROL_FORMING_AUTOPOSITION_PARAMETER_-SET calculates where to position various part sets as follows:

a) the tailor-welded blank part set ID 1 is to be positioned in the global Z-direction on top of the lower die cavity (part set ID 4);

b) the binder (part set ID 3) is to be positioned on top of the blank;

c) the upper punch (part set ID 2) is to be positioned on top of the blank.

The three positioning distances for the blank, upper binder and upper punch are calculated and stored in variables &blnkmv, &upbinmv, and &uppunmv, respectively. The keyword *PART_MOVE, with IFSET set to 1, is responsible for moving the three part sets, using the three corresponding positioning variables.

```

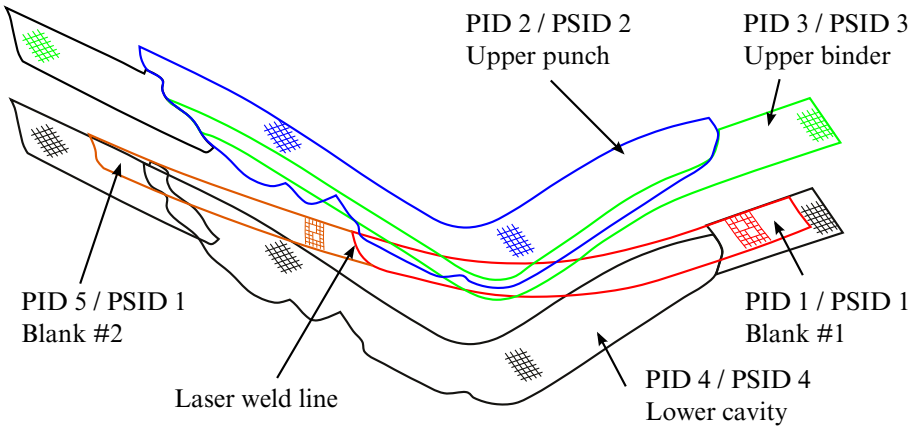

Figure 35-1. A tailor welded blank is positioned in a decklid (toggle draw).

Revision information:

This IFSET feature is available starting in LS-DYNA Dev Revision #62935. It is also implemented in all the applicable stamping processes in LS-PrePost Metal Forming Application eZ-Setup (http://ftp.lstc.com/anonymous/outgoing/lsprepost/).

*PART_SENSOR

Purpose: Activate and deactivate parts, based on sensor defined in *ELEMENT_SEAT-BELT_SENSOR. This option applies to discrete beam element only.

Sensor Part Coupling Cards. Include as many of the following cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	SIDA	ACTIVE					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
PID	Part ID which is controlled by sensor
SIDA	Sensor ID to activate or deactivate part
ACTIVE	Part activation flag: EQ.0: part is active from time zero until a signal is received by the part to deactivate. EQ.1: part is inactive from time zero and becomes active when a signal is received by the part to activate. The history variables for inactive parts are initialized at time zero.

*PART_STACKED_ELEMENTS

Purpose: This keyword provides a method of defining a stacked element model for shell-like structures. These types of plane load-bearing components possess a thickness which is small compared to their other (in-plane) dimensions. Their physical properties vary in the thickness direction according to distinct layers. Application examples include sandwich plate systems, composite laminates, plywood, and laminated glass.

With this keyword it is possible to discretize layered structures by an arbitrary sequence of shell and/or solid elements over the thickness. Whether a physical ply should be discretized by shell or solid elements depends on the individual thickness and other mechanical properties. Every single layer can consist of one shell element over the thickness or one or several solid elements over thickness.

The stacked element mesh can either be provided directly or it be automatically generated by LS-DYNA itself. For automatic generation extrusion methods are used to determine the new node locations that characterize the out-of-plane geometry. Each layer gets its own predefined properties such as individual thickness, material characteristic, and element type.

A more detailed description of this feature including a detailed description of the appropriate mesh generation procedure is given in Erhart [2015].

Card 1	1	2	3	4	5	6	7	8
Variable	HEADING							
Type	C							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	PIDREF	NUMLAY	ADPOPT	INPLCMP				
Type	I	I	I	I				
Default	none	none	0	0				

Layer Data Cards. The part ID, section ID, material ID, hourglass ID, thermal material ID, thickness, and number of through thickness solid elements for each layer *i* of a stacked element model are provided below. The layer data should be given sequentially starting with the bottommost layer. This card should be included NUMLAY times (one for each layer). The definitions in Card 3 replace the usual *PART cards.

Card 3	1	2	3	4	5	6	7	8
Variable	PID*i*	SID*i*	MID*i*	HGID*i*	TMID*i*	THK*i*	NSLD*i*	
Type	I	I	I	I	I	F	I	
Default	none	none	none	0	0	none	none	

VARIABLE	DESCRIPTION
HEADING	Heading for the part composition
PIDREF	Part ID of reference shell element mesh
NUMLAY	Number of layers
ADPOPT	Indicate if parts are adapted or not. (See also *CONTROL_ADAPTIVE): EQ.0: Inactive EQ.1: *h*-adaptive refinement
INPLCMP	Option for in-plane composed parts: EQ.0: Off EQ.1: On; see Remark 6.
PID*i*	Part identification
SID*i*	Section identification for layer *i* defined in a *SECTION keyword
MID*i*	Material identification for layer *i* defined in a *MAT keyword
HGID*i*	Hourglass identification for layer *i* defined in a *HOURGLASS keyword
TMID*i*	Thermal material identification for layer *i* defined in a *MAT_THERMAL keyword

VARIABLE	DESCRIPTION
THK*i*	Thickness of layer *i*
NSLD*i*	Number of through-thickness solid elements for layer *i*

Remarks:

1. **Provided vs. Automatically Generated Meshes.** In general, there are two different options for this keyword:

   a) The user provides a finished mesh comprising stacked shell and/or solid elements and then combines the corresponding part IDs using this keyword. This mode does not require a reference mesh in the PIDREF field nor does it require that either the layer thickness (THK*i* fields) and the the number of through-thickness solids elements (NSLD*i* fields) be specfied.

   b) The user may provide a shell reference mesh (PIDREF) together with the layup sequence. The stacked element mesh is automatically generated during the initialization phase of LS-DYNA. In that second case, layer thickness (THK*i*) and number of through-thickness solids (NSLD*i*) must be defined.

2. **Shell Solid Overlap.** In the mesh generation case, two consecutive layers (solid-solid or solid-shell) are firmly connected, meaning that they share nodes in the most obvious way possible (except they are both shell element layers, see Remark 3 for that case). This condition leads to the necessity that shell and solid elements partly overlap if they follow each other in the stacking sequence. This deficiency can be corrected afterwards by subsequent relocation of the shell midsurfaces via NLOC on *SECTION_SHELL (only works for first or last layer in this stacked element approach) or appropriate adjustment of the material stiffness for the solid elements.

3. **Stacked Shells.** Starting with the release of LS-DYNA version R10, it is possible to define shell element layers directly on top of each other (i.e. without solid elements in between). A potential connection/interaction of such layers has to be declared separately by additional contact definitions (standard, tied, or tiebreak) otherwise they are free to penetrate each other.

4. **Chained Calculations.** This keyword (*PART_STACKED_ELEMENTS) can also be used for modeling multi-stage processes. The *INTERFACE_SPRINGBACK_LSDYNA card can be used (where PSID should contain all the parts PID*i*, not PIDREF) to save a final state including deformed geometry, stresses, and strains to a dynain file. In a subsequent calculation the *INCLUDE keyword can

be used with that dynain to apply the layup sequence without regenerating the mesh. LS-DYNA automatically detects if a reference shell element mesh is present or not.

5. **Example.** An example specifying a three layer shell-solid-shell structure is given below:

```
*PART_STACKED_ELEMENTS
$ title
sandwich
$   pidref    numlay
         11         3
$#     pid       sid       mid      hgid      tmid       thk      nsld
       100       200         1         1         0      0.25         0
       101       201         2         0         0      0.60         3
       102       200         1         1         0      0.15         0
*SECTION_SHELL
$      sid    elform      shrf       nip     propt   qr/irid
       200         2     0.833       5.0       1.0       0.0
$       t1        t2        t3        t4
      0.25      0.25      0.25      0.25
*SECTION_SOLID
$      sid    elform
       201        -1
```

A sandwich structure is discretized by shell elements (SID = 200) on the outer layers with part identifiers 100 and 102. The interior of the "sandwich" consists of three solid elements (SID = 201, NSLD = 3) part identifier 101. In this case, the reference shell mesh belongs to part 11 (PIDREF). The thickness of each layer is defined by the value of the THK field, which will overwrite the thickness values from *SECTION_SHELL. Related materials (MID, TMID) and hourglass types (HGID) are treated as usual and therefore not shown here.

6. **In-Plane Composed Parts.** If the reference mesh is made up of several parts with matching nodes at their boundaries (such as tailor welded blanks), one *PART_STACKED_ELEMENTS must be defined for each reference part and option INPLCMP should be set to 1 for all of them. In addition, it is necessary to define *NODE_MERGE_SET for the newly generated parts, so that they stay together after new mesh generation.

7. **Boundary Conditions.** All node sets (*SET_NODE) containing nodes of the reference shell element mesh are automatically converted to node sets that include the corresponding new nodes of the generated mesh. Therefore, it is possible to transfer boundary conditions of the reference mesh to the stacked model when corresponding keywords *BOUNDARY_... or *LOAD_... refer to such node sets.

*PERTURBATION

The keyword *PERTURBATION provides a means of defining deviations from the designed structure such as buckling imperfections. These perturbations can be viewed in LS-PrePost as user-defined fringe plots. Available options are:

*PERTURBATION_MAT

*PERTURBATION_NODE

*PERTURBATION_SHELL_THICKNESS

***PERTURBATION**_*OPTION*

Available options are:

MAT

NODE

SHELL_THICKNESS

Purpose: Define a perturbation (stochastic field) over the whole model or a portion of the model, typically to trigger an instability. The NODE option modifies the three-dimensional coordinates for the whole model or a node set. For the SHELL_THICKNESS option, the shell thicknesses are perturbed for the whole model or a shell set. The MAT option perturbs a material parameter value for all the elements associated with that material.

Card Summary:

Card 1a. This card is included if and only if the MAT option is used.

TYPE	PID	SCL	CMP	ICOORD	CID		

Card 1b. This card is included if and only if the NODE option is used.

TYPE	NSID	SCL	CMP	ICOORD	CID		

Card 1c. This card is used if and only if the SHELL_THICKNESS option is used.

TYPE	EID	SCL	CMP	ICOORD	CID		

Card 2a. This card is included if and only if TYPE = 1.

AMPL	XWL	XOFF	YWL	YOFF	ZWL	ZOFF	

Card 2b. This card is included if and only if TYPE = 2.

Data Card Definitions:

Material Perturbation Card. Card 1 for MAT keyword option. Perturb a material parameter.

Card 1a	1	2	3	4	5	6	7	8
Variable	TYPE	PID	SCL	CMP	ICOORD	CID		
Type	I	I	F	I	I	I		
Default	1	0	1.0	5	0	0		

VARIABLE	DESCRIPTION
TYPE	Type of perturbation: EQ.1: Harmonic Field (see Remark 3) EQ.3: Read perturbations from a file EQ.4: Spectral field
PID	Part ID
SCL	Scale factor
CMP	Component. See Remark 10 and *MAT_238.
ICOORD	Coordinate system to use (see Remarks 7, 8 and 9): EQ.0: Global Cartesian EQ.1: Cartesian EQ.2: Cylindrical (computed and applied) EQ.3: Spherical (computed and applied)

VARIABLE	DESCRIPTION
	EQ.-2: Computed in cartesian but applied in cylindrical
	EQ.-3: Computed in cartesian but applied in spherical
CID	Coordinate system ID; see *DEFINE_COORDINATE_NODES.

Node Perturbation Card. Card 1 for NODE keyword option. Perturb the coordinates of a node set (or all nodes).

Card 1b	1	2	3	4	5	6	7	8
Variable	TYPE	NSID	SCL	CMP	ICOORD	CID		
Type	I	I	F	I	I	I		
Default	1	{all}	1.0	7	0	0		

VARIABLE	DESCRIPTION
TYPE	Type of perturbation: EQ.1: Harmonic Field (see Remark 3) EQ.2: Fade out all perturbations at this node set (see Remark 4) EQ.3: Read perturbations from a file EQ.4: Spectral field EQ.8: Random value from uniform distribution
NSID	Node set ID. Specify 0 to perturb all the nodes in the model.
SCL	Scale factor
CMP	Component as given below: EQ.1: x coordinate EQ.2: y coordinate EQ.3: z coordinate EQ.4: x and y coordinates EQ.5: y and z coordinates EQ.6: z and x coordinates

VARIABLE	DESCRIPTION
	EQ.7: x, y, and z coordinates
ICOORD	Coordinate system to use (see Remarks 7, 8 and 9): EQ.0: Global Cartesian EQ.1: Cartesian EQ.2: Cylindrical (computed and applied) EQ.3: Spherical (computed and applied) EQ.-2: Computed in cartesian but applied in cylindrical EQ.-3: Computed in cartesian but applied in spherical
CID	Coordinate system ID; see *DEFINE_COORDINATE_NODES

Shell Thickness Card. Card 1 for SHELL_THICKNESS keyword option. Perturb the thickness of a set of shells (or all shells).

Card 1c	1	2	3	4	5	6	7	8
Variable	TYPE	EID	SCL	CMP	ICOORD	CID		
Type	I	I	F	I	I	I		
Default	1	{all}	1.0	none	0	0		

VARIABLE	DESCRIPTION
TYPE	Type of perturbation: EQ.1: Harmonic Field (see Remark 3) EQ.2: Fade out all perturbations at this element set (see Remark 4) EQ.3: Read perturbations from a file EQ.4: Spectral field EQ.8: Random value from uniform distribution
EID	Element set ID. Specify 0 to perturb all the elements in the model.
SCL	Scale factor

VARIABLE	DESCRIPTION
CMP	Component as given below: EQ.1: x coordinate EQ.2: y coordinate EQ.3: z coordinate EQ.4: x and y coordinates EQ.5: y and z coordinates EQ.6: z and x coordinates EQ.7: x, y, and z coordinates
ICOORD	Coordinate system to use (see Remarks 7, 8 and 9): EQ.0: Global Cartesian EQ.1: Cartesian EQ.2: Cylindrical (computed and applied) EQ.3: Spherical (computed and applied) EQ.-2: Computed in cartesian but applied in cylindrical EQ.-3: Computed in cartesian but applied in spherical
CID	Coordinate system ID; see *DEFINE_COORDINATE_NODES.

Harmonic Perturbation Cards (TYPE = 1). Card format 2 for TYPE = 1. Include as many cards of the following card as necessary. The input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	AMPL	XWL	XOFF	YWL	YOFF	ZWL	ZOFF	
Type	F	F	F	F	F	F	F	
Default	1.0	0.0	0.0	0.0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
AMPL	Amplitude of the harmonic perturbation
XWL	x wavelength of the harmonic field

VARIABLE	DESCRIPTION
XOFF	x offset of harmonic field
YWL	y wavelength of the harmonic field
YOFF	y offset of harmonic field
ZWL	z wavelength of the harmonic field
ZOFF	z offset of harmonic field

Fade Field Perturbation Card (TYPE = 2). Card format 2 for TYPE = 2. See Remark 4.

Card 2b	1	2	3	4	5	6	7	8
Variable	FADE							
Type	F							
Default	1.0							

VARIABLE	DESCRIPTION
FADE	Parameter controlling the distance over which faded perturbations are faded (material perturbations are not faded).

Perturbation from File Card (TYPE = 3). Card format 2 for TYPE = 3.

Card 2c	1	2	3	4	5	6	7	8
Variable	FNAME							
Type	A							

VARIABLE	DESCRIPTION
FNAME	Name of file containing the perturbation definitions

Spectral Field Perturbation Card (TYPE = 4). Card format 2 for TYPE = 4 (fade field).

Card 2d	1	2	3	4	5	6	7	8
Variable	CSTYPE	ELLIP1	ELLIP2	RND				
Type	I	F	F	I				
Default	none	1.0	1.0	0				

VARIABLE	DESCRIPTION
CSTYPE	Correlation structure: EQ.1: 3D isotropic. The *x*, *y* and *z* correlations are described using one correlation function. Define CFC1. EQ.2: 3D product. The *x*, *y* and *z* correlations are described using a correlation function each. Define CFC1, CFC2 and CFC3. EQ.3: 2D isotropic. A correlation function describes the *x* correlation while the *yz* isotropic relationship is described using another correlation function. Define CFC1 and CFC2. EQ.4: 2D isotropic. The *xz* isotropic relationship is described using a correlation function, while another correlation function describes the *y* correlation while. Define CFC1 and CFC2. EQ.5: 2D isotropic. The *xy* isotropic relationship is described using a correlation function, while another correlation function describes the *z* correlation while. Define CFC1 and CFC2. EQ.6: 3D elliptic. Define CSE1, CSE2 and CFC1. EQ.7: 2D elliptic. A correlation function describes the *x* correlation while the *yz* elliptic relationship is described using another correlation function. Define CSE1 and CFC1. EQ.8: 2D elliptic. A correlation function describes the *y* correlation while the *zx* elliptic relationship is described using another correlation function. Define CSE1 and CFC1. EQ.9: 2D elliptic. The *xy* elliptic relationship is described using a correlation function, while another correlation function describes the *z* correlation while. Define CSE1 and CFC1.

VARIABLE	DESCRIPTION
ELLIP1	Elliptic constant for 2D and 3D elliptic fields
ELLIP2	Elliptic constant for 3D elliptic field
RND	Seed for random number generator. EQ.0: LS-DYNA will generate a random seed. GT.0: Value to be used as seed

Spectral Perturbation Parameter Cards. Include one, two, or three cards of this format, depending on the value of CSTYPE.

Card 2d.1	1	2	3	4	5	6	7	8
Variable	CFTYPE	CFC1	CFC2	CFC3				
Type	I	F	F	F				
Default	none	1.0	1.0	1.0				

VARIABLE	DESCRIPTION
CFTYPE	Correlation function (see Remark 6) EQ.1: Gaussian EQ.2: Exponential EQ.3: Exponential Cosine EQ.4: Rational EQ.5: Linear
CFC*i*	Correlation function constant *i*

Random Value Perturbation Card (TYPE = 8). Card format 2 for TYPE = 8.

Card 2e	1	2	3	4	5	6	7	8
Variable	AMPL	DTYPE						
Type	F	F						
Default	1.0	0.0						

VARIABLE	DESCRIPTION
AMPL	Amplitude of the random perturbation
DTYPE	Distribution type: EQ.0.0: Uniform distribution between SCL × [0, AMPL] EQ.1.0: Uniform distribution between SCL × [−AMPL, AMPL]

Remarks:

1. **Postprocessing.** The perturbation can be viewed in LS-PrePost. For the NODE option, LS-DYNA creates files named pert_node_x/y/z/res, which can be viewed as user-defined fringe plots. For the SHELL_THICKNESS and MAT options, the files are named pert_shell_thickness and pert_mat respectively. If a coordinate system with a radial component is used, then the file pert_node_radial is also written.

2. **Linear Combinations and Maximum Amplitudes.** Perturbations specified using separate *PERTURBATION cards are created separately and then added together. This is true as well for special cases, such as CMP = 7 in which case the x, y and z fields are created separately and added together afterwards, which can result in an absolute amplitude greater than specified using AMPL or SCL.

3. **Harmonic Perturbations.** The harmonic perturbation is

$$p_{\mathrm{CMP}}(x,y,z) = \mathrm{SCL} \times \mathrm{AMPL} \times \left[\sin\left(2\pi \frac{x + \mathrm{XOFF}}{\mathrm{XWL}}\right) + \sin\left(2\pi \frac{y + \mathrm{YOFF}}{\mathrm{YWL}}\right) + \sin\left(2\pi \frac{z + \mathrm{ZOFF}}{\mathrm{ZWL}}\right)\right]$$

Note that the harmonic perturbations can sum to values greater than SCL × AMPL.

4. **Fade Perturbation.** The fade perturbation is

$$p'(x,y,z) = \text{SCL} \times \left(1 - \frac{1}{e^{-\frac{\ln 0.05}{\text{FADE}} \times x'}}\right) p(x,y,z)$$

where x' is the shortest distance to a node in the node set or element set specified, and FADE is the parameter controlling the sharpness of the fade perturbation.

5. **Keyword Format for FNAME Field.** The file FNAME must contain the perturbation in the LS-DYNA keyword format. This file can be created from the d3plot results using the LS-PrePost Output capability. The data must be arranged into two columns with the first column being the node ids. Lines starting with the character $ will be ignored.

6. **Correlation Functions.** The correlation functions are defined as follows:

   a) Gaussian: $B(t) = e^{-(at)^2}$

   b) Exponential: $B(t) = e^{-|at|^b}$

   c) Exponent and Cosine: $B(t) = e^{-|at|}\cos(bt)$

   d) Rational: $B(t) = (1 + |at|^b)^{-c}$

   e) Piecewise Linear: $B(t) = (1 - |at|)\chi(1 - |at|)$

   with χ the Heaviside step function and a, b and c corresponding to CFC1, CFC2 and CFC3, respectively.

7. **Cylindrical Coordinates.** For the cylindrical coordinate system option (ICOORD = 2), the default is to use the global coordinate system for the location of the cylindrical part, with the base of the cylinder located at the origin, and the global z-axis aligned with the cylinder axis. For cylindrical parts not located at the global origin, define a coordinate system (numbered CID) using *DEFINE_COORDINATE_NODES by selecting any three nodes on the base of the cylinder in a clockwise direction (resulting in the local z-axis to be aligned with the cylinder).

8. **Spherical Coordinates.** For the spherical coordinate system (ICOORD = 3), the coordinates are the radius, zenith angle $[0,\pi]$, and the azimuth angle $[0,2\pi]$. The default is to use the global coordinate system with the zenith measured from the z-axis and the azimuth measured from the x-axis in the xy-plane. For spherical parts not located at the global origin, define a coordinate system using *DEFINE_COORDINATE_NODES by selecting any three nodes as follows: the first node is the center of the sphere, the second specifies the x-axis of the coordinate

system, while the third point specifies the plane containing the new y-axis. The z-axis will be normal to this plane.

9. **Computed in Cartesian Applied to Cylindrical or Spherical.** It is possible to compute the perturbations in a Cartesian coordinate system, but to apply them in a cylindrical or spherical coordinate system (ICOORD = -2, -3). This is the natural method of doing say a radial perturbation of a sphere using a spectral perturbation field. We expect that computing the perturbation in the spherical coordinate system should be rare (ICOORD = 3). Computing a perturbation in a cylindrical coordinate system should be common though; for example, a circumferential harmonic perturbation.

10. **Material Perturbation Feature.** Only *MAT_238 (*MAT_PERT_PIECEWISE_LINEAR_PLASTICITY) and solid elements in an explicit analysis can be perturbed using *PERTURBATION_MAT. See the documentation of this material for allowable components. Only one part per model can be perturbed. For some perturbed quantity c, the material perturbation is applied on an element-by-element basis as

$$c_{\text{new}} = (1 + p)c_{\text{base}}$$

where p is a random number, which is written to the pert_mat file during the calculation. Values of p less than -1 are not allowed because the material behavior is not defined.

Completely independent of *PERTURBATION_MAT, see *DEFINE_STOCHASTIC_VARIATION for a way to define a stochastic variation of yield stress and/or failure strain in material models 10, 15, 24, 81, and 98 and the shell version of material 123.

*RAIL

Two keywords are defined in this section.

*RAIL_TRACK

*RAIL_TRAIN

*RAIL_TRACK

Purpose: Wheel-rail contact algorithm intended for railway applications but can also be used for other purposes. The wheel nodes (defined on *RAIL_TRAIN) represent the contact patch between wheel and rail. A penalty method is used to constrain the wheel nodes to slide along the track. A track consists of two rails, each of which is defined by a set of beam elements.

Card Sets. For each track include one pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	BSETID1	NORGN1	LCUR1	OSET1	SF1	GA1	IDIR
Type	I	I	I	I	F	F	F	I
Default	none	none	none	↓	0.0	1.0	0.0	0

Card 2	1	2	3	4	5	6	7	8
Variable		BSETID2	NORGN2	LCUR2	OSET2	SF2	GA2	
Type		I	I	I	F	F	F	
Default		none	none	↓	0.0	1.0	0.0	

VARIABLE	DESCRIPTION
ID	Track ID
BSETID1,2	Beam set ID for rails 1 and 2 containing all beam elements that make up the rail; see *SET_BEAM.
NORGN1,2	Reference node at one end of each rail, used as the origin for the roughness curve. The train will move in a direction away from this node.

VARIABLE	DESCRIPTION
LCUR1,2	Load curve ID (see *DEFINE_CURVE) defining track roughness (vertical displacement from line of beam elements) of the rail as a function of distance from the reference node NORIGIN. Distance from reference node is the x-axis of the curve while roughness is on the y-axis. Default: no roughness.
OSET1,2	Origin of curve LCUR is shifted by distance OSET towards the reference node.
SF1,2	Roughness values are scaled by SF. Default: 1.0.
GA1,2	Shear stiffness of rail per unit length (used to calculate local rail shear deformation within each beam element). GA = shear modulus × cross-sectional area. Default: local shear deformation is ignored.
IDIR	Contact forces are calculated in local directions relative to the plane containing the two rails at the contact point. IDIR determines which side of the plane is "up", that is, the direction in which the wheel can lift off the rail. "Up" is either **c** or −**c**,where **c** = **a** × **b**. **a** is the direction along rail 1 heading away from node NORGN1 and **b** is the vector from rail 1 to rail 2. Both **a** and **b** are determined locally. EQ.0: Whichever out of **c** or −**c** has a positive global Z component is "up" (default). EQ.1: −**c** is "up". EQ.-1: **c** is "up".

Remarks:

*RAIL_TRACK and *RAIL_TRAIN were written by Arup to represent wheel-rail contact. They have been used to generate loading on models of bridges for vibration predictions, for stress calculations, and for estimating accelerations experienced by passengers. Other non-railway uses are possible: the algorithm causes the "train" nodes to follow the line defined by the "rail" beam elements and transfers forces between them. In some cases (especially vibration modeling), double precision versions of LS-DYNA may give superior results because of the small relative deflections between wheel and rail.

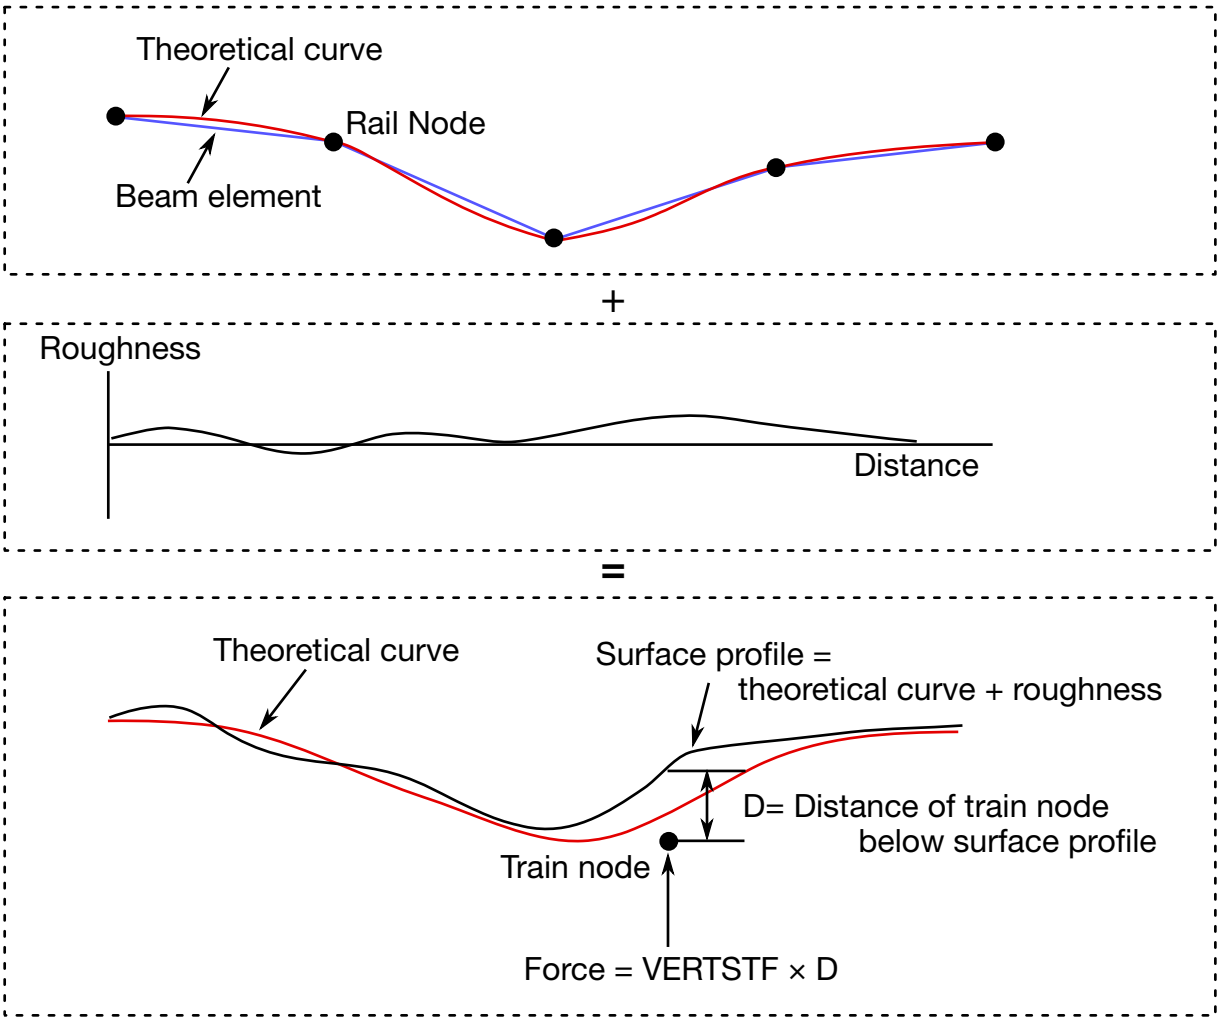

Figure 37-1. Track Model

Track Modeling:

The rails of the track should be modeled by two parallel lines of beam elements. The track can be curved or straight and the rails can be modeled as deformable or rigid. If required, rail pads, sleepers and ballast may also be modeled – typically with spring, damper and beam elements. It is also possible to use this algorithm to control the motion of simple road vehicle models: beam element "rails" made of null material can be embedded in the road surface. It is recommended that the mesh size of the two rails should be similar: LS-DYNA calculates a local coordinate system for each train node based on the alignment of the currently contacted beam element and the nearest node on the other rail.

Because wheel-rail contact stiffness is generally very high, and wheel masses are large, small deviations from a straight line or smooth curve can lead to large transient forces. It is recommended that great care be taken in generating and checking the geometry for the track, especially where the track is curved. Some pre-processors write the coordinates

with insufficient precision to the LS-DYNA input file which can cause unintended roughness in the geometry. For the same reason, if the line of the track were taken as straight between nodes, spurious forces would be generated when the wheel passes from one rail element to the next. This is avoided because the *RAIL algorithm calculates a theoretical curved centerline for the rail element to achieve continuity of slope from one element to the next. Where the length of the rail elements is similar to or shorter than the maximum section dimension, shear deformation may be significant, and it is possible to include this in the theoretical centerline calculation to further reduce spurious forces at the element boundaries (inputs GA1, GA2).

Roughness (small deviations in the vertical profile from a perfect straight line) does exist in real life and is a principal source of vibration. *RAIL allows the roughness to be modeled by a load curve giving the vertical deviation (in length units) of the rail surface from the theoretical centerline of the beam elements as a function of distance along the track from the origin node of the rail. The roughness curve is optional. Ideally, roughness profiles measured from both rails of the same piece of track should be used so that the relationship between bump and roll modes is correctly captured.

Whether roughness is included or not, it is important to select as the origin nodes (NORIGIN1 and NORIGIN2) the nodes at the end of the rails away from which the train will be traveling. The train can start at any point along the rails but must travel away from the origin nodes.

Train Modeling:

The vehicles are typically modeled using spring, damper and rigid elements, or simply a point mass at each wheel position. Each node in the set referred to on *RAIL_TRAIN represents the contact patch of one wheel (note: not the center of the wheel). These nodes should be initially on or near the line defined by either of the two rails. LS-DYNA will move the train nodes initially onto the rails to achieve the correct initial wheel-rail forces. If the results are viewed with magnified displacements, the initial movements can appear surprising.

Wheel roughness input is available. This will be applied in addition to track roughness. The input curve must continue for the total rolled distance – it is not assumed to repeat with each wheel rotation. This is to avoid problems associated with ensuring continuity between the start and end of the profile around the wheel circumference, especially since the profiles might be generated from roughness spectra rather than taken directly from measured data.

Wheel-Rail Interface:

The wheel-rail interface model is a simple penalty function designed to ensure that the train nodes follow the line of the track. It does not attempt to account for the shape of the

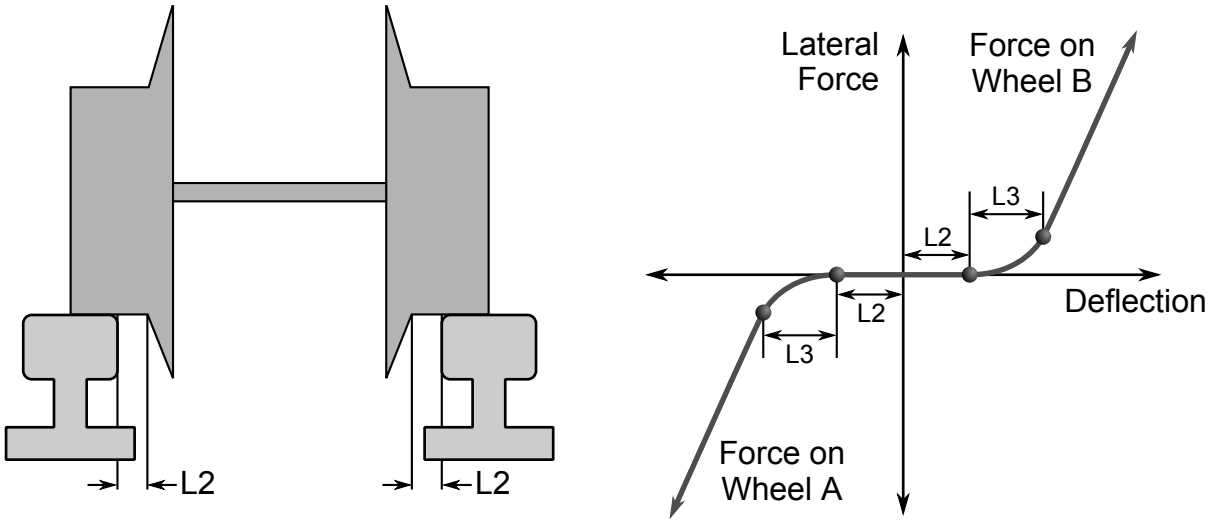

Figure 37-2. Illustration of lateral drift parameters L2 and L3 from *RAIL_-TRAIN. Diagram shows configuration for LATDIR = 0.

rail profile. Vertical and lateral loads are treated independently. For this reason, the algorithm is not suitable for rail vehicle dynamics calculations.

Wheel-rail contact stiffness is input on *RAIL_TRAIN. "Vertical" means normal to the plane containing the two rails at the contact point. "Horizontal" means the direction in the plane of the two rails perpendicular to the contacted rail. Vertical contact works like a normal penalty-based contact. A linear force-deflection relationship is assumed in compression (see VERTSTF on *RAIL_TRAIN); no tensile force is generated if the train wheel lifts up off the rail. The direction treated as "up" is controlled by IDIR. Typical contact stiffness is 2 MN/mm. Lateral deflections away from the theoretical centerline of the rail beams are penalized by a linear stiffness LATSTF (see *RAIL_TRAIN).

Optionally, a "gap" can be defined in input parameter L2 such that the wheel-set can drift laterally by L2 length units before any lateral force is generated. A further option is to allow smooth transition between "gap" and "contact" by means of a transition distance input as parameter L3. Figure 37-2 illustrates the geometry of parameters L2 and L3. A further option is FRIC on *RAIL_TRAIN. The friction force resists lateral motion of the train wheels relative to the track and is applied along with the forces calculated from LATSTF, L2 and L3 described above.

Generally, with straight tracks a simple linear stiffness is sufficient. With curved tracks, a reasonable gap and transition distance should be defined to avoid unrealistic forces being generated in response to small inaccuracies in the distance between the rails.

Gravity loading is expected, in order to maintain contact between rail and wheel. This is normally applied by an initial phase of dynamic relaxation. To help achieve convergence quickly, or in some cases avoid the need for dynamic relaxation altogether, the initial force expected on each train node can be input (field FINIT on *RAIL_TRAIN). LS-DYNA

positions the nodes initially such that the vertical contact force will be FINIT at each node. If the suspension of the rail vehicles is modeled, it is recommended that the input includes pre-compression of the spring elements; if this is not done, the train model may take a long time to reach equilibrium under gravity loading.

The *RAIL algorithm ensures that the train follows the rails but does not provide forward motion. This is generally applied using *INITIAL_VELOCITY, or for straight tracks, *BOUNDARY_PRESCRIBED_MOTION.

Output:

LS-DYNA generates an additional output file train_force.csv, containing force time-histories for each train node, output at the same time intervals as the binary time history file (DT on *DATABASE_BINARY_D3THDT). R12 and previous versions of LS-DYNA generated a file in a different ASCII format, train_force_*n*, where *n* is an integer. For backward compatibility of post-processing tools that format is still available by setting FMT = 1 on *RAIL_TRAIN.

Checking:

We recommend testing the track and train models separately before adding the *RAIL cards. You should check that the models respond stably to impulse forces and that they achieve equilibrium under gravity loading. Most problems we have encountered have been due to unstable behavior of train or track. Often, these are first detected by the *RAIL algorithm, and an error message will result.

*RAIL_TRAIN

Purpose: Define train properties. A train is defined by a set of nodes in contact with a rail defined by *RAIL_TRACK. See description under *RAIL_TRACK.

Card Sets. For each train include one pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	NSETID	FMT	FINIT	VGAP	TRID	LCUR	OFFS
Type	I	I	F	F	F	I	I	F
Default	none	none	0.0	0.0	0.0	0	↓	0.0

Card 2	1	2	3	4	5	6	7	8
Variable	VERTSTF	LATSTF	V2	V3	L2	L3	LATDIR	FRIC
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
ID	Train ID
NSETID	Node set ID containing all nodes that are in contact with rails
FMT	Format of output file containing force time-histories for all train nodes: EQ.0.0: CSV format EQ.1.0: ASCII file, same as R12 and previous versions
FINIT	Estimate of initial vertical force on each wheel (optional) – speeds up the process of initial settling down under gravity loading.
VGAP	Initial gap between wheel and track. If VGAP is defined, FINIT must be zero.

VARIABLE	DESCRIPTION
TRID	ID of track for this train (see *RAIL_TRACK)
LCUR	Load curve ID (see *DEFINE_CURVE) containing wheel roughness (distance of wheel surface away from perfect circle) as a function of distance traveled. The curve does not repeat with each rotation of the wheel – the last point should be at a greater distance than the train is expected to travel. Default: no wheel roughness.
OFFS	Offset distance used to generate different roughness curves for each wheel from the roughness curve LCUR. The curve is offset on the x-axis by a different whole number multiple of OFFS for each wheel.
VERTSTF	Vertical stiffness of rail contact
LATSTF	Lateral stiffness of rail contact
V2, V3	Unused variables – leave blank.
L2	Lateral clearance from rail to wheel flange (see Figure 37-2 of *RAIL_TRACK). Lateral force is applied to a wheel only when it has moved more than L2 laterally relative to the rail in the direction determined by LATDIR.
L3	Further lateral distance before full lateral stiffness applies (force-deflection curve follows a parabola up to this point). See Figure 37-2 of *RAIL_TRACK.
LATDIR	Determines the lateral direction (relative to the track) in which wheel movement is resisted by flange contact. If two wheels are fixed to an axle, lateral force is generally applied to one or other of the two wheels, depending on the direction of lateral movement. EQ.0.0: Wheel flanges run on inside faces of rails EQ.1.0: Wheel flanges run on outside faces of rails EQ.2.0: Wheel flanges on both faces of rails (both wheels resist lateral motion in both directions).
FRIC	Coefficient for additional friction force resisting lateral motion of wheel relative to rail.

*RIGIDWALL

Two keywords are used in this section to define rigid surfaces:

*RIGIDWALL_GEOMETRIC*_OPTION_{OPTION}_{OPTION}}_{OPTION}*

*RIGIDWALL_PLANAR*_{OPTION}_{OPTION}_{OPTION}*

The RIGIDWALL option provides a simple way of treating contact between a rigid surface and nodal points of a deformable body, called tracked nodes. Tracked nodes which belong to rigid parts are not, in general, checked for contact with only one exception. The RIGIDWALL_PLANAR option may be used with nodal points of rigid bodies if the planar wall defined by this option is fixed in space and the RWPNAL parameter is set to a positive nonzero value on the control card, *CONTROL_CONTACT.

When the rigid wall defined in this section moves with a prescribed motion, the equations of rigid body mechanics are not involved. For a general rigid body treatment with arbitrary surfaces and motion, refer to the *CONTACT_ENTITY definition. The *CONTACT_ENTITY option is for treating contact between rigid and deformable surfaces only.

Energy dissipated due to rigidwalls (sometimes called stonewall energy or rigid wall energy) is computed only if the parameter RWEN is set to 2 in *CONTROL_ENERGY.

The following keyword causes the forces acting on a rigid wall to be computed:

*RIGIDWALL_FORCE_TRANSDUCER

*RIGIDWALL_FORCE_TRANSDUCER

Purpose: Define a force transducer for a rigid wall. The output of the transducer is written to the rwforc file.

Card 1	1	2	3	4	5	6	7	8
Variable	TID	RWID						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
TID	Transducer ID.
RWID	Rigid wall ID.

Card 2	1	2	3	4	5	6	7	8
Variable	HEADING							
Type	C							
Default	none							
Remarks	1							

VARIABLE	DESCRIPTION
HEADING	Description for force transducer

Node Set Cards. For each node set add one card. This input ends at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	NSID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
NSID	Node set ID.

Remarks:

1. **Reporting for Node Set.** The forces acting on rigid wall RWID are reported separately for each NSID.

2. **Segment Option for Rigid Walls.** For rigid walls using the segment option, the forces acting on each segment are reported separately for each NSID.

***RIGIDWALL_GEOMETRIC**_*SHAPE_{OPTION}_{OPTION}_{OPTION}*

RIGIDWALL_GEOMETRIC_*SHAPE is a family of keywords all sharing a common set of data cards and option flags. The available shape variants are:

*RIGIDWALL_GEOMETRIC_FLAT

*RIGIDWALL_GEOMETRIC_PRISM

*RIGIDWALL_GEOMETRIC_CYLINDER

*RIGIDWALL_GEOMETRIC_SPHERE

If prescribed motion is desired an additional option is available:

MOTION

One of the shape types **[FLAT, PRISM, CYLINDER, SPHERE]** must be specified, followed by the optional definition of **MOTION**, both on the same line with ***RIGIDWALL_GEOMETRIC.** If an ID number is specified, the additional option is available:

ID

If active, the ID card is the first card following the keyword. To view the rigid wall, the option:

DISPLAY

is available. With this option a rigid body is automatically defined which represents the shape, the physical position of the wall, and follows the walls motion if the MOTION option is active. Additional input is optional if DISPLAY is active.

For the CYLINDER and SPHERE, the option:

INTERIOR

is available. Nodes are confined to the interior of these geometric forms.

For the CYLINDER, the option:

DEFORM

is available. With this option you can rotate and change the shape of the cylinder.

The order of the *OPTIONS* is arbitrary, that is, LS-DYNA will read *RIGIDWALL_GEOMETRIC_*SHAPE*_MOTION_DISPLAY the same as *RIGIDWALL_GEOMETRIC_*SHAPE*_DISPLAY_MOTION. However, the data cards have a strict order as indicated in the Card Summary.

Purpose: Define a rigid wall with an analytically described form. Four forms are possible. A prescribed motion is optional. For general rigid bodies with arbitrary surfaces and motion, refer to the *CONTACT_ENTITY definition. This option is for treating contact between rigid and deformable surfaces only.

Card Summary:

Card Sets. For each rigid wall include one set of the following data cards. This input ends at the next keyword ("*") card.

Card ID. First data card of the card set if the ID keyword option is used in the keyword name. Otherwise Card 1 is the first data card.

RWID	HEADING

Card 1. This card is required.

NSID	NSIDEX	BOXID	BIRTH	DEATH			

Card 2. This card is required.

XT	YT	ZT	XH	YH	ZH	FRIC	

Card 3a. This card is included only for the FLAT shape.

XHEV	YHEV	ZHEV	LENL	LENM			

Card 3b. This card is included only for the PRISM shape.

XHEV	YHEV	ZHEV	LENL	LENM	LENP		

Card 3c. This card is included only for the CYLINDER shape.

RADCYL	LENCYL	NSEGS					

Card 3c.1. NSEGS instances of this card are included only for the CYLINDER shape.

VL	HEIGHT						

Card 3c.2. This card is included only for the CYLINDER shape with DEFORM option.

XP	YP	ZP	NL	NARC	NR		

Card 3c.3. This card is included only for the CYLINDER shape with DEFORM option.

LCIDR	LCIDA	LCIDB	LCIDG				

Card 3d. This card is included only for the SPHERE shape.

RADSPH							

Card 4. This card is required if the MOTION keyword option is used.

LCID	OPT	VX	VY	VZ			

Card 5. This card is read only if the DISPLAY keyword option is used. It is optional and may be omitted unless more than one card set is being read in; if more than one card set is being used, then at least a blank line must be included for all, but the last card set. If not input, the defaults will be used.

PID	RO	E	PR				

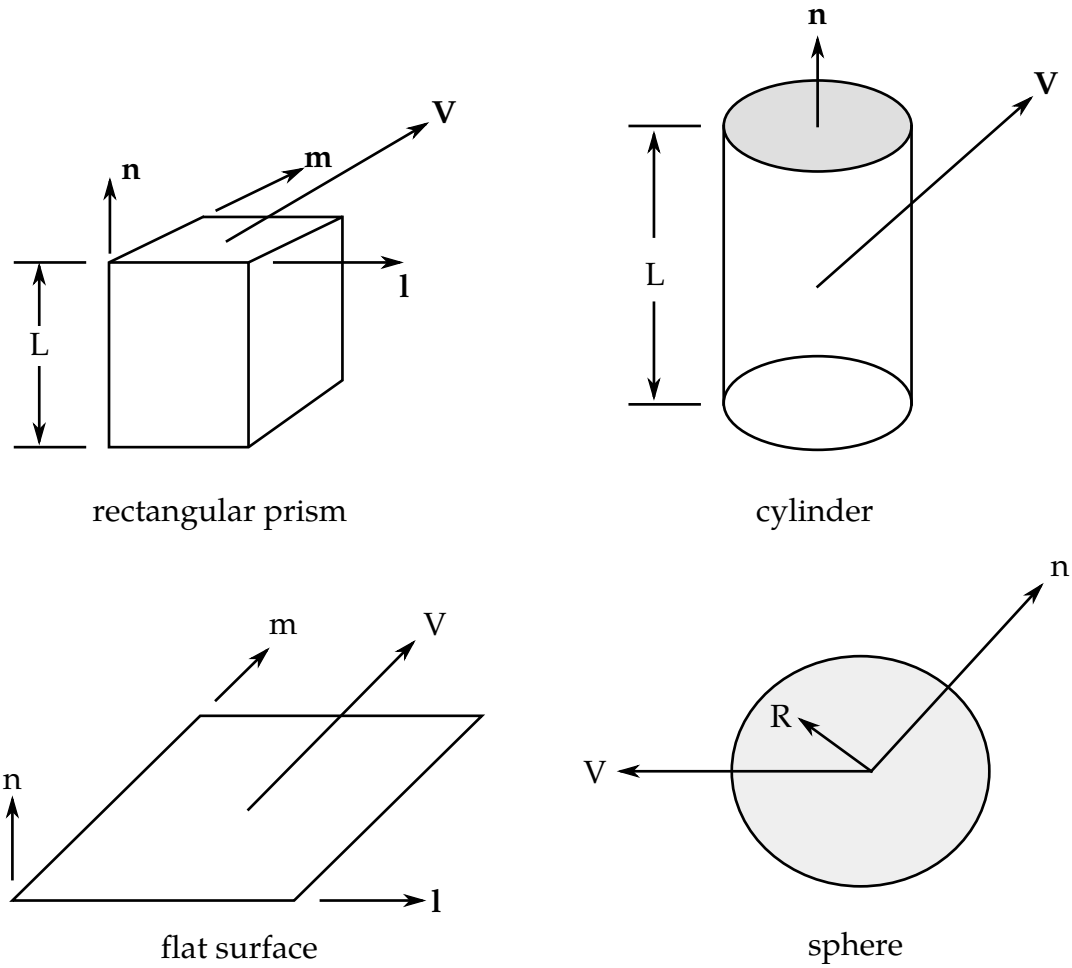

Figure 38-1. Vector **n** determines the orientation of the rigidwall. By including the MOTION option, motion of the rigidwall can be prescribed in any direction **V** as defined by variables VX, VY, VZ.

Data Card Definitions:

ID Card. Additional card for ID keyword option. This heading is picked up by some of the peripheral LS-DYNA codes to aid in post-processing.

Card ID	1	2	3	4	5	6	7	8
Variable	RWID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
RWID	Rigid wall ID. This must be a unique number.
HEADING	Rigid wall descriptor. It is suggested that unique descriptions be used. This field can be left undefined.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	NSIDEX	BOXID	BIRTH	DEATH			
Type	I	I	I	F	F			
Default	{all}	{∅}	{∅}	0.	10^{20}			

VARIABLE	DESCRIPTION
NSID	Nodal set ID containing tracked nodes; see *SET_NODE_*OPTION*: EQ.0: All nodes are tracked with respect to the rigid wall.
NSIDEX	Nodal set ID containing nodes exempted as tracked nodes; see *SET_NODE_*OPTION*.
BOXID	If defined, only nodes in box are included as tracked nodes for the rigid wall.
BIRTH	Birth time of rigid wall. The time values of the load curves that control the motion of the wall are offset by the birth time.

VARIABLE	DESCRIPTION
DEATH	Death time of rigid wall. At this time the wall is deleted from the calculation. If dynamic relaxation is active at the beginning of the calculation and if BIRTH = 0.0, the death time is ignored during the dynamic relaxation.

Card 2	1	2	3	4	5	6	7	8
Variable	XT	YT	ZT	XH	YH	ZH	FRIC	
Type	F	F	F	F	F	F	F	
Default	0.	0.	0.	0.	0.	0.	0.	

VARIABLE	DESCRIPTION
XT	x-coordinate of tail of any outward drawn normal vector, **n**, originating on wall (tail) and terminating in space (head); see Figure 38-1.
YT	y-coordinate of tail of normal vector **n**
ZT	z-coordinate of tail of normal vector **n**
XH	x-coordinate of head of normal vector **n**
YH	y-coordinate of head of normal vector **n**
ZH	z-coordinate of head of normal vector **n**
FRIC	Coulomb friction coefficient, except as noted below: EQ.0.0: Frictionless sliding when in contact EQ.1.0: No sliding when in contact

Flat Rigidwall Card. Card 3 for FLAT keyword option. A plane with a finite size or with an infinite size can be defined; see Figure 38-1. The vector **m** is computed as the vector cross product **n** × **l**. The origin, which is the tail (the start) of the normal vector, is the corner point of the finite size plane.

Card 3a	1	2	3	4	5	6	7	8
Variable	XHEV	YHEV	ZHEV	LENL	LENM			
Type	F	F	F	F	F			
Default	0.	0.	0.	infinity	infinity			

VARIABLE	DESCRIPTION
XHEV	*x*-coordinate of head of edge vector **l**; see Figure 38-1.
YHEV	*y*-coordinate of head of edge vector **l**
ZHEV	*z*-coordinate of head of edge vector **l**
LENL	Length of **l** edge. A zero value defines an infinite size plane.
LENM	Length of **m** edge. A zero value defines an infinite size plane.

Prismatic Rigidwall Card. Required card for PRISM keyword option that is input after Card 2. The description of the definition of a plane with finite size is enhanced by an additional length in the direction negative to **n**; see Figure 38-1.

Card 3b	1	2	3	4	5	6	7	8
Variable	XHEV	YHEV	ZHEV	LENL	LENM	LENP		
Type	F	F	F	F	F	F		
Default	none	0.	0.	infinity	infinity	infinity		

VARIABLE	DESCRIPTION
XHEV	*x*-coordinate of head of edge vector **l**, see Figure 38-1.
YHEV	*y*-coordinate of head of edge vector **l**

VARIABLE	DESCRIPTION
ZHEV	z-coordinate of head of edge vector **l**
LENL	Length of **l** edge. A zero value defines an infinite size plane.
LENM	Length of **m** edge. A zero value defines an infinite size plane.
LENP	Length of prism in the direction negative to **n**; see Figure 38-1.

Cylindrical Rigidwall Card. Required card for CYLINDER keyword option that is input after Card 2. The tail of **n** specifies the top plane of the cylinder. The length is defined in the direction negative to **n**. See Figure 38-1.

Card 3c	1	2	3	4	5	6	7	8
Variable	RADCYL	LENCYL	NSEGS					
Type	F	F	I					
Default	none	infinity	0					

VARIABLE	DESCRIPTION
RADCYL	Radius of cylinder
LENCYL	Length of cylinder; see Figure 38-1. Only if a value larger than zero is specified is a finite length assumed. For the DEFORM keyword option, the length of the cylinder must be finite.
NSEGS	Number of subsections along cylinder to output forces for post-processing. The force vector for each subsection is output to rwforc. This gives a better idea of the force distribution along the length of the cylinder.

NSEGS Card. For the CYLINDER option, NSEGS of this card must be input after Card 3c.

Card 3c.1	1	2	3	4	5	6	7	8
Variable	VL	HEIGHT						
Type	F	F						
Default	none	none						

VARIABLE	DESCRIPTION
VL	Distance from the top plane of the cylinder where the subsection begins.
HEIGHT	Section height. The subsection starts at VL and extends the length, HEIGHT, in the *negative* **n**-direction.

DEFORM Card 1. If the DEFORM option is used for the CYLINDER shape, this card must be input after Card 3c.1.

Card 3c.2	1	2	3	4	5	6	7	8
Variable	XP	YP	ZP	NL	NARC	NR		
Type	F	F	F	I	I	I		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
XP, YP, ZP	Coordinates of a point in the local *xz*-plane of the local coordinate system for cylinder. See Remark 1.
NL	Number of auto-generated elements in the longitudinal direction. If DISPLAY option is not used, NL will be ignored. See Remark 2.
NARC	Number of auto-generated elements in the circumferential direction. If DISPLAY option is not used, NARC will be ignored.

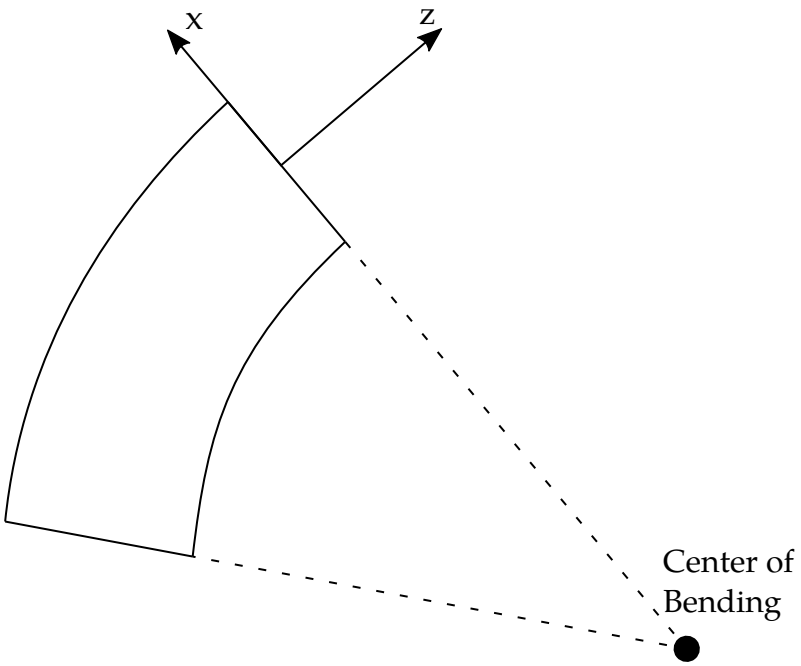

Figure 38-2. Example of cylinder bending for DEFORM keyword option

VARIABLE	DESCRIPTION
NR	Number of auto-generated elements in the radius direction. If DISPLAY option is not used, NR will be ignored.

DEFORM Card 2. If the DEFORM option is used for the CYLINDER shape, this card must be input after Card 3c.2.

Card 3c.3	1	2	3	4	5	6	7	8
Variable	LCIDR	LCIDA	LCIDB	LCIDG				
Type	I	I	I	I				
Default	0	0	0	0				

VARIABLE	DESCRIPTION
LCIDR	Load curve ID to describe the change of the radius over time
LCIDA	Load curve ID to specify the change of the rotation in radians about the local *x*-axis over time.

VARIABLE	DESCRIPTION
LCIDB	Load curve ID to describe the change of the bending curvature over time. Bending occurs in the local *xz*-plane with the center of the bending lying on the negative side of the local *x*-axis. See Figure 38-2.
LCIDG	Load curve ID to describe the change of the rotation in radians about the local *z*-axis over time.

Card 3d	1	2	3	4	5	6	7	8
Variable	RADSPH							
Type	F							
Default	0.							

VARIABLE	DESCRIPTION
RADSPH	Radius of sphere

Motion Card. Additional card for MOTION keyword option.

Card 4	1	2	3	4	5	6	7	8
Variable	LCID	OPT	VX	VY	VZ			
Type	I	I	F	F	F			
Default	none	0	none	none	none			

VARIABLE	DESCRIPTION
LCID	Rigidwall motion curve ID; see *DEFINE_CURVE.
OPT	Type of motion: EQ.0: velocity specified, EQ.1: displacement specified.

VARIABLE	DESCRIPTION
VX	x-direction cosine of velocity/displacement vector
VY	y-direction cosine of velocity/displacement vector
VZ	z-direction cosine of velocity/displacement vector

Display Card. Optional card for DISPLAY keyword option. If this card is omitted, default values are set. The values set here have no effect on the solution other than the PID appearing in the post-processing.

Card 5	1	2	3	4	5	6	7	8
Variable	PID	RO	E	PR				
Type	I	I	I	F				
Default	↓	10^{-9}	10^{-4}	0.3				

VARIABLE	DESCRIPTION
PID	Unique part ID for moving geometric rigid wall. If zero or left empty for default behavior, a part ID will be set that is larger than the maximum of all user defined part IDs.
RO	Density of rigid wall. The default is set to 10^{-9}.
E	Young's modulus. The default is set to 10^{-4}.
PR	Poisson's ratio. The default is set to 0.30.

Remarks:

1. **Local coordinate system of the cylinder.** When keyword option DEFORM is used, the deformations of the cylinder are based upon a local coordinate system. The origin of the coordinate system is (XT,YT,ZT). The local z-direction is aligned with vector **n**. The cross product of vector **n** with the vector that has its the tail at the origin and head at (XP,YP,ZP) gives the local y-axis. The direction of the local x-axis is the cross product of a vector on the local y-axis and vector **n**.

2. **Visualization of the cylinder with DEFORM option**. Elements generated by defining NL, NARC and NR are only for visualization. These elements are not used in analysis.

Example:

***RIGIDWALL_PLANAR**_{OPTION}_{OPTION}_{OPTION}

Available options include:

<BLANK>

ORTHO

FINITE

MOVING

FORCES

The ordering of the input below as specified in the Card Summary must be observed, but the ordering of the options in the keyword name is unimportant. For example, both *RIGIDWALL_PLANAR_ORTHO_FINITE and *RIGIDWALL_PLANAR_FINITE_ORTHO are valid and have the same effect. The ORTHO option does not apply if the MOVING option is used.

An ID number may be assigned to the rigid wall using the following option:

ID

If this option is active, the ID card is the first card following the keyword.

Display of a non-moving, planar rigid wall is on by default (see SKIPRWG in *CONTROL_CONTACT). The option

DISPLAY

is available for display of moving rigid walls. With this option active, a rigid body is automatically created which represents the shape of the rigid wall and tracks its position without need for additional input. The part ID of the rigid body defaults to RWID if the ID option is active and RWID is a unique ID within the set of all part IDs.

Purpose: Define planar rigid walls with either finite (FINITE) or infinite size. Orthotropic friction can be defined (ORTHO). Also, the plane can possess a mass and an initial velocity (MOVING); otherwise, the wall is assumed to be stationary. The FORCES option allows the specification of segments on the rigid walls on which the contact forces are computed. For a more physical reaction related to the force as function of time curve, the SOFT value on the FORCES card can be specified.

Card Summary:

Card Sets. For each rigid wall matching the specified keyword options include one set of the following data cards. This input ends at the next keyword ("*") card.

Card ID. This card is included if the ID keyword option is used.

ID							

Card 1. This card is required.

NSID	NSIDEX	BOXID	OFFSET	BIRTH	DEATH	RWKSF	

Card 2. This card is required.

XT	YT	ZT	XH	YH	ZH	FRIC	WVEL

Card 3. This card is included if the ORTHO option is used.

SFRICA	SFRICB	DFRICA	DFRICB	DECAYA	DECAYB		

Card 4. This card is included if the ORTHO option is used.

NODE1	NODE2	D1	D2	D3			

Card 5. This card is included if the FINITE option is used.

XHEV	YHEV	ZHEV	LENL	LENM			

Card 6. This card is included if the MOVING option is used.

MASS	V0						

Card 7. This card is included if the FORCES option is used.

SOFT	SSID	N1	N2	N3	N4		

Data Card Definitions:

ID. Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	RWID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
RWID	Rigid wall ID. Up to 8 characters can be used.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	NSIDEX	BOXID	OFFSET	BIRTH	DEATH	RWKSF	
Type	I	I	I	F	F	F	F	
Default	all nodes	{∅}	{∅}	0.	0.	10^{20}	1.0	

VARIABLE	DESCRIPTION
NSID	Nodal set ID containing tracked nodes; see *SET_NODE: EQ.0: All nodes are tracked for interacting with the rigid wall.
NSIDEX	Nodal set ID containing nodes that are exempted as tracked nodes; see *SET_NODE.
BOXID	All nodes in box are included as tracked nodes for interacting with the rigid wall; see *DEFINE_BOX. If options NSID or NSIDEX are active, then only the subset of nodes activated by these options are checked to see if they are within the box.
OFFSET	All nodes within a normal offset distance, OFFSET, to the rigid wall are included as tracked nodes for the rigid wall. If options NSID, NSIDEX, or BOXID are active, then only the subset of nodes activated by these options are checked to see if they are within the offset distance.
BIRTH	Birth time of rigid wall. The time values of the load curves that control the motion of the wall are offset by the birth time.
DEATH	Death time of rigid wall. At this time the wall is deleted from the calculation. If dynamic relaxation is active at the beginning of the calculation and BIRTH = 0.0, the death time is ignored during the dynamic relaxation.
RWKSF	Stiffness scaling factor. If RWKSF is also specified in *CONTROL_CONTACT, the stiffness is scaled by the product of the two values.

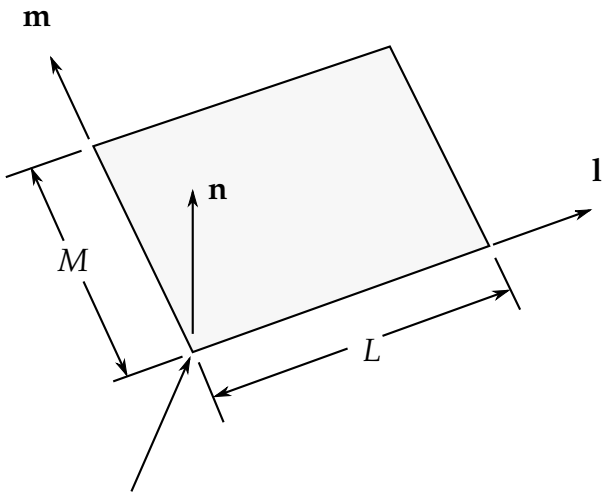

Figure 38-3. Vector **n** is normal to the rigidwall. An optional vector **l** can be defined such that $\mathbf{m} = \mathbf{n} \times \mathbf{l}$. The extent of the rigidwall is limited by defining L (LENL) and M (LENM). A zero value for either of these lengths indicates that the rigidwall is infinite in that direction.

Card 2	1	2	3	4	5	6	7	8
Variable	XT	YT	ZT	XH	YH	ZH	FRIC	WVEL
Type	F	F	F	F	F	F	F	F
Default	0.	0.	0.	0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
XT	x-coordinate of tail of any outward drawn normal vector, **n**, originating on wall (tail) and terminating in space (head), see Figure 38-3.
YT	y-coordinate of tail of normal vector **n**
ZT	z-coordinate of tail of normal vector **n**
XH	x-coordinate of head of normal vector **n**
YH	y-coordinate of head of normal vector **n**

VARIABLE	DESCRIPTION
ZH	z-coordinate of head of normal vector **n**
FRIC	Coulomb friction coefficient except as noted below: EQ.0.0: frictionless sliding after contact, EQ.1.0: no sliding after contact, EQ.2.0: node is welded after contact with frictionless sliding. Welding occurs if and only if the normal value of the impact velocity exceeds the critical value specified by WVEL. EQ.3.0: node is welded after contact with no sliding. Welding occurs if and only if the normal value of the impact velocity exceeds the critical value specified by WVEL. In summary, FRIC could be any positive value. Three special values of FRIC trigger special treatments as follows:
WVEL	Critical normal velocity at which nodes weld to wall (FRIC = 2 or 3).

FRIC	1.0	2.0	3.0
Bouncing back from wall	allowed	not allowed	not allowed
Sliding on wall	not allowed	allowed	not allowed

Orthotropic Friction Card 1. Additional card for ORTHO keyword option. See Figure 38-4 for the definition of orthotropic friction.

Card 3	1	2	3	4	5	6	7	8
Variable	SFRICA	SFRICB	DFRICA	DFRICB	DECAYA	DECAYB		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

Orthotropic Friction Card 2. Additional card for ORTHO keyword option. See Figure 38-4 for the definition of orthotropic friction.

Card 4	1	2	3	4	5	6	7	8
Variable	NODE1	NODE2	D1	D2	D3			
Type	I	I	F	F	F			
Default	0	0	0.	0.	0.			

VARIABLE	DESCRIPTION
SFRICA	Static friction coefficient in local a-direction, μ_{sa}; see Figure 38-4 and Remark 1.
SFRICB	Static friction coefficient in local b-direction, μ_{sb}
DFRICA	Dynamic friction coefficient in local a-direction, μ_{ka}
DFRICB	Dynamic friction coefficient in local b-direction, μ_{kb}
DECAYA	Decay constant in local a-direction, d_{ya}
DECAYB	Decay constant in local b-direction, d_{yb}
NODE1	Node 1, alternative to definition of vector **d** using components below. See Figure 38-4. With the node definition, the direction changes if the nodal pair rotates. See Remark 2.
NODE2	Node 2
D1	d_1, x-component of vector, alternative to definition with nodes above. See Figure 38-4. This vector is fixed as a function of time. See Remark 2.
D2	d_2, y-component of vector
D3	d_3, z-component of vector

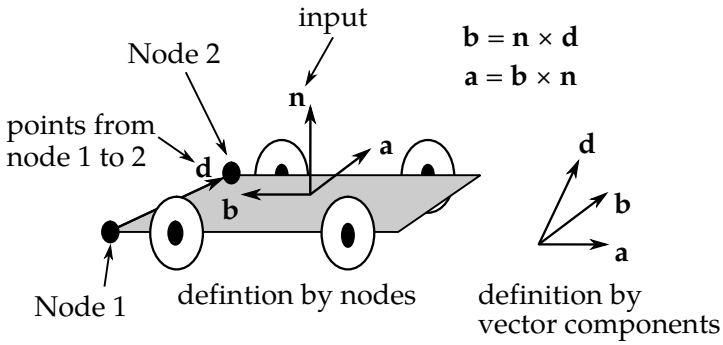

Figure 38-4. Definition of orthotropic friction vectors. The two methods of defining the vector, **d**, are shown. If vector **d** is defined by nodes 1 and 2, the local coordinate system may rotate with the body which contains the nodes; otherwise, **d** is fixed in space, thus on the rigid wall, and the local system is stationary.

Finite Wall Size Card. Additional card for FINITE keyword option. See Figure 38-4 for the definition of orthotropic friction. See Figure 38-3. The $\boldsymbol{m}$ vector is computed as the vector cross product $\boldsymbol{m} = \boldsymbol{n} \times \boldsymbol{l}$. The origin, the tail of the normal vector, is taken as the corner point of the finite size plane.

Card 5	1	2	3	4	5	6	7	8
Variable	XHEV	YHEV	ZHEV	LENL	LENM			
Type	F	F	F	F	F			
Default	0.	0.	0.	infinity	infinity			

VARIABLE	DESCRIPTION
XHEV	x-coordinate of head of edge vector $\boldsymbol{l}$, see Figure 38-3.
YHEV	y-coordinate of head of edge vector $\boldsymbol{l}$
ZHEV	z-coordinate of head of edge vector $\boldsymbol{l}$
LENL	Length of $\boldsymbol{l}$ edge
LENM	Length of $\boldsymbol{m}$ edge

Moving Wall Card. Additional card for MOVING keyword option. Note: The MOVING option is *not* compatible with the ORTHO option.

Card 6	1	2	3	4	5	6	7	8
Variable	MASS	V0						
Type	F	F						
Default	none	0.						

VARIABLE	DESCRIPTION
MASS	Total mass of rigidwall
V0	Initial velocity of rigidwall in direction of defining vector, **n**

Forces Card. Additional card for FORCES keyword option. This option allows the force distribution to be monitored on the plane. Also four points can be defined for visualization of the rigid wall. A shell or membrane element must be defined with these four points as the connectivity for viewing in LS-PREPOST.

Card 7	1	2	3	4	5	6	7	8
Variable	SOFT	SSID	N1	N2	N3	N4		
Type	I	I	I	I	I	I		
Default	0	{∅}	no node	no node	no node	no node		

VARIABLE	DESCRIPTION
SOFT	Number of cycles to zero relative velocity to reduce force spike
SSID	Segment set ID for defining areas for force output; see *SET_SEGMENT and Remark 3 below.
N1-N4	Optional node for visualization. See Remark 4.

Remarks:

1. **Orthotropic Coefficients of Friction.** The coefficients of friction are defined in terms of the static, dynamic and decay coefficients and the relative velocities in the local a and b-directions as

$$\mu_a = \mu_{ka} + (\mu_{sa} - \mu_{ka})e^{-d_{va}|V_{\text{relative},a}|}$$
$$\mu_b = \mu_{kb} + (\mu_{sb} - \mu_{kb})e^{-d_{vb}|V_{\text{relative},b}|}$$

2. **Modeling Rolling Objects.** Orthotropic rigid walls can be used to model rolling objects on rigid walls where the frictional forces are substantially higher in a direction transverse to the rolling direction. To use this option, define a vector **d** to determine the local frictional directions by:

$$\mathbf{b} = \mathbf{n} \times \mathbf{d}, \qquad \mathbf{a} = \mathbf{b} \times \mathbf{n}$$

where **n** is the normal vector to the rigid wall. If **d** is in the plane of the rigid wall, then **a** is identical to **d**.

3. **Resultant Forces.** The segment set defines areas for computing resultant forces. These segments translate with the moving rigidwall and allow the force distribution to be determined. The resultant forces are written in file rwforc.

4. **Visualization with LS-PrePost.** These four nodes are for visualizing the movement of the wall, that is, they move with the wall. To view the wall in LS-PREPOST a single shell element with these four nodes as its connectivity need to be defined. The single element must be deformable (non-rigid) or else the segment will be treated as a rigid body and the nodes will have their motion modified independently of the rigidwall.

Example:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$   *RIGIDWALL_PLANAR_MOVING_FORCES
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  Define a moving planar rigid wall:
$     - that is parallel to the y-z plane starting at x = 250 mm
$     - with an initial velocity of 8.94 mm/ms in the negative z-direction
$     - that has a mass of 800 kg
$     - which prevents all nodes in the model from penetrating the wall
$     - with a friction coefficient for nodes sliding along the wall of 0.1
$     - track the motion of the wall by creating a node (numbered 99999)
$         at the tail of the wall and assigning the node to move with the wall

*SECTION

In this section, the element formulation, integration rule, nodal thicknesses, and cross sectional properties are defined. All section identifiers (SECIDs) defined in this section must be unique, i.e., if a number is used as a section ID for a beam element then this number cannot be used again as a section ID for a solid element. The keyword cards in this section are defined in alphabetical order:

*SECTION_ALE1D

*SECTION_ALE2D

*SECTION_AUTODYN

*SECTION_BEAM

*SECTION_BEAM_AISC

*SECTION_DISCRETE

*SECTION_FPD

*SECTION_POINT_SOURCE

*SECTION_POINT_SOURCE_MIXTURE

*SECTION_SEATBELT

SECTION_SHELL_*{OPTION}

SECTION_SOLID_*{OPTION}

**SECTION_SOLID_PERI*

SECTION_SPH_*{OPTION}

*SECTION_TSHELL

The location and order of these cards in the input file are arbitrary.

An additional option **TITLE** may be appended to all the ***SECTION** keywords. If this option is used then an addition line is read for each section in 80a format which can be used to describe the section. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

*SECTION_ALE1D

Purpose: Define section properties for 1D ALE elements

Card Sets. For each ALE1D section add one pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ALEFORM	AET	ELFORM				
Type	I/A	I	I	I				
Default	none	none	0	none				

Card 2	1	2	3	4	5	6	7	8
Variable	THICK	THICK						
Type	F	F						
Default	none	none						

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ALEFORM	ALE formulation: EQ.11: Multi-Material ALE formulation
AET	Ambient Element Type: EQ.4: Pressure inflow
ELFORM	Element formulation: EQ.7: plane strain EQ.8: axisymmetric (per radian) EQ.-8: spherical (per unit of solid angle)

VARIABLE	DESCRIPTION
THICK	Nodal thickness. See Remark 1.

Remarks:

1. **Nodal Thickness.** *SECTION_ALE1D is using the common *SECTION_BEAM reader which expects two thickness values. The ALE 1D will simply take the average of these two values as the beam thickness. The thickness, however, is not used for ELFORM = -8, but the reader routine expects values on the 2nd line.

2. **Output to d3plot.** Unlike normal beams, ALE beams have history variables for more than one material. Since ALE beams only have one integration point, we use BEAMIP in *DATABASE_EXTENT_BINARY in a similar fashion to NEIPH for solids to tell LS-DYNA how much data needs to be exported to the d3plot file. Normally BEAMIP just tells LS-DYNA how many integration points for which data is output. By doing this, we can access for each ALE group in an element, 6 stresses, 1 plastic strain and a number of history variables that depend on the material and equation of state for the ALE group. Note that each increase in the value of BEAMIP leads to an increase of 5 data slots in the output file.

   Because this is an overloaded use of BEAMIP, LS-PrePost labels will not match the data being output. The data being output will be under beam integration points (bintpt) which can be accessed with Post → FriComp → Beam. The interpretation of the data will be described with examples below.

   For all cases of BEAMIP including BEAMIP = 0, d3plot will include 5 volume averaged items that will be under the first integration point. These five values will be under the first integration point in LS-PrePost and are described in the table below. Their real meaning is in the column labeled Variable Description.

LS-PrePost Label	Variable Description	ALE Group
axial stress	pressure	averaged
rs-shear stress	density	averaged
tr-shear stress	compression ratio	averaged
plastic strain	internal energy/vol	averaged
axial strain	ALE group ID	

Now suppose that we have 2 ALE groups, one with 8 history variables and one with 3 history variables. If we want all the output data, the number of data variables that we need output to d3plot would be

$$5 + \text{number of ALE groups} \times 7 + \sum_{i=1}^{n} \text{history variables of ALE group } i$$

since the 5 averaged variables listed above are always output, each ALE group has 7 values for the stress and effective plastic strain, and each ALE group has history variables. In our current example, this would $5 + 2 \times 7 + 8 + 3 = 30$. Since each integration points has 5 data slots as understood by LS-PrePost, then 6 integration points of data are needed, so BEAMIP should be set to 5 (note that this is because BEAMIP = 0 causes one integration point worth of data to be output with this implementation). If it is not set to 5, then d3plot will only include the data up to the number of integration points being output. The description for the values starting with the second integration point are listed in the table below.

Integration Point in LS-PrePost	LS-PrePost Label	Variable Description	ALE Group
2	axial stress	*xx*-stress	1
2	*rs*-shear stress	*yy*-stress	1
2	*tr*-shear stress	*zz*-stress	1
2	plastic strain	*xy*-stress	1
2	axial strain	*yz*-stress	1
3	axial stress	*zx*-stress	1
3	*rs*-shear stress	effective plastic strain	1
3	*tr*-shear stress	history variable # 1	1
3	plastic strain	history variable # 2	1
3	axial strain	history variable # 3	1
4	axial stress	history variable # 4	1
4	*rs*-shear stress	history variable # 5	1
4	*tr*-shear stress	history variable # 6	1

Integration Point in LS-PrePost	LS-PrePost Label	Variable Description	ALE Group
4	plastic strain	history variable # 7	1
4	axial strain	history variable # 8	1
5	axial stress	*xx*-stress	2
5	*rs*-shear stress	*yy*-stress	2
5	*tr*-shear stress	*zz*-stress	2
5	plastic strain	*xy*-stress	2
5	axial strain	*yz*-stress	2
6	axial stress	*zx*-stress	2
6	*rs*-shear stress	effective plastic strain	2
6	*tr*-shear stress	history variable # 1	2
6	plastic strain	history variable # 2	2
6	axial strain	history variable # 3	2

*SECTION_ALE2D

Purpose: Define section properties for 2D ALE elements. This supersedes the old way of defining section properties for 2D ALE elements using *SECTION_SHELL.

Section Cards. For each ALE2D section include a card. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ALEFORM	AET	ELFORM				
Type	I/A	I	I	I				
Default	none	none	0	none				

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ALEFORM	ALE formulation: EQ.11: Multi-Material ALE formulation.
AET	Part type flag: EQ.0: This is a regular or non-ambient part (default) EQ.4: Reservoir or ambient type part EQ.5: Reservoir or ambient type part, but only used together with *LOAD_BLAST_ENHANCED (LBE). It defines this part as an "ambient receptor part" for the transient blast load supplied by a corresponding LBE KW (see *LOAD_BLAST_ENHANCED, available only for ALEFORM = 11).
ELFORM	Element formulation: EQ.13: Plane strain (xy-plane) EQ.14: Axisymmetric solid (xy-plane, y-axis of symmetry) – area weighted (see Remark 2)

Remarks:

1. **Lagrangian-ALE Coupling.** For coupling between 2D Lagrangian elements and 2D ALE elements, use *CONSTRAINED_LAGRANGE_IN_SOLID rather than *CONTACT_2D_AUTOMATIC_SURFACE_IN_CONTINUUM.

2. **Axisymmetric Analysis.** For an axisymmetric analysis, ELFORM for *SECTION_ALE2D can only be set to 14 (area-weighted). In the same analysis, axisymmetric Lagrangian elements are not restricted to an area-weighted formulation. In other words, shell formulation 14 or 15 are permitted for Lagrangian shells and beam formulation 8 is permitted for Lagrangian beams. Coupling forces between the axisymmetric ALE elements and axisymmetric Lagrangian elements are automatically adjusted as needed.

*SECTION_BEAM

Purpose: Define cross sectional properties for beam, truss, discrete beam, and cable elements.

Card Summary:

Card Sets. For each BEAM section in the model add one set of Cards 1 and 2 (maybe additionally Card 3 for ELFORM = 12) cards. This input ends at the next keyword ("*") card.

Card 1. This card is required.

SECID	ELFORM	SHRF	QR/IRID	CST	SCOOR	NSM	NAUPD

Card 2a. Card 2 for ELFORM set to either 1 or 11.

TS1	TS2	TT1	TT2	NSLOC	NTLOC		

Card 2b. Card 2 for ELFORM set to 2, 3, or 12 and when the first 7 characters of the card spell out "SECTION."

STYPE	D1	D2	D3	D4	D5	D6	

Card 2c. Card 2 for ELFORM set to 2, 12, or 13 and when the first 7 characters of the card *do not* spell out "SECTION."

A	ISS	ITT	J	SA	IST	ITORM	

Card 2c.1. Card 3 for ELFORM equal to 12 and when the first 7 characters of Card 2 *do not* spell "SECTION."

YS	ZS	IYR	IZR	IRR	IW	IWR	

Card 2d. Card 2 for ELFORM set to 3 and when the first 7 characters of Card 2 *do not* spell "SECTION."

A	RAMPT	STRESS					

Card 2e. Card 2 for ELFORM equal to 4 or 5.

TS1	TS2	TT1	TT2				

Card 2f. Card 2 for ELFORM equal to 6 for any material other than material type 146.

VOL	INER	CID	CA	OFFSET	RRCON	SRCON	TRCON

Card 2g. Card 2 for ELFORM equal to 6 for material type 146.

VOL	INER	CID	DOFN1	DOFN2			

Card 2h. Card 2 for ELFORM equal to 7 or 8.

TS1	TS2						

Card 2i. Card 2 for ELFORM equal to 9.

TS1	TS2	TT1	TT2	PRINT		ITOFF	

Card 2j. Card 2 for ELFORM equal to 14.

PR	IOVPR	IPRSTR	PR	IOVPR			

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ELFORM	SHRF	QR/IRID	CST	SCOOR	NSM	NAUPD
Type	I/A	I	F	F	F	F	F	I
Default	none	1	1.0	2.0	0.0	0.0	0.0	0

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ELFORM	Element formulation options: EQ.1: Hughes-Liu with cross section integration (default) EQ.2: Belytschko-Schwer resultant beam (resultant) EQ.3: truss (resultant) EQ.4: Belytschko-Schwer full cross-section integration EQ.5: Belytschko-Schwer tubular beam with cross-section integration EQ.6: Discrete beam/cable

VARIABLE	DESCRIPTION
	EQ.7: 2D plane strain shell element (xy-plane) EQ.8: 2D axisymmetric volume weighted shell element (xy-plane, y-axis of symmetry) EQ.9: Spot weld beam; see *MAT_SPOTWELD. EQ.11: Integrated warped beam. See Remark 3. EQ.12: Resultant warped beam EQ.13: Small displacement, linear Timoshenko beam with exact stiffness. See Remark 5. EQ.14: Elbow integrated tubular beam element. A user defined integration rule with tubular cross section (9) must be used. Note that the 2D and 3D element types must not be mixed, and different types of 2D elements must not be used together. For example, the plane strain element type must not be used with the axisymmetric element type. In 3D the different beam elements types, that is, 1-6 and 9 can be freely mixed together.
SHRF	Shear factor. This factor is not needed for truss, resultant beam, discrete beam, and cable elements. The recommended value for rectangular sections is 5/6, the default is 1.0.
QR/IRID	Quadrature rule or rule number for user defined rule for integrated beams. See Remark 9 regarding beam formulations 7 and 8. EQ.1.0: One integration point EQ.2.0: 2×2 Gauss quadrature (default beam) EQ.3.0: 3×3 Gauss quadrature EQ.4.0: 3×3 Lobatto quadrature EQ.5.0: 4×4 Gauss quadrature EQ.-n: |n| is the number of the user defined rule. IRID integration rule n is defined using *INTEGRATION_BEAM card.
CST	Cross section type, not needed for truss, resultant beam, discrete beam, and cable elements: EQ.0.0: Rectangular, EQ.1.0: Tubular (circular only),

VARIABLE	DESCRIPTION
	EQ.2.0: Arbitrary (user defined integration rule).
SCOOR	Affects the discrete beam formulation (see Remark 6) and the update of the local coordinate system of the discrete beam element. This field does not apply to cable elements. The force and moment resultants in the output databases are output in the local coordinate system. See Remark 8 for more on the local coordinate system update. EQ.-13.0: Like -3.0, but with correction for beam rotation EQ.-12.0: Like -2.0, but with correction for beam rotation EQ.-3.0: Beam node 1; the angular velocity of node 1 rotates triad. EQ.-2.0: Beam node 1. The angular velocity of node 1 rotates triad, but the *r*-axis is adjusted to lie along the line between the two beam nodal points. This option is not recommended for zero length discrete beams. EQ.-1.0: Beam node 1; the angular velocity of node 1 rotates triad. EQ.0.0: Centered between beam nodes 1 and 2; the average angular velocity of nodes 1 and 2 is used to rotate the triad. EQ.+1.0: Beam node 2; the angular velocity of node 2 rotates triad. EQ.+2.0: Beam node 2. The angular velocity of node 2 rotates triad, but the r-axis is adjusted to lie along the line between the two beam nodal points. This option is not recommended for zero length discrete beams. EQ.+3.0: Beam node 2; the angular velocity of node 2 rotates triad. EQ.+12.0: Like +2.0, but with correction for beam rotation EQ.+13.0: Like +3.0, but with correction for beam rotation
NSM	Nonstructural mass per unit length. This option applies to beam types 1-5 and does not apply to discrete, 2D, and spot weld beams.
NAUPD	Neutral axis update option. See Remark 11. EQ.0: Not used

VARIABLE	DESCRIPTION
	EQ.1: Update the neutral axis when damage or failure occurs at one or more integration points.

Integrated Beam Card (types 1 and 11). Card 2 for ELFORM set to either type 1 or 11.

Card 2a	1	2	3	4	5	6	7	8
Variable	TS1	TS2	TT1	TT2	NSLOC	NTLOC		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
TS1	Beam thickness (CST = 0.0, 2.0) or outer diameter (CST = 1.0) in s-direction at node n_1. Note that the thickness defined on the *ELEMENT_BEAM_THICKNESS card overrides the definition give here.
TS2	Beam thickness (CST = 0.0, 2.0) or outer diameter (CST = 1.0) in s-direction at node n_2.
TT1	Beam thickness (CST = 0.0, 2.0) or inner diameter (CST = 1.0) in t-direction at node n_1.
TT2	Beam thickness (CST = 0.0, 2.0) or inner diameter (CST = 1.0) in t-direction at node n_2.
NSLOC	Location of reference surface normal to s-axis for Hughes-Liu beam elements only. See Remark 4. EQ.1.0: Side at $s = 1.0$ EQ.0.0: Center EQ.-1.0: Side at $s = -1.0$
NTLOC	Location of reference surface normal to t-axis for Hughes-Liu beam elements only. See Remark 4. EQ.1.0: Side at $t = 1.0$ EQ.0.0: Center EQ.-1.0: Side at $t = -1.0$

Resultant Beam with Shape Card (types 2, 3, and 12). Card 2 for ELFORM equal to 2, 3, or 12 and when first 7 characters of the card spell out "SECTION."

Card 2b	1	2	3	4	5	6	7	8
Variable	STYPE	D1	D2	D3	D4	D5	D6	
Type	A10	F	F	F	F	F	F	

VARIABLE	DESCRIPTION
STYPE	Section type (A format) of resultant beam (see Figure 39-1):

EQ.SECTION_01: I-Shape
EQ.SECTION_02: Channel
EQ.SECTION_03: L-shape
EQ.SECTION_04: T-shape
EQ.SECTION_05: Tubular box
EQ.SECTION_06: Z-Shape
EQ.SECTION_07: Trapezoidal
EQ.SECTION_08: Circular
EQ.SECTION_09: Tubular
EQ.SECTION_10: I-Shape 2
EQ.SECTION_11: Solid Box
EQ.SECTION_12: Cross
EQ.SECTION_13: H-Shape
EQ.SECTION_14: T-Shape 2
EQ.SECTION_15: I-Shape 3
EQ.SECTION_16: Channel 2
EQ.SECTION_17: Channel 3
EQ.SECTION_18: T-Shape 3
EQ.SECTION_19: Box-Shape 2
EQ.SECTION_20: Hexagon
EQ.SECTION_21: Hat-Shape
EQ.SECTION_22: Hat-Shape 2

D1-D6	Input parameters for section option using STYPE above. See Figures 39-1 through 39-22.

Resultant Beam Card 1 (types 2, 12, and 13). Card 2 for ELFORM equal to 2, 12, or 13 and when first 7 characters of card *do not* spell "SECTION."

Card 2c	1	2	3	4	5	6	7	8
Variable	A	ISS	ITT	J	SA	IST	ITORM	
Type	F	F	F	F	F	F	F	

VARIABLE	DESCRIPTION
A	Cross-sectional area. The definition on *ELEMENT_BEAM_-THICKNESS overrides the value defined here.

VARIABLE	DESCRIPTION
ISS	I_{ss}, area moment of inertia about local s-axis. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here.
ITT	I_{tt}, area moment of inertia about local t-axis. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here.
J	J, torsional constant. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here. If J is zero, then J is reset to the sum of ISS + ITT as an approximation for warped beam.
SA	Shear area. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here.
IST	I_{st}, product area moment of inertia with respect to the local s- and t-axes. This is only non-zero for asymmetric cross sections and it can take positive and negative values; for example, it is negative for SECTION_03.
ITORM	Flag for improved representation of torsional modes which can be activated only if an eigenvalue analysis is performed. Applies only to beam type 13. EQ.0.0: Not active. The torsional inertia from structural analysis is used. This may result in too large eigenvalues related to torsional modes. EQ.1.0: The mass related to the torsional mode is recomputed more accurately.

Resultant Beam Card 2 (type 12 only). *Card 3* for ELFORM equal to 12 and when first 7 characters of *Card 2 do not* spell "SECTION".

Card 2c.1	1	2	3	4	5	6	7	8
Variable	YS	ZS	IYR	IZR	IRR	IW	IWR	
Type	F	F	F	F	F	F	F	

VARIABLE	DESCRIPTION
YS	s coordinate of shear center of cross-section. The coordinate system is located at the centroid.

VARIABLE	DESCRIPTION
ZS	t coordinate of shear center of cross-section. The coordinate system is located at the centroid.
IYR	$\int_A sr^2 dA$, where $r^2 = s^2 + t^2$
IZR	$\int_A tr^2 dA$, where $r^2 = s^2 + t^2$
IRR	$\int_A r^4 dA$, where $r^2 = s^2 + t^2$
IW	Warping constant. $\int_A \omega^2 dA$, where ω is the sectorial area.
IWR	$\int_A \omega r^2 dA$

Resultant Beam Card (type 3). Card 2 for ELFORM equal to 3.

Card 2d	1	2	3	4	5	6	7	8
Variable	A	RAMPT	STRESS					
Type	F	F	F					

VARIABLE	DESCRIPTION
A	Cross-sectional area. The definition on *ELEMENT_BEAM_-THICKNESS overrides the value defined here.
RAMPT	Optional ramp-up time for dynamic relaxation. At the end of the ramp-up time, a uniform stress, STRESS, will exist in the truss in the truss element. This option will not work for hyperelastic materials.
STRESS	Optional initial stress for dynamic relaxation. At the end of dynamic relaxation, a uniform stress equal to this value should exist in the truss element.

Integrated Beam Card (types 4 and 5). Card 2 for ELFORM equal to 4 or 5.

Card 2e	1	2	3	4	5	6	7	8
Variable	TS1	TS2	TT1	TT2				
Type	F	F	F	F				

VARIABLE	DESCRIPTION
TS1	Beam thickness (CST = 0.0, 2.0) or outer diameter (CST = 1.0) in s-direction at node n_1. Note that the thickness defined on the *ELEMENT_BEAM_THICKNESS card overrides the definition give here.
TS2	Beam thickness (CST = 0.0, 2.0) or outer diameter (CST = 1.0) in s-direction at node n_2.
TT1	Beam thickness (CST = 0.0, 2.0) or inner diameter (CST = 1.0) in t-direction at node n_1.
TT2	Beam thickness (CST = 0.0, 2.0) or inner diameter (CST = 1.0) in t-direction at node n_2.

Discrete Beam Card (type 6). Card 2 for ELFORM equal to 6 for any material *other* than material type 146.

Card 2f	1	2	3	4	5	6	7	8
Variable	VOL	INER	CID	CA	OFFSET	RRCON	SRCON	TRCON
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
VOL	Volume of discrete beam and scalar (MAT_146) beam. Used in calculating mass. If VOL = 0 for cable elements, volume is calculated as the product of cable length and cable area. If the mass density of the material model for the discrete beam is set to unity, the magnitude of the lumped mass can be defined here instead. This lumped mass is partitioned to the two nodes of the beam element. The translational time step size for the type 6 beam is dependent on the volume, mass density, and the translational stiffness values,

VARIABLE	DESCRIPTION
	so it is important to define this parameter. Defining the volume is also essential for mass scaling if the type 6 beam controls the time step size.
INER	Mass moment of inertia for the six degree of freedom discrete beam and scalar (MAT_146) beam. This parameter does not apply to cable elements. This lumped inertia is partitioned to the two nodes of the beam element. The rotational time step size for the type 6 beam is dependent on the lumped inertia and the rotational stiffness values, so it is important to define this parameter if the rotational springs are active. Defining the rotational inertia is also essential for mass scaling if the type 6 beam rotational stiffness controls the time step size. It is recommended to always set this parameter to a reasonable nonzero value to avoid instabilities and/or having model dependent rotational inertia properties; if the value set is smaller than that of an equivalent solid sphere, LS-DYNA will issue a warning.
CID	Coordinate system ID for orientation (material types 66-69, 93, 95, 97), see *DEFINE_COORDINATE_*OPTION*. If CID = 0, a default coordinate system is defined in the global system or on the third node of the beam, which is used for orientation. This option is not defined for material types that act between two nodal points, such as cable elements. The coordinate system rotates with the discrete beam, see SCOOR above.
CA	Cable area. See material type 71, *MAT_CABLE_DISCRETE_BEAM. For a crushable beam using *MAT_119 with IFLAG = 2, CA is the cross-sectional area ratio between end 2 and end 1. A crushable beam of uniform cross-section has CA = 1, the default value.
OFFSET	Optional offset for cable. See material type 71, *MAT_CABLE_DISCRETE_BEAM.
RRCON	*r*-rotational constraint for local coordinate system (see Remark 7) EQ.0.0: Coordinate ID rotates about *r*-axis with nodes. EQ.1.0: Rotation is constrained about the *r*-axis
SRCON	*s*-rotational constraint for local coordinate system (see Remark 7) EQ.0.0: Coordinate ID rotates about *s*-axis with nodes. EQ.1.0: Rotation is constrained about the *s*-axis

VARIABLE	DESCRIPTION
TRCON	*t*-rotational constraint for local coordinate system (see Remark 7) EQ.0.0: Coordinate ID rotates about *t*-axis with nodes. EQ.1.0: Rotation is constrained about the *t*-axis.

Discrete Beam Card (type 6, mat 146). Card 2 for ELFORM equal to 6 for material type 146.

Card 2g	1	2	3	4	5	6	7	8
Variable	VOL	INER	CID	DOFN1	DOFN2			
Type	F	F	F	F	F			

VARIABLE	DESCRIPTION
VOL	Volume of discrete beam and scalar (MAT_146) beam. Used in calculating mass. If VOL = 0 for cable elements, volume is calculated as the product of cable length and cable area. If the mass density of the material model for the discrete beam is set to unity, the magnitude of the lumped mass can be defined here instead. This lumped mass is partitioned to the two nodes of the beam element. The translational time step size for the type 6 beam is dependent on the volume, mass density, and the translational stiffness values, so it is important to define this parameter. Defining the volume is also essential for mass scaling if the type 6 beam controls the time step size.
INER	Mass moment of inertia for the six degree of freedom discrete beam and scalar (MAT_146) beam. This parameter does not apply to cable elements. This lumped inertia is partitioned to the two nodes of the beam element. The rotational time step size for the type 6 beam is dependent on the lumped inertia and the rotational stiffness values, so it is important to define this parameter if the rotational springs are active. Defining the rotational inertia is also essential for mass scaling if the type 6 beam rotational stiffness controls the time step size. It is recommended to always set this parameter to a reasonable nonzero value to avoid instabilities and/or having model dependent rotational inertia properties; if the value set is smaller than that of an equivalent solid sphere, LS-DYNA will issue a warning.

VARIABLE	DESCRIPTION
CID	Coordinate system ID for orientation, material type 146, see *DEFINE_COORDINATE_SYSTEM. If CID = 0, a default coordinate system is defined in the global system.
DOFN1	Active degree-of-freedom at node 1, a number between 1 and 6 where 1 is x-translation and 4 is x-rotation.
DOFN2	Active degree-of-freedom at node 2, a number between 1 and 6.

2D Shell Card (types 7 and 8). Card 2 for ELFORM equal to 7 or 8.

Card 2h	1	2	3	4	5	6	7	8
Variable	TS1	TS2						
Type	F	F						

VARIABLE	DESCRIPTION
TS1	Thickness at node n_1.
TS2	Thickness at node n_2.

Spot Weld Card (type 9). Card 2 for ELFORM equal to 9.

Card 2i	1	2	3	4	5	6	7	8
Variable	TS1	TS2	TT1	TT2	PRINT		ITOFF	
Type	F	F	F	F	F		F	

VARIABLE	DESCRIPTION
TS1	Beam thickness (CST = 0.0, 2.0) or outer diameter (CST = 1.0) in s-direction at node n_1. Note that the thickness defined on the *ELEMENT_BEAM_THICKNESS card overrides the definition give here.
TS2	Beam thickness (CST = 0.0, 2.0) or outer diameter (CST = 1.0) in s-direction at node n_2.

VARIABLE	DESCRIPTION
TT1	Beam thickness (CST = 0.0, 2.0) or inner diameter (CST = 1.0) in t-direction at node n_1.
TT2	Beam thickness (CST = 0.0, 2.0) or inner diameter (CST = 1.0) in t-direction at node n_2.
PRINT	Output spot force resultant from spot welds. EQ.0.0: Data is output to swforc file. EQ.1.0: Output is suppressed.
ITOFF	Option to specify torsional behavior for spot weld beams. EQ.0.0: Torsional stiffness is active. EQ.1.0: Torsional stiffness is zero (free to twist).

Integrated Beam Card (types 14). Card 2 for ELFORM equal to 14.

Card 2j	1	2	3	4	5	6	7	8
Variable	PR	IOVPR	IPRSTR					
Type	F	F	F	F				

VARIABLE	DESCRIPTION
PR	Pressure inside ELBOW elements that belong to the section. The pressure acts as a stiffener and will reduce the ovalization of the pipe. Pressure acting on the inside wall is taken as positive.
IOVPR	Print flag for the ELBOW ovalization degrees of freedom. EQ.1.0: An ASCII file named elbwov is created and filled with the ovalization. Default no file is created.
IPRSTR	Flag for adding stress due to pressure PR into the material routine. EQ.0: No stress is added to the material. In this case the pressure only acts as a stiffener for the tube. EQ.1: The pressure PR is used to calculate additional axial and circumferential stresses due to the applied pressure PR. The stress added is given by:

VARIABLE	DESCRIPTION

$$\sigma_{\text{axial}} = \text{PR} \times \frac{D}{4T}, \qquad \sigma_{\text{circ}} = \text{pr} \times \frac{D}{2T}$$

for a straight pipe, and

$$\sigma_{\text{axial}} = \text{PR} \times \frac{D}{4T}, \qquad \sigma_{\text{circ}} = \text{PR} \times \frac{D}{4T} \frac{[2R + r\cos(\theta)]}{[R + r\cos(\theta)]}$$

for a curved pipe. D is the pipe diameter, T is the thickness, R is the curvature of the bend, r is the pipe radius (mean) and θ is an angle pointing out a point on the pipe. This option also includes the stiffening effect.

Remarks:

1. **Implicit Time Integrator.** For implicit calculations all the beam element choices are implemented.

2. **Local Coordinate System Rotation.** The local coordinate system rotates as the nodal points that define the beam rotate. In some cases this may lead to unexpected results if the nodes undergo significant rotational motions. In the definition of the local coordinate system using *DEFINE_COORDINATE_NODES, if the option to update the system each cycle is active then this updated system is used. This latter technique seems to be more stable in some applications.

3. **Integrated Warped Beam.** The integrated warped beam (type 11) is a 7 degree of freedom beam that must be used with an integration rule of the open standard cross sections, see *INTEGRATION_BEAM. To incorporate the additional degrees of freedom corresponding to the twist rates, one scalar node (*NODE_SCALAR) should be declared for each node attached to a warped beam. This degree of freedom is associated to the beam element using the warpage option on the *ELEMENT_BEAM card.

4. **Beam Offsets.** Beam offsets are sometimes necessary for correctly modeling beams that act compositely with other elements such as shells or other beams. A beam offset extends from the beam's n_1-to-n_2 axis to the reference axis of the beam. The beam reference axis lies at the origin of the local s- and t-axes. This origin is located at the center of the cross-section footprint for beam formulations 1 and 11, but it is located at the cross-section centroid for beam formulation 2. Note that for cross-sections that are not doubly symmetric, such as a T-section, the center of the cross-section footprint and the centroid of the cross-section do not coincide. The offset in the positive s-direction is

$$\text{s-offset} = -0.5 \times \text{NSLOC} \times (\text{beam cross-section dimension in } s\text{-direction}).$$

Similarly, the offset in the positive t-direction is

$$\text{t-offset} = -0.5 \times \text{NTLOC} \times (\text{beam cross-section dimension in } t\text{-direction}).$$

If IRID is used to point to an integration rule with ICST > 0, then offsets must be defined using SREF and TREF on the *INTEGRATION_BEAM card as they will override NSLOC and NTLOC even if SREF = 0 or TREF = 0. See also *ELEMENT_BEAM_OFFSET for an alternate approach to defining beam offsets.

5. **Three-Dimensional Timoshenko Beam.** Element type 13 is a three-dimensional Timoshenko resultant-based beam element with two nodes for small displacement, linear isotropic elasticity. The stiffness matrix is identical to the residual stiffness formulation used in the Belytschko-Schwer element (type 2). This element only works with *MAT_ELASTIC. It uses the reference geometry to calculate the element stiffness and calculates the element forces by multiplying the element stiffness by the displacements. Offsets work but they are fixed for all time like the reference geometry.

6. **SCOOR.** If the magnitude of SCOOR is less than or equal to unity, then zero length discrete beams are assumed with infinitesimal separation between the nodes in the deformed state. For large separations or nonzero length beams set |SCOOR| to 2, 3, 12, or 13, in which case true beam-like behavior is invoked to provide equilibrating torques to offset any force couples that arise due to translational stiffness or translational damping. Also, rigid body rotation is measured, and the spring strain modified so that rotation does not create strain. A flaw in this strain modification was found in the implementation of |SCOOR| = 2 and 3; the improved formulation is activated by setting |SCOOR| = 12 and 13. The original options were left in place to allow legacy data to run without change.

7. **Disabling Nodal Rotations.** RRCON, SRCON, and TRCON are optional and apply only to non-cable discrete beams. If set to 1, RRCON, SRCON, and TRCON will prevent nodal *rotations* about the local *r*-, *s*-, and *t*-axes, respectively, from affecting the update of the local coordinate system. These three parameters have no influence on how nodal translations may affect the local coordinate system update.

8. **Note about Local Coordinate Updates and FLAG.** If CID is nonzero for a discrete beam and the coordinate system identified by CID uses *DEFINE_COORDINATE_NODES with FLAG = 1, the beam local system is updated based on the current orientation of the three nodes identified in *DEFINE_COORDINATE_NODES. In this case, local coordinate system updates per SCOOR types 0, ±1, ±3, and ±13 are inactive while for SCOOR types ±2 and ±12 a final

adjustment is made to the local coordinate system so that the local r-axis lies along the n_1 to n_2 axis of the beam. An optional output database (*DATABASE_-DISBOUT) will report relative displacements, rotations, and force resultants of discrete beams, all in the local coordinate system.

9. **Beam Forms 7 and 8.** Beam formulations 7 and 8 are two-dimensional shell elements. For these two formulations, variable QR/IRID is the number of through thickness integration points for the shell. Output for these integration points is controlled by the variable BEAMIP in *DATABASE_EXTENT_BINARY.

10. **Beam Form 1.** The integration points for beam formulation 1 are located at mid-length and are arranged in the cross-section according to the specified integration rule. Stresses are reported at integration points according to the variable BEAMIP in *DATABASE_EXTENT_BINARY.

11. **NAUPD.** Integrated beams have integration points arranged about the neutral axis. Therefore, axial stress at each point will generate both an axial force and a moment at each node. The moment is proportional to the distance from the neutral axis. For a pure axial load, the moments calculated from the integration points cancel and only the force remains. However, if damage or failure occurs at one or more integration points, then the moments will no longer cancel and an axial load will produce moments at the nodes. To prevent this default behavior, set NAUPD to 1 to activate the neutral axis update option. With this option, the neutral axis will be updated such that partially failed elements will continue to generate balanced moments during axial loading. This option applies to beam forms 1, 9, 11, and 14 when used with material types 3, 98, 100, 124, and 158.

Example:

```

*SECTION_BEAM_AISC

Purpose: Define cross-sectional properties for beams and trusses using section labels from the AISC Steel Construction Manual, 2005, 13th Edition, as published in the AISC Shapes Database V13.1.1

Card Summary:

Card Sets. For each BEAM_AISC section include one pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

Card 1. This card is required.

SECID	LABEL

Card 2a. Card 2 for ELFORM equal to 1 or 11.

ELFORM	SHRF	NSM	LFAC	NSLOC	NTLOC	K	

Card 2b. Card 2 for ELFORM equal to 2 or 12.

ELFORM	SHRF	NSM	LFAC				

Card 2c. Card 2 for ELFORM equal to 3.

ELFORM	LFAC	RAMPT	STRESS				

Card 2d. Card 2 for ELFORM equal to 4 or 5.

ELFORM	SHRF	NSM	LFAC	K			

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	LABEL						
Type	I	A70						

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
LABEL	AISC section label

Integrated Beam Card (types 1 and 11). Card 2 for ELFORM equal to 1 or 11.

Card 2a	1	2	3	4	5	6	7	8
Variable	ELFORM	SHRF	NSM	LFAC	NSLOC	NTLOC	K	
Type	I	F	F	F	F	F	I	

Resultant Beam Card (types 2 and 12). Card 2 for ELFORM equal to 2 or 12.

Card 2b	1	2	3	4	5	6	7	8
Variable	ELFORM	SHRF	NSM	LFAC				
Type	I	F	F	F				

Truss Beam Card (type 3). Card 2 for ELFORM equal to 3.

Card 2c	1	2	3	4	5	6	7	8
Variable	ELFORM	LFAC	RAMPT	STRESS				
Type	I	F	F	F				

Integrated Beam Card (types 4 and 5). Card 2 for ELFORM equal to 4 or 5.

Card 2d	1	2	3	4	5	6	7	8
Variable	ELFORM	SHRF	NSM	LFAC	K			
Type	I	F	F	F	F			

VARIABLE	DESCRIPTION
ELFORM	Element formulation (see *SECTION_BEAM). Only types 1–5,11,12 are allowed
SHRF	Shear factor (see *SECTION_BEAM)
NSM	Non-structural mass per unit length

VARIABLE	DESCRIPTION
LFAC	GT.0.0: Length scale factor to convert dimensions from standard units If LFAC < 0, then a predefined length factor for specific model units is used: EQ.-1.0: ft EQ.-2.0: m EQ.-3.0: in EQ.-4.0: mm EQ.-5.0: cm
NSLOC	Location of reference surface (see *SECTION_BEAM)
NTLOC	Location of reference surface (see *SECTION_BEAM)
K	Integration refinement parameter (see *INTEGRATION_BEAM)
RAMPT	Optional ramp-up time (see *SECTION_BEAM)
STRESS	Optional initial stress (see *SECTION_BEAM)

Remarks:

This keyword uses the dimensions of the standard AISC beams sections — as defined by the section label — to define *SECTION_BEAM and *INTEGRATION_BEAM cards with the appropriate parameters.

The AISC section label may be specified either as the shape designation as seen in the AISC Steel Construction Manual, 2005, or the designation according to the AISC Naming Convention for Structural Steel Products for Use in Electronic Data Interchange (EDI), 2001. As per the EDI convention, the section labels are to be case-sensitive and space sensitive, i.e. “W36X150” is acceptable but “W36 x 150” is not. Labels can be specified in terms of either the U.S. Customary units (in) or metric units (mm), which will determine the length units for the section dimensions. The parameter LFAC may be used as a multiplier to convert the dimensions to other lengths units. For user convenience, predefined conversion factors are provided for specific choices of the model length unit.

AISC requires the following legal notice specifying that LS-DYNA users may not extract AISC shapes data in any manner from LS-DYNA to create commercial software. Users are certainly allowed to create LS-DYNA input models for commercial purposes using this card.

AISC FLOW-DOWN LICENSE TERMS (TERMS OF USE)

This application contains software from the American Institute of Steel Construction, Inc. of Chicago, Illinois d/b/a AISC ("AISC"). The software from AISC (the "AISC Shapes Database") enables this application to provide dimensions and properties of structural steel shapes and to perform other functions. You may use AISC Data only by means of the intended End User functions of this application software. You agree that you will use AISC Data for non-commercial use only, meaning that it will not be used to develop or create revenue-producing software. You agree not to assign, copy, transfer or transmit the AISC Shapes Database or any AISC Data to any third party.
YOU AGREE NOT TO USE OR EXPLOIT AISC DATA OR THE AISC SHAPES DATA-BASE EXCEPT AS EXPRESSLY PERMITTED HEREIN.

*SECTION_DISCRETE

Purpose: Defined spring and damper elements for translation and rotation. These definitions must correspond with the material type selection for the elements, that is, *MAT_SPRING_... and *MAT_DAMPER_...

Card Sets. For each DISCRETE section include a pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	DRO	KD	V0	CL	FD		
Type	I/A	I	F	F	F	F		

Card 2	1	2	3	4	5	6	7	8
Variable	CDL	TDL						
Type	F	F						

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
DRO	Displacement/Rotation Option: EQ.0: the material describes a translational spring/damper, EQ.1: the material describes a torsional spring/damper.
KD	Dynamic magnification factor, k_d. See Remarks 1 and 2 below.
V0	Test velocity, V_0. See Remarks 1 and 2 below.
CL	Clearance. See Remark 3 below.
FD	Failure deflection (twist for DRO = 1). Negative for compression, positive for tension.
CDL	Deflection (twist for DRO = 1) limit in compression. See Remark 4 below.

VARIABLE	DESCRIPTION
TDL	Deflection (twist for DRO = 1) limit in tension. See Remark 4 below.

Remarks:

1. **Optional Constants.** The constants from KD to TDL are optional and do not need to be defined.

2. **Forces and Amplification Factors.** If k_d is nonzero, the forces computed from the spring elements are assumed to be the static values and are scaled by an amplification factor to obtain the dynamic value:

$$F_{\text{dynamic}} = \left(1. + k_d \frac{V}{V_0}\right) F_{\text{static}} \ ,$$

where

V = absolute value of the relative velocity between the nodes.

V_0 = dynamic test velocity.

For example, if it is known that a component shows a dynamic crush force at 15 m/s equal to 2.5 times the static crush force, use $k_d = 1.5$ and $V_0 = 15$.

3. **Clearance.** Here, "clearance" defines a compressive displacement which the spring sustains before beginning the force-displacement relation given by the load curve defined in the material selection. If a non-zero clearance is defined, the spring is compressive only.

4. **Deflection Limits.** The deflection limit in compression and tension is restricted in its application to no more than one spring per node subject to this limit and to deformable bodies only. For example, in the former case, if three springs are in series, either the center spring or the two end springs may be subject to a limit, but not all three. When the limiting deflection is reached, momentum conservation calculations are performed, and a common acceleration is computed in the appropriate direction. An error termination will occur if a rigid body node is used in a spring definition where deflection is limited.

   Constrained boundary conditions on the *NODE cards and the BOUNDARY_SPC cards must not be used for nodes of springs with deflection limits.

5. **Implicit.** Discrete elements can be included in implicit applications.

Examples:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$  *SECTION_DISCRETE
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  Note: These examples are in kg, mm, ms, kN units.
$
$  A translational spring (dro = 0) is defined to have a failure deflection
$  of 25.4 mm (fd = 25.4).  The spring has no dynamic effects or
$  deflection limits, thus, those parameters are not set.

*SECTION_FPD

Purpose: Define section properties for incompressible smoothed particle Galerkin (ISPG) element.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ELFORM						
Type	I/A	I						

Card 2	1	2	3	4	5	6	7	8
Variable	DX	DY	DZ		KERNEL			
Type	F	F	F		I			
Default	1.5	1.5	1.5		0			

Card 3	1	2	3	4	5	6	7	8
Variable				TSTART	DT_IMP	DTSCL		
Type				F	F	F		
Default				0.0	optional	0.1		

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ELFORM	Element formulation options. EQ.49: Incompressible smoothed particle Galerkin formulation
DX, DY, DZ	Normalized dilation parameters of the kernel function in the x, y and z directions. The normalized dilation parameters of the kernel function are introduced to provide the smoothness and compact

VARIABLE	DESCRIPTION
	support properties on the construction of the mesh-free shape functions. Values between 1.4 and 1.8 are recommended. The nodal support size of particles will be automatically adjusted with the material's deformation, but it is not allowed to be decreased
KERNEL	Kernel type. KERNEL = 0 is for Updated Lagrangian (UL) kernel. Currently, only the UL kernel is supported.
TSTART	Starting time for the fully implicit ISPG iterations. Before TSTART, only 10 ISPG iterations are done in each thermal-structural implicit step with one-way coupling to guarantee that the fluid moves with the solid boundaries. After TSTART, the ISPG algorithm will perform full iterations in the two-way coupled thermal-structural implicit analysis. This option is very useful for cases where the structural simulation time is very long (e.g., in seconds or minutes) while the reflow process to a steady state is very short. With this option, we can let the full ISPG iterations start from TSTART and save some computational resources.
DT_IMP	Reset the implicit structural time step size to DT_IMP after TSTART. Because the solder reflow process is very fast, a small implicit structural time step size is needed. Generally, the value of DT_IMP should be around 10 to 50 times the ISPG time step size to guarantee the convergence of the solution if the gravity-driven simulation is deployed. This field is optional.
DTSCL	The time step size scaling factor for ISPG iteration. We recommend a value between 0.1 and 0.5. Large DTSCL may cause contact detection issues.

*SECTION_IGA_SHELL

Purpose: Define section properties for isogeometric shell elements.

Card Summary:

Card Sets. For each isogeometric shell section include one set of data cards. This input ends at the next keyword ("*") card.

Card 1. This card is required.

SECID	ELFORM	SHRF	NIP	IRL	QR / IRID	ICOMP	

Card 2. This card is required.

T				NLOC			

Card 3. Include ceil(NIP/8) cards if ICOMP = 1.

B1	B2	B3	B4	B5	B6	B7	B8

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ELFORM	SHRF	NIP	IRL	QR / IRID	ICOMP	
Type	I/A	I	F	F	I	F	I	
Default	none	0	1.0	2.0	0	0.0	0	

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ELFORM	Element formulation: EQ.0: Reissner-Mindlin with fibers at the control points EQ.1: Kirchhoff-Love with fibers at the control points EQ.2: Kirchhoff-Love with fibers at the integration points EQ.3: Reissner-Mindlin with fibers at the integration points

VARIABLE	DESCRIPTION
	EQ.5: Thick shell with thickness stretch based on the ELFORM = 0. See Remark 1.
	EQ.6: Thick shell with thickness stretch based on ELFORM = 3. See Remark 1.
SHRF	Shear correction factor which scales the transverse shear stress; see Remark 2.
NIP	Number of through thickness integration points (up to 10 points). See Remark 3.
IRL	Lamina integration rule: EQ.0: Reduced Gauss-Legendre EQ.1: Gauss-Legendre EQ.2: Patchwise reduced Gauss-Legendre (for biquadratic NURBS only)
QR/IRID	Fiber quadrature rule or fiber integration rule ID (see *INTEGRATION_SHELL): LT.0.0: Absolute value is specified rule number. EQ.0.0: Gauss-Legendre/Gauss-Lobatto (up to 10 points) EQ.1.0: Trapezoidal, not recommended for accuracy reasons
ICOMP	Flag for anisotropic layered composite material model (see Remark 4): EQ.1: A material angle in degrees is defined for each through thickness integration point. Thus, each layer has one integration point.

Card 2	1	2	3	4	5	6	7	8
Variable	T				NLOC			
Type	F				F			
Default	0.0				0.0			

VARIABLE	DESCRIPTION
T	Shell thickness
NLOC	Location of reference surface; see Remark 5.

Material Orientation Angle Cards. Include ceil(NIP/8) cards if ICOMP = 1 in order to define material orientation angle with respect to the baseline orientation at the fiber integration points.

Card 3	1	2	3	4	5	6	7	8
Variable	B1	B2	B3	B4	B5	B6	B7	B8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
B*i*	Material angle at the i^{th} fiber integration point

Remarks:

1. **Thick Shell Formulations.** Element formulations 5 and 6 permit linear strains to develop in the thickness direction in a manner similar to the type 25 and 26 finite element shells (see *SECTION_SHELL). Thus solid materials with damage models that depend on the full stress tensor are compatible with these elements. For instance, these elements can be used with ductile fracture models that require accurate pressures for the nucleation and growth of voids.

2. **Shear Correction Factor.** Reissner-Mindlin shell formulations (FORM = 0 or 3) are based on a first order shear deformation theory that yields constant transverse shear strains. This approximation violates the condition of zero traction on the top and bottom surfaces of the shell. The shear correction factor is an attempt to compensate for this error. A suggested value is 5/6 for isotropic materials. This value is incorrect for sandwich or laminated shells; consequently, laminated/sandwich shell theory is now an option in some of the constitutive models, that is, material types 22, 54, and 55.

3. **Fiber Integration Rule.** Either Gauss-Legendre (default) or Gauss-Lobatto integration can be used to integrate along the fiber. The flag for Gauss-Lobatto integration is set with INTGRD in *CONTROL_SHELL.

If NIP is 0 or 1 and the *MAT_SIMPLIFIED_JOHNSON_COOK model is used, then a resultant plasticity formulation is activated. NIP is always set to 1 if a constitutive model based on resultants is used.

4. **Material Orientation.** This option applies to material types 21, 22, 23, 33, 33_96, 34, 36, 40, 41-50, 54, 55, 58, 59, 103, 103_P, 104, 108, 116, 122, 133, 135, 135_PLC, 136, 157, 158, 190, 219, 226, 233, 234, 235, 242, 243, 261, and 262. See also Remark 5 under *MAT_034 for additional information specific to fiber directions for fabrics.

5. **Shell Offset.** If NLOC $\neq 0$, the offset distance from the mid-surface to the reference surface of the shell in the direction of the shell normal vector is computed as

$$\text{offset} = -0.5 \times \text{NLOC} \times (\text{average shell thickness}).$$

Except for Mortar contacts, this offset is not considered in the contact subroutines unless CNTCO is set to 1 in *CONTROL_SHELL.

*SECTION_IGA_SOLID

Purpose: Define section properties for isogeometric solid elements.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ELFORM	IR					
Type	I/A	I	I					
Default	none	0	0					

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ELFORM	Element formulation: EQ.0: Standard
IR	Integration rule: EQ.0: Reduced Gauss-Legendre EQ.1: Gauss-Legendre

*SECTION_POINT_SOURCE

Purpose: This command provides the inlet boundary condition for single gas in flow (inflation potential) using a set of point source(s). It also provides the inflator orifice geometry information. It requires 3 curves defining the inlet condition for the inflator gas coming into the tank or an airbag as input ($\overline{T}_{\text{gas corrected}}(t)$, $v_r(t)$, and vel(t)). Please see also the *ALE_TANK_TEST card for additional information.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	LCIDT	LCIDVR	LCIDVEL	NIDLC1	NIDLC2	NIDLC3	
Type	I/A	I	I	I	I	I	I	
Default	0	0	0	0	0	0	0	

Source Node Cards. Include one card for each source node. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	NODEID	VECID	ORIFA					
Type	I	I	F					
Default	0	0	0.0					

VARIABLE	DESCRIPTION
SECID	Section ID. A unique number or label must be specified.
LCIDT	Temperature load curve ID
LCIDVR	Relative volume load curve ID
LCIDVEL	Inlet flow velocity load curve ID
NIDLC1	The 1st node ID defining a local coordinate (See Remark 2).
NIDLC2	The 2nd node ID defining a local coordinate (See Remark 2).

VARIABLE	DESCRIPTION
NIDLC3	The 3rd node ID defining a local coordinate (See Remark 2).
NODEID	The node ID(s) defining the point source(s).
VECID	The vector ID defining the direction of flow at each point source.
ORIFA	The orifice area at each point source.

Remarks:

1. **Airbag Inflator Tank Test.** In an airbag inflator tank test, the tank pressure data is measured. This pressure is used to derive $\dot{m}(t)$ and the estimated $\overline{T}_{\text{gas}}(t)$, usually using a lumped-parameter method, a system of conservation equations and EOS. Subsequently $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$ (stagnation temperature) are used as input to obtain $\overline{T}_{\text{gas\_corrected}}(t)$ (static temperature), $v_r(t)$, and $\text{vel}(t)$. These 3 curves are then used to describe inflator gas inlet condition (see *ALE_TANK_TEST for more information).

2. **Local Coordinate System.** In a car crash model, the inflator housing may get displaced during the impact. The 3 node IDs defines the local reference coordinate system to which the point sources are attached. These 3 reference nodes may be located on a rigid body which can translate and rotate as the inflator moves during the impact. This allows for the point sources to move in time. These reference nodes may be used as the point sources themselves.

3. **ALE Tank Test Keyword.** If the *ALE_TANK_TEST card is present, please see the Remarks under that card.

Example:

Consider a tank test model which consists of the inflator gas (PID 1) and the air inside the tank (PID 2). The 3 load curves define the thermodynamic and kinetic condition of the incoming gas. The nodes define the center of the orifice, and the vector the direction of flow at each orifice.

*SECTION_POINT_SOURCE_MIXTURE

Purpose: This command provides (a) an element formulation for a solid ALE part of the type similar to ELFORM = 11 of *SECTION_SOLID, and (b) the inlet gas injection boundary condition for multiple-gas mixture in-flow using a set of point source(s). It also provides the inflator orifice geometry information. This must be used in combination with the *MAT_GAS_MIXTURE and/or *INITIAL_GAS_MIXTURE card (see Remark 1).

VARIABLE	DESCRIPTION
LCIDT	Inflator gas mixture average stagnation temperature load curve ID (all gases of the mixture are assumed to have the same average temperature).
LCIDVEL	User-defined inflator gas mixture average velocity load curve ID. If LCIDVEL = 0 or blank, LSDYNA will estimate the inlet gas velocity.
NIDLC001	The 1st node ID defining a local coordinate (see Remark 2).
NIDLC002	The 2nd node ID defining a local coordinate (see Remark 2).
NIDLC003	The 3rd node ID defining a local coordinate (see Remark 2).
IDIR	A flag for constraining the nodal velocity of the nodes of the ALE element containing a point source. EQ.0: ALE nodes behind the point source (relative position of nodes based on the vector direction of flow of point source) will have zero velocity (default). EQ.1: all ALE nodes will have velocity distributed based on energy conservation. This option seems to be more robust in airbag modeling (see Remark 5).
LCMD*n*	The mass flow rate load curve ID of the n^{th} gas in the mixture. See Remark 3.
NODEID	The node ID(s) defining the point sources (see Remark 7).
VECID	The vector ID defining the direction of flow at each point source.
ORIFA	The orifice area at each point source.

Remarks:

1. **Keyword Applications.** This command is used to define a part that acts as the ideal gas mixture injection source. The associated ALE material (gas mixture) may not be present at time zero but can be introduced (injected) into an existing ALE domain. For airbag applications, the input from control volume analysis, inlet mass flow rate, $\dot{m}(t)$, and, inlet stagnation gas temperature, $\overline{T}_{\text{gas}}(t)$ may be used as direct input for ALE analysis. If available, the user may input a load curve for the gas mixture average inlet velocity. If not, LS-DYNA will estimate the inlet gas velocity.

2. **Local Coordinate System.** In a car crash model, the inflator housing may get displaced during the impact. The 3 node IDs defines the local reference coordinate system to which the point sources are attached. These 3 reference nodes may be located on a rigid body which can translate and rotate as the inflator moves during the impact. This allows for the point sources to move in time. These reference nodes may be used as the point sources themselves.

3. **Mass Flow Rate.** The gas mixture is assumed to have a uniform temperature ($\overline{T} \approx T_i$) and inlet velocity. However, the species in the mixture may each have a different inlet mass flow rate.

4. **Model.** A brief review of the concept used is presented. The total energy, e_t, is the sum of internal (e_i) and kinetic ($V^2/2$) energies (per unit mass).

$$e_T = e_i + \frac{V^2}{2}$$
$$C_V T_{stag} = C_V T + \frac{V^2}{2}$$
$$T_{stag} = T + \frac{V^2}{2C_V}$$

The distinction between stagnation and static temperatures is shown above. C_V is the constant-volume heat capacity. The gas mixture average internal energy per unit mass in terms of mixture species contribution is

$$e_i = \bar{C}_V \overline{T} = \sum_i \left(\frac{\rho_i}{\rho_{mixture}}\right) C_{V_i} T_i = \left[\sum_i \left(\frac{\rho_i}{\rho_{mixture}}\right) C_{V_i}\right] \overline{T}$$
$$\bar{C}_V = \left[\sum_i \left(\frac{\rho_i}{\rho_{mixture}}\right) C_{V_i}\right]$$

Since we approximate $\overline{T} \approx T_i$, then gas mixture average static temperature is related to the mixture average internal energy per unit mass as following

$$\overline{T} = \frac{e_i}{\left[\sum_i \left(\frac{\rho_i}{\rho_{mixture}}\right) C_{V_i}\right]}$$

Note that the "i" subscript under "e" denotes "internal" energy, while the other "i" subscripts denote the "i^{th}" species in the gas mixture. The total mixture pressure is the sum of the partial pressures of the individual species.

$$\bar{p} = \sum_i p_i$$

The ideal gas EOS applies to each individual species (by default)

$$P_i = \rho_i (C_{P_i} - C_{V_i}) T_i$$

5. **Energy Conservation.** Generally, conservation of both momentum and kinetic (KE) at the same time is impossible. Typically, internal energy (IE) is conserved

and KE may not be. This may result in some KE loss (hence, total energy loss). For many analyses this is tolerable, but for an airbag, a reduction of the inflating potential of the inflator gas may result.

In *MAT_GAS_MIXTURE computation, any kinetic energy not accounted for during advection is stored in the internal energy. Therefore, no kinetic energy is lost, and the total energy of the element is conserved over the advection step. This simple, ad hoc approach is not rigorously derived for the whole system based on first principles. Therefore, it is not guaranteed to apply universally to all scenarios. The user must validate the model with data.

6. **EOS.** Since ideal gas is assumed, there is no need to define the EOS for the gases in the mixture.

7. **Point Source Location.** In general, it is best to locate a point source near the center of an ALE element. Associated with each point source is an area and a vector indicating flow direction. Each point source should occupy one ALE element by itself, and there should be at least two empty ALE elements between any two point sources. A point source should be located at least three elements away from the free surface of an ALE mesh for stability.

Example 1:

Consider a tank test model without coupling which consists of:

-a background mesh with air (PID 1 = gas 1) initially inside that mesh (tank space), and
-the inflator gas mixture (PID 2 consisting of inflator gases 2, 3, and 4).

The mixture is represented by one AMMGID and the air by another AMMGID.

The tank internal space is simply modeled with an Eulerian mesh of the same volume. The tank itself is not modeled thus no coupling is required. The inflator gases fill up this space mixing with the air initially inside the tank.

The background air (gas 1) is included in the gas mixture definition in this case because that air will participate in the mixing process. Only include in the mixture those gases that actually undergo mixing (gases 1, 2, 3 and 4). Note that for an airbag model, the "outside" air should not be included in the mixture (it should be defined independently) since it does not participate in the mixing inside the airbag. This is shown in the next example.

The nodes define the center of the orifices, and the vectors define the directions of flow at these orifices.

Example 2:

Consider an airbag inflation model which consists of:

-a background Eulerian mesh for air initially outside the airbag (PID 1)
-the inflator gas mixture (PID 2 consisting of inflator gases 1, 2, and 3).

The mixture is represented by one AMMGID and the air by another AMMGID.

The background air (PID 1) is NOT included in the gas mixture definition in this case because that air will NOT participate in the mixing process. Only include in the mixture those gases that actually undergo mixing (gases 1, 2, and 3). Gases 1, 2, and 3 in this example correspond to gases 2, 3, and 4 in example 1. Compare the air properties in PID

1 here to that of example 1. Note that the *INITIAL_GAS_MIXTURE card is not required to initialize the background mesh in this case.

*SECTION_SEATBELT

Purpose: Define section properties for the seat belt elements. This card is required for the *PART Section. Currently, only the ID is required.

Seatbelt Section Cards. Include one card for each SEATBELT section. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	AREA	THICK					
Type	I/A	F	F					
Default	none	0.01	↓					

VARIABLE	DESCRIPTION
SECID	Section ID. A unique number or label must be specified.
AREA	Optional area of cross-section used in the calculation of contact stiffness, which is proportional to the cross-section area.
THICK	Optional contact thickness which can be overwritten by a nonzero SAST defined in *CONTACT. If not defined, a value proportional to element length is used as the contact thickness.

Remarks:

Seatbelt elements are implemented for both explicit and implicit calculations.

***SECTION_SHELL**_*{OPTION}*

Available options include:

<BLANK>

EFG

THERMAL

XFEM

MISC

Purpose: Define section properties for shell elements.

Card Summary:

Card Sets. For each shell section, of a type matching the keyword's options, include one set of data cards. This input ends at the next keyword ("*") card.

Card 1. This card is required.

SECID	ELFORM	SHRF	NIP	PROPT	QR / IRID	ICOMP	SETYP

Card 2. This card is required.

T1	T2	T3	T4	NLOC	MAREA	IDOF	EDGSET

Card 3. Additional cards for ICOMP = 1. Include the minimum number of cards necessary to input NIP values: 8 values per card ⇒ number of cards = ceil(NIP/8) where ceil(x) = the smallest integer greater than x.

B1	B2	B3	B4	B5	B6	B7	B8

Card 4a. This card is included if the EFG keyword option is used.

DX	DY	ISPLINE	IDILA	IEBT	IDIM		

Card 4b. This card is included if the THERMAL keyword option is used.

ITHELFM							

Card 4c. This card is included if the XFEM keyword option is used.

CMID	BASELM	DOMINT	FAILCR	PROPCR	FS	LS/FS1	NC/CL

Card 4d. This card is included if the MISC keyword option is used.

THKSCL							

Card 5. Additional card for ELFORM = 101, 102, 103, 104 or 105.

NIPP	NXDOF	IUNF	IHGF	ITAJ	LMC	NHSV	ILOC

Card 5.1. Additional card for ELFORM = 101, 102, 103, 104 or 105. Define NIPP of this card.

XI	ETA	WGT					

Card 5.2. Additional card for ELFORM = 101, 102, 103, 104 or 105. Include the minimum number of cards necessary to input LMC values: 8 values per card ⇒ number of cards = ceil(LMC/8) where ceil(x) = the smallest integer greater than x.

P1	P2	P3	P4	P5	P6	P7	P8

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ELFORM	SHRF	NIP	PROPT	QR / IRID	ICOMP	SETYP

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ELFORM	Element formulation options (see Remarks 1 and 3 below): EQ.1: Hughes-Liu EQ.2: Belytschko-Tsay EQ.3: BCIZ triangular shell EQ.4: C0 triangular shell EQ.5: Belytschko-Tsay membrane

VARIABLE	DESCRIPTION
	EQ.6: Selectively reduced Hughes-Liu
	EQ.7: Selectively reduced, co-rotational Hughes-Liu
	EQ.8: Belytschko-Leviathan shell
	EQ.9: Fully integrated Belytschko-Tsay membrane
	EQ.10: Belytschko-Wong-Chiang
	EQ.11: Fast (co-rotational) Hughes-Liu
	EQ.12: Plane stress (*xy*-plane)
	EQ.13: Plane strain (*xy*-plane)
	EQ.14: Axisymmetric solid (*xy*-plane, *y*-axis of symmetry) - area weighted (see Remark 11)
	EQ.15: Axisymmetric solid (*xy*-plane, *y*-axis of symmetry) - volume weighted
	EQ.16: Fully integrated shell element (very fast)
	EQ.-16: Fully integrated shell element modified for higher accuracy. See Remark 14.
	EQ.17: Fully integrated DKT, triangular shell element. See Remark 10.
	EQ.18: Fully integrated linear DK quadrilateral/triangular shell. See Remarks 2 and 3.
	EQ.20: Fully integrated linear assumed strain C0 shell. See Remark 3.
	EQ.21: Fully integrated linear assumed strain C0 shell (5 DOF)
	EQ.22: Linear shear panel element. 3 DOF per node. See Remark 4.
	EQ.23: 8-node quadratic quadrilateral shell (see IRQUAD in *CONTROL_SHELL)
	EQ.24: 6-node quadratic triangular shell
	EQ.25: Belytschko-Tsay shell with thickness stretch
	EQ.26: Fully integrated shell with thickness stretch
	EQ.27: C0 triangular shell with thickness stretch
	EQ.29: Cohesive shell element for edge-to-edge connection of shells. See Remark 13.

VARIABLE	DESCRIPTION
EQ.-29:	Cohesive shell element for edge-to-edge connection of shells (more suitable for pure shear). See Remark 13.
EQ.30:	Fast fully integrated element with 2 in-plane integration points based on ELFORM 16
EQ.41:	Mesh-free (EFG) shell local approach (more suitable for crashworthiness analysis).
EQ.42:	Mesh-free (EFG) shell global approach (more suitable for metal forming analysis).
EQ.43:	Mesh-free (EFG) plane strain formulation (xy-plane)
EQ.44:	Mesh-free (EFG) axisymmetric solid formulation (xy-plane, y-axis of symmetry)
EQ.46:	Cohesive element for two-dimensional plane strain, plane stress, and area-weighted axisymmetric problems (use with type 14 shells). See Remark 16.
EQ.47:	Cohesive element for two-dimensional volume-weighted axisymmetric problems (use with type 15 shells). See Remark 16.
EQ.52:	Plane strain (xy-plane) XFEM, base element type 13 with full integration. See Remark 9.
EQ.54:	Shell XFEM, base element type defined by BASELM (default 2). See Remark 9.
EQ.55:	8-node singular plane strain (xy-plane) finite element. See Remark 12.
EQ.98:	Interpolation shell
EQ.99:	Simplified linear element for time-domain vibration studies. See Remark 5.
EQ.101:	User defined shell
EQ.102:	User defined shell
EQ.103:	User defined shell
EQ.104:	User defined shell
EQ.105:	User defined shell
EQ.201:	Isogeometric shells with NURBS. See *ELEMENT_SHELL_NURBS_PATCH.
GE.1000:	Generalized shell element formulation (user defined). See *DEFINE_ELEMENT_GENERALIZE_SHELL.

VARIABLE	DESCRIPTION
	Note that the 2D and 3D element types must not be mixed, and different types of 2D elements must not be used together. For example, two-dimensional axisymmetric calculations can use either element types 14 or 15, but these element types must not be mixed together. Likewise, the plane strain element type must not be used with either the plane stress element or the axisymmetric element types. In three dimensions, the different shell element types, i.e., 1-11 and 16, can be freely mixed together.
SHRF	Shear correction factor which scales the transverse shear stress. The shell formulations in LS-DYNA, with the exception of the BCIZ and DK elements, are based on a first order shear deformation theory that yields constant transverse shear strains which violates the condition of zero traction on the top and bottom surfaces of the shell. The shear correction factor is an attempt to compensate for this error. A suggested value is 5/6 for isotropic materials. This value is incorrect for sandwich or laminated shells. Consequently, laminated/sandwich shell theory is now an option in some of the constitutive models, that is, material types 22, 54, and 55.
NIP	Number of through thickness integration points. Either Gauss (default) or Lobatto integration can be used. INTGRD in *CONTROL_SHELL specifies the integration rule. The tables Gaussian Quadrature Points and Lobatto Quadrature Points below tabulate the location of the Gauss and Lobatto integration points. EQ.0.0: Set to 2 integration points for shell elements. EQ.1.0: 1 point (no bending) EQ.2.0: 2 points EQ.3.0: 3 points EQ.4.0: 4 points EQ.5.0: 5 points EQ.6.0: 6 points EQ.7.0: 7 points EQ.8.0: 8 points EQ.9.0: 9 points EQ.10.0: 10 points GT.10.0: Trapezoidal or user defined rule

VARIABLE	DESCRIPTION
	Through thickness integration for two-dimensional elements (options 12-15, 43, 44, 52 and 55 above) and cohesive shells (option ±29) is not meaningful; consequently, the default is 1 integration point. Fully integrated two-dimensional elements are available for options 13 and 15 (but not 12 and 14) by setting NIP equal to a value of 4, corresponding to a 2 by 2 Gaussian quadrature. For element type 55, NIP can be 4, 9 or 16. If NIP is 0 or 1 and the *MAT_SIMPLIFIED_JOHNSON_COOK model is used, then a resultant plasticity formulation is activated. NIP is always set to 1 if a constitutive model based on resultants is used.
PROPT	Printout option (***NOT ACTIVE***): EQ.1.0: Average resultants and fiber lengths EQ.2.0: Resultants at plan points and fiber lengths EQ.3.0: Resultants, stresses at all points, fiber lengths
QR/IRID	Quadrature rule or integration rule ID, see *INTEGRATION_SHELL: LT.0.0: Absolute value is specified rule number. EQ.0.0: Gauss/Lobatto (up to 10 points are permitted) EQ.1.0: Trapezoidal, not recommended for accuracy reasons
ICOMP	Flag for orthotropic/anisotropic layered composite material model. This option applies to material types 21, 22, 23, 33, 33_96, 34, 36, 40, 41-50, 54, 55, 58, 59, 103, 103_P, 104, 108, 116, 122, 133, 135, 135_PLC, 136, 157, 158, 190, 219, 226, 233, 234, 235, 242, and 243. For these material types, see *PART_COMPOSITE as an alternative to *SECTION_SHELL. Note: Please refer to *Remark 5* under *MAT_034 for additional information specific to fiber directions for fabrics. EQ.1: A material angle in degrees is defined for each through thickness integration point. Thus, each layer has one integration point.
SETYP	Not used (obsolete)

Card 2	1	2	3	4	5	6	7	8
Variable	T1	T2	T3	T4	NLOC	MAREA	IDOF	EDGSET
Type	F	F	F	F	F	F	F	I
Default	0.0	T1	T1	T1	0.0	0.0	0.0	↓

VARIABLE	DESCRIPTION
T1	Shell thickness at node n_1, unless the thickness is defined on the *ELEMENT_SHELL_*OPTION* card.
T2	Shell thickness at node n_2, see comment for T1 above.
T3	Shell thickness at node n_3, see comment for T1 above.
T4	Shell thickness at node n_4, see comment for T1 above.
NLOC	Location of reference surface (shell mid-thickness) for three-dimensional shell elements. If nonzero, the offset distance from the plane of the nodal points to the reference surface of the shell in the direction of the shell normal vector is a value, $\text{offset} = -0.50 \times \text{NLOC} \times (\text{average shell thickness})$. Alternatively, the offset can be specified with the OFFSET keyword option of *ELEMENT_SHELL. Except for Mortar contacts, the contact subroutines do not consider this offset unless CNTCO = 1 in *CONTROL_SHELL. For Mortar contacts, NLOC or OFFSET determines the location of the contact surface regardless of the value of CNTCO. EQ.1.0: Nodes are located at top surface of shell. EQ.0.0: Nodes are located at mid-thickness of shell (default). EQ.-1.0: Nodes are located at bottom surface of shell. For nonzero offset distances, the time step size is reduced to prevent instabilities. See NLOCDT in *CONTROL_SHELL.
MAREA	Non-structural mass per unit area. This is additional mass which comes from materials, such as carpeting. This mass is not directly included in the time step calculation. An often more convenient alternative for defining distributed mass is with *ELEMENT_MASS_PART, which allows additional non-structural mass to be

VARIABLE	DESCRIPTION
	distributed by an area weighted distribution to all nodes of a given part ID.
IDOF	Treatment of through thickness strain (see Remark 7).
	LT.0: Same as IDOF = 3 but the contact pressure is averaged over a time –IDOF to reduce noise and thus improve stability.
	EQ.1: The thickness field is continuous across the element edges for metal forming applications. This option applies to element types 25, 26 and 27.
	EQ.2: The thickness field is discontinuous across the element edges. This is necessary for crashworthiness simulations due to shell intersections, sharp included angles, and non-smooth deformations. This option applies to and is the default for element types 25, 26 and 27.
	EQ.3: The thickness strain is governed by stress from contact and pressure loads, meaning that the strain is adjusted for the through thickness stress to equilibrate the contact and load pressure. Please note that the pressure is assumed positive, meaning acting towards the shell surface. Thus, vacuum loads cannot be used with this option. This option applies to element types 2, 4, and ±16.
	EQ.11: Same as IDOF = 1 but the through thickness strain is simplified in the kinematics in order to reduce locking effects which were observed for considerable thickness changes. This option applies to element type 25 only.
	EQ.12: Same as IDOF = 2 but the through thickness strain is simplified in the kinematics in order to reduce locking effects which were observed for considerable thickness changes. This option applies to element type 25 only.
EDGSET	Edge node set required for shell type seatbelts. See Remark 8. See Figure 19-17 in *ELEMENT_SEATBELT for additional clarification.

Angle Cards. Additional cards for ICOMP = 1. Include the minimum number of cards necessary to input NIP values: 8 values per card ⇒ number of cards = ceil(NIP/8) where ceil(x) = the smallest integer greater than x.

Card 3	1	2	3	4	5	6	7	8
Variable	B1	B2	B3	B4	B5	B6	B7	B8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
Bi	β_i, material angle at the i^{th} integration point

EFG Card. Additional card for EFG keyword option. See *CONTROL_EFG.

Card 4a	1	2	3	4	5	6	7	8
Variable	DX	DY	ISPLINE	IDILA	IEBT	IDIM		
Type	F	F	I	I	I	I		
Default	1.1	1.1	0	0	-1 or 1	2 or 1		

VARIABLE	DESCRIPTION
DX, DY	Normalized dilation parameters of the kernel function in X and Y directions. The normalized dilation parameters of the kernel function are introduced to provide the smoothness and compact support properties on the construction of the mesh-free shape functions. Values between 1.0 and 2.0 are recommended. Values smaller than 1.0 are not allowed. Larger values will increase the computation time and will sometimes result in a divergence problem.
ISPLINE	Replace the choice for the EFG kernel functions definition in *CONTROL_EFG which permits defining different ISPLINE in different sections.
IDILA	Replace the choice for the normalized dilation parameter definition in *CONTROL_EFG which permits defining different IDILA in different sections.

VARIABLE	DESCRIPTION
IEBT	Essential boundary condition treatment EQ.1: Full transformation (default for ELFORM = 42) EQ.-1: Without full transformation (default for ELFORM = 41) EQ.3: Coupled FEM/EFG EQ.7: Maximum entropy approximation
IDIM	For mesh-free shell local approach (ELFORM = 41) EQ.1: First-kind local boundary condition method EQ.2: Gauss integration (default) For mesh-free shell global approach (ELFORM = 42) EQ.1: First-kind local boundary condition method (default) EQ.2: Second-kind local boundary condition method

Thermal Card. Additional Card for THERMAL keyword option.

Card 4b	1	2	3	4	5	6	7	8
Variable	ITHELFM							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
ITHELFM	Thermal shell formulation EQ.0: Default is governed by THSHEL on *CONTROL_SHELL EQ.1: Thick thermal shell EQ.2: Thin thermal shell

XFEM Card. Additional card for XFEM keyword option. See Remark 9.

Card 4c	1	2	3	4	5	6	7	8
Variable	CMID	BASELM	DOMINT	FAILCR	PROPCR	FS	LS/FS1	NC/CL
Type	I	I	I	I	I	F	F	I/F
Default	none	none	0	1	0	0.0	0.0	none

VARIABLE	DESCRIPTION
CMID	Cohesive material ID. *MAT_185 is available for both brittle and ductile fracture, and *MAT_240 is available for ductile material. See Remark 18.
BASELM	Base element type for XFEM (type 13 for 2D, types 2, 16 or 17 for shell)
DOMINT	Option for domain integration in XFEM: EQ.0: Phantom element integration (default) EQ.1: Subdomain integration with triangular local boundary integration (available in 2D only)
FAILCR	Option for different failure criteria: EQ.0: Failure criterion from *MAT_ADD_EROSION / GISSMO model EQ.1: Maximum tensile stress (failure value given in cohesive law) EQ.2: Maximum shear stress (failure value given in cohesive law) EQ.-1: Effective plastic strain (EPS) EQ.-2: Crack length dependent EPS. See Remark 15. EQ.-4: Stress triaxiality based failure plastic strain
PROPCR	PROPCR is interpreted digit-wise: $\text{PROPCR} = [IP] = P + 10 \times I$ P determines the crack propagation direction: P.EQ.0: First principal strain direction if FAILCR < 0 (default for ductile fracture), first principal stress if FAILCR = 1, or

VARIABLE	DESCRIPTION
	maximum shear stress if FAILCR = 2. P = 0 is the only option for brittle fracture (FAILCR > 0). P.EQ.2: Center of effective plastic strain P.EQ.3: Directional center of effective plastic strain *I* determines crack initiation: I.EQ.0: Crack initiates at boundary (default) I.EQ.3: Crack initiates anywhere
FS	Failure value for FAILCR = -1 or -2: FAILCR.EQ.-1: Failure strain/failure critical value FAILCR.EQ.-2: Initial failure plastic strain Curve ID or Table ID for stress triaxiality based failure plastic strain for FAILCR = -4.
LS	Length scale for strain regularization (FAILCR = -1 only)
FS1	Final failure plastic strain (FAILCR = -2 only)
NC	Number of cracks allowed in the part (FAILCR ≠ -2)
CL	Crack length at which the failure strain is FS1 (FAILCR = -2 only)

Miscellaneous Settings Card. Additional card for MISC keyword option.

Card 4d	1	2	3	4	5	6	7	8
Variable	THKSCL							
Type	F							
Default	1.0							

VARIABLE	DESCRIPTION
THKSCL	Thickness scale factor. Shell thicknesses for all elements of this section including those with thickness specified using *ELEMENT_SHELL_THICKNESS are scaled by THKSCL.

User Defined Element Card. Additional card for ELFORM = 101,102,103,104 or 105. See Appendix C

Card 5	1	2	3	4	5	6	7	8
Variable	NIPP	NXDOF	IUNF	IHGF	ITAJ	LMC	NHSV	ILOC
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

User Defined Element Integration Point Cards. Additional cards for ELFORM = 101, 102, 103, 104 or 105. Define NIPP cards according to the following format. See Appendix C.

Card 5.1	1	2	3	4	5	6	7	8
Variable	XI	ETA	WGT					
Type	F	F	F					
Default	none	none	none					

User Defined Element Property Cards. Include the minimum number of cards necessary to input LMC values: 8 values per card $\Rightarrow$ number of cards = ceil(LMC/8) where ceil(x) = the smallest integer greater than x. See Appendix C.

Card 5.2	1	2	3	4	5	6	7	8
Variable	P1	P2	P3	P4	P5	P6	P7	P8
Type	F	F	F	F	F	F	F	F
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
NIPP	Number of in-plane integration points for user-defined shell (0 if resultant/discrete element)

VARIABLE	DESCRIPTION
NXDOF	Number of extra degrees of freedom per node for user-defined shell
IUNF	Flag for using nodal fiber vectors in user-defined shell: EQ.0: Nodal fiber vectors are not used. EQ.1: Nodal fiber vectors are used.
IHGF	Flag for using hourglass stabilization (NIPP is greater than 0) EQ.0: Hourglass stabilization is not used. EQ.1: LS-DYNA hourglass stabilization is used. EQ.2: User-defined hourglass stabilization is used. EQ.3: Same as 2, but the resultant material tangent moduli are passed
ITAJ	Flag for setting up finite element matrices (NIPP is greater than 0) EQ.0: Set up matrices with respect to isoparametric domain EQ.1: Set up matrices with respect to physical domain
LMC	Number of property parameters
NHSV	Number of history variables
ILOC	Coordinate system option: EQ.0: Pass all variables in LS-DYNA local coordinate system EQ.1: Pass all variables in global coordinate system
XI	First isoparametric coordinate
ETA	Second isoparametric coordinate
WGT	Isoparametric weight
P*i*	i^{th} user defined element property

#9				+1.0	+0.9195339
#10					+1.0

Location of through thickness Lobatto integration points. The coordinate is referenced to the shell midsurface at location 0. The inner surface of the shell is at -1 and the outer surface is at +1.

Remarks:

1. **Formulations.** The default shell formulation is 2 unless overridden by THEORY in *CONTROL_SHELL. ELFORM in *SECTION_SHELL overrides THEORY.

   For implicit calculations the following element formulations are implemented: 2, 5, 6, 10, 12,12, 13, 14, 15, 16, -16, 17, 18, 20, 21, 22, 23, 24, 25, 26, 27, 29, 41, 42, 55.

   If another element formulation is requested for an implicit analysis, LS-DYNA will substitute one of the above in place of the one chosen.

2. **Problem types for the type 18 element.** The type 18 element is only for linear static and normal modes. It can also be used for linear springback in sheet metal stamping.

3. **Description of linear element types 18 and 20.** The linear elements consist of an assembly of membrane and plate elements. They have six degrees of freedom per node and can, therefore, be connected to beams or used in complex shell surface intersections. These elements possess the required zero energy rigid body modes and have exact constant strain and curvature representation, that is, they pass all the first order patch tests. In addition, the elements have behavior approaching linear bending (cubic displacement) in the plate-bending configuration.

   a) The membrane component is based on an 8-node/6-node isoparametric mother element which incorporates nodal in-plane rotations through cubic displacement constraints of the sides [Taylor 1987; Wilson 2000].

   b) The plate component of element 18 is based on the Discrete Kirchhoff Quadrilateral (DKQ) [Batoz 1982]. Because the Kirchhoff assumption is enforced, the DKQ is transverse-shear rigid and can only be used for thin shells. No transverse shear stress information is available. The triangle is based on a degeneration of the DKQ. This element sometimes gives slightly lower eigenvalues when compared with element type 20.

   c) The plate component of element 20 is based on the 8-node serendipity element. At the mid-side, the parallel rotations and transverse displacements are constrained, and the normal rotations are condensed to yield a 4-node element. The element is based on thick plate theory and is recommended for thick and thin plates.

   d) The quadrilateral elements contain a warpage correction using rigid links.

   e) The membrane component of element 18 has a zero-energy mode associated with in-plane rotations. This is automatically suppressed in a non-flat shell by the plate stiffness of the adjacent elements. In contrast, element 20 has no spurious zero energy modes.

4. **Linear shear element (22).** The linear shear panel element resists tangential in plane shearing along the four edges and can only be used with the elastic material constants of *MAT_ELASTIC. Membrane forces and out-of-plane loads are not resisted.

5. **Simplified element for time domain vibrations (99).** Element type 99 is intended for vibration studies carried out in the time domain. These models may have very large numbers of elements and may be run for relatively long durations. The purpose of this element is to achieve substantial CPU savings. This

is achieved by imposing strict limitations on the range of applicability, thereby simplifying the calculations:

a) Elements must be rectangular; all edges must parallel to the global *x*-, *y*- or *z*-axis;

b) Small displacement, small strain, negligible rigid body rotation;

c) Elastic material only.

If these conditions are satisfied, the performance of the element is similar to the fully integrated shell (ELFORM = 16) but at less CPU cost than the default Belytschko-Tsay shell element (ELFORM = 2). Single element torsion and in-plane bending modes are included; meshing guidelines are the same as for fully integrated shell elements.

No damping is included in the element formulation (such as volumetric damping). It is strongly recommended that damping be applied with keywords such as *DAMPING_PART_MASS or *DAMPING_FREQUENCY_RANGE.

6. **2D formulations.** For 2D formulations (12-15, 43, 44, 46, 47, 52, and 55), nodes must lie in the global *xy*-plane, so the *z*-coordinate must be zero. Furthermore, the element normal should be in positive *z* direction. For axisymmetric element formulations, the global *y*-axis is taken as the axis of symmetry, and all nodes must have *x*-coordinate values greater than or equal to 0.

   Shell thickness values on Card 2 are ignored by formulations 13, 14, 15, 43, 44, 52, and 55. For formulation 14 input values of loads, lumped masses, discrete element stiffnesses, etc. in axisymmetric models are interpreted as values per unit circumference (that is per unit length in the circumferential direction) whereas for formulation 15 they are interpreted per radian. Output of forces for shell formulation 15 are in units of force per radian in the output files, such as bndout, nodfor, secforc, spcforc, and rcforc. The units of forces output for shell formulation 14 are, at present, inconsistent. For defining contact in 2D simulations, see the entry for the *CONTACT_2D keyword.

7. **Shells with thickness stretch.** Shell element formulation 25 and 26 are the fully integrated shell element based on the Belytschko-Tsay element but with two additional degrees of freedom allowing for a linear variation of strain through the thickness. By specifying IDOF = 1, the thickness field is continuous across the element edges implying that there can be no complex intersections since this would lock up the structure. It assumes a relatively flat surface and is intended primarily for sheets in metal forming. By default, the thickness field is decoupled between elements which makes the element suited for crash.

8. **Seat belts.** You must input a set of nodes along one of the transverse edges of a seatbelt. If there is no retractor associated with a belt, the node set can be on either edge. If the retractor exists, the edge should be on the retractor side and input in the same sequence as the retractor's node set. Therefore, each seat belt must have its own section definition and own part.

9. **Fracture.** XFEM 2D and shell formulations are recommended for brittle or semi-brittle fracture with pre-crack (see *BOUNDARY_PRECRACK) or with geometry imperfection such as a notch or a hole, and for ductile fracture analysis with regularized effective plastic strain criterion or nonlocal continuum damage material models (provided with GISSMO model).

10. **Discrete Kirchoff Theory shell (17).** Shell element formulation 17 (DKT) is based on Discrete Kirchhoff Theory. It neglects out-of-plane shear strain energy and is thus valid only for thin plates where shear strain energy is negligible compared to bending energy.

11. **Limitations of area-weighted shells (14).** The exact stiffness matrix for the area-weighted shell formulation type 14 is nonsymmetric. The nonsymmetric terms are dropped for computational efficiency, making this formulation unsuitable for implicit linear analysis and eigenvalue analysis. For implicit modal computations element type 14 must be switched to type 15. It may, however, be used effectively for implicit nonlinear analysis.

    For explicit dynamics, viscous hourglass limits high frequency noise that may otherwise lead to nonphysical element distortion when nodes are on or near the axis of symmetry. Viscosity can be added to type 6 or 7 hourglass control by using VDC > 0 under the *HOURGLASS keyword. Alternatively, type 1 hourglass control is viscous.

12. **Eight node singular shell (55).** The eight node singular element for fracture analysis is based on the eight node quadratic quadrilateral element. There are two ways to include the singularity around the crack tip:

    a) Move the two mid-nodes on the edges connected to the crack tip to the quarter location and obtain a strain singularity of $1/\sqrt{r}$ along the edges with quarter-point mid-nodes and of weaker than one-half order elsewhere.

    b) Collapse the three nodes on one side of a quadrilateral element to the crack tip (but the three nodes remain independent) and move the two neighboring mid-nodes to the quarter location to obtain a strain singularity of exact one-half order $1/\sqrt{r}$ everywhere around the crack tip..

    This element uses 2 × 2, 3 × 3, or 4 × 4 quadrature (default 2 × 2) and is available in implicit analysis only. The reference coordinates of the quadrature points are

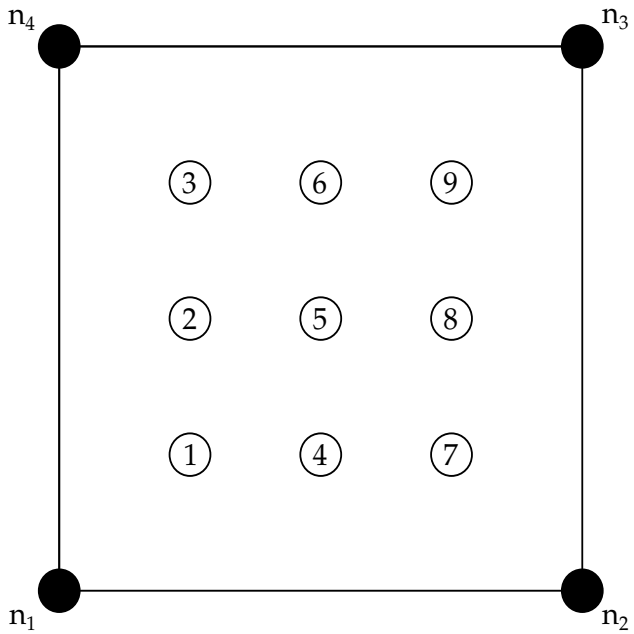

Figure 39-23. Integration point locations for a type 55 element with a 3 × 3 quadrature scheme

as in the Gaussian Quadrature Points table but have a different order (#2, #1 and #3) in one direction for the 3 × 3 quadrature scheme. The global coordinates of the quadrature points depend on the connectivity of the element, as shown in Figure 39-23.

To easily access the stress data, the stress components at all the integration points are output to the ELOUT file.

13. **Cohesive shell (+/-29).** Element type +/-29 is a cohesive element that models cohesive interfaces between shell element edges. The element takes bending forces into account and uses drilling force stabilization.

Consider two shell elements in the same plane with nodes m_1, m_2, m_3, m_4, n_1, n_2, n_3, and n_4 such that the (m_3, m_4) edge and the (n_1, n_2) edge are connected through a cohesive shell having nodes m_4, m_3, n_2, and n_1; see Figure 39-24. The initial area of the cohesive element may be zero, in which case density is defined in terms of the length of the single connecting edge.

Element type +/-29 works similarly to solid element type 20. For example, extruding the two non-cohesive shells in their respective normal directions defines two 8 node solids. The cohesive mid-surface is located between the opposing faces of the solids, and tractions are calculated in four mid-surface points using differences of displacements between the opposing faces, giving rise to nodal forces and moments in the cohesive shell nodes m_4, m_3, n_2, and n_1. Note that, regardless of the value of INTFAIL, a 2 x 2 Newton-Cotes quadrature is used in the force integrals. Additional details can be found in the Theory Manual.

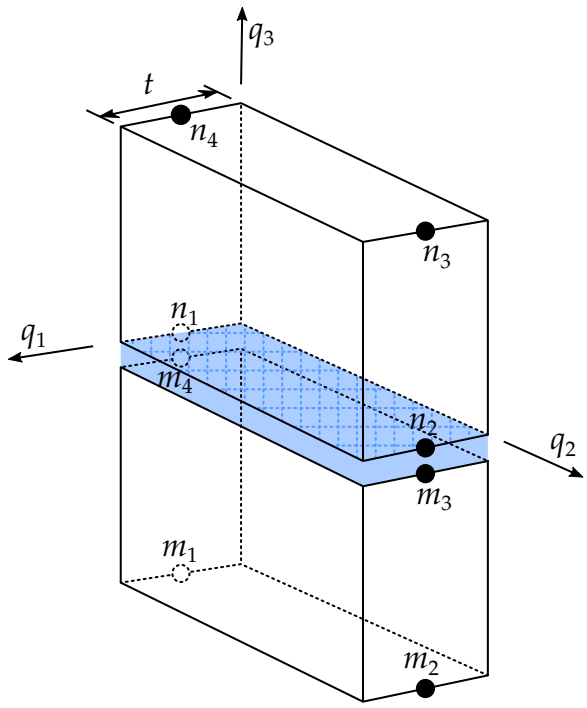

Figure 39-24. Cohesive interface coordinate system for element type +/-29

Difference between type 29 and -29: In both formulations, the cohesive coordinate system direction q_2 is defined by the midpoints of the (n_1, m_4) and (n_2, m_3) edges. Type 29 defines the cohesive midsurface normal q_3 using the midpoints on the far side edges (m_1, m_2) and (n_3, n_4), while type -29 defines q_1 to be the mean of the neighboring element normals. Thus, in pure out-of-plane shear, type 29 will initially have pure tangential traction that turns into a normal traction as the separation increases, while type -29 will only have tangential traction.

Cohesive shell formulations +/-29 output three tractions having units of force per unit area into the d3plot database rather than the usual six stress components. The out-of-plane shear traction replaces the x-stress (mode III), the in-plane shear traction replaces the y-stress (mode II), and the traction in the normal direction replaces the z-stress (mode I). The tractions on the four midsurface points on the cohesive interface can be saved in d3plot by setting MAXINT to -1 on *DATABASE_EXTENT_BINARY or *DATABASE_D3PART.

14. **Accurate fully-integrated shell (-16).** Accuracy issues have been observed in shell formulation 16 under large deformations/rotations over a single time step. Formulation -16 is a version of formulation 16 which has been enhanced to address those accuracy issues. Formulation 16 is unchanged to maintain back compatibility and, although element -16 is supported in explicit mode, it is primarily intended for implicit time integration. A strongly objective version can be activated by combining ELFORM = -16 and IACC = 1 on *CONTROL_ACCURA-

CY, thereby ensuring that arbitrarily large rigid body rotation in a single step will transform stresses correctly and not generate any spurious strains.

15. **XFEM ductile fracture.** This feature is supported by joint research among Honda, JSOL and LST. For FAILCR = -2, the failure strain is given by:

$$\text{EPS} = \text{FS} + (\text{FS1} - \text{FS}) \times \min(L/\text{CL}, 1.0)$$

16. **Cohesive formulations 46 and 47.** We intend cohesive formulations 46 and 47 for cohesive elements with nonzero initial thickness. Instabilities may occur if the element has zero initial thickness.

17. Like for cohesive solids, LS-DYNA outputs three tractions having units of force per unit area for plane strain and axisymmetric cohesive formulations 46 and 47 into the d3plot database rather than the usual six stress components. The in-plane shear traction along the 1-2 edge replaces the x-stress, the orthogonal in plane shear traction replaces the y-stress, and the traction in the normal direction replaces the z-stress.

18. **Cohesive material law for XFEM.** For the XFEM formulation, modeling the fracture process zone around the crack tip is simplified with a cohesive zone model. The initially rigid cohesive material law provides the kinetic relationship (traction force as a function of crack opening displacement) for the cohesive crack surface inserted in the element. The work done by the traction represents the energy release rate in brittle fracture or plastic work in ductile fracture to create a real crack surface where the traction force becomes zero. When a non-local continuum damage constitutive model is used for ductile fracture, the cohesive law is not needed since the stresses in the failed element become zero due to the damage induced stress softening.

Example:

***SECTION_SOLID**_{OPTION}

Available options include:

<BLANK>

EFG

SPG

MISC

Purpose: Define section properties for solid continuum and fluid elements.

Card Summary:

Card Sets. For each unique solid section, include one set of data cards. The EFG and SPG options cannot appear in the same model. This input ends at the following keyword ("*") card.

Card 1. This card is required.

SECID	ELFORM	AET				COHOFF	GASKETT

Card 2a.1. This card is included if the EFG keyword option is used.

DX	DY	DZ	ISPLINE	IDILA	IEBT	IDIM	TOLDEF

Card 2a.2. This card is read only if the EFG keyword option is used. It is optional.

IPS	STIME	IKEN	SF	CMID	IBR	DS	ECUT

Card 2b.1. This card is included if the SPG keyword option is used.

DX	DY	DZ	ISPLINE	KERNEL		SMSTEP	MSC

Card 2b.2. This card is read only if the SPG keyword option is used. It is optional.

IDAM	FS	STRETCH	ITB	MSFAC	ISC	BOXID	PDAMP

Card 2c. This card is read only if the MISC keyword option is used. It is optional.

COHTHK							

Card 3. This card is included if ELFORM = 101, 102, 103, 104, or 105.

NIP	NXDOF	IHGF	ITAJ	LMC	NHSV	XNOD	

Card 4. This card is included if ELFORM = 101, 102, 103, 104, or 105. Include NIP of this card.

XI	ETA	ZETA	WGT				

Card 5. This card is included if ELFORM = 101, 102, 103, 104, or 105. Include ceil(LMC/8) of this card.

P1	P2	P3	P4	P5	P6	P7	P8

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ELFORM	AET				COHOFF	GASKETT
Type	I/A	I	I				F	F

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ELFORM	Element formulation options. Remark 2 enumerates the element formulations available for implicit calculations: EQ.-18: 8 point enhanced strain solid element with 13 incompatible modes (see Remarks 5 and 17) EQ.-2: 8 point hexahedron intended for elements with poor aspect ratios, accurate formulation (see Remark 13) EQ.-1: 8 point hexahedron intended for elements with poor aspect ratios, efficient formulation (see Remark 13) EQ.0: 1 point corotational for *MAT_MODIFIED_HONEYCOMB (see Remark 3) EQ.1: Constant stress solid element: default element type. By specifying hourglass type 10 with this element, a Cosserat Point Element is invoked; see *CONTROL_HOURGLASS. EQ.2: 8 point hexahedron (see Remark 5)

VARIABLE	DESCRIPTION
EQ.3:	Fully integrated quadratic 8 node element with nodal rotations
EQ.4:	S/R quadratic tetrahedron element with nodal rotations
EQ.5:	1 point ALE
EQ.6:	1 point Eulerian
EQ.7:	1 point Eulerian ambient
EQ.8:	Acoustic
EQ.9:	1 point corotational for *MAT_MODIFIED_HONEYCOMB (see Remark 3)
EQ.10:	1 point tetrahedron (see Remark 1)
EQ.11:	1 point ALE multi-material element (see Remark 4)
EQ.12:	1 point integration with single material and void
EQ.13:	1 point nodal pressure tetrahedron (see Remark 12)
EQ.14:	8 point acoustic
EQ.15:	2 point pentahedron element (see Remark 1)
EQ.16:	4 or 5 point 10-noded tetrahedron (see Remark 11). By specifying hourglass type 10 with this element, a Cosserat Point Element is invoked; see *CONTROL_HOURGLASS.
EQ.17:	10-noded composite tetrahedron (see Remark 11)
EQ.18:	9 point enhanced strain solid element with 12 incompatible modes (implicit only; see Remarks 5 and 17)
EQ.19:	8-noded, 4 point cohesive element (see Remarks 1 and 7)
EQ.20:	8-noded, 4 point cohesive element with offsets for use with shells (see Remarks 1, 7, and 9)
EQ.21:	6-noded, 1 point pentahedron cohesive element (see Remarks 1 and 8)
EQ.22:	6-noded, 1 point pentahedron cohesive element with offsets for use with shells (see Remarks 1, 8, and 9)
EQ.23:	20-node solid formulation
EQ.24:	27-noded, fully integrated S/R quadratic solid element (see Remark 16)

VARIABLE	DESCRIPTION
	EQ.25: 21-noded, quadratic pentahedron (see Remark 16)
	EQ.26: 15-noded, quadratic tetrahedron (see Remark 16)
	EQ.27: 20-noded, cubic tetrahedron (see Remark 16)
	EQ.28: 40-noded, cubic pentahedron (see Remark 16)
	EQ.29: 64-noded, cubic hexahedron (see Remark 16)
	EQ.41: Mesh-free (EFG) solid formulation (see Remark 19)
	EQ.42: Adaptive 4-noded mesh-free (EFG) solid formulation (see Remark 19)
	EQ.43: Mesh-free enriched finite element
	EQ.45: Tied mesh-free enriched finite element
	EQ.47: Smoothed Particle Galerkin (SPG) method (see Remark 14)
	EQ.60: 1 point tetrahedron (see Remark 15)
	EQ.62: 8 point brick with incompatible modes by assumed strain (see Remarks 5 and 18)
	EQ.98: Interpolation solid
	EQ.99: Simplified linear element for time-domain vibration studies (See Remark 6)
	EQ.101: User-defined solid
	EQ.102: User-defined solid
	EQ.103: User-defined solid
	EQ.104: User-defined solid
	EQ.105: User-defined solid
	EQ.115: 1 point pentahedron element with hourglass control
	GE.201: Isogeometric solids with NURBS (see *ELEMENT_SOLID_NURBS_PATCH)
	GE.1000: Generalized user-defined solid element formulation (see *DEFINE_ELEMENT_GENERALIZED_SOLID)
AET	Ambient element type (can be defined for ELFORM 7, 11, and 12):
	EQ.0: Non-ambient
	EQ.1: Temperature (not currently available)
	EQ.2: Pressure and temperature (not currently available)

VARIABLE	DESCRIPTION
	EQ.3: Pressure outflow (obsolete) EQ.4: Pressure inflow/outflow (default for ELFORM 7) EQ.5: Receptor for blast load (See *LOAD_BLAST_ENHANCED. Available only for ELFORM = 11.)
COHOFF	Applies to cohesive solid elements 20 and 22. COHOFF specifies the relative location of the cohesive layer. It must be a number between -1 and 1. A value of -1 will place it on the bottom face of the cohesive element, while a value of +1 will place it on the top face. This parameter is preferably used when the cohesive element connects shells with different thicknesses. In this case, the cohesive layer should not be located exactly between the bottom and top layer, which is the default location (COHOFF = 0).
GASKETT	Gasket thickness for converting ELFORM 19, 20, 21, and 22 to gasket elements and use with *MAT_COHESIVE_GASKET.

EFG Card. Additional card for the EFG keyword option. See *CONTROL_EFG.

Card 2a.1	1	2	3	4	5	6	7	8
Variable	DX	DY	DZ	ISPLINE	IDILA	IEBT	IDIM	TOLDEF
Type	F	F	F	I	I	I	I	F
Default	1.01	1.01	1.01	0	0	3	2	0.01

VARIABLE	DESCRIPTION
DX, DY, DZ	Normalized dilation parameters of the kernel function in x, y, and z-directions. The normalized dilation parameters of the kernel function are introduced to provide the smoothness and compact support properties on the construction of the mesh-free shape functions. Values between 1.0 and 1.5 are recommended. Values smaller than 1.0 are not allowed. Larger values will increase the computation time and sometimes result in a divergence problem.
ISPLINE	Replace the choice for the EFG kernel functions definition in *CONTROL_EFG, which allows for different spline functions in different sections.

VARIABLE	DESCRIPTION
	EQ.0: Cubic spline function (default) EQ.1: Quadratic spline function EQ.2: Cubic spline function with a circular shape
IDILA	Replace the choice for the normalized dilation parameter definition in *CONTROL_EFG. This allows users to define different IDILA in different sections. EQ.0: Maximum distance based on the background elements. EQ.1: Maximum distance based on surrounding nodes.
IEBT	Essential boundary condition treatment (see Remarks 20 and 21): EQ.1: Full transformation method EQ.-1: (W/o transformation) EQ.2: Mixed transformation method EQ.3: Coupled FEM/EFG method (default) EQ.4: Fast transformation method EQ.-4: (W/o transformation) EQ.5: Fluid particle method for EOS and *MAT_ELASTIC_FLUID materials, currently supports only 4-noded background elements. EQ.7: Maximum entropy approximation
IDIM	Domain integration method (see Remark 22): EQ.1: Local boundary integration EQ.2: Two-point Gauss integration (default) EQ.3: Improved Gauss integration for IEBT = 4 or -4 EQ.-1: Stabilized EFG integration method (apply to 6-noded cell, 8-noded cell, or combination of these two) EQ.-2: EFG fracture method (apply to 4-noded cell and SMP only). The EFG fracture method is obsolete – see Remark 24.
TOLDEF	Deformation tolerance for the activation of adaptive EFG Semi-Lagrangian and Eulerian kernel. See Remark 23. EQ.0.0: Lagrangian kernel

VARIABLE	DESCRIPTION
	GT.0.0: Semi-Lagrangian kernel
	LT.0.0: Eulerian kernel

Optional EFG Card. Additional optional card for the EFG keyword option. See *CONTROL_EFG.

Card 2a.2	1	2	3	4	5	6	7	8
Variable	IPS	STIME	IKEN	SF	CMID	IBR	DS	ECUT
Type	I	F	I	I	I	I	F	F
Default	0	10^{20}	0	0.0	0	1	1.01	0.1

VARIABLE	DESCRIPTION
IPS	Pressure smoothing flag: EQ.0: No pressure smoothing (default) EQ.1: Moving-least squared pressure recovery (material response is slightly more compressible when turning on this function). Only the adaptive 4-noded mesh-free (EFG) solid formulation (ELFORM = 42) is supported.
STIME	Time to switch from stabilized EFG to standard EFG formulation. Obsolete - see Remark 24.
IKEN	EQ.0: Moving-least-square approximation (default, recommended) EQ.1: Maximum entropy approximation Obsolete - see Remark 24.
SF	Failure strain. It is recommended as an additional condition for crack initiation under slow loading besides the stress-based cohesive law. Obsolete - see Remark 24.
CMID	Cohesive material ID for EFG fracture analysis (only Mode I crack is considered, and only *MAT_COHESIVE_TH is available). Obsolete - see Remark 24.

VARIABLE	DESCRIPTION
IBR	EQ.1: No branching allowed. EQ.2: Branching is allowed. Obsolete - see Remark 24.
DS	Normalized support defined for computing the displacement jump in fracture analysis. Obsolete - see Remark 24.
ECUT	Define the minimum distance to the node that a crack surface can cut to the edge. Obsolete - see Remark 24.

SPG Card. Additional card for the SPG keyword option.

Card 2b.1	1	2	3	4	5	6	7	8
Variable	DX	DY	DZ	ISPLINE	KERNEL		SMSTEP	MSC
Type	F	F	F	I	I		I	F
Default	↓	↓	↓	0	0		↓	0

VARIABLE	DESCRIPTION
DX, DY, DZ	Normalized dilation parameters of the kernel function in x, y, and z directions, respectively. The normalized dilation parameters of the kernel function provide the smoothness and locality on the construction of the mesh-free shape functions. Values between 1.4 and 1.8 are recommended. Values smaller than 1.0 are not allowed. Larger values will increase the computation time and sometimes result in divergence of the solution. The default value depends on the choice of KERNEL:

KERNEL	Default
0	1.6
1	1.8
2	1.5

ISPLINE	Type of kernel function: EQ.0: Cubic spline function with cubical support (default) EQ.1: Quadratic spline function with cubical support

VARIABLE	DESCRIPTION
	EQ.2: Cubic spline function with spherical support
KERNEL	Type of kernel support update scheme: EQ.0: Updated Lagrangian, failure or no failure analysis, tension dominant problem EQ.1: Eulerian, failure analysis, global extreme deformation EQ.2: Pseudo Lagrangian, failure analysis, local extreme deformation
SMSTEP	Interval of time steps to conduct displacement smoothing. The default value depends on the choice of KERNEL:

KERNEL	Default
0	15
1	5
2	30

MSC	Smoothing scheme for momentum consistent SPG only (ITB = 3 on Card 2b.2): EQ.0: Regular smoothing scheme EQ.1: New smoothing scheme for very low-speed deformation, with better controls of the low energy modes than the regular smoothing scheme

Optional SPG Card. Additional optional card for the SPG keyword option.

Card 2b.2	1	2	3	4	5	6	7	8
Variable	IDAM	FS	STRETCH	ITB	MSFAC	ISC	BOXID	PDAMP
Type	I	F	F	I	F	I	I	F
Default	1	↓	10^{10}	↓	↓	0	0	-0.001

VARIABLE	DESCRIPTION
IDAM	Option of bond failure mechanism

VARIABLE	DESCRIPTION
	EQ.1: Effective plastic strain (phenomenological strain damage, default)
	EQ.2: Maximum principal stress
	EQ.3: Maximum shear strain
	EQ.4: Minimum principal strain (input must be positive)
	EQ.5: Effective plastic strain and maximum shear strain
	EQ.7: Anisotropic damage for honeycomb modeled with *MAT_126 only. We recommend only using this with ITB = 3. This feature is available starting with R13.
	EQ.11: Pre-damage model for brittle material failure (with crack propagation). It includes both bond failure and stress degradation. It is available as of R13. We recommend using this with ITB = 3.
	EQ.13: Pre-damage model for ductile material failure. It includes stress degradation but not bond failure. It is available as of R13. We recommend using this with ITB = 3.
FS	Critical value of the quantity indicated by IDAM for triggering bond failure. The default value is 10^{10}, meaning no failure analysis in general. However, starting with R14.0, if an SPG part has a material law with *MAT_ADD_EROSION, bond failure will be checked for using the failure criterion defined in *MAT_ADD_EROSION, even when FS = 0.0. FS on the material cards overwrites this value for *MAT_003 and *MAT_024. When FS is defined on the data cards for these materials, bond failure will occur when it is reached, and stress will be set to zero according to material law. If FS is defined here only, bond failure will occur without the stress being set to zero.
STRETCH	Critical relative deformation (stretching or compression ratio) between the two nodes forming the bond for bond failure
ITB	Option of stabilization:
	EQ.1: Fluid particle approximation (accurate but slow), used with KERNEL = 0 or 1

VARIABLE	DESCRIPTION

EQ.2: Simplified fluid particle approximation (efficient and robust), used with KERNEL = 2

EQ.3: Momentum consistent SPG (MC-SPG) formulation (we recommend the latest beta version or R14). MC-SPG can be applied for large deformation, tension-dominant problems. For coupled thermal-mechanical problems, MC-SPG is the only option. KERNEL = 1 is recommended for MC-SPG.

The default for ITB depends on the value of KERNEL:

KERNEL	Default
0	1
1	1
2	2

MSFAC: For momentum consistent SPG invoked with ITB = 3 only, quadrature factor for surface nodes to suppress shear locking in thin structures. We recommend using the latest beta version or R14. The default for a regular solid structure is 1.00 while for a thin structure is 0.75.

ISC: Self-contact indicator:

EQ.0: No self-contact between the bond-failed particles in the same part.

EQ.1: Self-contact is defined between the bond-failed particles in the same part. The penalty factor in the self-contact is between 0.01 to 0.1 × Young's modulus. This option is available for SMP only.

BOXID: ID of a box defining the active SPG region. Outside this region, the particles are not included in the SPG calculation. See *DEFINE_BOX.

PDAMP: Particle-to-particle damping coefficient. It is used for momentum consistent SPG (ITB = 3) *only*. The recommended range of values is -0.01 to -0.001. A positive value is not recommended.

Optional MISC Card. Additional optional card for the MISC keyword option.

Card 2c	1	2	3	4	5	6	7	8
Variable	COHTHK							
Type	F							
Default	optional							

VARIABLE	DESCRIPTION
COHTHK	Cohesive thickness. This value supersedes the THICK value from *MAT_240 or *MAT_ADD_COHESIVE, allowing a section- or part-wise definition of cohesive thickness.

User-Defined Element Card. Additional card for ELFORM = 101, 102, 103, 104, or 105. See Appendix C.

Card 3	1	2	3	4	5	6	7	8
Variable	NIP	NXDOF	IHGF	ITAJ	LMC	NHSV	XNOD	
Type	I	I	I	I	I	I	I	
Default	0	0	0	0	0	0	0	

VARIABLE	DESCRIPTION
NIP	Number of integration points for user-defined solid (0 if resultant element)
NXDOF	Number of extra degrees-of-freedom per node for user-defined solid
IHGF	Flag for using hourglass stabilization (NIP > 0) EQ.0: Hourglass stabilization is not used EQ.1: LS-DYNA hourglass stabilization is used EQ.2: User-defined hourglass stabilization is used

VARIABLE	DESCRIPTION
	EQ.3: Same as 2, but the resultant material tangent moduli are passed
ITAJ	Flag for setting up finite element matrices (NIP > 0) EQ.0: Set up matrices with respect to the isoparametric domain EQ.1: Set up matrices with respect to the physical domain
LMC	Number of property parameters
NHSV	Number of history variables
XNOD	Controls how the mass of extra degrees-of-freedom is interpreted when defined using user subroutine. EQ.0: The mass is to be defined per degree-of-freedom. EQ.1: The mass is to be defined as a nodal mass, where each scalar node has three extra degrees-of-freedom. See Extra Degrees-Of-Freedom in Appendix C.

Integration Point Card. Additional card for ELFORM = 101, 102, 103, 104, or 105. Add NIP cards adhering to the format below. Because the default value for NIP is 0, these cards are read only for user-defined elements. See Appendix C.

Card 4	1	2	3	4	5	6	7	8
Variable	XI	ETA	ZETA	WGT				
Type	F	F	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
XI	First isoparametric coordinate
ETA	Second isoparametric coordinate
ZETA	Third isoparametric coordinate
WGT	Isoparametric weight

Property Parameter Cards. Additional card for ELFORM = 101, 102, 103, 104, or 105. Add LMC property parameters by packing eight parameters per card. See Appendix C.

Card 5	1	2	3	4	5	6	7	8
Variable	P1	P2	P3	P4	P5	P6	P7	P8
Type	F	F	F	F	F	F	F	F
Default	0.	0.	0.	0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
P*i*	i^{th} property parameter

Remarks:

1. **ESORT to Stabilize Degenerate Solids.** The ESORT variable of the *CONTROL_SOLID keyword can be set to automatically convert degenerate tetrahedrons and degenerate pentahedrons into more suitable solid element formulations. The sorting is performed internally and is transparent to the user. See *CONTROL_SOLID for details.

2. **Implicit Analysis.** For implicit calculations, the following element choices are implemented:

   EQ.-18: 8 point enhanced strain solid element (13 incompatible modes)

   EQ.-2: 8 point hexahedron for poor aspect ratios, accurate formulation

   EQ.-1: 8 point hexahedron for poor aspect ratios, efficient formulation

   EQ.1: Constant stress solid element

   EQ.2: 8 point hexahedron

   EQ.3: Fully integrated 8 node solid with rotational DOFs

   EQ.4: Fully integrated S/R 4 node tetrahedron with rotational DOFs

   EQ.10: 1 point tetrahedron

   EQ.13: 1 point nodal pressure tetrahedron

   EQ.15: 2 point pentahedron element

   EQ.16: 5 point 10-noded tetrahedron

   EQ.17: 10-noded composite tetrahedron

EQ.18: 9 point enhanced strain solid element (12 incompatible modes)

EQ.19: 8-noded, 4 point cohesive element

EQ.20: 8-noded, 4 point cohesive element with offsets for use with shells

EQ.21: 6-noded, 1 point pentahedron cohesive element

EQ.22: 6-noded, 1 point pentahedron cohesive element with offsets for use with shells

EQ.23: 20-node solid formulation

EQ.24: 27-node solid formulation

EQ.25: 21-noded, quadratic pentahedron

EQ.26: 15-noded, quadratic tetrahedron

EQ.27: 20-noded, cubic tetrahedron

EQ.28: 40-noded, cubic pentahedron

EQ.29: 64-noded, cubic hexahedron

EQ.41: Mesh-free (EFG) solid formulation

EQ.42: 4-noded mesh-free (EFG) solid formulation

EQ.43: Mesh-free enriched finite element

EQ.62: 8 point brick with incompatible modes by assumed strain

If another element formulation is requested, LS-DYNA will substitute, when possible, one of the above in place of the one chosen. The type 1 element, constant stress, is generally much more accurate than the type 2 element, the selectively reduced integrated element for implicit problems.

3. **Elements for Modified Honeycomb Material.** Element formulations 0 and 9 behave essentially as nonlinear springs to permit severe distortions sometimes seen in honeycomb materials. They are applicable only to *MAT_MODIFIED_HONEYCOMB, but as of R14, *MAT_ADD_EROSION can also be enabled. For formulation 0, the local coordinate system follows the element rotation, whereas, for formulation 9, the local coordinate system is based on axes passing through the centroids of the element faces. Formulation 0 is preferred for severe shear deformation where the barrier is fixed in space. If the barrier is attached to a moving body, which can rotate, then formulation 9 is usually preferred.

4. **ALE Element (ELFORM = 11) Shapes.** We designed the ALE solver assuming hexahedral meshes of ALE elements. The ALE solver treats tetrahedral elements as degenerate hexahedrons. Thus, the advection calculation may be inaccurate and cause LS-DYNA to crash. We recommend only using ALE meshes with exclusively hexahedral elements.

5. **8/9 Point Hexahedrons: Types 2, 18, and 62.** Solid formulation 2 often employs a B-bar method and thereby assumes that pressure is constant throughout the element to avoid pressure locking during nearly incompressible flow. But when using material model 2, 21-23, 30, 38, 54, 57, 59, 63, 83, 91-92, 126, 143, 176-179, 181 (compressible option), 183, 189, 213, 215, 218, 221, 227, 249, 261-262, 266, 269, 274-275 or 295, solid formulation 2 employs full integration to treat compressible behavior better. IHYPER=±10 on *MAT_USER_DEFINED_MATERIAL_MODELS will also invoke full integration of solid form 2 when using the corresponding hyperelastic user material. If the element aspect ratios are poor, shear locking will lead to an excessively stiff response of solid form 2. Given poor aspect ratios, a better choice is the one point solid element (formulation 1), the 8 point solid formulation -1, or the 8 point solid formulation -2 (see Remark 13). Elements with formulations -1 and -2 are insensitive to a lousy aspect ratio but become very stiff if skewed or distorted. The enhanced assumed strain solid formulations -18 (8 point) and 18 (9 point) work well for elements with poor aspect ratios and can handle some distortion. Highly distorted elements lead to excessive stiffness for element formulations -18 and 18. Element form 62 is also an enhanced assumed strain element with 8 nodes that is not susceptible to volumetric or shear locking.

6. **Element Type 99 for Vibration.** Element type 99 is intended for vibration studies in the time domain. This model type may have a large number of elements and run for a relatively long duration. The purpose of this element is to achieve substantial CPU savings. This is achieved by imposing strict limitations on the range of applicability, thereby simplifying the calculations:

   a) Elements must be cubed; all edges must parallel to the global *x*-, *y*- or *z*-axis;

   b) Small displacement, small strain, negligible rigid body rotation;

   c) Elastic material only

   If these conditions are satisfied, the performance of the element is similar to the fully integrated S/R solid (ELFORM = 2) but at less CPU cost than the default solid element (ELFORM = 1). Single-element bending and torsion modes are included, so meshing guidelines are the same as for fully integrated solids, e.g., relatively thin structures can be modeled with a single solid element through the thickness if required. Typically, the CPU requirement per element-cycle is roughly two-thirds that of the default solid element.

   No damping is included in the element formulation (for example, volumetric damping). It is strongly recommended that damping be applied, using keywords including *DAMPING_PART_MASS or *DAMPING_FREQUENCY_RANGE.

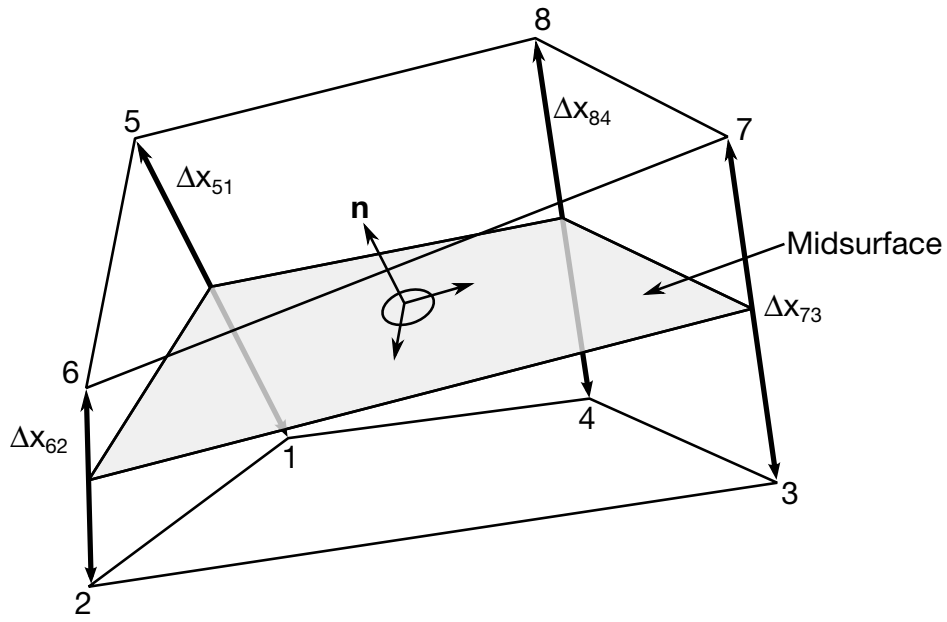

Figure 39-25. Illustration of solid local coordinates.

7. **8-Node Cohesive Element: Type 19.** Element type 19 is a cohesive element. The tractions on the mid-surface, defined as the mid-points between the nodal pairs 1-5, 2-6, 3-7, and 4-8, are functions of the differences of the displacements between nodal pairs interpolated to the four integration points. The initial volume of the cohesive element may be zero, in which case, the density may be defined in terms of the area of nodes 1-2-3-4. See Appendix A and the user material description for additional details. See also *MAT_ADD_COHESIVE. See Remark 10 regarding output for cohesive solids.

   The tractions are calculated in the local coordinate system defined at the centroid of the element; see Figure 39-25. Representing the rotation matrix from the local to the global coordinate system at time t as $\mathbf{R}(t)$, the initial coordinates as $\mathbf{X}$, and the current coordinates as $\mathbf{x}$, the displacements at an integration point are

$$\Delta\mathbf{u} = \mathbf{R}^{\mathrm{T}}(t)\Delta\mathbf{x} - \mathbf{R}^{\mathrm{T}}(0)\Delta\mathbf{X}$$

$$\Delta\mathbf{x} = \sum_{i=1}^{4} N_i(s,t)\Delta\mathbf{x}_{i+4,i}$$

$$\Delta\mathbf{X} = \sum_{i=1}^{4} N_i(s,t)\Delta\mathbf{X}_{i+4,i}$$

   The forces are obtained by integrating the tractions over the mid-surface and rotating them into the global coordinate system. It is the sum over integration points g = 1,2,3,4.

$$\mathbf{F}_i = \mathbf{R}(t) \sum_{g=1}^{4} \mathbf{T}_g N_i(s_g, t_g) \det(\mathrm{J}_g), \quad \text{for } 1 \le i \le 4, \quad \text{and } \mathbf{F}_{i+4} = -\mathbf{F}_i$$

where,

$\mathbf{T}_g$ = the traction stress in the local coordinate system

N_i = the shape function of the cohesive element at node i

s_g and t_g = the parametric coordinates of the 4 integration points (determined by INTFAIL on the cohesive material card).

J_g = the integration point's portion of the determinate of the cohesive element, which is equivalent to the element volume

8. **6-Node Cohesive Element: Type 21.** Element type 21 is the pentahedral counterpart to element type 19, with three nodes on the bottom and top surfaces. The tractions on the mid-surface are defined as the mid-points between the nodal pairs 1-5, 2-6, and 3-7 are functions of the differences of the displacements between nodal pairs interpolated to one integration point. The ordering of the nodal points in *ELEMENT_SOLID is given by:

6-node (cohesive) pentahedron	N1, N2, N3, N3, N5, N6, N7, N7, 0, 0

Setting ESORT > 0 in *CONTROL_SOLID will automatically sort degenerated cohesive elements type 19 to cohesive pentahedron elements type 21. See Remark 10 regarding output for cohesive solids.

9. **Cohesive Element with Offsets: Types 20 and 22.** Element type 20 is identical to element 19 but with offsets for use with shells. The element is assumed to be centered between two layers of shells on the cohesive element's lower (1-2-3-4) and upper (5-6-7-8) surfaces. The offset distances for both shells are one-half the initial thicknesses of the nodal pairs (1-5, 2-6, 3-7, and 4-8), separating the two shells. These offsets are used with the nodal forces to calculate moments that are applied to the shells. Element type 20 in tied contacts will work correctly with the option TIED_SHELL_EDGE_TO_SURFACE, which transmits moments. Other tied options will leave the rotational degrees-of-freedom unconstrained with the possibility that the rotational kinetic energy will cause a significant growth in the energy ratio.

Element type 22 is the pentahedron counterpart to element type 20, with three nodes on the bottom and top surfaces. The ordering of the nodal points in *ELEMENT_SOLID is identical to element type 21 (see Remark 8). Setting ESORT > 0 in *CONTROL_SOLID will automatically sort degenerated cohesive elements type 20 to cohesive pentahedron elements type 22.

See Remark 10 regarding output for cohesive solids.

10. **Cohesive Element Output.** Cohesive solids (formulations 19, 20, 21, 22) output three tractions, having units of force per unit area, into the d3plot database rather than the usual six stress components. The in-plane shear traction along the 1-2 edge replaces the x-stress, the orthogonal in-plane shear traction replaces the y-stress, and the traction in the normal direction replaces the z-stress.

11. **10-Node Tetrahedra: Types 16 and 17.** Formulations 16 and 17 are 10-noded tetrahedral formulations. The parameter NIPTETS in *CONTROL_SOLID controls the number of integration points for these formulations. Formulation 17 is generally preferred over formulation 16 in explicit analysis because, unlike formulation 16, the nodal weighting factors are equal, and thus nodal forces from contact and applied pressures are distributed correctly.

    When applying loads to 10-noded tetrahedrons via segments, no load will be applied to the mid-side nodes if the segments contain only corner nodes. When defining contact, it is recommended that *CONTACT_AUTOMATIC_… be used and the contact surface of the 10-noded tetrahedral part be specified by its part ID. In this manner, mid-side nodes receive contact forces.

    If the 10-noded element connectivity is not defined in accordance with Figure 19-31 shown in *ELEMENT_SOLID, the order of the nodes can be quickly changed using a permutation vector specified with *CONTROL_SOLID. If *ELEMENT_SOLID defines 4-noded tetrahedrons, the command *ELEMENT_SOLID_TET4TOTET10 can easily convert them to 10-noded tetrahedrons. Because the characteristic length of a 10-noded tetrahedron is half that of a 4-noded tetrahedron, the time step for the tetrahedrons will be smaller by a factor of 2. Setting the variable TET10S8 to 1 in *CONTROL_OUTPUT causes the full 10-node connectivity to be written to the d3plot and d3part databases.

12. **1-Point Nodal Pressure Tetrahedron: Type 13.** Element type 13 is identical to type 10 but includes additional averaging of nodal pressures, which significantly decreases the chance of volumetric locking. Therefore, it is well suited for applications with incompressible and nearly incompressible material behavior, such as rubber materials or ductile metals with isochoric plastic deformations (e.g., bulk forming). Compared to the standard tetrahedron (type 10), a speed penalty with a maximum of 25% can be observed. For implicit simulations, all material models supported for type 10 are also supported for this element, while for explicit currently material models *MAT_001 (excluding FLUID option), 003, 006, 007, 015, 024, 027, 041-050, 077, 081, 082, 089, 091, 092, 098, 103, 106, 120, 122, 123, 124, 128, 129, 133, 157, 181, 183, 187, 199, 224, 225, 228, 233, 244, 260, 263, 266, 269, 271, 272 and 273 are fully supported. For other materials, this element behaves like the type 10 tetrahedron. Type 13 tetrahedral elements that use two different material models should not share nodes because the nodal pressure averaging will cause spurious energy. An exception to this rule is if the different materials have the same bulk modulus.

13. **8 point Hexahedrons with Poor Aspect Ratio: Types -1 and -2.** Solid formulations -1 and -2 employ an assumed strain approach to avoid the shear locking behavior seen in formulation 2 elements with poor aspect ratios. Formulation -1 is a more computationally efficient implementation of formulation -2. Formulation -1 has a side effect: resistance to a particular deformation mode, similar to an hourglass mode, is weakened. This side effect is not truly hourglassing behavior, so there is no hourglass energy, and the behavior is not affected by hourglass parameters. For material models 57, 83, 181 (compressible option), and 274, formulations -1 and -2 employ full integration, rather than a B-bar method, to better deal with compressible behavior. If IHYPER = ±10 on *MAT_USER_DEFINED_MATERIAL_MODELS, this will also invoke full integration of the hyperelastic user material.

14. **Smoothed Particle Galerkin (SPG) method: Type 47.** With the SPG method, LS-DYNA converts finite element nodes into particles. This method supports 4-noded, 6-noded, and 8-noded *solid* elements. The method is suitable for severe deformation and failure analysis.

15. **1-Point Tetrahedron: Type 60.** Aside from including additional averaging of element volumetric locking, element type 60 is identical to type 10. In contrast to type 13, type 60 averages the normal stress between two adjacent elements, so nodes can be shared between the different materials with different bulk moduli. This element supports explicit analysis but is still under development for implicit simulations.

16. **Higher Order Elements.** Quadratic solids (ELFORM = 24, 25, and 26) and cubic solids (ELFORM = 27, 28, and 29) remain under development.

17. **Incompatible Modes Elements: Types -18 and 18.**

    a) Element type -18 is available for both implicit and explicit analysis. This is an 8-point integrated element, using 9 (Wilson) modes to alleviate Poisson locking in bending and another 4 to alleviate volumetric locking. The element is costly for explicit analysis; an additional factor of between 2 and 5 in simulation time is expected compared to element type 2. The exact number depends on the number of iterations needed to solve the compatibility equation for each element; typically, more iterations are needed for severely deformed elements and/or nonlinear effects in materials. In implicit analysis, the expense of the element is the same as in explicit, but this cost becomes insignificant relative to the global linear algebra. Increased accuracy seems to compensate for the cost. Therefore, the element should perform well in many types of analyses.

    b) Element type 18 is a similar element formulation to -18 but uses 9 integration points instead of 8. Similar to -18, it uses 9 modes to alleviate Poisson locking in bending. Unlike -18, it uses 3 instead of 4 incompatible modes

for the volumetric treatment. This element is not available for explicit analysis, and when used, it will be switched to element formulation 1. Both elements 18 and -18 are based on the works of Simo and Rafai (1990) and Simo et al. (1993).

18. **Fully Integrated QBI Element.** Element form 62 is a fully integrated 8 node hexahedral element that uses an assumed strain field to prevent shear and volumetric locking and enhance bending stiffness. In Belytschko and Bindeman (1993), this assumed strain field is called the quintessential bending incompressible or QBI field. Element form 62 is available for implicit and explicit analysis. It is about 10% slower in explicit analyses than the fully integrated element formulation 2.

19. **EFG Solid Elements: Types 41 and 42.** EFG element type 41 is supported for 4-node, 6-node, and 8-node solid elements. Element type 42 is only supported for 4-node tetrahedral meshes, but it is optimized to achieve better computational efficiency than 41. For three-dimensional tetrahedron *r*-adaptive analysis (ADPTYP = 7 in *CONTROL_ADAPTIVE and ADPOPT = 2 in *PART), the initial mesh must be purely comprised of tetrahedrons, and element type 42 should be used.

    The EFG method still uses elements (so-called background elements or cells) to integrate nodal forces and stiffness in implicit analysis. The number of integration points for EFG depends on the EFG formulation and element type. For EFG type 41, the standard EFG formulation (IDIM = 1, 2, and 3) always allocates memory for 8 integration points, but the actual number of points used for the domain integration changes with the type of background element: 8 points for an 8-node element, 2 for a 6-node element, and 1 for a 4-node element. The stabilized formulation (IDIM = -1) only allocates and uses one integration point. It applies to 6-node elements, 8-node elements, or a mixed mesh of these two types of cells. EFG type 42 has only the standard formulation. It uses and allocates memory for one integration point since it applies to a pure tetrahedral mesh.

20. **Automatic Sorting for EFG Background Mesh.** The current EFG formulation performs automatic sorting for finite element tetrahedral, pentahedron, and hexahedral elements of the background mesh to identify the mesh-free geometry and provide the contact surface definition in the computation.

21. **Essential Boundary Conditions.** The mixed transformation method, the coupled FEM/EFG method, and the fast transformation method were implemented for the EFG 3D solid formulation. These three features were added to improve the efficiency of the imposition of essential boundary conditions and the transfer of actual nodal and generalized nodal values. The mixed transformation method is equivalent to the full transformation method with improved efficiency. The behavior of the coupled FEM/EFG method is between FEM and

EFG. The fast transformation method provides the most efficient and robust results.

22. **IDIM.** For compressible materials like foam and soil, IDIM = 1 is recommended. IDIM = 2 (default) is recommended for nearly incompressible materials like metal and rubber.

23. **TOLDEF.** This field is introduced to improve the negative volume problem usually seen during large deformation analysis. For the same analysis, the larger the magnitude of TOLDEF, the earlier the Semi-Lagrangian or Eulerian kernel is introduced into the EFG computation, so more CPU time is expected. A value between 0.0 and 0.1 is suggested for crashworthiness analysis. We suggest the Semi-Lagrangian kernel for solid materials and the Eulerian kernel for fluid and EOS materials.

24. **EFG Fracture.** The EFG fracture method (IDIM = -2) is obsolete. For ductile failure, consider using *SECTION_SOLID_SPG.

*SECTION_SOLID_PERI

Purpose: Define section properties for Peridynamics solid and laminate elements.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ELFORM						
Type	I/A	I						

Card 2	1	2	3	4	5	6	7	8
Variable	DR	PTYPE						
Type	F	I						
Default	1.01	1						

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ELFORM	Element formulation options (see Remarks): EQ.48: Peridynamics element formulation. This formulation works for both peridynamics solids (4, 6 and 8 node elements) and peridynamics laminates (4 node surface elements)
DR	Normalized horizon size, 0.6 – 1.2 is recommended
PTYPE	Peridynamics formulation: EQ.1: Bond based formulation (default)

Remarks:

1. **Peridynamics Solids.** The elements in a Peridynamics solid part should be defined with *ELEMENT_SOLID. These elements can be meshed with a 3D solid mesher. To represent material split, the elements should not share nodes. Thus, shared corners will have coincident nodes, one for each element. The total

number of nodes is then the summation over the number of elements of the number of nodes in each element.

2. **Peridynamics Laminates.** Elements in a Peridynamics laminate part should be specified with *ELEMENT_SOLID_PERI. See *ELEMENT_SOLID_PERI.

***SECTION_SPH**_*{OPTION}*

Available options include:

<BLANK>

ELLIPSE

INTERACTION (See Remark 3)

USER (See Remark 2)

Purpose: Define section properties for SPH particles.

> **NOTE:** This feature is not supported for use in implicit calculations.

Card Sets. For each SPH section add one set of the following cards (depending on the keyword option). This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	CSLH	HMIN	HMAX	SPHINI	DEATH	START	SPHKERN
Type	I/A	F	F	F	F	F	F	I
Default	none	1.2	0.2	2.0	0.0	10^{20}	0.0	0

Ellipse Card. Additional card for ELLIPSE keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	HXCSLH	HYCSLH	HZCSLH	HXINI	HYINI	HZINI		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.

VARIABLE	DESCRIPTION
CSLH	Constant used to calculate the initial smoothing length of the particles. The default value works for most problems. Values between 1.05 and 1.3 are acceptable. Taking a value less than 1 is inadmissible. Values larger than 1.3 will increase the computational time. The default value is recommended. See Remark 1.
HMIN	Scale factor for the minimum smoothing length. Ignored if FORM = 12 in *CONTROL_SPH. See Remark 1.
HMAX	Scale factor for the maximum smoothing length. Ignored if FORM = 12 in *CONTROL_SPH. See Remark 1.
SPHINI	Optional initial smoothing length (overrides true smoothing length). With this option LS-DYNA will not calculate the smoothing length during initialization, and the field CSLH is ignored.
DEATH	Time imposed SPH approximation is stopped.
START	Time imposed SPH approximation is activated.
SPHKERN	Option for SPH kernel functions (smoothing functions): EQ.0: Cubic spline kernel function (default). EQ.1: Quintic spline kernel function: a higher order smoothing function with a larger support size. It is only available for the 3D case with FORM = 0, 1, 5, 6, 9 and 10 (see *CONTROL_SPH). EQ.2: Quadratic spline kernel function: it helps to relieve the problem of compressive instability and aims for HVI problems. It is only available for the 3D case with FORM = 0, 1, 5, and 6 (see *CONTROL_SPH). EQ.3: Quartic kernel function: this kernel function is very close to cubic spline kernel function but is more stable. It is only available for the 3D case with FORM = 0, 1, 5, and 6 (see *CONTROL_SPH).
HXCSLH	Constant applied for the smoothing length in the x-direction for the ellipse case.
HYCSLH	Constant applied for the smoothing length in the y-direction for the ellipse case.
HZCSLH	Constant applied for the smoothing length in the z-direction for the ellipse case.

VARIABLE	DESCRIPTION
HXINI	Optional initial smoothing length in the x-direction for the ellipse case (overrides true smoothing length)
HYINI	Optional initial smoothing length in the y-direction for the ellipse case (overrides true smoothing length)
HZINI	Optional initial smoothing length in the z-direction for the ellipse case (overrides true smoothing length)

Remarks:

1. **Smoothing Length.** The SPH processor in LS-DYNA employs a variable smoothing length. LS-DYNA computes the initial smoothing length, h_0, for each SPH part by taking the maximum of the minimum distance between every particle and then scaling this value by CSLH. The recommended values of CSLH should be used so that the radius of the support domain covers more than two layers of SPH particles along each direction. Every particle has its own smoothing length which varies in time according to the following equation:

$$\frac{d}{dt}h(t) = h(t)\nabla \cdot \mathbf{v} \ ,$$

where $h(t)$ is the smoothing length, and $\nabla \cdot \mathbf{v}$ is the divergence of the flow. The smoothing length increases as particles separate and reduces as the concentration increases. This scheme is designed to hold constant the number of particles in each neighborhood. In addition to being governed by the above evolution equation, the smoothing length is constrained to be between a user-defined upper and lower value,

$$\text{HMIN} \times h_0 < h(t) < \text{HMAX} \times h_0.$$

Defining a value of 1 for HMIN and 1 for HMAX will result in a constant smoothing length in time and space.

When formulation 12 is employed (FORM = 12 in *CONTROL_SPH), the smoothing length remains constant with HMIN and HMAX set to 1.0 internally.

2. **USER Option.** The USER option allows the definition of customized subroutine for the variation of the smoothing length. A subroutine called *hdot* is defined in the file dyn21.F (Unix/linux) or lsdyna.f (Windows).

3. **Inter-Part Particle Interaction.** There are two fundamental ways that particles from different SPH parts can interact with each other. One way is through "particle approximation" and the other way is through *DEFINE_SPH_TO_SPH_-

COUPLING. When CONT = 0 in *CONTROL_SPH, "particle approximation" is used for all SPH parts in treating inter-part particle interaction. When CONT = 1 in *CONTROL_SPH, inter-part particle interaction by "particle approximation" occurs only for those SPH parts that use *SECTION_SPH_INTERACTION, while any SPH part that does not make use of *SECTION_SPH_INTERACTION will not participate in inter-part particle interaction, *except* as defined using *DEFINE_SPH_TO_SPH_COUPLING.

*SECTION_TSHELL

Purpose: Define section properties for thick shell elements.

Card Sets. For each TSHELL section include a set of the following cards. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SECID	ELFORM	SHRF	NIP	PROPT	QR	ICOMP	TSHEAR
Type	I/A	I	F	I	I	F	I	I
Default	none	1	1.0	2	1	0.0	0	0

Angle Cards. If ICOMP = 1 specify NIP angles putting 8 on each card. Include as many cards as necessary.

Card 2	1	2	3	4	5	6	7	8
Variable	B1	B2	B3	B4	B5	B6	B7	B8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
SECID	Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.
ELFORM	Element formulation: EQ.1: one point reduced integration (default), EQ.2: selective reduced 2 × 2 in plane integration. EQ.3: assumed strain 2 × 2 in plane integration, see remark below. EQ.5: assumed strain reduced integration with brick materials EQ.6: assumed strain reduced integration with shell materials EQ.7: assumed strain 2 × 2 in plane integration.
SHRF	Shear factor. A value of 5/6 is recommended (see Remark 4).

VARIABLE	DESCRIPTION
NIP	Number of through thickness integration points for the thick shell. See the variable INTGRD in *CONTROL_SHELL for details of the through thickness integration rule. EQ.0: set to 2 integration points.
PROPT	Printout option: EQ.1: average resultants and fiber lengths, EQ.2: resultants at plan points and fiber lengths, EQ.3: resultants, stresses at all points, fiber lengths.
QR	Quadrature rule: LT.0.0: absolute value is specified rule number, EQ.0.0: Gauss (up to ten points are permitted), EQ.1.0: trapezoidal, not recommended for accuracy reasons.
ICOMP	Flag for layered composite material mode: EQ.1: a material angle is defined for each through thickness integration point. For each layer one integration point is used.
TSHEAR	Flag for transverse shear strain or stress distribution (see Remarks 4 and 5): EQ.0: Parabolic, EQ.1: Constant through thickness.
B1	β_1, material angle at first integration point. The same procedure for determining material directions is use for thick shells that is used for the 4 node quadrilateral shell.
B2	β_2, material angle at second integration point
B3	β_3, material angle at third integration point
⋮	⋮
BNIP	β_{NIP}, material angle at NIPth integration point

Remarks:

1. **Thick Shell Element Formulations.** Thick shell elements are bending elements that have 4 nodes on the bottom face and 4 on the top face. Thick shell element formulations 1, 2 and 6 are extruded thin shell elements and use thin shell material models and have an uncoupled stiffness in the z-direction. Thick shell element formulations 3, 5, and 7 are layered brick elements that use 3D brick material models. Thick shell formulations 3 and 5, and 6 are distortion sensitive and should not be used in situations where the elements are badly shaped. A single thick shell element through the thickness will capture bending response, but with thick shell formulation 3, at least two elements through the thickness are recommended to avoid excessive softness.

2. **Formulation 1 Quadrature Quirk.** When using Gaussian quadrature with element formulation 1, the number of integration points is automatically switched to 3 when NIP = 2 and 5 when NIP = 4.

3. **Implicit Time Integration.** Thick shell elements are available for implicit analysis with the exception of thick shell formulation 1. If an element of type 1 is specified in an implicit analysis, it is internally switched to type 2

4. **SHRF Field.** For ELFORM = 1, 2 and 6, the transverse shear stiffness is scaled by the SHRF parameter. Since the strain is assumed to be constant through the thickness, setting SHRF = 5/6 is recommended to obtain the correct shear energy. For ELFORM = 3 and 5, the SHRF parameter is not used, except for material types 33, 36, 133, 135, and 243. For ELFORM = 3, the shear stiffness is assumed constant through the thickness. For ELFORM = 5, 6, and 7, the shear distribution is assumed either parabolic if TSHEAR = 0, or constant if TSHEAR = 1. The parabolic assumption is good when the elements are used in a single layer to model a shell type structure, but the constant option may be better when elements are stacked one on top of the other.

5. **Modeling Composites.** Thick shell elements of all formulations can be used to model layered composites, but element formulations 5 and 6 use assumed strain to capture the complex Poisson's effects and through thickness stress distribution in layered composites. To define the layers of a composite, use QR < 0 to point to *INTEGRATION_SHELL data. Alternatively, the *PART_COMPOSITE_TSHELL keyword offers a simplified way to define the layers.

   When modeling composites, laminated shell theory may be used to correct the transverse shear strain if the shear stiffness varies by layer. Laminated shell theory is activated by setting LAMSHT = 4 or 5 on *CONTROL_SHELL. When laminated shell theory is active, the TSHEAR parameter works with all ELFORM values to select either a parabolic or constant shear stress distribution.

*SENSOR

The keyword *SENSOR provides a convenient way of activating and deactivating boundary conditions, airbags, discrete elements, joints, contact, rigid walls, single point constraints, and constrained nodes. The sensor capability is available as of the second release of version 971 and will evolve in later releases to encompass many more LS-DYNA capabilities and replace some of the existing capabilities, such as the airbag sensor logic. The keyword commands in this section are defined below in alphabetical order:

*SENSOR_CONTROL

*SENSOR_CPM_AIRBAG

*SENSOR_DEFINE_CALC-MATH

*SENSOR_DEFINE_ELEMENT

*SENSOR_DEFINE_FORCE

*SENSOR_DEFINE_FUNCTION

*SENSOR_DEFINE_MISC

*SENSOR_DEFINE_NODE

*SENSOR_SWITCH

*SENSOR_SWITCH_CALC-LOGIC

*SENSOR_SWITCH_SHELL_TO_VENT

An additional option **TITLE** may be appended to all the ***SENSOR** keywords. If this option is used, then an addition line is read for each sensor in 80a format which can be used to describe the sensor. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

To define and use a sensor, three categories of sensor keyword commands are needed as shown in Figure 40-1.

1. Sensors are defined using the *SENSOR_DEFINE commands. Sensors provide a time history of model response that may be referred to by *SENSOR_SWITCH as a switching criterion. (Note: The time history of any sensor can be output using the SENSORD function in *DEFINE_CURVE_FUNCTION and *DATABASE_CURVOUT.)

   a) *SENSOR_DEFINE(_ELEMENT, _FORCE, _MISC, _NODE)

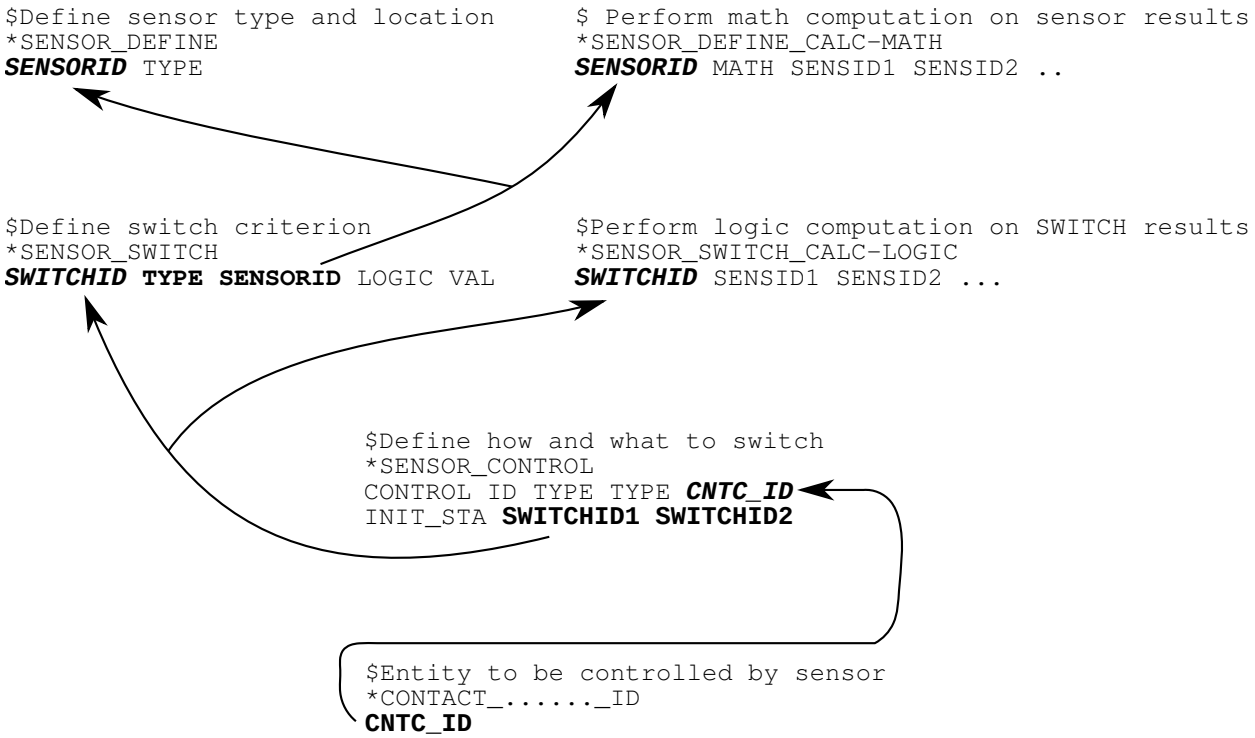

Figure 40-1. Relationship between sensor keyword definitions.

These commands define a sensor's ID, type, and location.

b) *SENSOR_DEFINE_CALC-MATH, *SENSOR_DEFINE_FUNCTION

These commands define a sensor whose value is a mathematical expression involving the values from other sensors.

2. The *SENSOR_SWITCH family of keywords define sensor switching criterion. *SENSOR_SWITCH can be combined with the logical calculation command *SENSOR_SWITCH_CALC-LOGIC for more complicated definitions. The logic value yielded by this category of commands can be referred by *SENSOR_CONTROL to determine if a status switch condition is met.

a) *SENSOR_SWITCH

This command compares the numerical value from *SENSOR_DEFINE or *SENSOR_DEFINE_CALC-MATH with the given criterion to see if a switching condition is met.

b) *SENSOR_SWITCH_CALC-LOGIC

This command performs logical calculation on the information from SENSOR_SWITCH.

3. *SENSOR_CONTROL determines how and what to switch based on the logical values from *SENSOR_SWITCH and/or *SENSOR_SWITCH_CALC-LOGIC.

*SENSOR_CONTROL

Purpose: This command uses switches (*SENSOR_SWITCH) to toggle on or off the effects of other LS-DYNA keywords, such as *CONTACT or *AIRBAG.

Card Summary:

Card Sets. For each sensor control, include a set of the following cards. This input ends at the next keyword ("*") card.

Card 1a. This card is included for all values of TYPE, except PRESC-MOT, PRESC-ORI, PRESSURE, and ELESET.

CNTLID	TYPE	TYPEID		NREP			

Card 1b. This card is included for TYPE = PRESC-MOT, PRESC-ORI, or PRESSURE (controlling *BOUNDARY_PRESCRIBED_MOTION, *BOUNDARY_PRESCRIBED_-RIGID_ORIENTATION, or *LOAD_SEGMENT_SET).

CNTLID	TYPE	TYPEID	TIMEOFF	NREP			

Card 1c. This card is included for TYPE = ELESET (controlling erosion of a set of elements of a specified type).

CNTLID	TYPE	TYPEID	IDISCL	NREP	ESTYP		

Card 2. This card is required.

INITSTT	SWIT1	SWIT2	SWIT3	SWIT4	SWIT5	SWIT6	SWIT7

All other values of Type Card. This card is included for all values of TYPE, except PRESC-MOT, PRESC-ORI, PRESSURE, and ELESET.

Card 1a	1	2	3	4	5	6	7	8
Variable	CNTLID	TYPE	TYPEID		NREP			
Type	I	A	I		I			

VARIABLE	DESCRIPTION
CNTLID	Sensor control ID

VARIABLE	DESCRIPTION
TYPE	Entity to be controlled:
	EQ.AIRBAG: *AIRBAG
	EQ.BAGVENTPOP: Opening and closing the airbag venting holes (see Remark 1)
	EQ.BELTPRET: Belt pretensioner firing (see Remark 2)
	EQ.BELTRETRA: Locking the belt retractor (see Remark 2)
	EQ.BELTSLIP: Controlling the slippage of slip ring element (see Remark 3)
	EQ.CONTACT: *CONTACT
	EQ.CONTACT2D: *CONTACT_2D
	EQ.CONSTRL: *CONSTRAINED_LOCAL
	EQ.CNRB: *CONSTRAINED_NODAL_RIGID_-BODY
	EQ.CPM: *AIRBAG_PARTICLE
	EQ.DEF2RIG: *DEFORMABLE_TO_RIGID_AUTOMATIC (see Remark 4)
	EQ.EM: EM solver (see Remark 6)
	EQ.FUNCTION: *DEFINE_CURVE_FUNCTION (see Remark 5)
	EQ.JOINT: *CONSTRAINED_JOINT
	EQ.JOINTSTIF: *CONSTRAINED_JOINT_STIFFNESS
	EQ.LOADTHM: *LOAD_THERMAL_VARIABLE
	EQ.M PRESSURE: *LOAD_MOVING_PRESSURE
	EQ.POREAIR: *MAT_ADD_PORE_AIR
	EQ.PZBC: *BOUNDARY_PZEPOT
	EQ.RWALL: *RIGID_WALL
	EQ.SPC: *BOUNDARY_SPC
	EQ.SPOTWELD: *CONSTRAINED_SPOTWELD
	EQ.BPWPN: *BOUNDARY_PWP_NODE/SET_ID

VARIABLE	DESCRIPTION
TYPEID	ID of entity to be controlled if TYPE ≠ FUNCTION, LOADTHM, or POREAIR. If TYPE = FUNCTION, see Remark 5. For TYPE = LOADTHM, TYPEID is the node set for which the temperature boundary condition specified by either *LOAD_THERMAL_VARIABLE or *LOAD_THERMAL_VARIABLE_NODE will be controlled. For TYPE = POREAIR, TYPEID is the ID of the part containing material with pore air.
NREP	Number of times to repeat a cycle of switches, SWIT*n*, defined on Card 2. For example, a definition of SWIT*n* like "601, 602, 601, 602, 601, 602" can be replaced by setting NREP to 3 and SWIT*n* to "601, 602". Setting NREP = -1 repeats the cycle for an infinite number of times. Default is 0.

TYPE PRESC-MOT, PRESC-ORI, and PRESSURE Card. This card is included for TYPE = PRESC-MOT, PRESC-ORI, or PRESSURE.

Card 1b	1	2	3	4	5	6	7	8
Variable	CNTLID	TYPE	TYPEID	TIMEOFF	NREP			
Type	I	A	I	I	I			

VARIABLE	DESCRIPTION
CNTLID	Sensor control ID
TYPE	Entity to be controlled: EQ.PRESC-MOT: *BOUNDARY_PRESCRIBED_MOTION EQ.PRESC-ORI: *BOUNDARY_PRESCRIBED_ORIENTATION_RIGID EQ.PRESSURE: *LOAD_SEGMENT_SET
TYPEID	ID of entity to be controlled
TIMEOFF	Flag to offset time in curve: EQ.0: No offset is applied. EQ.1: Offset the abscissa of the time-dependent curve by the time value at which the sensor is triggered.

Type Of Control	Curve Affected

VARIABLE	DESCRIPTION

PRESSURE	*LOAD_SEGMENT_SET
PRESC-MOT	*BOUNDARY_PRESCRIBED_MOTION
PRESC-ORI	*BOUNDARY_PRESCRIBED_ORIENTATION_RIGID

NREP — Number of times to repeat a cycle of switches, SWIT*n*, defined on Card 2. For example, a definition of SWIT*n* like "601, 602, 601, 602, 601, 602" can be replaced by setting NREP to 3 and SWIT*n* to "601, 602". Setting NREP = -1 repeats the cycle for an infinite number of times. Default is 0.

TYPE ELESET Card. This card is included when TYPE is ELESET.

Card 1c	1	2	3	4	5	6	7	8
Variable	CNTLID	TYPE	TYPEID	IDISCL	NREP	ESTYP		
Type	I	A	I	I	I	A		

VARIABLE	DESCRIPTION

CNTLID — Sensor control ID

TYPE — Entity to be controlled:

EQ.ELESET: Element set; see "ESTYP" below.

TYPEID — ID of entity to be controlled

IDISCL — For ESTYP = DISC, flag for updating the reference length of the discrete element with its length when it is turned on:

EQ.0: Discrete element's reference length remains the same when it is turned on.

EQ.1: Discrete element's length when it is turned on is used as its new reference length.

NREP — Number of times to repeat a cycle of switches, SWIT*n*, defined on Card 2. For example, a definition of SWIT*n* like "601, 602, 601, 602, 601, 602" can be replaced by setting NREP to 3 and SWIT*n* to "601, 602". Setting NREP = -1 repeats the cycle for an infinite number of times. Default is 0.

VARIABLE	DESCRIPTION
ESTYP	Type of element set to be controlled. With initial status set to "ON," all the elements included in set TYPEID can be eroded when the controller status is changed to "OFF." When TYPEID is not defined, all elements of type ESTYP in the whole system will be eroded. EQ.BEAM: Beam element set EQ.DISC: Discrete element set EQ.SHELL: Thin shell element set EQ.SOLID: Solid element set EQ.TSHELL: Thick shell element set

Card 2	1	2	3	4	5	6	7	8
Variable	INITSTT	SWIT1	SWIT2	SWIT3	SWIT4	SWIT5	SWIT6	SWIT7
Type	A	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
INITSTT	Initial status: EQ.On: Initial status is on. EQ.Off: Initial status is off.
SWIT*n*	ID of n^{th} switch. At the start of the calculation SWIT1 is *active*, meaning that it controls the state of the feature specified in TYPEID. After SWIT1 triggers, then SWIT2 becomes active; after SWIT2 triggers, then SWIT3 becomes active; this process will continue until the entire stack of switches has been exhausted.

Remarks:

1. **Activation of Bag Venting.** BAGVENTPOP activates (opens) or deactivates (closes) the venting holes of *AIRBAG_HYBRID and *AIRBAG_-WANG_NEFSKE. It overwrites the definitions of PVENT of *AIRBAG_HYBRID and PPOP of *AIRBAG_WANG_NEFSKE. More than one switch can be input to open/close initially closed/opened holes, and then reclose/reopen the holes.

2. **Seatbelt Retractors.** The locking (or firing) of seatbelt retractor (or pretensioner) can be controlled through either general sensor, option BELTRETRA (or BELTPRET), or seatbelt sensors, *ELEMENT_SEATBELT_SENSOR. When BELTRETRA (or BELTPRET) is used, the SBSID*i* in *ELEMENT_-SEATBELT_RETRACTOR (or PRETENSIONER) should be left blank.

3. **Seatbelt Slip Ring.** For a one-way slip ring, a non-zero DIRECT in *ELEMENT_SEATBELT_SLIPRING, BELTSLIP activates the constraint of one-way slippage when the status of *SENSOR_CONTROL is on. When the *SENSOR_-CONTROL is turned off, the one-way slippage constraint is deactivated, therefore allowing slippage in both directions.

   For a two-way slip ring (DIRECT = 0), BELTSLIP activates slippage in both directions when the status of *SENSOR_CONTROL is on. When the status of *SENSOR_CONTROL is off, the slip ring locks up, allowing no slippage.

4. **Switching Between Rigid and Deformable.** DEF2RIG provides users more flexibility controlling the material switch between rigid and deformable. Status of ON triggers the switch, so the deformable material becomes rigid. Rigidized material can then return to deformable status when status becomes OFF. As many as 7 switches can be input; any of them will change the status triggered by its preceding switch or the initial condition, INTSTT.

5. **Function for Sensor Control.** When the input parameter TYPE of *SENSOR_-CONTROL is set to "FUNCTION", the function "SENSOR(cntlid)" as described in *DEFINE_CURVE_FUNCTION takes on a value that depends on the current status of the *SENSOR_CONTROL. That status is either on or off at any given point in time. If the status is on, the value of function SENSOR(cntlid) is set to the integer value 1. If the status is off, the value of function SENSOR(cntlid) is set to the input parameter TYPEID (an integer) as specified in *SENSOR_CONTROL.

   To help clarify the relationship between *SENSOR_CONTROL and *DEFINE_-CURVE_FUNCTION, consider the following example. Suppose a *SENSOR_-CONTROL defined with CNTLID = 101, TYPE="FUNCTION", and TYPEID = -2 has a status of off. Then a *DEFINE_CURVE_FUNCTION defined as “2+3*sensor(101)” will have a value of 2 + 3(-2) = -4. On the other hand, if the status of the *SENSOR_CONTROL changes to on, the *DEFINE_CURVE_FUNCTION takes on a value of 2 + 3(1) = 5.

6. **EM Solver.** TYPE = EM can be used to turn on/off EM solver. Since it serves the same function as *EM_CONTROL_SWITCH, it cannot be in an input deck with *EM_CONTROL_SWITCH.

***SENSOR_CPM_AIRBAG**_*{OPTION}*

Available options include:

ID

TITLE

OPTION provides a means to specify an airbag ID number and a heading for the airbag.

Purpose: This command will associate a CPM airbag with a sensor switch (see *SENSOR_SWITCH). When the condition flag is raised, the specified CPM airbag will deploy. All time dependent curves used for the CPM airbag are shifted by the activation time including the *AIRBAG_PARTICLE curves for the inflator and vent as well as the *MAT_FABRIC curves for TSRFAC.

ID Card. Additional card for the ID or TITLE keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ABID	HEADING						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	CPMID	SWITID	TBIRTH	TDEATH	TDR	DEFPS	RBPID	
Type	I	I	F	F	F	I	I	

VARIABLE	DESCRIPTION
ABID	Airbag ID
HEADING	Airbag descriptor
CPMID	Bag ID of *AIRBAG_PARTICLE_ID
SWITID	Switch ID of *SENSOR_SWITCH

VARIABLE	DESCRIPTION
TBIRTH	If SWITID is set, TBIRTH is not active. If SWITID is 0, TBIRTH is the activation time for the bag with ID = CPMID. All of the time dependent curves that are used in this bag will be offset by the value of TBIRTH.
TDEATH	Disable the CPMID bag when the simulation time exceeds this value.
TDR	If TDR is greater than 0 the bag with ID = CPMID will be rigid starting at first cycle and switch to deformable at time TDR.
DEFPS	Part set ID specifiying which parts of the bag with ID = CPMID are deformable.
RBPID	Part ID of the rigid body to which the part is merged.

***SENSOR_DEFINE_CALC-MATH**_{OPTION}

Available options include:

<BLANK>

UPDATE

With the UPDATE keyword option, you can specify the birth time, death time, and value update frequency for the sensor. Note that without the UPDATE keyword option LS-DYNA updates the sensor value every time step.

Purpose: Defines a new sensor with a unique ID. The values associated with this sensor are computed by performing mathematical calculations with the information obtained from sensors defined by the *SENSOR_DEFINE_*OPTION*.

Card Summary:

Card 1. Include this card or, if using the UPDATE keyword option, a set of this card and Card 2 for each math sensor. This input ends at the next keyword ("*") card.

SENSID	CALC	SENS1	SENS2	SENS3	SENS4	SENS5	SENS6

Card 2. Include a set of Card 1 and this card if using the UPDATE keyword option.

BIRTH	DEATH	DTUPD					

Data Card Definitions:

Math Sensor Cards. For each math sensor, include this card or, if using the UPDATE keyword option, a set of this card and Card 2. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SENSID	CALC	SENS1	SENS2	SENS3	SENS4	SENS5	SENS6
Type	I	A	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SENSID	Sensor ID
CALC	Mathematical calculation. See Table 40-2.

VARIABLE	DESCRIPTION
SENS*i*	i^{th} Sensor ID

UPDATE Card. Include a set of Card 1 and this card if using the UPDATE keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH	DTUPD					
Type	F	F	F/I					

VARIABLE	DESCRIPTION
BIRTH	Birth time of this sensor
DEATH	Death time of this sensor
DTUPD	Time interval between updates. If negative, -DTUPD is the curve defining update interval as a function of time.

Remarks:

All sensors, SENS*i*, defined with either SENSOR_DEFINE_NODE_SET or SENSOR_DEFINE_ELEMENT_SET, must refer to either the same node set or the same element set.

Mathematical Functions:

FUNCTION	DESCRIPTION	MATHEMATICAL FORM
ABSSUM	Absolute value of the sum of sensor values	$\lvert SENS1 + SENS2 + \cdots \rvert$
MIN	The minimum of sensor values	$\min(SENS1, SENS2, \ldots)$
MAX	The maximum of sensor values	$\max(SENS1, SENS2, \ldots)$
MAXMAG	The maximum of magnitude of sensor values	$\max(\lvert SENS1 \rvert, \lvert SENS2 \rvert, \ldots)$
MINMAG	The minimum of the magnitude of sensor values	$\min(\lvert SENS1 \rvert, \lvert SENS2 \rvert, \ldots)$
MULTIPLY	Multiplication of sensor values; negative for division (performed left to right)	$SENS1 \times SENS2 \times \cdots$

FUNCTION	DESCRIPTION	MATHEMATICAL FORM
SQRE	Summation of squared values of sensor values	$SENS1^2 + SENS2^2 + \cdots$
SQRTSQRE	Square root of the sum of squared values	$\sqrt{SENS1^2 + SENS2^2 + \cdots}$
SQRT	Summation of square root of sensor values; negative for subtracting values	$\sqrt{SENS1} + \sqrt{SENS2} + \cdots$
SUMABS	Summation of absolute sensor values	$\lvert SENS1\rvert + \lvert SENS2\rvert + \cdots$
SUM	Summation of sensor values; negative for subtracting values	$SENS1 + SENS2 + \cdots$

Table 40-2. Available mathematical functions.

Example:

```
$
$ assume set_2 to have 100 solid elements
*SENSOR_DEFINE_ELEMENT_SET
$ this sensor traces xx-strain of all 100 solid elements in set-2
        91     SOLID        -2        XX    STRAIN
*SENSOR_DEFINE_ELEMENT_SET
$ this sensor traces yy-strain of all 100 solid elements in set-2
        92     SOLID        -2        YY    STRAIN
*SENSOR_DEFINE_ELEMENT_SET
$ this sensor traces zz-strain of all 100 solid elements in set-2
        93     SOLID        -2        ZZ    STRAIN
*SENSOR_DEFINE_CALC-MATH
$ this sensor traces strain magnitudes of all 100 solid elements in set-2
       104  SQRTSQRE        91        92        93         0         0         0
*SENSOR_SWITCH
$ Because ELEMID of *sensor_define_element_set was input as "-2", SWITCH-1 will be
$ turned on if at least one of 100 elements has a strain magnitude>2.0E-4
$ On the other hand, If ELEMID was input as "2", SWITCH-1 will be turned on if
$ all 100 elements have strain magnitudes>2.0E-4
         1    SENSOR       104        GT    2.0E-4         0     0.001
$
```

*SENSOR_DEFINE_ELEMENT_{OPTION1}_{OPTION2}

For *OPTION1* the available options are:

<BLANK>

SET

With the SET option active, the sensor value or values depends on a set of elements. See Remark 1.

For *OPTION2* the available options are:

<BLANK>

UPDATE

With the UPDATE keyword option, you can specify the birth time, death time, and value update frequency for the sensor. Note that without the UPDATE keyword option LS-DYNA updates the sensor value every time step.

Purpose: Define a strain gage type element sensor that checks the stress, strain, or resultant force of an element or element set.

Card Summary:

Card Sets. For each element sensor matching the specified keyword options include one set of the following data cards. Include as many sets as needed. This input ends at the next keyword ("*") card.

Card 1. This card is required.

SENSID	ETYPE	ELEMID	COMP	CTYPE	LAYER	SF	PWR

Card 2. This card is included only if the SET option is used. If only one element set is specified and the UPDATE keyword option is not used, this card may be omitted if not needed. Otherwise, it must be included, but it may be left blank. Note that if this card is included and ELEMID < 0, then this card must be blank.

SETOPT							

Card 3. This card is included if the UPDATE keyword option is used.

BIRTH	DEATH	DTUPD					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SENSID	ETYPE	ELEMID	COMP	CTYPE	LAYER	SF	PWR
Type	I	A	I	A	A	A/I	R	R

VARIABLE	DESCRIPTION
SENSID	Sensor ID
ETYPE	Element type. Available options include: EQ.BEAM: Beam element EQ.SHELL: Shell element EQ.SOLID: Solid element EQ.DISC-ELE: Discrete element EQ.SEATBELT: Seatbelt element EQ.TSHELL: Thick shell element
ELEMID	Element ID or element set ID when the SET keyword option is active. In the case of the SET keyword option with SETOPT not defined, determining the status of a related *SENSOR_SWITCH depends on the sign of ELEMID. If SETOPT is defined, then ELEMID must be greater than 0. See Remark 1.
COMP	Component type. The definition of component, and its related coordinate system, is consistent with that of elout. Leave blank for discrete elements. Available options for elements other than discrete element include: EQ.XX: x-normal component for shells and solids EQ.YY: y-normal component for shells and solids EQ.ZZ: z-normal component for shells and solids EQ.XY: xy-shear component for shells and solids EQ.YZ: yz-shear component for shells and solids EQ.ZX: zx-shear component for shells and solids

VARIABLE	DESCRIPTION
	EQ.AXIAL: Axial EQ.SHEARS: Local *s*-direction EQ.SHEART: Local *t*-direction
CTYPE	Sensor type: EQ.STRAIN: Strain component for shells and solids EQ.STRESS: Stress component for shells and solids EQ.FORCE: Force resultants for beams, seatbelt, or translational discrete element; moment resultant for rotational discrete element EQ.MOMENT: Moment resultants for beams EQ.DLEN: Change in length for discrete or seatbelt element EQ.FAIL: Failure of element, sensor value = 1 when element fails, = 0 otherwise.
LAYER	Layer of integration point in shell or thick shell element. Options include: EQ.BOT: Component at lower surface meaning the integration point with the smallest through-the-thickness local coordinate EQ.TOP: Component at upper surface meaning the integration point with the largest through-the-thickness local coordinate When CTYPE = STRESS, LAYER could be an integer i to monitor the stress of the i^{th} integration point.
SF, PWR	Optional parameters, scale factor and power, for users to adjust the resultant sensor value. The resultant sensor value is $[\text{SF} \times (\text{Original Value})]^{\text{PWR}}$

SET Card. Additional card for the SET keyword option. If you specify more than one element set sensor or additionally use the UPDATE keyword option, this card must be included for each set sensor even if left blank. If ELEMID < 0 and this card is included, it must be blank.

Card 2	1	2	3	4	5	6	7	8
Variable	SETOPT							
Type	A							
Default	Optional							

VARIABLE	DESCRIPTION
SETOPT	Option to process set of data when the SET keyword option is specified (see Remark 1). If you set SETOPT, then ELEMID must be greater than 0. When SETOPT is defined, a single value will be reported. The single reported value could be: EQ.AVG: The average value of the dataset EQ.MAX: The maximum value of the dataset EQ.MIN: The minimum value of the dataset EQ.SUM: The sum of the dataset

UPDATE Card. This card is included if the UPDATE keyword option is used.

Card 3	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH	DTUPD					
Type	F	F	F/I					

VARIABLE	DESCRIPTION
BIRTH	Birth time of this sensor
DEATH	Death time of this sensor
DTUPD	Time interval between updates. If negative, -DTUPD is the curve defining update interval as a function of time.

Remarks:

1. **SET Option.** When SETOPT is not defined for the SET option, a list of elemental data will be reported, one for each element in the element set. *SENSOR_DEFINE_FUNCTION and *SENSOR_DEFINE_CALC-MATH can process these reported elemental values, resulting in a list of processed values. Note that all sensor definitions referred to by these two processing commands must have the same number of data points. These elemental values also can determine if the status of a *SENSOR_SWITCH will be changed. Depending on the sign of ELEMID, it can take only one single data point (ELEMID < 0) or the whole data set (ELEMID > 0) to meet the switch condition to change the status of the related *SENSOR_SWITCH. The reported elemental values cannot be accessed by commands like *DEFINE_CURVE_FUNCTION; see SENSORD option.

   When SETOPT is defined, the elemental values of all elements in the element set will be processed, depending on the definition of SETOPT; the resulting value is reported as the single sensor value. The reported value can be processed by both *SENSOR_DEFINE_FUNCTION and *SENSOR_DEFINE_CALC-MATH as well as other regular sensors. It can also be used to determine the status of a *SENSOR_SWITCH. A *DEFINE_CURVE_FUNCTION using the SENSORD option may also access this reported value. Note that ELEMID *must be greater* than 0 for this case.

*SENSOR_DEFINE_FORCE_{OPTION}

Available options include:

<BLANK>

UPDATE

With the UPDATE keyword option, you can specify the birth time, death time, and value update frequency for the sensor. Note that without the UPDATE keyword option LS-DYNA updates the sensor value every time step.

Purpose: Define a force transducer type sensor.

Card Summary:

Card 1. For each force sensor, include one of this card or, if using the UPDATE keyword option, a set of this card and Card 2. This input ends at the next keyword ("*") card.

SENSID	FTYPE	TYPEID	VID	CRD			

Card 2. Include this card in a set with Card 1 for the UPDATE keyword option.

BIRTH	DEATH	DTUPD					

Data Card Definitions:

Force Sensor Cards. Include one additional card for each force sensor. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SENSID	FTYPE	TYPEID	VID	CRD			
Type	I	A	I	A/I	I			

VARIABLE	DESCRIPTION
SENSID	Sensor ID.
FTYPE	Force type. See Table 40-3.
TYPEID	ID defined in the associated KEYWORD command. See Table 40-3.

VARIABLE	DESCRIPTION
VID	Vector along which the forces is measured.
	EQ.X: x-direction in coordinate system CRD
	EQ.Y: y-direction in coordinate system CRD
	EQ.Z: z-direction in coordinate system CRD
	EQ.XL: x-direction in the local coordinate system for JOINTSTIF only
	EQ.YL: y-direction in the local coordinate system for JOINTSTIF only
	EQ.ZL: z-direction in the local coordinate system for JOINTSTIF only
	EQ.M: Force magnitude
	EQ.XMOMENT: x-direction moment for JOINT, JOINTSTIF, PRESC-MOT or SPC
	EQ.YMOMENT: y-direction moment for JOINT, JOINTSTIF, PRESC-MOT or SPC
	EQ.ZMOMENT: z-direction moment for JOINT, JOINTSTIF, PRESC-MOT or SPC
	EQ.XLMOMENT: x-direction moment in the local coordinate system for JOINTSTIF only
	EQ.YLMOMENT: y-direction moment in the local coordinate system for JOINTSTIF only
	EQ.ZLMOMENT: z-direction moment in the local coordinate system for JOINTSTIF only
	EQ.MMOMENT: Moment magnitude for JOINT, JOINTSTIF, PRESC-MOT or SPC
	VID$\in${INT}: Vector ID n in coordinate system CRD
CRD	Optional coordinate system, defined by *DEFINE_COORDINATE_NODES, to which vector VID is attached. If blank, the global coordinate system is assumed.

UPDATE card. Include this card in a set with Card 1 for the UPDATE keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH	DTUPD					
Type	F	F	F/I					

VARIABLE	DESCRIPTION
BIRTH	Birth time of this sensor
DEATH	Death time of this sensor
DTUPD	Time interval between updates. If negative, -DTUPD is the curve defining update interval as a function of time.

FTYPE	TYPEID (Enter ID defined in following KEYWORD commands)	OUTPUT	ASCII FILE

***SENSOR_DEFINE_FUNCTION**_*{OPTION}*

Available options include:

<BLANK>

UPDATE

With the UPDATE keyword option, you can specify the birth time, death time, and value update frequency for the sensor. Note that without the UPDATE keyword option LS-DYNA updates the sensor value every time step.

Purpose: Defines a new sensor with a unique ID. The value associated with this sensor is computed by performing mathematical calculations defined in *DEFINE_FUNCTION, with the information obtained from other sensors defined by the *SENSOR_DEFINE_*OPTION*.

Card 1	1	2	3	4	5	6	7	8
Variable	SENSID	FUNC	SENS1	SENS2	SENS3	SENS4	SENS5	SENS6
Type	I	I	I	I	I	I	I	I

Sensor Cards. Additional Cards needed when SENS1 < -5. Include as many cards as needed to specify all |SENS1| cards.

Card 2	1	2	3	4	5	6	7	8
Variable	SENS7	SENS8	SENS9	SENS10	SENS11	SENS12	SENS13	SENS14
Type	I	I	I	I	I	I	I	I

UPDATE Card. Additional card for the UPDATE keyword option to control how often the sensor value will be updated.

Card 3	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH	DTUPD					
Type	F	F	F/I					

VARIABLE	DESCRIPTION
SENSID	Sensor ID
FUNC	Function ID
SENS1	1st sensor ID, the value of which will be used as the 1st argument of function FUNC. If defined as negative, the absolute value of SENS1, |SENS1|, is the number of sensors to be input. If |SENS1| > 5, additional cards will be needed to input the ID of all sensors. The number of sensors is limited to 15.
SENS*i*	*i*th Sensor ID, the value of which will be used as the *i*th argument of function FUNC
BIRTH	Birth time of this sensor
DEATH	Death time of this sensor
DTUPD	Time interval between updates. If negative, -DTUPD is the curve defining update interval as a function of time.

***SENSOR_DEFINE_MISC**_*{OPTION}*

Available options include:

<BLANK>

UPDATE

With the UPDATE keyword option, you can specify the birth time, death time, and value update frequency for the sensor. Note that without the UPDATE keyword option LS-DYNA updates the sensor value every time step.

Purpose: Trace the value of a miscellaneous item. This card replaces *SENSOR_DEFINE_ANGLE.

Force Sensor Cards. For each miscellaneous sensor include this card or, if the UPADTE keyword option is use, sets of this card and Card 2. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SENSID	MTYPE	I0	I1	I2	I3	I4	I5
Type	I	A	I/A	I/A	I/A	I/A	I/A	I/A

UPDATE Card. This card is included in a set with Card 1 for each miscellaneous sensor if the UPDATE keyword option is used. It controls how often the sensor value will be updated.

Card 2	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH	DTUPD					
Type	F	F	F/I					

VARIABLE	DESCRIPTION
SENSID	Sensor ID
MTYPE	Entity to be traced:
	EQ.ANGLE: Angular accelerometer sensor tracing the angle between two lines, $0° \le \theta \le 180°$. The fields I1 and I2 are node numbers defining the

VARIABLE	DESCRIPTION
	1st line, while I3 and I4 are node numbers defining the 2nd line.
EQ.BNDOUT:	Boundary condition energy as reported in file bndout. I1 is the ID as defined in *BOUNDARY_PRESCRIBED_MOTION
EQ.CURVE:	The value of a time-dependent curve defined by *DEFINE_CURVE_FUNCTION or *DEFINE_CURVE. I1 is the curve ID.
EQ.CVBAG:	Information reported in ABSTAT for control volume airbag I1, including
	I0.EQ.TEMP: Airbag temperature
	I0.EQ.VOL: Airbag volume
EQ.ICVOL:	Information reported in ICVOUT for incompressible control volume I1, see *DEFINE_CONTROL_VOLUME, including
	I0.EQ.PRES: Temperature of control volume
	I0.EQ.VOL: Volume of control volume
EQ.MATSUM:	Information reported in MATSUM for part set I1, including
	I0.EQ.KINETIC: Kinetic energy
	I0.EQ.INTERNAL: Internal energy
	I0.EQ.ERODEKE: Eroded kinetic energy
	I0.EQ.ERODEIE: Eroded internal energy
EQ.NFAILE:	Number of failed elements of type I0 in set I1 will be traced. I0, element type, can be "SOLID" for solid elements, "SHELL" for thin shell elements, "TSHELL" for thick shell elements, "BEAM" for beam elements or "DISC" for discrete elements. I1 is the related element set number. If undefined, the failure of all elements of type I0 will be traced.
EQ.RETRACTOR:	The seatbelt retractor payout rate is traced. I1 is the retractor ID.
EQ.RIGIDBODY:	Accelerometer sensor tracing the kinematics of a rigid body with ID I1. The I2 field specifies which kinematical component is to be

VARIABLE	DESCRIPTION
	traced. It may be set to "TX", "TY", or "TZ" for *X*, *Y*, and *Z* translations and to "RX", "RY", or "RZ" for the *X*, *Y*, and *Z* components of the rotation. The I3 field specifies the kinematics type: "D" for displacement, "V" for velocity and "A" for acceleration. Output is calculated with respect to the global coordinate system when the I4 field is set to "0", its default value; the local rigid-body coordinate system is used when I4 is set to "1".
EQ.TIME:	The current analysis time is traced.
I0, …, I5	See MTYPE.
BIRTH	Birth time of this sensor
DEATH	Death time of this sensor
DTUPD	Time interval between updates. If negative, -DTUPD is the curve defining update interval as a function of time.

*SENSOR_DEFINE_NODE_{OPTION1}_{OPTION2}

For *OPTION1* the available options are:

<BLANK>

SET

For *OPTION2* the available options are:

<BLANK>

UPDATE

With the SET keyword option, you can specify a sensor for a set of nodes (see Remark 2 for details). This option can be useful when you want to specify a sensor switching condition based on a group of nodes. With the UPDATE keyword option, you can specify the birth time, death time, and value update frequency for the sensor. Note that without the UPDATE keyword option LS-DYNA updates the sensor value every time step.

Purpose: Define an accelerometer type sensor or temperature sensor.

a) *Accelerometer Sensor*. For an accelerometer sensor, this feature outputs the relative linear acceleration, velocity, or relative coordinate of Node 1 with respect to Node 2 along vector VID.

b) *Temperature Sensor.* For a temperature sensor, this feature outputs the temperature.

Card Summary:

Card Sets. For each nodal sensor matching the specified keyword options include one set of the following data cards. Include as many sets as needed. This input ends at the next keyword ("*") card.

Card 1. This card is required.

SENSID	NODE1	NODE2	VID		CTYPE	SETOPT	

Card 2. This card is included if the UPDATE keyword option is used.

BIRTH	DEATH	DTUPD					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SENSID	NODE1	NODE2	VID		CTYPE	SETOPT	
Type	I	I	I	I		A	A	

VARIABLE	DESCRIPTION
SENSID	Sensor ID
NODE1,2	For an accelerometer sensor, these fields are the nodes defining the accelerometer. If CTYPE = TEMP, then the temperature at NODE1 will be output. If both NODE1 and NODE2 are defined, then the difference in temperature between these two nodes will be output. When the keyword option SET is active, NODE1 is a node set ID. If NODE2 is needed, it must be a node set of the same length as NODE1 with SETOPT defined, but it can be either a node or node set without SETOPT defined. When the SET option is active but SETOPT is not defined, determining the status of a related *SENSOR_SWITCH depends on the sign of NODE1. See Remark 2 for details.
VID	ID of vector along which the nodal values are measured, see *DEFINE_VECTOR. The magnitude of nodal values (coordinate, velocity, or acceleration) will be output if VID is 0 or undefined.
CTYPE	Output component type (character string): EQ.ACC: Acceleration EQ.VEL: Velocity EQ.COORD: Coordinate EQ.TEMP: Temperature
SETOPT	Option to process set of data when SET option is specified. When SETOPT is specified, a single value will be reported. The single reported value could be: EQ.AVG: The average value of the dataset EQ.MAX: The maximum value of the dataset

VARIABLE	DESCRIPTION
	EQ.MIN: The minimum value of the dataset
	EQ.SUM: The sum of the dataset

UPDATE Card. Additional card for the UPDATE keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH	DTUPD					
Type	F	F	F/I					

VARIABLE	DESCRIPTION
BIRTH	Birth time of this sensor
DEATH	Death time of this sensor
DTUPD	Time interval between updates. If negative, -DTUPD is the curve defining update interval as a function of time.

Remarks:

1. **Time Evolution of Vector VID.** The vector direction is determined by *DEFINE_VECTOR. This vector direction is updated with time only if the coordinate system CID (see *DEFINE_VECTOR) is defined using *DEFINE_COORDINATE_NODES and the parameter FLAG is set to 1. Otherwise, the vector direction is fixed.

2. **SET Option.** When SETOPT is not defined for the SET option, a list of nodal data will be reported, one for each node in the node set, NODE1. *SENSOR_DEFINE_FUNCTION and *SENSOR_DEFINE_CALC-MATH can process these reported nodal values, resulting in a list of processed values. Note that all sensor definitions referred to by these two processing commands must have the same number of data points. These nodal values also can determine if the status of a *SENSOR_SWITCH will be changed. Depending on the sign of NODE1, it can take only one single data point (NODE1 < 0) or the whole data set (NODE1 > 0) to meet the switch condition to change the status of the related *SENSOR_SWITCH. The reported nodal values cannot be accessed by commands like *DEFINE_CURVE_FUNCTION; see SENSORD option.

   When SETOPT is defined, the nodal values of all nodes in the node set will be processed, depending on the definition of SETOPT; the resulting value is

reported as the single sensor value. The reported value can be processed by both *SENSOR_DEFINE_FUNCTION and *SENSOR_DEFINE_CALC-MATH as well as other regular sensors. It can also be used to determine the status of a *SENSOR_SWITCH. A *DEFINE_CURVE_FUNCTION using the SENSORD option may also access this reported value. If the reference node, NODE2, is needed, NODE2 must be a node set containing the same number of nodes as node set NODE1. The nodes in sets NODE1 and NODE2 must be arranged in the same sequence so that the nodal value of nodes in set NODE1 can be measured with respect to the correct node in set NODE2. For example, the following input traces the average of a relative coordinate.

```
*SENSOR_DEFINE_NODE_SET
$ trace the average of rel coord, i.e.,
$ (c(5)-c(12)+c(10)-c(19)+c(27)-c(38))/3
$   SENSID     NODE1     NODE2       VID       CRD     CTYPE    SETOPT
        40         5        12         1        99     COORD       AVG
*SET_NODE_LIST
5
5,10,27
*SET_NODE_LIST
12
12,19,38
```

3. **Rigid Body Acceleration Measurement Frequency.** When NODE1 is a node that belongs to a rigid body and CTTYPE = "ACC," the acceleration recorded by the sensor is approximated, not exact. *SENSOR_DEFINE_MISC with MTYPE = "RIGIDBODY" returns exact acceleration and is recommended for such application.

*SENSOR_SWITCH

Purpose: This command compares the value of a sensor, *SENSOR_DEFINE or *SENSOR_DEFINE_CALC-MATH, to a given criterion to check if the switch condition is met. It output a logic value of TRUE or FALSE.

Sensor Switch Cards. Include one additional card for each sensor switch. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SWITID		SENSID	LOGIC	VALUE	FILTRID	TIMWIN	TDELAY
Type	I		I	A	F	I	F	F

VARIABLE	DESCRIPTION
SWITID	Switch ID can be referred directly by *SENSOR_CONTROL to control the status of entities like CONTACT and AIRBAG or can be referred to by *SENSOR_SWITCH_CALC-LOGIC for logic computation.
SENSID	ID of the sensor whose value will be compared to the criterion to determine if a switch condition is met.
LOGIC	Logic operator, could be either LT (<) or GT (>).
VALUE	Critical value
FILTER	Filter ID (optional). See *DEFINE_FILTER for how to define a filter. See Remark 1.
TIMWIN	Trigger a status change when the value given by the sensor is less than or greater than (depending on LOGIC) the VALUE for a duration defined by TIMWIN.
TDELAY	Optional time delay. The status change will not happen immediately when both the switch condition and TIMWIN are met. Instead the status change is delayed by TDELAY.

Remarks:

1. **FILTER with *SENSOR_DEFINE.** The filter receives data from the sensor defined with *SENSOR_DEFINE either every time step or at the frequency specified with DTUPD when using the UPDATE keyword option.

*SENSOR_SWITCH_CALC-LOGIC

Purpose: This command performs a logic calculation for the logic output of other *SENSOR_SWITCH or *SENSOR_SWITCH_CALC-LOGIC definitions. The output is a logic value of either TRUE or FALSE.

Log Cards. Include one additional card for each logic rule. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SWITID	SWIT1	SWIT2	SWIT3	SWIT4	SWIT5	SWIT6	SWIT7
Type	I	I	I	I	I	I	I	I

Switch Cards. Additional switch cards needed when the logic calculation involves more than seven switches. The first column must be occupied by the plus sign, "+". Include as many cards as needed.

Card 2	1	2	3	4	5	6	7	8
Variable	+	SWIT8	SWIT9	SWIT10	SWIT11	SWIT12	SWIT13	SWIT14
Type	A	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SWITID	Switch ID can be referred directly by *SENSOR_CONTROL to control the status of entities like CONTACT and AIRBAG or can be referred to by *SENSOR_SWITCH_CALC-LOGIC for logic computation.
SWIT*n*	Input a positive sensor switch ID for "AND" and negative sensor switch ID for "OR". SWIT1 must always be positive.

This keyword implements standard Boolean logic:

true = 1,
false = 0,
and = multiplication,
or = addition

An expression evaluating to 0 is false, while any expression that evaluates to greater than 0 is true, and, therefore, set to 1.

Example:

Consider 5 switches defined as follows:

switch(11) = true
switch(12) = false
switch(13) = true
switch(14) = true
switch(15) = false.

To evaluate the expression

[switch(11) or switch(12) or switch(13)] and [switch(14) or switch(15)]

and assign the value to switch(103), the following would apply:

```
*SENSOR_SWITCH_CALC-LOGIC
101,11,-12,-13
102,14,-15
103,101,102
```

This translates into

$$\begin{aligned}
\text{switch}(101) &= \text{switch}(11) \text{ or switch}(12) \text{ or switch}(13) \\
&= \min((1 + 0 + 1), 1) \\
&= 1 \text{ (true)} \\
\text{switch}(102) &= \text{switch}(14) \text{ or switch}(15) \\
&= \min((1 + 0), 1) \\
&= 1 \text{ (true)} \\
\text{switch}(103) &= \text{switch}(101) \text{ and switch}(102) \\
&= \min((1 \times 1), 1) \\
&= 1 \text{ (true)}
\end{aligned}$$

Therefore,

$$\overbrace{[\text{switch}(11) \text{ or switch}(12) \text{ or switch}(13)]}^{\text{switch}(101)=\text{true}} \text{ AND } \overbrace{[\text{switch}(14) \text{ or switch}(15)]}^{\text{switch}(102)=\text{true}}$$
$$= \text{switch}(103)$$
$$= \text{true}$$

***SENSOR_SWITCH_SHELL_TO_VENT**_*{OPTION}*

Available options include:

ID

TITLE

OPTION provides a means to specify an airbag ID number and a heading for the airbag.

Purpose: This option will treat the failed shell elements as vent holes for the airbag defined by *AIRBAG_PARTICLE. The mass escaped from the vent will be reported in the abstat_cpm file.

ID Card. Additional card for the ID or TITLE keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ABID	HEADING						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	ID	ITYPE	C23	AMAX				
Type	I	I	F	F				

Shell Fail Time Cards. Optional Cards for setting time at which shells in a shell list (see *SHELL_LIST) change into vents. This card may be repeated up time 15 times. This input ends at the next keyword ("*") cards.

Optional	1	2	3	4	5	6	7	8
Variable	SSID	FTIME	C23V					
Type	I	F	F					
Default	none	0.	C23					

VARIABLE	DESCRIPTION
ABID	Airbag ID
HEADING	Airbag descriptor
ID	Part set ID/part ID
TYPE	Type for ID: EQ.0: part EQ.1: part set
C23	Vent Coefficient (Default = 0.7) LT.0: User defined load curve ID. The vent coefficient is a function of pressure.
AMAX	Maximum allowable area for failed vent surface area (VA). If the area is bigger than AMAX, C23 will be scaled down by a factor of AMAX/VA. Otherwise, C23 will be used.
SSID	ID of *SET_SHELL_LIST
FTIME	Time to convert shell list to vent
C23V	Vent Coefficient. LT.0: User defined load curve ID. The vent coefficient is a function of pressure.

*SET

The keyword family *SET provides a convenient way of defining groups of nodes, parts, elements, and segments. The sets can be used in the definitions of contact interfaces, loading conditions, boundary conditions, and other inputs. This keyword family also provides a convenient way of defining groups of vibration modes to be used in frequency domain analysis. Each set type must have a unique numeric identification. The keyword control cards in this section are defined as follows:

SET_BEAM_*{OPTION1}_{OPTION2}

*SET_BEAM_ADD

*SET_BEAM_INTERSECT

*SET_BOX

SET_DISCRETE_*{OPTION1}_{OPTION2}

*SET_DISCRETE_ADD

SET_MODE_*{OPTION}

*SET_MULTI

*SET_MULTIMATERIAL_GROUP_LIST

SET_NODE_*{OPTION1}_{OPTION2}

SET_NODE_ADD_*{OPTION}

*SET_NODE_INTERSECT

SET_PART_*{OPTION1}_{OPTION2}

*SET_PART_ADD

*SET_PART_TREE

*SET_PERI_LAMINATE

SET_SEGMENT_*{OPTION1}_{OPTION2}

*SET_SEGMENT_ADD

*SET_SEGMENT_INTERSECT

SET_2D_SEGMENT_*{OPTION1}_{OPTION2}

SET_SHELL_*{OPTION1}_{OPTION2}

*SET_SHELL_ADD

*SET_SHELL_INTERSECT

SET_SOLID_*{OPTION1}_{OPTION2}

*SET_SOLID_ADD

*SET_SOLID_INTERSECT

SET_TSHELL_*{OPTION1}_{OPTION2}

An additional keyword option**TITLE** may be appended to all the ***SET** keywords. If this option is used, then an addition line is read for each section in 80a format which can be used to describe the set. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

The **GENERAL** keyword option is available for set definitions. In this option, the commands are executed in the order defined. For example, the delete option cannot delete a node or element unless the node or element was previously added using a command such as BOX or ALL.

The **COLLECT** keyword option allows for the definition of multiple sets that share the same ID and combines them into one large set whenever this option is found. If two or more sets of the same type have definitions that share the same set IDs, they are combined if and only if the **COLLECT** option is specified in each definition. If the **COLLECT** option is not specified for one or more set definitions of the same type that share identical set IDs, an error termination will occur. For include files using ***INCLUDE_TRANSFORM** where set offsets are specified, the offsets are not applied for the case where the **COLLECT** option is present.

***SET_BEAM**_*{OPTION1}_{OPTION2}*

For *OPTION1* the available options are:

<BLANK>

GENERATE

GENERATE_INCREMENT

GENERAL

For *OPTION2* the available option is:

COLLECT

The GENERATE and GENERATE_INCREMENT options will generate block(s) of beam element ID's between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the set.

Purpose: Define a set of beam elements or a set of seat belt elements (see BSID of *DATABASE_CROSS_SECTION_SET).

Card Summary:

Card 1. This card is required.

SID							

Card 2a. Include this card if the keyword option is unset (<BLANK>). Include as many cards as needed. This input ends at the next keyword ("*") card.

K1	K2	K3	K4	K5	K6	K7	K8

Card 2b. Include this card if the GENERATE option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END

Card 2c. Include this card if the GENERATE_INCREMENT option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

BBEG	BEND	INCR					

Card 2d. Include this card if the GENERAL option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

OPTION	E1	E2	E3	E4	E5	E6	E7

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
SID	Set ID

Beam Element ID Cards. This Card 2 format applies to the case of an unset (<BLANK>) keyword option. Set one value per element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	K1	K2	K3	K4	K5	K6	K7	K8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
K*i*	i^{th} beam element

Beam Element Range Cards. This Card 2 format applies to the GENERATE keyword option. Set one pair of BNBEG and BNEND values per block of elements. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
B[N]BEG	First beam element ID in block N.

VARIABLE	DESCRIPTION
B[N]END	Last beam element ID in block N. All defined ID's between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the element numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the ID's and not element ID's.

Beam Element Range with Increment Cards. This Card 2 format applies to the GENERATE_INCREMENT keyword option. For each block of elements add one card to the deck. This input ends at the next keyword ("*") card.

Card 2c	1	2	3	4	5	6	7	8
Variable	BBEG	BEND	INCR					
Type	I	I	I					

VARIABLE	DESCRIPTION
BBEG	First beam element ID in block.
BEND	Last beam element ID in block.
INCR	Beam ID increment. Beam IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set.

Generalized Beam Element Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2d	1	2	3	4	5	6	7	8
Variable	OPTION	E1	E2	E3	E4	E5	E6	E7
Type	A	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
OPTION	Option for GENERAL. See table below.
E1, …, E7	Specified entity. Each card must have the option specified. See table below.

The General Option:

The "OPTION" column in the table below enumerates the allowed values for the "OPTION" variable in Card 2 for the GENERAL option. Likewise, the variables E1, …, E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of E*n* left unspecified are ignored.

Note that the order of the selected operations matters. Elements are only excluded from the set if they were previously added to the set. For instance, if you exclude beam element 5 and then include it, element 5 will be included in the set. For the example set below, suppose that part 6 includes beam elements 10, 15, 20, and 32, box 7 contains beam elements 5, 20, and 32, and part 10 includes beam elements 5, 22, and 106. Then, beam element set 1 contains beam elements 5, 10, 15, 22, and 106.

```
*SET_BEAM_GENERAL
1
PART, 6
DBOX, 7
PART, 10
```

OPTION	DESCRIPTION
ALL	All beam elements will be included in the set.
BOX	Elements inside boxes E1, E2, E3, ... will be included. (see *DEFINE_BOX)
DBOX	Previously added elements that are inside boxes E1, E2, E3, ... will be excluded.
ELEM	Elements E1, E2, E3, ... will be included.
DELEM	Elements E1, E2, E3, ... if previously added will be excluded.
PART	Elements of parts E1, E2, E3, ... will be included.
DPART	Elements that have been previously added and are of parts E1, E2, E3, ... will be excluded.
SET	Elements of beam element sets E1, E2, E3, … will be included.
DSET	Previously added elements that are members of beam element sets E1, E2, E3, … will be excluded.

*SET_BEAM_ADD

Purpose: Define a beam set by combining beam sets.

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

Beam Element Set Cards. Each card can be used to specify up to 8 beam element sets. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	BSID1	BSID2	BSID3	BSID4	BSID5	BSID6	BSID7	BSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new beam set. All beam sets should have a unique set ID.
BSID[N]	The N^{th} beam set ID on the card

*SET_BEAM_INTERSECT

Purpose: Define a beam set as the intersection, ∩, of a series of beam sets. The new beam set, SID, contains only the elements common to of all beam sets listed on the cards of format 2.

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

Beam Set Cards. Each card can be used to specify up to 8 beam sets. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	BSID1	BSID2	BSID3	BSID4	BSID5	BSID6	BSID7	BSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new beam set. All beam sets should have a unique set ID.
BSID[N]	The N^{th} beam set ID on Card 2

*SET_BOX

Purpose: Define a set of boxes. See *DEFINE_BOX.

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

Box Set Cards. Each card can be used to specify up to 8 box IDs. Include as many cards as desired. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	BID1	BID2	BID3	BID4	BID5	BID6	BID7	BID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new box set. All box sets should have a unique set ID.
BID[N]	The N^{th} box ID

***SET_DISCRETE**_*{OPTION1}_{OPTION2}*

For *OPTION1* the available options are:

<BLANK>

GENERATE

GENERAL

For *OPTION2* the available option is:

COLLECT

The option GENERATE will generate a block of discrete element IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the set.

Purpose: Define a set of discrete elements.

Card Summary:

Card 1. This card is required.

SID							

Card 2a. This card is included if the keyword option is unset (<BLANK>). Include as many cards as needed. This input ends at the next keyword ("*") card.

DPART	Elements that have been previously added and are of parts E1, E2, E3, ... will be excluded.
SET	Elements of discrete element sets E1, E2, E3, … will be included.
DSET	Previously added elements that are members of discrete element sets E1, E2, E3, … will be excluded.

*SET_DISCRETE_ADD

Purpose: Define a discrete set by combining discrete sets.

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

Discrete Element Set Cards. Each card can be used to specify up to 8 discrete element sets. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	DSID1	DSID2	DSID3	DSID4	DSID5	DSID6	DSID7	DSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new discrete element set. All discrete element sets must have a unique ID.
DSID[N]	The N^{th} discrete set ID on Card 2

SET_IGA_EDGE_*OPTION1_{OPTION2}_{OPTION3}

Purpose: Define a set of parametric or physical edges (see *IGA_EDGE_UVW and *IGA_-EDGE_XYZ) with optional attributes.

For *OPTION1* the available options are:

UVW

XYZ

For *OPTION2* the available options are:

<BLANK>

LIST

LIST_GENERATE

LIST_GENERATE_INCREMENT

For *OPTION3* the available option is:

COLLECT

The LIST_GENERATE and LIST_GENERATE_INCREMENT options will generate block(s) of parametric/physical edge IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the parametric/physical edge set.

Card Summary:

Card 1. This card is required.

SID	DA1	DA2	DA3	DA4	SOLVER		

Card 2a. This card is included if *OPTION2* is left unset or is set to LIST. Include as many cards as needed. This input ends at the next keyword ("*") card.

EID1	EID2	EID3	EID4	EID5	EID6	EID7	EID8

Card 2b. This card is included if the GENERATE keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END

Card 2c. This card is included if the LIST_GENERATE_INCREMENT keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

BBEG	BEND	INCR					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4	SOLVER		
Type	I	F	F	F	F	A		
Default	none	0.	0.	0.	0.	MECH		

VARIABLE	DESCRIPTION
SID	Set ID. A unique number must be chosen.
DA1	First attribute default value; see Remark 1.
DA2	Second attribute default value
DA3	Third attribute default value
DA4	Fourth attribute default value
SOLVER	Name of solver using this set (MECH, CESE, etc.). See Remark 2.

Parametric/Physical Edge ID Cards. This Card 2 format applies when *OPTION2* is LIST or unset (<BLANK>). Set one value per parametric/physical edge in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	EID1	EID2	EID3	EID4	EID5	EID6	EID7	EID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
EID*i*	i^{th} parametric/physical edge ID

Parametric/Physical Edge ID Range Cards. This Card 2 format applies to the GENERATE keyword option. Set one pair of B[N]BEG and B[N]END values per block of parametric/physical edge IDs. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
B[N]BEG	First parametric/physical edge ID in block N
B[N]END	Last parametric/physical edge ID in block N. All defined IDs between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the parametric/physical edge numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the IDs and not parametric/physical edge IDs.

Parametric/Physical Edge ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of parametric/physical edges add one card to the deck. This input ends at the next keyword ("*") card.

Card 2c	1	2	3	4	5	6	7	8
Variable	BBEG	BEND	INCR					
Type	I	I	I					

VARIABLE	DESCRIPTION
BBEG	First parametric/physical edge ID in block.
BEND	Last parametric/physical edge ID in block.

VARIABLE	DESCRIPTION
INCR	Parametric/physical edge ID increment. Parametric/physical edge IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set.

Remarks:

1. **Parametric/Physical Edge Attributes.** Parametric/physical edge attributes can be assigned for some input types.

2. **Solvers.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

SET_IGA_FACE_*OPTION1_{OPTION2}_{OPTION3}

Purpose: Define a set of parametric or physical faces (see *IGA_FACE_UVW and *IGA_-FACE_XYZ) with optional attributes.

For *OPTION1* the available options are:

UVW

XYZ

For *OPTION2* the available options are:

<BLANK>

LIST

LIST_GENERATE

LIST_GENERATE_INCREMENT

For *OPTION3* the available option is:

COLLECT

The LIST_GENERATE and LIST_GENERATE_INCREMENT options will generate block(s) of parametric/physical face IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the parametric/physical face set.

Card Summary:

Card 1. This card is required.

SID	DA1	DA2	DA3	DA4	SOLVER		

Card 2a. This card is included if *OPTION2* is left unset or is set to LIST. Include as many cards as needed. This input ends at the next keyword ("*") card.

FID1	FID2	FID3	FID4	FID5	FID6	FID7	FID8

Card 2b. This card is included if the GENERATE keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END

Card 2c. This card is included if the LIST_GENERATE_INCREMENT keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

BBEG	BEND	INCR					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4	SOLVER		
Type	I	F	F	F	F	A		
Default	none	0.	0.	0.	0.	MECH		

VARIABLE	DESCRIPTION
SID	Set ID. A unique number must be chosen.
DA1	First attribute default value; see Remark 1.
DA2	Second attribute default value
DA3	Third attribute default value
DA4	Fourth attribute default value
SOLVER	Name of solver using this set (MECH, CESE, etc.). See Remark 2.

Parametric/Physical Face ID Cards. This Card 2 format applies to *OPTION2* set to LIST or left unset (<BLANK>). Set one value per parametric/physical face in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	FID1	FID2	FID3	FID4	FID5	FID6	FID7	FID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
FID*i*	i^{th} parametric/physical face ID

Parametric/Physical Face ID Range Cards. This Card 2 format applies to the GENERATE keyword option. Set one pair of B[N]BEG and B[N]END values per block of parametric/physical face IDs. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
B[N]BEG	First parametric/physical face ID in block N.
B[N]END	Last parametric/physical face ID in block N. All defined IDs between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the parametric/physical face numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the IDs and not parametric/physical face IDs.

Parametric/Physical Face ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of parametric/physical faces add one card to the deck. This input ends at the next keyword ("*") card.

Card 2c	1	2	3	4	5	6	7	8
Variable	BBEG	BEND	INCR					
Type	I	I	I					

VARIABLE	DESCRIPTION
BBEG	First parametric/physical face ID in block
BEND	Last parametric/physical face ID in block

VARIABLE	DESCRIPTION
INCR	Parametric/physical face ID increment. Parametric/physical face IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set.

Remarks:

1. **Parametric/Physical Face Attributes.** Parametric/physical face attributes can be assigned for some input types.

2. **Solvers.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_IGA_POINT_UVW_{OPTION1}_{OPTION2}

Purpose: Define a set of parametric points (see *IGA_POINT_UVW) with optional attributes.

For *OPTION1* the available options are:

<BLANK>

LIST

LIST_GENERATE

LIST_GENERATE_INCREMENT

For *OPTION2* the available option is:

COLLECT

The LIST_GENERATE and LIST_GENERATE_INCREMENT options will generate block(s) of parametric point IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the parametric point set.

Card Summary:

Card 1. This card is required.

SID	DA1	DA2	DA3	DA4	SOLVER		

Card 2a. This card is included if *OPTION1* is unset or is set to LIST. Include as many cards as needed. This input ends at the next keyword ("*") card.

PID1	PID2	PID3	PID4	PID5	PID6	PID7	PID8

Card 2b. This card is included if the GENERATE keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END

Card 2c. This card is included if the LIST_GENERATE_INCREMENT keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

BBEG	BEND	INCR					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4	SOLVER		
Type	I	F	F	F	F	A		
Default	none	0.	0.	0.	0.	MECH		

VARIABLE	DESCRIPTION
SID	Set ID. A unique number must be chosen.
DA1	First attribute default value; see Remark 1.
DA2	Second attribute default value
DA3	Third attribute default value
DA4	Fourth attribute default value
SOLVER	Name of solver using this set (MECH, CESE, etc.). See Remark 2.

Parametric Point ID Cards. This Card 2 format applies to *OPTION1* set to list or left unset (<BLANK>). Set one value per parametric point in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	PID1	PID2	PID3	PID4	PID5	PID6	PID7	PID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
PID*i*	i^{th} parametric point ID

Parametric Point ID Range Cards. This Card 2 format applies to the GENERATE keyword option. Set one pair of B[N]BEG and B[N]END values per block of parametric point IDs. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
B[N]BEG	First parametric point ID in block N
B[N]END	Last parametric point ID in block N. All defined ID's between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the parametric point numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the IDs and not parametric point IDs.

Parametric Point ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of parametric points add one card to the deck. This input ends at the next keyword ("*") card.

Card 2c	1	2	3	4	5	6	7	8
Variable	BBEG	BEND	INCR					
Type	I	I	I					

VARIABLE	DESCRIPTION
BBEG	First parametric point ID in block
BEND	Last parametric point ID in block
INCR	Parametric point ID increment. Parametric point IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set.

Remarks:

1. **Parametric Point Attributes.** Parametric point attributes can be assigned for some input types.

2. **Solvers.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

***SET_MODE**_*{OPTION}*

Available options include:

<BLANK>

LIST

LIST_GENERATE

The last option, LIST_GENERATE, will generate a block of mode IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the set.

Purpose: Define a set of modes.

Card Summary:

Card 1. This card is required.

SID							

Card 2a. This card is included if and only if the keyword option is set to LIST or left unset. Include as many cards as needed. This input ends at the next keyword ("*") card.

MID1	MID2	MID3	MID4	MID5	MID6	MID7	MID8

Card 2b. This card is included if and only if the LIST_GENERATE keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

M1BEG	M1END	M2BEG	M2END	M3BEG	M3END	M4BEG	M4END

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

Mode ID Cards. This card is included when the keyword option is set to LIST *or* left unset (<BLANK>). Set one value per mode in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	MID1	MID2	MID3	MID4	MID5	MID6	MID7	MID8
Type	I	I	I	I	I	I	I	I

Mode Range Cards. This card applies to the LIST_GENERATE keyword option. Set one pair of MNBEG and MNEND values per block of modes. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	M1BEG	M1END	M2BEG	M2END	M3BEG	M3END	M4BEG	M4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set identification. All mode sets should have a unique set ID.
MID[N]	Mode ID N.
M[N]BEG	First mode ID in block N.
M[N]END	Last mode ID in block N. All defined IDs between and including M[N]BEG and M[N]END are added to the set.

Remarks:

The available mode IDs can be found in ASCII file eigout, or binary database d3eigv.

*SET_MULTI

Note that this keyword's name has been shortened. Its older long form, however, is still also valid.

*SET_MULTI-MATERIAL_GROUP_LIST

Purpose: This command defines an ALE multi-material set ID (AMMSID) which contains a collection of one or more ALE multi-material group ID(s) (AMMGID). This provides a means for selecting any specific ALE multi-material(s). Applications include, for example, a selection of any particular fluid(s) to be coupled to a fluid-structure interaction.

Card 1	1	2	3	4	5	6	7	8
Variable	AMMSID							
Type	I							
Default	0							

Multi-Material Group ID Cards. Set one value per element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	AMMGID1	AMMGID2	AMMGID3	AMMGID4	AMMGID5	AMMGID6	AMMGID7	AMMGID8
Type	I/A	I/A	I/A	I/A	I/A	I/A	I/A	I/A
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
AMMSID	An ALE multi-material set ID (AMMSID) which contains a collection of one or more ALE multi-material group ID(s) (AMMGID).
AMMGID*i*	Desired ALE multi-material referenced with its AMMGID for general ALE or with either its AMMGID or AMMG name (AMMGNM) for S-ALE. See Remarks.

Remarks:

For the general ALE solver, you define each AMMG with *ALE_MULTI-MATERIAL_-GROUP. In this case, each AMMG can only be referred to by their AMMGID. The AMMGID for each AMMG is based on the order of appearance of the AMMG in the input deck.

For the S-ALE solver, you can define the AMMG using *ALE_STRUCTURED_MULTI-MATERIAL_GROUP instead of *ALE_MULTI-MATERIAL_GROUP. With *ALE_-STRUCTURED_MULTI-MATERIAL_GROUP, you give each AMMG a name with the field AMMGNM. Each AMMG defined with that keyword can then be referred with either its name or its AMMGID (which is again based on order of appearance). We recommend using the name as it leads to fewer errors. For instance, if you add or delete AMMGs, then the AMMGIDs may change. Then, you must find all those references and change them accordingly. With the name, you do not need to modify the input deck for unchanged AMMGs.

*SET_NODE_{OPTION1}_{OPTION2}

For *OPTION1* the available options are:

<BLANK>

LIST

COLUMN

LIST_GENERATE

LIST_GENERATE_INCREMENT

GENERAL

LIST_SMOOTH

For *OPTION2* the available option is:

COLLECT

The LIST option generates a set for a list of node IDs. The LIST_GENERATE and LIST_-GENERATE_INCREMENT options will generate block(s) of node IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the node set. The option LIST_SMOOTH is used to define a local region on a distorted tooling mesh to be smoothed. The LIST_SMOOTH option is documented in the Local Smoothing of Tooling Mesh section of the manual page for *INTERFACE_COMPENSATION_3D. The COLUMN option is for setting nodal attributes, which pass data to other keyword cards, on a node-by-node basis.

Purpose: Define a nodal set with some identical or unique attributes.

Card Summary:

Card 1. This card is required.

SID	DA1	DA2	DA3	DA4	SOLVER	ITS	

Card 2a. This card is included if the keyword option is unset (<BLANK>), LIST, or LIST_SMOOTH. Include as many cards as needed. This input ends at the next keyword ("*") card.

NID1	NID2	NID3	NID4	NID5	NID6	NID7	NID8

Card 2b. This card is included if the keyword option is COLUMN. Include one card per node in the set. This input ends at the next keyword ("*") card

NID	A1	A2	A3	A4			

Card 2c. This card is included if the LIST_GENERATE keyword option is used. Set one pair of BNBEG and BNEND values per block of nodes. This input ends at the next keyword ("*") card

B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END

Card 2d. This card is included if the LIST_GENERATE_INCREMENT keyword option is used. For each block of nodes add one card to the deck. This input ends at the next keyword ("*") card.

BBEG	BEND	INCR					

Card 2e. This card is included if the GENERAL keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

OPTION	E1	E2	E3	E4	E5	E6	E7

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4	SOLVER	ITS	
Type	I	F	F	F	F	A	I	
Default	none	0.	0.	0.	0.	MECH	0	
Remark		1	1	1	1	3		

VARIABLE	DESCRIPTION
SID	Set identification. All node sets should have a unique set ID.
DA1	First nodal attribute default value
DA2	Second nodal attribute default value

VARIABLE	DESCRIPTION
DA3	Third nodal attribute default value
DA4	Fourth nodal attribute default value
SOLVER	Name of solver using this set (MECH, CESE, etc.)
ITS	Specify coupling type across different scales in two-scale co-simulation. This flag should only be included for node sets that provide coupling information in the input file referred to by *INCLUDE_-COSIM. EQ.1: Tied contact coupling EQ.2: Solid-in-shell immersed coupling

Node ID Cards. This Card 2 format applies to LIST and LIST_SMOOTH keyword options. Additionally, it applies to the case of an unset (<BLANK>) keyword option. Set one value per node in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	NID1	NID2	NID3	NID4	NID5	NID6	NID7	NID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
NID*i*	Node ID *i*

Node ID with Column Cards. This Card 2 format applies to the COLUMN keyword option. Include one card per node in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	NID	A1	A2	A3	A4			
Type	I	F	F	F	F			

VARIABLE	DESCRIPTION
NID	Nodal ID
A1	First nodal attribute (see Remark 2)
A2	Second nodal attribute (see Remark 2)
A3	Third nodal attribute (see Remark 2)
A4	Fourth nodal attribute (see Remark 2)

Node ID Range Cards. This Card 2 format applies to the LIST_GENERATE keyword option. Set one pair of BNBEG and BNEND values per block of nodes. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2c	1	2	3	4	5	6	7	8
Variable	B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
B*n*BEG	First node ID in block *n*.
B*n*END	Last node ID in block *n*. All defined IDs between and including B*n*BEG to B*n*END are added to the set. These sets are generated after all input is read so that gaps in the node numbering are not a problem. B*n*BEG and B*n*END may simply be limits on the IDs and not nodal IDs.

Node ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of nodes add one card to the deck. This input ends at the next keyword ("*") card.

Card 2d	1	2	3	4	5	6	7	8
Variable	BBEG	BEND	INCR					
Type	I	I	I					

VARIABLE	DESCRIPTION
BBEG	First node ID in block.
BEND	Last node ID in block.
INCR	Node ID increment. Node IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set.

Generalized Node ID Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2e	1	2	3	4	5	6	7	8
Variable	OPTION	E1	E2	E3	E4	E5	E6	E7
Type	A	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
OPTION	Option for GENERAL. See table below.
E1, …, E7	Specified entity. Each card must have the option specified. See table below.

The General Option:

The "OPTION" column in the table below enumerates the allowed values for the "OPTION" variable in Card 2e for the GENERAL option. Likewise, the variables E1, …, E7 refer to the GENERAL option Card 2e.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of "E*n*" left unspecified are ignored.

Note that the order of the selected operations matters. Nodes are only excluded from the set if they were previously added to the set. For instance, if you exclude node 5 and then include it, node 5 will be included in the set. For the example set below, suppose that part 6 includes nodes 10, 15, 20, and 32, box 7 contains nodes 5, 20, and 32, and part 10 includes nodes 5, 22, and 106. Then, node set 1 contains nodes 5, 10, 15, 22, and 106.

```
*SET_NODE_GENERAL
1
PART, 6
DBOX, 7
PART, 10
```

OPTION	DESCRIPTION
ALL	All nodes will be included in the set.
BRANCH	Nodes inside tree branches E1, E2, E3, … will be included. (see *SET_PART_TREE)
DBRANCH	Previously added nodes that are inside tree branches E1, E2, E3, … will be excluded.
BOX	Nodes inside boxes E1, E2, E3, … will be included. (see *DEFINE_-BOX)
DBOX	Previously added nodes that are inside boxes E1, E2, E3, … will be excluded.
NODE	Nodes E1, E2, E3, … will be included.
DNODE	Nodes E1, E2, E3, … if previously added will be excluded.
PART	Nodes of parts E1, E2, E3, … will be included.
DPART	Nodes that have been previously added and are of parts E1, E2, E3, … will be excluded.
SET_NODE	Nodes from node sets with IDs E1, …, E7 will be included.
DSET_NODE	Nodes that have been previously added and are from node sets with IDs E1, …, E7 will be excluded.
SET_*XXXX*	Include nodal points of element sets defined by SET_*XXXX*_LIST, where *XXXX* could be SHELL, SOLID, BEAM, TSHELL and DIS-CRETE.
SALECPT	Nodes inside a box in a Structured ALE mesh. E1 here is the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to IMIN, IMAX, JMIN, JMAX, KMIN, KMAX. They are the minimum and the maximum nodal indices along each direction in S-ALE mesh. This option is only to be used for Structured ALE mesh. It can be used with SALEFAC but should not be used with other "_GENER-AL" options. Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details.

OPTION	DESCRIPTION
SALEFAC	Nodes that are on the face of a Structured ALE mesh. E1 gives the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to -x, +x, -y, +y, -z, +z faces. Assigning 1, for instance, to these 6 values would include all the surface segments at these faces in the segment set. This option is only to be used for Structured ALE mesh. It can be used with SALECPT but should not be used with other "_GENERAL" options. Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details.
VOL	Nodes inside contact volumes E1, E2, E3, … will be included. (see *DEFINE_CONTACT_VOLUME)
DVOL	Previously added nodes that are inside contact volumes E1, E2, E3, … will be excluded.

Remarks:

1. **Nodal Attributes.** Nodal attributes can be assigned to pass data to other keywords. For example, for contact option, *CONTACT_TIEBREAK_NODES_TO_SURFACE the attributes are:

   DA1 = NFLF ⇒ Normal failure force,

   DA2 = NSFL ⇒ Shear failure force,

   DA3 = NNEN ⇒ Exponent for normal force,

   DA4 = NMES ⇒ Exponent for shear force.

2. **Overriding Nodal Attributes.** The nodal attributes set in Card 1 can be overridden on a node by node basis by using the COLUMN keyword option. Card 2b for this keyword option allows the user to set the attributes for each node. If left unset on Card 2b, the values default to those set in Card 1, that is, A1 = DA1, etc.

3. **Solvers.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics solver's mesh.

4. **LIST_SMOOTH Option.** The option *SET_NODE_LIST_SMOOTH is used for localized tooling surface smoothing, and it is used in conjunction with keywords *INTERFACE_COMPENSATION_NEW_LOCAL_SMOOTH, *INCLUDE_-

COMPENSATION_ORIGINAL_RIGID_TOOL, and *INCLUDE_COMPENSATION_NEW_RIGID_TOOL.

*SET_NODE_ADD_{OPTION}

Available options include:

<BLANK>

ADVANCED

Purpose: Define a node set by combining node sets or for the ADVANCED option by combining, NODE, SHELL, SOLID, BEAM, SEGMENT, DISCRETE and THICK SHELL sets.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	DA1	DA2	DA3	DA4	SOLVER		
Type	I	F	F	F	F	A		
Default	none	none	none	none	none	MECH		

Node Set Cards. This card is included when the keyword option is left unset (<BLANK>). Each card can be used to specify up to 8 node set IDs. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	NSID1	NSID2	NSID3	NSID4	NSID5	NSID6	NSID7	NSID8
Type	I	I	I	I	I	I	I	I

Node Set Advanced Cards. This card is included when the keyword option is set to ADVANCED. Each card can be used to specify up to 4 set IDs (node sets, beam sets, etc…). Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	SID1	TYPE1	SID2	TYPE2	SID3	TYPE3	SID4	TYPE4
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
NSID	Set ID of new node set. All node sets should have a unique set ID.
DA1	First nodal attribute default value; see Remark 1 below.
DA2	Second nodal attribute default value
DA3	Third nodal attribute default value
DA4	Fourth nodal attribute default value
SOLVER	Name of solver using this set (MECH, CESE, etc.). See Remark 1.
NSID[N]	The N^{th} node set ID on Card 2a.
SID[N]	The N^{th} set ID on Card 2b.
TYPE[N]	Type of set for SID[N]: EQ.1: Node set EQ.2: Shell set EQ.3: Beam set EQ.4: Solid set EQ.5: Segment set EQ.6: Discrete set EQ.7: Thick shell set

Remarks:

1. **Solvers and Mesh.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_NODE_INTERSECT

Purpose: Define a node set as the intersection, ∩, of a series of node sets. The new node set, NSID, contains all common elements of all node sets listed on all cards in format 2.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4	SOLVER		
Type	I	F	F	F	F	A		
Default	none	0.	0.	0.	0.	MECH		
Remarks						1		

Node Set Cards. For each SID in the intersection specify one field. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	NSID1	NSID2	NSID3	NSID4	NSID5	NSID6	NSID7	NSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new node set. All node sets should have a unique set ID.
DA*i*	i^{th} nodal attribute
SOLVER	Name of solver using this set (MECH, CESE, etc.)
NSID[N]	The N^{th} node set ID.

Remarks:

1. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

***SET_PART**_*{OPTION1}_{OPTION2}*

For *OPTION1* available options are:

<BLANK>

COLUMN

GENERAL

LIST

LIST_GENERATE

LIST_GENERATE_INCREMENT

For *OPTION2* the available option is:

COLLECT

The LIST_GENERATE and LIST_GENERATE_INCREMENT options will generate block(s) of part IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the part set.

Purpose: Define a set of parts with optional attributes. For the COLUMN option, see *AIRBAG or *CONSTRAINED_RIGID_BODY_STOPPERS.

Card Summary:

Card 1. This card is required.

SID	DA1	DA2	DA3	DA4	SOLVER		

Card 2a. This card is included if the keyword option is left unset or is LIST. Include as many cards as needed. This input ends at the next keyword ("*") card.

PID1	PID2	PID3	PID4	PID5	PID6	PID7	PID8

Card 2b. This card is included if the COLUMN keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

PID	A1	A2	A3	A4			

Card 2c. This card is included if the LIST_GENERATE keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END

Card 2d. This card is included if the LIST_GENERATE_INCREMENT keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

BBEG	BEND	INCR					

Card 2e. This card is included if *OPTION1* is GENERAL. Include as many cards as necessary. This input ends at the next keyword ("*") card.

OPTION	E1	E2	E3	E4	E5	E6	E7

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4	SOLVER		
Type	I	F	F	F	F	A		
Default	none	0.	0.	0.	0.	MECH		

VARIABLE	DESCRIPTION
SID	Set ID. All part sets should have a unique set ID.
DA1	First attribute default value; see Remark 1.
DA2	Second attribute default value
DA3	Third attribute default value
DA4	Fourth attribute default value
SOLVER	Name of solver using this set (MECH, CESE, etc.). See Remark 3.

Part ID Cards. This Card 2 format applies to the LIST keyword option and the unset (<BLANK>) keyword option. Set one value per part in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	PID1	PID2	PID3	PID4	PID5	PID6	PID7	PID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
PID*i*	i^{th} part ID

Part ID with Column Cards. This Card 2 format applies to the COLUMN keyword option. Include one card per part in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	PID	A1	A2	A3	A4			
Type	I	F	F	F	F			
Remark		2	2	2	2			

VARIABLE	DESCRIPTION
PID	Part ID
A1	First part attribute
A2	Second part attribute
A3	Third part attribute
A4	Fourth part attribute

Part ID Range Cards. This Card 2 format applies to the LIST_GENERATE keyword option. Set one pair of BNBEG and BNEND values per block of part IDs. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2c	1	2	3	4	5	6	7	8
Variable	B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
B[N]BEG	First part ID in block N.
B[N]END	Last part ID in block N. All defined ID's between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the part numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the ID's and not part ID's.

Part ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of parts add one card to the deck. This input ends at the next keyword ("*") card.

Card 2d	1	2	3	4	5	6	7	8
Variable	BBEG	BEND	INCR					
Type	I	I	I					

VARIABLE	DESCRIPTION
BBEG	First part ID in block.
BEND	Last part ID in block.
INCR	Part ID increment. Part IDs BBEG, BBEG+INCR, BBEG + 2 × INCR, and so on through BEND are added to the set.

Generalized Part ID Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2e	1	2	3	4	5	6	7	8
Variable	OPTION	E1	E2	E3	E4	E5	E6	E7
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
OPTION	Option for GENERAL. See table below
E1, …, E7	Specified entity. Each card must have an option specified. See table below.

The General Option:

The "OPTION" column in the table below enumerates the allowed values for the "OPTION" variable in Card 2 for the GENERAL option. Likewise, the variables E1, …, E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of "E*n*" left unspecified are ignored.

Note that the order of the selected operations matters. Parts are only excluded from the set if they were previously added to the set. Consider the following example:

```
*SET_PART
1
1,2
*SET_PART
2
2,3
*SET_PART_GENERAL
1001
SET,1
DSET,2
*SET_PART_GENERAL
1002
DSET,2
SET,1
```

Because of the order dependence, part sets 1001 and 1002 are not the same. Part set 1001 includes part 1 while part set 1002 includes parts 1 and 2.

OPTION	DESCRIPTION
ALL	All parts will be included in the set.
PART	Parts E1, …, E7 will be included.
DPART	Parts E1, …, E7 if previously added will be excluded.
SET	Parts of part sets E1, …, E7 will be included.
DSET	Previously added parts that are members of part sets E1, …, E7 will be excluded.

Remarks:

1. **Part Attributes.** Part attributes can be assigned for some input types. For example, for airbags a time delay, DA1 = T1, can be defined before pressure begins to act along with a time delay, DA2 = T2, before full pressure is applied (default T2 = T1). For *CONSTRAINED_RIGID_BODY_STOPPERS one attribute can be defined: DA1 as the closure distance which activates the stopper constraint.

2. **Individual Part Attributes.** The default part attributes can be overridden on the part cards with the COLUMN keyword option; otherwise, A1 = DA1, etc.

3. **Solvers.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_PART_ADD

Purpose: Define a part set by combining part sets.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4	SOLVER		
Type	I	F	F	F	F	A		
Default	none	0.0	0.0	0.0	0.0	MECH		
Remarks		1, 2	1, 2	1, 2	1, 2	3		

Part Set Cards. Each card can be used to specify up to 8 part set IDs. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

Card 2…	1	2	3	4	5	6	7	8
Variable	PSID1	PSID2	PSID3	PSID4	PSID5	PSID6	PSID7	PSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID. All part sets should have a unique set ID.
DA1	First attribute default value
DA2	Second attribute default value
DA3	Third attribute default value
DA4	Fourth attribute default value
SOLVER	Name of solver using this set (MECH, CESE, etc.)

VARIABLE	DESCRIPTION
PSID[N]	The N^{th} part set ID GT.0: PSID[N] is added to SID, LT.0: all part sets with ID between PSID[N-1] and -PSID[N], including PSID[N-1] and -PSID[N], will be added to SID. PSID[N-1] must be > 0 and must have a magnitude smaller or equal to -PSID[N] when PSID[N] < 0.

Remarks:

1. **Part Attributes.** Part attributes can be assigned for some input types. For example, for airbags a time delay, DA1 = T1, can be defined before pressure begins to act along with a time delay, DA2 = T2, before full pressure is applied, (default T2 = T1). For the constraint option, *CONSTRAINED_RIGID_BODY_STOPPERS one attribute can be defined: DA1, the closure distance which activates the stopper constraint.

2. **Overriding Part Attributes.** The default values for the part attributes are given in the contributing *SET_PART_{*OPTION*} commands. Nonzero values of DA1, DA2, DA3, or DA4 in *SET_PART_ADD will override the respective default values.

3. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_PART_TREE

Purpose: Define a branch in a tree structure. A branch is a part set that can be defined using parts and/or sub-branches. With this keyword, the whole model can be modeled as a hierarchical tree structure.

Card Summary:

Card 1. This card is required.

BRID							

Card 2. This card is required.

HEADING	

Card 3. Include as many cards as needed. This input ends at the next keyword ("*") card.

COMP1	COMP2	COMP3	COMP4	COMP5	COMP6	COMP7	COMP8

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	BRID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
BRID	Branch identification. A unique number must be specified.

Card 2	1	2	3	4	5	6	7	8
Variable	HEADING							
Type	C							
Default	none							

VARIABLE	DESCRIPTION
HEADING	Heading for the branch

Component Data Cards. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	COMP1	COMP2	COMP3	COMP4	COMP5	COMP6	COMP7	COMP8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
COMP*i*	Components of branch BRID: GT.0: ID of a sub-branch LT.0: ID of a part

Remarks:

1. A branch is basically a part set. A branch that does *not* belong to any other branch is considered to belong to the root of the whole model.

2. A branch or part cannot belong to more than one branch.

3. Parts which are never referenced, directly or indirectly, in *SET_PART_TREE are considered the children of the root of the whole model.

*SET_PERI_LAMINATE

Purpose: Assemble laminae (each lamina must be defined as one individual part) into a laminate and define the fiber angles for laminae.

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

Repeat this card as many times as needed to specify each lamina of the laminate. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	PID1	A1	T1	PID2	A2	T2		
Type	I	F	F	I	F	F		

VARIABLE	DESCRIPTION
SID	Set ID for the laminate
PID*i*	Part ID of i^{th} lamina
A*i*	Fiber angle of i^{th} lamina. This angle is relative to the direction (V1,V2,V3) specified in *MAT_ELASTIC_PERI_LAMINATE
T*i*	Thickness of i^{th}

*SET_SEGMENT_{OPTION1}_{OPTION2}

For *OPTION1* the available options are:

<BLANK>

GENERAL

For *OPTION2* the available option is

COLLECT

Purpose: Define a set of segments with optional identical or unique attributes. For three-dimensional geometries, a segment can be triangular or quadrilateral. For two-dimensional geometries, a segment is a line defined by two nodes and the GENERAL option does not apply.

Card Summary:

Card 1. This card is required.

SID	DA1	DA2	DA3	DA4	SOLVER	ITS	

Card 2a. This card is included if *OPTION1* is <BLANK>. Include as many cards as necessary. This input ends at the next keyword ("*") card.

N1	N2	N3	N4	A1	A2	A3	A4

Card 2b. This card is included if *OPTION1* is GENERAL. Include as many cards as necessary. This input ends at the next keyword ("*") card.

OPTION	E1	E2	E3	E4	E5	E6	E7

Data Cards:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4	SOLVER	ITS	
Type	I	F	F	F	F	A	I	
Default	none	0.	0.	0.	0.	MECH	0	

VARIABLE	DESCRIPTION
SID	Set ID. All segment sets should have a unique set ID.
DA1	First segment attribute default value. See Remark 1.
DA2	Second segment attribute default value. See Remark 1.
DA3	Third segment attribute default value. See Remark 1.
DA4	Fourth segment attribute default value. See Remark 1.
SOLVER	Name of solver using this set (MECH, CESE, etc.). See Remark 3.
ITS	Define coupling type across different scales in two-scale co-simulation. This flag should only be included for segment sets that provide coupling information in the input file referred to by *INCLUDE_COSIM. EQ.1: Tied contact coupling EQ.2: Solid-in-shell immersed coupling

Segment Cards. For each segment in the set include one card of this format unless the GENERAL option is used. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	A1	A2	A3	A4
Type	I	I	I	I	F	F	F	F

VARIABLE	DESCRIPTION
N1	Nodal point n_1
N2	Nodal point n_2
N3	Nodal point n_3
N4	Nodal point n_4. To define a triangular segment, set N4 = N3.
A1	First segment attribute. See Remark 2.
A2	Second segment attribute. See Remark 2.

VARIABLE	DESCRIPTION
A3	Third segment attribute. See Remark 2.
A4	Fourth segment attribute. See Remark 2.

Generalized Part ID Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	OPTION	E1	E2	E3	E4	E5	E6	E7
Type	A	I	I	I	I or F	I or F	I or F	I or F

VARIABLE	DESCRIPTION
OPTION	Option for GENERAL. See table below.
E1, …, E7	Specified entity. Each card must have an option specified. See table below.

The General Option:

The "OPTION" column in the table below enumerates the allowed values for the "OPTION" variable in Card 2 for the GENERAL option. Likewise, the variables E1, …, E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of "E*n*" left unspecified are ignored.

OPTION	DESCRIPTION
ALL	All exterior segments will be included in the set.
BOX	Generate segments inside boxes having IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. For shell elements one segment per shell is generated. For solid elements only those segments wrapping the solid part and pointing outward from the part will be generated.

OPTION	DESCRIPTION
BOX_SHELL	Generate segments inside boxes having IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. The segments are only generated for shell elements. One segment per shell is generated.
BOX_SLDIO	Generate segments inside boxes having IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. Both exterior segments and inter-element segments are generated.
BOX_SOLID	Generate segments inside boxes having IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. The segments are only generated for exterior solid elements
BRANCH	Generate segments of tree branches E1, E2, and E3 with attributes E4, E5, E6, and E7. For shell elements one segment per shell is generated. For solid elements, only those segments wrapping the solid part and pointing outward from the part will be generated. See *SET_PART_TREE.
BRANCH_IO	Generate segments from tree branches E1, E2, E3 with attributes E4, E5, E6, and E7. Same as the BRANCH option above except that inter-element segments inside parts will be generated as well. This option is sometimes useful for single surface contact of solid elements to prevent negative volumes.
BRSLDF*i*	Generate segments from the *i*th face of solid tree branches E1, E2, E3 with attributes E4, E5, E6, and E7. See Table 41-1 below for face definition.
DBOX	Segments inside boxes with IDs E1, …, E7 will be excluded.
DBOX_SHELL	Shell related segments inside boxes of IDs E1, …, E7 will be excluded.
DBOX_SOLID	Solid related segments inside boxes of IDs E1, …, E7 will be excluded.
DPART	Segments of parts with IDs E1, …, E7 will be excluded.
DSEG	Segment with node IDs E1, E2, E3, and E4 will be deleted.
DVOL	Segments inside contact volumes having IDs E1, …, E7 will be excluded.

OPTION	DESCRIPTION
DVOL_SHELL	Shell related segments inside contact volumes having IDs E1, …, E7 will be excluded.
DVOL_SOLID	Solid related segments inside contact volumes having IDs E1, …, E7 will be excluded.
PART	Generate segments of parts E1, E2, and E3 with attributes E4, E5, E6, and E7. For shell elements one segment per shell is generated. For solid elements only those segments wrapping the solid part and pointing outward from the part will be generated. PART could refer to beam parts when defining 2D segments for traction application.
PART_IO	Generate segments from parts E1, E2, E3 with attributes E4, E5, E6, and E7. Same as the PART option above except that inter-element segments inside parts will be generated as well. This option is sometimes useful for single surface contact of solid elements to prevent negative volumes.
PSLDF*i*	Generate segments from the i^{th} face of solid parts E1, E2, E3 with attributes E4, E5, E6, and E7. See Table 41-1 below for face definition.
SALECPT	Segments inside a box in a Structured ALE mesh. E1 here is the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to IMIN, IMAX, JMIN, JMAX, KMIN, KMAX. They are the minimum and the maximum nodal indices along each direction in the S-ALE mesh. This option is only to be used for Structured ALE mesh. It can be used with SALEFAC but should not be used with other "_GENERAL" options. Please refer to *ALE_STRUCTURED_MESH_CONTROL_-POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details.
SALEFAC	Segments on the face of Structured ALE mesh. E1 here is the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to -X, +X, -Y, +Y, -Z, +Z faces. Assigning 1 to these 6 values would include all the surface segments at these faces in the segment set. This option is only to be used for Structured ALE mesh. It can be used with SALECPT but should not be used with other "_GENERAL" options.

OPTION	DESCRIPTION
	Please refer to *ALE_STRUCTURED_MESH_CONTROL_-POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details.
SEG	Create segment with node IDs E1, E2, E3, and E4.
SET_SHELL	Generate segments for shell elements in SET_SHELL_LIST with IDs E1, E2, and E3 with attributes E4, E5, E6, and E7.
SET_SOLID	Generate segments for solid elements in SET_SOLID_LIST with IDs E1, E2, and E3 with attributes E4, E5, E6, and E7.
SET_SLDIO	Generate segments for solid elements in SET_SOLID_LIST with IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. Both exterior and interior segments are generated.
SET_SLDF*i*	Generate segments from the i^{th} face of solid elements in SET_SOLID_LIST with IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. See Table 41-1 below for face definition.
SET_TSHELL	Generate segments for thick shell elements in SET_TSHELL_LIST with IDs of E1, E2, and E3 with attributes E4, E5, E6, and E7. Only exterior segments are generated.
SET_TSHIO	Generate segments for thick shell elements in SET_TSHELL_LIST with IDs of E1, E2, and E3 with attributes E4, E5, E6, and E7. Both exterior and interior segments are generated.
SHELL	Generate segments for shell elements with IDs of E1, E2, and E3 with attributes E4, E5, E6, and E7.
VOL	Generate segments inside contact volume IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. See BOX option for other details.
VOL_SHELL	Generate segments for shells inside contact volume IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7
VOL_SLDIO	Generate segments for solid elements inside contact volume IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. See BOX_-SLDIO for other details.
VOL_SOLID	Generate segments for solid elements inside contact volume IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. See BOX_SOL-ID for other details.

FACE	Hexahedron	Pentahedron	Tetrahedron
1	N1, N5, N8, N4	N1, N2, N5	N1, N2, N4
2	N2, N3, N7, N6	N4, N6, N3	N2, N3, N4
3	N1, N2, N6, N5	N1, N4, N3, N2	N1, N3, N2
4	N4, N8, N7, N3	N2, N3, N6, N5	N1, N4, N3
5	N1, N4, N3, N2	N1, N5, N6, N4	
6	N5, N6, N7, N8		

Table 41-1. Face definition of solid elements

Remarks:

1. **Segment Attributes.** Segment attributes can be assigned for some input types. For example, for the contact options:

   The attributes for the SURFA surface are:

   DA1 (NFLS) = Normal failure stress, *CONTACT_TIEBREAK_SURFACE contact only,

   DA2 (SFLS) = Shear failure stress, *CONTACT_TIEBREAK_SURFACE contact only,

   DA3 (FSF) = Coulomb friction scale factor,

   DA4 (VSF) = Viscous friction scale factor,

   and the attributes for the SURFB surface are:

   DA3 (FSF) = Coulomb friction scale factor,

   DA4 (VSF) = Viscous friction scale factor.

   For airbags, see *AIRBAG, a time delay, DA1 = T1, can be defined before pressure begins to act on a segment along with a time delay, DA2 = T2, before full pressure is applied to the segment, (default T2 = T1), and for the constraint option,

2. **Setting Individual Attributes.** The default segment attributes can be overridden on Card 2a; otherwise, A1 = DA1, A2 = DA2, etc.

3. **Solvers.** The SOLVER field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_SEGMENT_ADD

Purpose: Define a segment set by combining segment sets.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	SOLVER						
Type	I	A						
Default	none	MECH						
Remarks		1						

Segment Set Cards. Each card can be used to specify up to 8 segment set IDs. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	SSID1	SSID2	SSID3	SSID4	SSID5	SSID6	SSID7	SSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new segment set. All segment sets should have a unique set ID.
SOLVER	Name of solver using this set (MECH, CESE, etc.)
SSID[N]	The N^{th} segment set ID.

Remarks:

1. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_SEGMENT_INTERSECT

Purpose: Define a segment set as the intersection, ∩, of a series of segment sets. The new segment set, SID, contains all segments common to the sets listed on all of the cards in format 2.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	SOLVER						
Type	I	A						
Default	none	MECH						
Remarks		1						

Segment Set Cards. For each SID in the intersection specify one field. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	SSID1	SSID2	SSID3	SSID4	SSID5	SSID6	SSID7	SSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new segment set. All segment sets should have a unique set ID.
SOLVER	Name of solver using this set (MECH, CESE, etc.)
SSID[N]	The N^{th} segment set ID

Remarks:

1. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_2D_SEGMENT_{OPTION1}_{OPTION2}

For *OPTION1* the available options are:

<BLANK>

SET

For *OPTION2* the available option is:

COLLECT

Purpose: Define a set of boundary line segments in two-dimensional axisymmetric, plane stress, and plane strain geometries with optional attributes. This command does not apply to beam formulations 7 and 8. This feature is sometimes convenient for two-dimensional parts that are subject to adaptivity because the segments in the set are updated as the geometry adapts.

Card Sets. For each set include a pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4			
Type	I	F	F	F	F			
Default	none	0.	0.	0.	0.			
Remarks		1	1	1	1			

Card 2	1	2	3	4	5	6	7	8
Variable	PID/PSID							
Type	I							
Remarks	2							

VARIABLE	DESCRIPTION
SID	Set ID. All segment sets should have a unique set ID.
DA1	First segment attribute default value, see Remark 1 below.
DA2	Second segment attribute default value
DA3	Third segment attribute default value
DA4	Fourth segment attribute default value
PID/PSID	Part ID or part set ID if SET option is specified.

Remarks:

1. **Axisymmetric Problems.** The boundary along $r = 0$ is not included in axisymmetric problems.

2. **Common Boundary in Part Sets.** The common boundary between parts in the part set PSID is not included in the boundary segments.

***SET_SHELL**_*{OPTION1}_{OPTION2}*

For *OPTION1* the available options are:

<BLANK>

LIST

COLUMN

LIST_GENERATE

LIST_GENERATE_INCREMENT

GENERAL

For *OPTION2* the available option is:

COLLECT

The LIST_GENERATE and LIST_GENERATE_INCREMENT options will generate block(s) of shell element IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the shell element set.

Purpose: Define a set of shell elements with optional identical or unique attributes.

Card Summary:

Card 1. This card is required.

SID	DA1	DA2	DA3	DA4			

Card 2a. This card is included if the keyword option is unused or if the LIST keyword option is used. Set one value per element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

EID1	EID2	EID3	EID4	EID5	EID6	EID7	EID8

Card 2b. This card is included if the COLUMN keyword option is used. Include one card per shell element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

EID	A1	A2	A3	A4			

Card 2c. This card is included if the GENERATE keyword option is used. Set one pair of BNBEG and BNEND values per block of shell element IDs. Include as many cards as needed. This input ends at the next keyword ("*") card.

B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END

Card 2d. This card is included if the LIST_GENERATE_INCREMENT keyword option is used. For each block of shell elements add one card to the deck. This input ends at the next keyword ("*") card.

BBEG	BEND	INCR					

Card 2e. This card is included if the GENERAL keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

OPTION	E1	E2	E3	E4	E5	E6	E7

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	DA1	DA2	DA3	DA4			
Type	I	F	F	F	F			
Default	none	0.	0.	0.	0.			
Remarks		1	1	1	1			

VARIABLE	DESCRIPTION
SID	Set ID. All shell sets should have a unique set ID.
DA1	First attribute default value
DA2	Second attribute default value
DA3	Third attribute default value
DA4	Fourth attribute default value

Shell Element ID Cards. This Card 2 format applies to LIST keyword option. Additionally, it applies to the case of an unset (<blank>) keyword option. Set one value per element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2a	1	2	3	4	5	6	7	8
Variable	EID1	EID2	EID3	EID4	EID5	EID6	EID7	EID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
EID*i*	i^{th} shell element ID

Shell Element ID with Column Cards. This Card 2 format applies to the COLUMN keyword option. Include one card per shell element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2b	1	2	3	4	5	6	7	8
Variable	EID	A1	A2	A3	A4			
Type	I	F	F	F	F			
Remarks		2	2	2	2			

VARIABLE	DESCRIPTION
EID	Element ID
A1	First attribute
A2	Second attribute
A3	Third attribute
A4	Fourth attribute

Shell Element ID Range Cards. This Card 2 format applies to the GENERATE keyword option. Set one pair of BNBEG and BNEND values per block of shell element IDs. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2c	1	2	3	4	5	6	7	8
Variable	B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
B[N]BEG	First shell ID in shell block N.
B[N]END	Last shell ID in block N. All defined ID's between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the element numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the ID's and not element IDs.

Shell Element ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of shell elements add one card to the deck. This input ends at the next keyword ("*") card.

Card 2d	1	2	3	4	5	6	7	8
Variable	BBEG	BEND	INCR					
Type	I	I	I					

VARIABLE	DESCRIPTION
BBEG	First shell element ID in block.
BEND	Last shell element ID in block.
INCR	Shell element ID increment. Shell element IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set.

Generalized Shell Element ID Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 2e	1	2	3	4	5	6	7	8
Variable	OPTION	E1	E2	E3	E4	E5	E6	E7
Type	A	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
OPTION	Option for GENERAL. See table below.
E1, …, E7	Specified entity. Each card must have the option specified. See table below.

The General Option:

The "OPTION" column in the table below enumerates the allowed values for the "OPTION" variable in Card 2 for the GENERAL option. Likewise, the variables E1, …, E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of "E*n*" left unspecified are ignored.

Note that the order of the selected operations matters. Elements are only excluded from the set if they were previously added to the set. For instance, if you exclude shell element 5 and then include it, element 5 will be included in the set. For the example set below, suppose that part 6 includes shell elements 10, 15, 20, and 32, box 7 contains shell elements 5, 20, and 32, and part 10 includes shell elements 5, 22, and 106. Then, shell element set 1 contains shell elements 5, 10, 15, 22, and 106.

```
*SET_SHELL_GENERAL
1
PART, 6
DBOX, 7
PART, 10
```

OPTION	DESCRIPTION
ALL	All shell elements will be included in the set.
BOX	Shell elements inside boxes E1, E2, E3, … will be included. (see *DEFINE_BOX)

OPTION	DESCRIPTION
DBOX	Previously added shell elements that are inside boxes E1, E2, E3, … will be excluded.
ELEM	Shell elements E1, E2, E3, … will be included.
DELEM	Shell elements E1, E2, E3, … if previously added will be excluded.
PART	Shell elements of parts E1, E2, E3, … will be included.
DPART	Shell elements that have been previously added and are of parts E1, E2, E3, … will be excluded.
SALECPT	Elements inside a box for a 2D Structured ALE mesh. E1 is the S-ALE mesh ID (MSHID). E2, E3, E4, and E5 correspond to IMIN, IMAX, JMIN, and JMAX, respectively. They are the minimum and the maximum nodal indices along each direction in the S-ALE mesh. This option is only to be used for a Structured ALE mesh. It can be used with SALEFAC to generate a shell set but should not be used with other "_GENERAL" options. Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH for more details.
SALEFAC	Elements on the face of a 2D Structured ALE mesh. E1 is the S-ALE mesh ID (MSHID). E2, E3, E4, and E5 correspond to the -*X*, +*X*, -*Y*, and +*Y* faces, respectively. Assigning 1 to these 4 values would include all the boundary elements at these faces in the shell element set. This option is only to be used for a Structured ALE mesh. It can be used with SALECPT to generate a shell set but should not be used with other "_GENERAL" options. Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH for more details.
SET	Elements of shell element sets (*SET_SHELL) E1, E2, E3, … will be included.
DSET	Previously added elements that are members of shell elements sets E1, E2, E3, ... will be excluded.

Remarks:

1. **Shell Attributes.** Shell attributes can be assigned for some input types.

For example, for contact options, the attributes for the SURFA surface are:

DA1 (NFLS) = Normal failure stress, *CONTACT_TIEBREAK_SURFACE contact only,

DA2 (SFLS) = Shear failure stress, *CONTACT_TIEBREAK_SURFACE contact only,

DA3 (FSF) = Coulomb friction scale factor,

DA4 (VSF) = Viscous friction scale factor,

and the attributes for the SURFB surface are:

DA1 (FSF) = Coulomb friction scale factor,

DA2 (VSF) = Viscous friction scale factor.

2. **Overriding Shell Attributes.** The default shell attributes for the set can be overridden for individual elements using Card 2b; otherwise, A1 = DA1, etc.

*SET_SHELL_ADD

Purpose: Define a shell set by combining shell sets.

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

Shell Element Set Cards. Each card can be used to specify up to 8 shell element set IDs. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	SSID1	SSID2	SSID3	SSID4	SSID5	SSID6	SSID7	SSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new shell set. All shell sets should have a unique set ID.
SSID[N]	The N^{th} shell set ID on Card 2

*SET_SHELL_INTERSECT

Purpose: Define a shell set as the intersection, ∩, of a series of shell sets. The new shell set, SID, contains all shells common to all sets on the cards of format 2.

Card 1	1	2	3	4	5	6	7	8
Variable	SID							
Type	I							
Default	none							

Shell Element Set Cards. For each shell element SID in the intersection input one field. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	SSID1	SSID2	SSID3	SSID4	SSID5	SSID6	SSID7	SSID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
SID	Set ID of new shell set. All shell sets should have a unique set ID.
SSID[N]	The N^{th} shell set ID

***SET_SOLID**_*{OPTION1}_{OPTION2}*

For *OPTION1* the available options are:

<BLANK>

GENERATE

GENERATE_INCREMENT

GENERAL

For *OPTION2* the available option is:

COLLECT

The GENERATE and GENERATE_INCREMENT options will generate block(s) of solid element IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the solid element set.

Purpose: Define a set of solid elements.

Card Summary:

Card 1. This card is required.

SID	SOLVER						

Card 2a. This card is included if the keyword option is left unset (<BLANK>). Set one value per solid element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

K1	K2	K3	K4	K5	K6	K7	K8

Card 2b. This card is included if the keyword option GENERATE is used. Set one pair of BNBEG and BNEND values per block of solid elements. Include as many cards as needed. This input ends at the next keyword ("*") card.

B1BEG	B1END	B2BEG	B2END	B3BEG	B3END	B4BEG	B4END

Card 2c. This card is included if the keyword option GENERATE_INCREMENT is used. For each block of solid elements add one card to the deck. This input ends at the next keyword ("*") card.

BBEG	BEND	INCR					

Card 2d. This card is included if the keyword option GENERAL is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

OPTION	E1	E2	E3	E4	E5	E6	E7

Data Card Definitions:

DSET	Previously added elements that are members of shell element sets E1, E2, E3, … will be excluded.

*RVE

The *RVE keywords control a Representative Volume Element (RVE) analysis. This method can predict macroscopic material properties for various types of composites from their microstructural information. Using this method, you can conduct virtual testing of numerically re-constructed material samples at their characteristic length scales. The algorithms invoked with *RVE keywords automatically create periodic or linear displacement boundary conditions, perform FEM-based computational homogenization, and predict the homogenized macroscopic constitutive responses as well as the detailed microscopic stress / strain fields.

The only available keyword is:

*RVE_ANALYSIS_FEM

*RVE_ANALYSIS_FEM

Purpose: Predict the macroscopic effective constitutive behaviors of composite materials under the micromechanics-based computational homogenization framework. Composite materials supported for this feature include but are not limited to fiber-reinforced composites, particulate composites, laminar composites, polycrystalline aggregates, and single-phase or multi-phase porous media.

We account for both the geometrical and material nonlinearities of the Representative Volume Element (RVE) with the nonlinear computational homogenization theory. Given the material microstructural information (geometry and constitutive properties for base materials), this keyword causes

1. Automatic creation of periodic displacement boundary conditions (or linear displacement boundary conditions) on the RVE finite element mesh;

2. A nonlinear quasi-static implicit finite element analysis of the RVE under user-defined loading conditions; and

3. The calculation of the macroscopic effective material responses through homogenization of the RVE's microscopic material responses as well as a detailed distribution and evolution of microscopic stress/strain fields within the RVE.

Double precision SMP/MPP LS-DYNA version R13 and newer versions support this RVE analysis function.

Default	none							

VARIABLE	DESCRIPTION
MESHFILE	Name of an input file that contains the mesh information (nodal coordinates, element connectivity) of the RVE model. Note that this file should be in keyword format [basename].k. The finite element mesh given in this file is for the spatial discretization of the material microstructures. Do not include dummy nodes for specifying control points in boundary conditions. See Remark 1.

Card 2	1	2	3	4	5	6	7	8
Variable	INPT	OUPT	LCID	IDOF	BC	IMATCH	IMAGE	
Type	I	I	I	I	I	I	I	
Default	0	1	none	none	0	1	0	

VARIABLE	DESCRIPTION
INPT	Type of input: EQ.0: RVE boundary conditions are fully defined by two factors: (1) the parameter BC of this input card, and (2) the mesh information in the file specified in MESHFILE. When running an RVE simulation, LS-DYNA automatically creates a file named rve_[basename].k. This file contains all the necessary information (e.g., dummy nodes, displacement constraints, etc.) for boundary condition enforcement. EQ.1: You provide a file named rve_[basename].k to specify the boundary condition keywords (e.g. *CONSTRAINED_MULTIPLE_GLOBAL, *BOUNDARY_SPC_NODE, etc.)

VARIABLE	DESCRIPTION
	and dummy nodes for enforcing RVE boundary conditions. We do not recommend this option since it is usually nontrivial to manually define all the keywords for RVE boundary conditions. If the file rve_[basename].k is not found when running RVE simulations, then LS-DYNA will create rve_[basename].k based on the parameter BC and the mesh information in the file specified with MESHFILE.
OUPT	Type of output: EQ.1: RVE homogenization results will be written out to a file named rveout. Please refer to the keyword *DATABASE_RVE.
LCID	Load curve ID for specifying loading history. This curve gives a scale factor on the macroscopic deformation measure (H11, H22, …, H13 input on Card 3) as a function of normalized loading time. Normalized time of 0.0 is the beginning of loading while 1.0 is the end of loading.
IDOF	Dimension of the RVE: EQ.2: 2D geometry EQ.3: 3D geometry
BC	Type of the RVE boundary condition (see Remark 2 and Figure 42-1): EQ.0: Periodic displacement boundary condition EQ.1: Linear displacement boundary condition EQ.2: Partially Periodic Displacement Boundary Condition (PDBC). Card 4 is required.
IMATCH	Type of the given RVE mesh (ignored unless BC = 0; see Remark 3): EQ.0: The mesh is non-matching for periodic displacement boundary condition. EQ.1: The mesh is periodic displacement boundary condition matching.
IMAGE	Create image RVE in specified directions. This feature is only available for IMATCH = 1. See Remark 11 and Figure 42-2.

VARIABLE	DESCRIPTION
	EQ.110: Create image RVE in x direction
	EQ.120: Create image RVE in y direction
	EQ.130: Create image RVE in z direction
	EQ.212: Create image RVE in both the x and y directions
	EQ.213: Create image RVE in both the x and z directions
	EQ.232: Create image RVE in both the y and z directions
	EQ.300: Create image RVE in the x, y and z directions

Card 3	1	2	3	4	5	6	7	8
Variable	H11	H22	H33	H12	H23	H13		
Type	F	F	F	F	F	F		
Default	optional	optional	optional	optional	optional	optional		

VARIABLE	DESCRIPTION
H*IJ*	Component *ij* of the prescribed macroscopic displacement gradient, $\widetilde{\mathbf{H}}$. $\widetilde{\mathbf{H}}$ is assumed to be symmetric (see Remark 4). Note that you should leave the component H*IJ* empty (instead of setting it to be zero) if you do not want to impose the corresponding constraints on the RVE. Please refer to Remarks 2 and 8.

PDBC Card. This card is required for BC = 2.

Card 4	1	2	3	4	5	6	7	8
Variable	PX	PY	PZ					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
P*i*	Flag to apply the periodic boundary condition in the i^{th} direction ($i = x$, y, or z) for PDBC: EQ.0: Periodic boundary condition is not applied for this direction. EQ.1: Periodic boundary condition is applied for this direction.

Remarks:

1. **RVE Mesh.** The RVE's mesh information (nodal coordinates, element connectivity) should be provided in a separate input file, of which the file name should be given in Card 1 of the keyword *RVE_ANALYSIS_FEM. Usually, a 3D RVE model has a cuboid shape with its edges parallel to the X-, Y-, and Z-axes of the global coordinate system, respectively. A 2D RVE model is rectangular with its edges parallel to the X- and Y- axes of the global coordinate system, respectively. The size of the RVE should be large enough to include sufficient statistical microstructural information (fibers, particles, voids, grains, etc.) of the composite material. It should, however, remain small enough to be considered as a volume element of continuum mechanics. The 3D RVE should be meshed with solid elements (see *ELEMENT_SOLID) while the 2D RVE should be meshed with shell elements (see *ELEMENT_SHELL).

2. **Boundary Conditions.** LS-DYNA can automatically create boundary conditions on the external boundary $\partial\Omega$ of the RVE. Two types of RVE boundary conditions can be created, depending on the input value of BC:

   a) *Periodic Displacement Boundary Condition (BC = 0).* When BC = 0, LS-DYNA imposes the following periodic displacement boundary condition:

   $$\mathbf{w}_\alpha^+ - \mathbf{w}_\alpha^- = \widetilde{\mathbf{H}}(\mathbf{X}_\alpha^+ - \mathbf{X}_\alpha^-) \ .$$

   Here $\mathbf{X}_\alpha^+ \in \partial\Omega_\alpha^+$ and $\mathbf{X}_\alpha^- \in \partial\Omega_\alpha^-$ denote the microscale material points located on a pair of opposite external boundaries $\partial\Omega_\alpha^+$ and $\partial\Omega_\alpha^-$, respectively, in the RVE's initial configuration (See Figure 42-1 for a 2D illustration). $\mathbf{w}_\alpha^+$ and $\mathbf{w}_\alpha^-$ are the microscale displacements of the material points $\mathbf{X}_\alpha^+$ and $\mathbf{X}_\alpha^-$, respectively. The subscript $\alpha = 1,2\ldots,d$ where $d = 2$ for 2D RVE models and $d = 3$ for 3D RVE models. To impose the periodicity constraint, a control point-based method is implemented, which is similar to the keywords *INCLUDE_UNITCELL and *CONSTRAINED_MULTIPLE_GLOBAL. Unlike these other keywords, *RVE_ANALYSIS_FEM automatically creates these control points.

   b) *Linear Displacement Boundary Condition (BC = 1).* When BC = 1, LS-DYNA imposes the following linear displacement boundary condition:

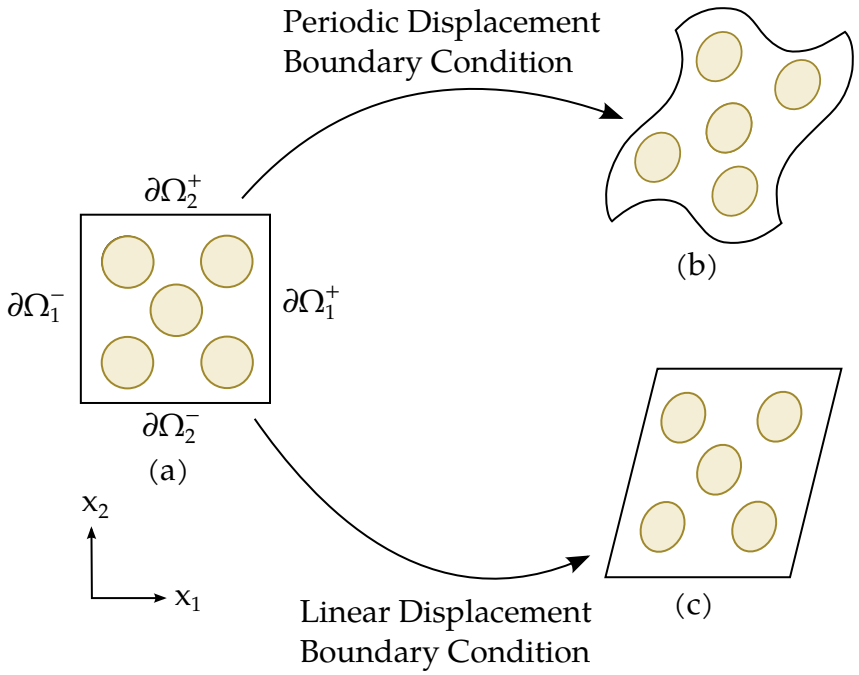

Figure 42-1. Schematic of the two types of displacement boundary conditions for RVE analysis. (a) The initial configuration of RVE occupying the domain Ω, where $\partial\Omega_\alpha^+$ and $\partial\Omega_\alpha^-$ denote a pair of opposite external boundaries. $\alpha = 1, 2$ for this 2D model. (b) The current configuration of RVE subjected to periodic displacement boundary conditions. (c) The current configuration of RVE subjected to linear displacement boundary conditions.

$$\mathbf{w}_\alpha = \widetilde{\mathbf{H}}\mathbf{X}_\alpha,$$

where $\mathbf{X}_\alpha \in \partial\Omega_\alpha$ denotes any micro-scale material point located on the external boundaries $\partial\Omega_\alpha = \partial\Omega_\alpha^+ \cup \partial\Omega_\alpha^-$ of the RVE. Note that the RVE's complete external boundary can be expressed as $\partial\Omega = \bigcup_{\alpha=1}^{d} \partial\Omega_\alpha$, in which $d = 2$ for 2D RVE models and $d = 3$ for 3D RVE models. It is noteworthy to mention that RVEs with linear displacement boundary conditions usually appear to be stiffer than RVEs with periodic displacement boundary conditions. When the size of RVE is large enough, however, the influence of different types of boundary conditions on the homogenized material properties becomes negligibly small.

The assignment of a zero value to any component of the macroscopic displacement gradient $\widetilde{\mathbf{H}}$ indicates the imposition of the boundary constraint based on the above constraint equations. If you do not want to impose constraints in certain directions (i.e., allow the associated RVE boundaries to deform freely), then you should leave the corresponding component of $\widetilde{\mathbf{H}}$ empty in the input card. Please refer to Remark 8 for an application scenario where most components of $\widetilde{\mathbf{H}}$ should be set empty.

3. **IMATCH for Periodic Displacement Boundary Conditions.** When the mesh is periodic displacement boundary condition matching, the nodal distributions on the RVE's opposite sides match well with each other. For instance, let us consider two opposite surfaces, surface A and surface B, that are both perpendicular to the X-axis. For any FEM node on surface A, if we draw a straight line that is parallel to the X-axis, then the intersection point of this line with surface B must also be an FEM node. For such periodic displacement boundary condition matching meshes, an efficient direct nearest neighbor search algorithm imposes the boundary condition. Thus, a matching mesh is preferred for imposing the periodic displacement boundary conditions. However, if complex material microstructures exist, it is not always straightforward to create matching meshes. In this case, set IMATCH to zero which calls a projection-based constraint imposition method.

4. **Prescribed Macroscopic Displacement Gradient.** The prescribed macroscopic displacement gradient is given as:

$$\widetilde{\mathbf{H}} \equiv \nabla_{\widetilde{\mathbf{X}}} \tilde{\mathbf{u}} = \tilde{\mathbf{F}} - \mathbf{I} \ ,$$

where $\nabla_{\widetilde{\mathbf{X}}}$ is the gradient operator with respect to the macroscale, $\tilde{\mathbf{u}}$ is the macroscopic displacement field, $\tilde{\mathbf{F}}$ is the macroscopic deformation gradient, and $\mathbf{I}$ is the identity tensor. Generally, $\tilde{\mathbf{F}}$ is not symmetric. Thus, $\widetilde{\mathbf{H}}$ is not usually symmetric. Through polar decomposition of the deformation gradient, $\tilde{\mathbf{F}} = \tilde{\mathbf{R}}\widetilde{\mathbf{U}}$. $\tilde{\mathbf{R}}$ represents the macroscopic rigid body rotation, and $\widetilde{\mathbf{U}}$ is a symmetric stretch tensor describing the pure material deformation. Since material constitutive behaviors are not affected by macroscopic rigid body rotations, we will assume $\tilde{\mathbf{R}} = \mathbf{I}$ in the RVE analysis. Under this condition, both the macroscopic deformation gradient $\tilde{\mathbf{F}}$ and macroscopic displacement gradient $\widetilde{\mathbf{H}}$ become symmetric.

Because $\widetilde{\mathbf{H}}$ is symmetric, only six components of $\widetilde{\mathbf{H}}$ are needed to prescribe boundary conditions for 3D RVE analysis. For 2D RVE problems, the inputs for H33, H23, and H13 are ignored, and only the inputs for H11, H22, and H12 are adopted for enforcing the boundary condition. Note that you should leave the component H*IJ* empty (instead of setting it to be zero) if you do not want to impose the corresponding constraints on the RVE. Please refer to Remarks 2 and 8.

5. **Constitutive Models for Base Materials.** Depending on the actual morphology of material microstructures, an RVE finite element model can consist of many parts. Each part can be assigned a unique constitutive law to describe the behaviors of the corresponding base material (e.g., fiber, particle, matrix, grain, etc.). Any constitutive model (linear/nonlinear, isotropic/anisotropic, etc.) can be selected for the base materials as long as the model is supported for implicit analysis. The part and material information should be contained in the main input file, not in MESHFILE. See the example below.

6. **Accuracy Control for the Implicit Calculation.** To ensure high accuracy of the nonlinear implicit finite element simulation, we recommend using the 2nd order objective stress update scheme specified with OSU = 1 on *CONTROL_ACCURACY. We also suggest specifying other control parameters for the implicit solver in relevant keywords, such as *CONTROL_IMPLICIT_GENERAL, *CONTROL_IMPLICIT_SOLUTION, and *CONTROL_IMPLICIT_SOLVER.

7. **Homogenized Results.** LS-DYNA writes out the homogenized material responses to a file named rveout. In this file, the macroscopic deformation gradient $\tilde{\mathbf{F}}^t$, Green strain $\tilde{\mathbf{E}}^t$, Cauchy stress $\tilde{\boldsymbol{\tau}}^t$, and the 1st Piola-Kirchhoff stress $\tilde{\mathbf{P}}^t$, are recorded at each output time t. Different measures for the macroscale stress and deformation can be obtained based on their relationships with the results in rveout. For instance, the 2nd Piola-Kirchhoff stress $\tilde{\mathbf{S}}$ is defined as $\tilde{\mathbf{S}} = \tilde{\mathbf{P}}\tilde{\mathbf{F}}^{-T}$. It can be easily calculated since $\tilde{\mathbf{P}}$ and $\tilde{\mathbf{F}}$ are available in rveout.

   Note that, as discussed in Remark 4, the macroscale rigid body rotations are excluded from the macroscopic displacement gradient. Accordingly, the macroscopic deformation gradient $\tilde{\mathbf{F}}^t$ and 1st Piola-Kirchoff stress $\tilde{\mathbf{P}}^t$ obtained from RVE analysis are both symmetric, so only six components of each symmetric tensor are written to rveout.

8. **Degeneration to Small Strain Analysis**. Although a nonlinear computational homogenization formulation is implemented in LS-DYNA to capture the RVE's finite deformation effects, the homogenized quantities will be close to those calculated by small strain homogenization theories when the actual macroscopic deformation is small. In this situation, the macroscopic Green strain $\tilde{\mathbf{E}}$ given in the rveout file will be approximately equal to the infinitesimal strain, and different stress measures ($\tilde{\mathbf{P}}$, $\tilde{\mathbf{S}}$, and $\tilde{\boldsymbol{\tau}}$) will have an identical magnitude.

   For small strain linear analysis, if we conduct 3D RVE simulations with six orthogonal loading conditions (e.g., three uniaxial tensile loadings and three pure shear loadings), respectively, then we will obtain the full macroscopic elasticity tensor for the composite material. Recall that the macroscale linear elastic constitutive relationship can be expressed as follows:

$$\tilde{\varepsilon} = \tilde{C}\tilde{\sigma} \quad .$$

   $\tilde{C}$ is the 6 × 6 macroscopic material compliance matrix:

$$\tilde{C} = \begin{bmatrix} \tilde{C}_{11} & \tilde{C}_{12} & \tilde{C}_{13} & \tilde{C}_{14} & \tilde{C}_{15} & \tilde{C}_{16} \\ \tilde{C}_{21} & \tilde{C}_{22} & \tilde{C}_{23} & \tilde{C}_{24} & \tilde{C}_{25} & \tilde{C}_{26} \\ \tilde{C}_{31} & \tilde{C}_{32} & \tilde{C}_{33} & \tilde{C}_{34} & \tilde{C}_{35} & \tilde{C}_{36} \\ \tilde{C}_{41} & \tilde{C}_{42} & \tilde{C}_{43} & \tilde{C}_{44} & \tilde{C}_{45} & \tilde{C}_{46} \\ \tilde{C}_{51} & \tilde{C}_{52} & \tilde{C}_{53} & \tilde{C}_{54} & \tilde{C}_{55} & \tilde{C}_{56} \\ \tilde{C}_{61} & \tilde{C}_{62} & \tilde{C}_{63} & \tilde{C}_{64} & \tilde{C}_{65} & \tilde{C}_{66} \end{bmatrix},$$

The vectors $\tilde{\varepsilon} = [\tilde{\varepsilon}_{11} \quad \tilde{\varepsilon}_{22} \quad \tilde{\varepsilon}_{33} \quad \tilde{\varepsilon}_{12} \quad \tilde{\varepsilon}_{23} \quad \tilde{\varepsilon}_{31}]^T$ and $\tilde{\sigma} = [\tilde{\sigma}_{11} \quad \tilde{\sigma}_{22} \quad \tilde{\sigma}_{33} \quad \tilde{\sigma}_{12} \quad \tilde{\sigma}_{23} \quad \tilde{\sigma}_{31}]^T$ contain six macroscopic strain and stress components, respectively.

If we specify uniaxial tensile loading (H11 = ϵ, where ϵ is a non-zero small number, and all other components of the macroscopic displacement gradient are left empty) in Card 3, then the finite element simulation of RVE will yield a homogenized stress vector $\tilde{\sigma} = [\tilde{\sigma}_1 \quad 0.0 \quad 0.0 \quad 0.0 \quad 0.0 \quad 0.0]^T$ and a homogenized strain vector $\tilde{\varepsilon} = [\tilde{\varepsilon}_1 \quad \tilde{\varepsilon}_2 \quad \tilde{\varepsilon}_3 \quad \tilde{\varepsilon}_4 \quad \tilde{\varepsilon}_5 \quad \tilde{\varepsilon}_6]^T$. These results are available in rveout. We can then calculate the first column of the macroscopic material compliance matrix as follows:

$$\tilde{C}_{11} = \tilde{\varepsilon}_1/\tilde{\sigma}_1, \quad \tilde{C}_{21} = \tilde{\varepsilon}_2/\tilde{\sigma}_1, \quad \tilde{C}_{31} = \tilde{\varepsilon}_3/\tilde{\sigma}_1,$$
$$\tilde{C}_{41} = \tilde{\varepsilon}_4/\tilde{\sigma}_1, \quad \tilde{C}_{51} = \tilde{\varepsilon}_5/\tilde{\sigma}_1, \quad \tilde{C}_{61} = \tilde{\varepsilon}_6/\tilde{\sigma}_1.$$

Similarly, all the other macroscopic compliance coefficients can be computed by applying different uniaxial tensile and pure shear loading conditions. By inverting the compliance matrix $\tilde{C}$, we can obtain the macroscopic material stiffness matrix.

9. **Calibration of Macroscale Constitutive Laws.** If a functional form of the macroscopic constitutive equation is available, then a series of numerical material tests can be properly designed and conducted on the RVE model to identify the material parameters for the assumed constitutive model. In other words, by treating RVEs as virtual material samples, we can fit macroscale material model parameters while reducing the amount of expensive (or unfeasible) physical experiments for composite materials.

10. **De-homogenization/Localization analysis.** After performing a standard macroscale structural finite element analysis in LS-DYNA, we can obtain the macroscale deformation history at any element or integration point of the macrostructure. If we convert such information to the macroscopic displacement gradient $\tilde{\mathbf{H}} \equiv \nabla_{\mathbf{X}}\tilde{\mathbf{u}}$, we can then apply this *RVE_ANALYSIS_FEM keyword to perform the RVE localization analysis (also called de-homogenization analysis) to evaluate the actual micro-scale material responses, including the evolution and distribution of microscopic stress/strain fields within the heterogeneous RVE. These detailed microscale material responses are available in the standard LS-DYNA output files (e.g., d3plot). The multiscale simulation can provide useful guidance to both microscopic material design and macroscopic structural analysis.

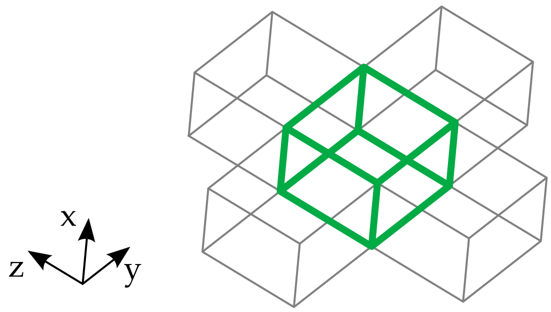

Figure 42-2. Example of image RVEs in both the y and z directions. The green lines outline the real RVE while the grey lines outline the image RVEs.

11. **Image RVE.** The RVE feature in LS-DYNA generally imposes periodic boundary conditions on the RVE boundary but does not impose periodic contact constraints. For some special RVEs, such as textile RVEs, no matrix exists and the yarns in the RVE tend to untangle from other yarns during deformation. To resolve this issue, we developed the image RVE feature. When IMAGE is nonzero, image RVEs are generated automatically in the specified directions. The motion of the image RVE will follow the motion of the real RVE but with an offset distance (equal to the displacement of the control nodes in the specified direction). Specifically, the offset is defined as

$$u_I = u_R + \alpha u_c \ ,$$

where u_I is the displacement of the nodes in the image RVE, u_R is the displacement of the nodes in the real RVE, u_C is the displacement of the control nodes in a certain direction, and α is the coefficient relating the position of the image RVE. The value of α will be 1 or -1. The following figure gives an example of a real RVE (outlined with green lines) and image RVEs in both the y and z directions (outlined with grey lines).

*TERMINATION

The keyword *TERMINATION provides an alternative way of stopping the calculation before the termination time is reached. The termination time is specified on the *CONTROL_TERMINATION input and will terminate the calculation whether or not the options available in this section are active. Different types of termination may be defined:

*TERMINATION_BODY

*TERMINATION_CONTACT

*TERMINATION_CURVE

*TERMINATION_DELETED_SHELLS

*TERMINATION_DELETED_SOLIDS

*TERMINATION_NODE

*TERMINATION_SENSOR

*TERMINATION_BODY

Purpose: Terminate calculation based on rigid body displacements. For *TERMINATION_BODY the analysis terminates when the center of mass displacement of the rigid body specified reaches either the maximum or minimum value (stops 1, 2 or 3) or the displacement magnitude of the center of mass is exceeded (stop 4). If more than one condition is input, the analysis stops when any of the conditions is satisfied. Termination by other means than *TERMINATION input is controlled by the *CONTROL_TERMINATION control card. Note that this type of termination is not active during dynamic relaxation.

Part Cards. Add one card for each part having termination criterion. Include as many cards as necessary. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	STOP	MAXC	MINC				
Type	I	I	F	F				
Default	none	none	-	-				

VARIABLE	DESCRIPTION
PID	Part ID of rigid body, see *PART_*OPTION*.
STOP	Stop criterion: EQ.1: global x direction, EQ.2: global y direction, EQ.3: global z direction, EQ.4: stop if displacement magnitude is exceeded.
MAXC	Maximum (most positive) displacement, options 1, 2, 3 and 4: EQ.0.0: MAXC set to 1.0e21.
MINC	Minimum (most negative) displacement, options 1, 2 and 3 above only: EQ.0.0: MINC set to -1.0e21.

*TERMINATION_CONTACT

Purpose: The analysis terminates when the magnitude of the contact interface resultant force is either zero or less than or equal to a threshold value. If more than one contact condition is input, the analysis stops when any of the conditions is satisfied. Termination by means other than *TERMINATION input is controlled by the *CONTROL_TERMINATION control card. Note that this type of termination is not active during dynamic relaxation and does not apply to 2D contact types.

Contact ID Cards. Add one card for each contact ID having a termination criterion. Include as many cards as necessary. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	CID	ACTIM	DUR	THRES	DOF			
Type	I	F	F	F	I			
Default	none	none	↓	0.0	0			

VARIABLE	DESCRIPTION
CID	Contact ID. The contact ID is defined by the ordering of the contact input unless the TITLE option which allows the CID to be defined is used in the *CONTACT section.
ACTIM	Activation time
DUR	Time duration of null resultant force prior to termination. This time is tracked only after the activation time is reached and the contact resultant forces are zero. EQ.0.0: Immediate termination after null force is detected.
THRES	Any measured force magnitude below or equal to this specified threshold is taken as a null force.
DOF	Option to consider only the force magnitude in the x, y, or z global directions corresponding to DOF = 1, 2, and 3, respectively.

*TERMINATION_CURVE

Purpose: Terminate the calculation when the load curve value returns to zero. This termination can be used with the contact option *CONTACT_AUTO_MOVE. With this option, the load curve is modified to account for the movement of the SURFB surface.

Load Curve Card. For each load curve used as a termination criterion add a card. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID	ATIME						
Type	I	F						
Default	none	↓						

VARIABLE	DESCRIPTION
LCID	Load curve ID governing termination.
ATIME	Activation time. After this time the load curve is checked. EQ.0.0: termination will occur after the load curve value becomes nonzero and then returns to zero

*TERMINATION_DELETED_SHELLS_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Terminate the calculation when the number of deleted shells for a specified part ID exceeds the value defined here. This input has no effect for a part ID that is left undefined. Generally, this option should be used with the NFAIL1 and NFAIL4 parameters that are defined in the *CONTROL_SHELL control information.

When using the SET option, termination will occur when NDS elements are deleted in any one of the parts in the part set PSID.

Part (set) Cards. Include one card for each part having a termination criterion based on shell deletion. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	NDS						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
PID / PSID	Part ID or if option SET is active, part set ID.
NDS	Number of elements that must be deleted for the specified part ID's, before an error termination occurs.

***TERMINATION_DELETED_SOLIDS**_*{OPTION}*

Available options include:

<BLANK>

SET

Purpose: Terminate the calculation when the number of deleted solids for a specified part ID exceeds the value defined here. This input has no effect for a part ID that is left undefined.

When using the SET option, termination will occur when NDS elements are deleted in any one of the parts in the part set PSID.

Part (set) Cards. Include one card for each part having a termination criterion based on solid element deletion. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID/PSID	NDS						
Type	I	I						
Default	none	1						

VARIABLE	DESCRIPTION
PID/PSID	Part ID or if option SET is active, part set ID.
NDS	Number of elements that must be deleted for the specified part ID's, before an error termination occurs.

*TERMINATION_NODE

Purpose: Terminate calculation based on nodal point *coordinates*. The analysis terminates for *TERMINATION_NODE when the current position of the node specified reaches either the maximum or minimum value (stops 1, 2 or 3), or picks up force from any contact surface (stops 4). Termination by other means than *TERMINATION is controlled by the *CONTROL_TERMINATION control card. Note that this type of termination is not active during dynamic relaxation.

Node Cards. Include one card for each node having a termination criterion. Include as many cards as desired. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NID	STOP	MAXC	MINC				
Type	I	I	F	F				
Default	none	none	↓	↓				

VARIABLE	DESCRIPTION
NID	Node ID, see *NODE_*OPTION*.
STOP	Stop criterion: EQ.1: global *x*-direction, EQ.2: global *y*-direction, EQ.3: global *z*-direction, EQ.4: stop if node touches contact surface.
MAXC	Maximum (most positive) coordinate (options 1, 2 and 3) above only.
MINC	Minimum (most negative) coordinate (options 1, 2 and 3) above only.

*TERMINATION_SENSOR

Purpose: Terminates the calculation when the switch condition defined in *SENSOR_-SWITCH is met.

Card 1	1	2	3	4	5	6	7	8
Variable	SWID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
SWID	ID of *SENSOR_SWITCH which will terminate the calculation when its condition is met. Only one *TERMINATION_SENSOR is allowed. If more than one *TERMINATION_SENSOR is defined; only the last one is effective.

Remarks:

An example allowing more than one sensor_switch to terminate calculation:

```
*SENSOR_DEFINE_ELEMENT
$ Axial force of beam element 1
44,BEAM,1,AXIAL,FORCE
*SENSOR_DEFINE_ELEMENT
$ Axial force of beam element 2
55,BEAM,21,AXIAL,FORCE
*SENSOR_SWITCH
$a switch condition is  met when the axial force of beam-1 >5.0
11,SENSOR,44,GT,5.
*SENSOR_SWITCH
$a switch condition is  met when the axial force of beam-2 >10.0
22,SENSOR,55,GT,10.
*SENSOR_SWITCH
$ a switch condition is  met when time >50.
33,TIME, , 50
*SENSOR_SWITCH_CALC-LOGIC
$ a switch condition is met if both conditions
$ of switch-11 and switch-33 are met, I.e.,
$ axial force of beam-1>5.0 and time>50
44,11,33
*SENSOR_SWITCH_CALC-LOGIC
$ a switch condition is met if both conditions
$ of switch-22 and switch-33 are met, I.e.,
$ axial force of beam-2>10.0 and time>50
55,33,22
*SENSOR_SWITCH_CALC-LOGIC
$ a switch condition is met if the conditions
```

```
$ of switch-44 or switch-55 is met, I.e.,
$ axial force of beam-1>5.0 and time>50 or
$ axial force of beam-2>10.0 and time>50
66,44,-55
*TERMINATION_SENSOR
$ job will be terminated when the switch condition of switch-66 is met, I.e.,
$ axial force of beam-1>5.0 and time>50 or
$ axial force of beam-2>10.0 and time>50
66
```

*TITLE

Purpose: Define job title.

Card 1	1	2	3	4	5	6	7	8
Variable	TITLE							
Type	C							
Default	LS-DYNA USER INPUT							

VARIABLE	DESCRIPTION
TITLE	Heading to appear on output and in output files.

*UNIT

The keyword *UNIT provides a coherent way to specify units in an LS-DYNA problem: Initially, it will be used to define the default units of a problem, and then the units in any LS-DYNA solver or keyword card that implements this capability. Its initial use is with the *DUALCESE solver. See Vol. III for details about those solvers. *DUALCESE uses this unit information to convert to and from external physical databases, such as the EOS libraries REFPROP and COOLPROP. Later, this information will also be used for connecting *DUALCESE with Chemkin-type chemistry databases.

*UNIT_AMOUNT

*UNIT_ANGLE

*UNIT_DEFAULTS

*UNIT_DERIVED

*UNIT_ELECTRIC_CURRENT

*UNIT_LENGTH

*UNIT_LUMINOUS_INTENSITY

*UNIT_MASS

*UNIT_SYSTEM

*UNIT_TEMPERATURE

*UNIT_TIME

WARNING: Including these cards in the same input deck with *INCLUDE_TRANSFORM with non-unity values for FCTMAS, FCTLEN, or FCTTIM is undefined. The same applies to the case of *INCLUDE_TRANSFORM with a non-blank specification for FCTTEM.

*UNIT_DEFAULTS

Purpose: Specify the user units for the current keyword input deck. These *UNIT cards are designed for when a solver and an external database to which the solver is connecting are in different units. It is also intended to be used for converting the units of data exchanged between solvers. Other applications are being planned.

Only one *UNIT_DEFAULTS card is allowed per problem.

Card 1	1	2	3	4	5	6	7	8
Variable	LENGTH	MASS	TIME	TEMP	CURRENT	AMOUNT	LUMIN	ANGLE
Type	A	A	A	A	A	A	A	A
Default	m	kg	sec	K	ampere	mole	candela	radian

VARIABLE	DESCRIPTION	
LENGTH	Length units:	
	EQ.M:	meter (default)
	EQ.KM:	kilometer
	EQ.MM:	millimeter
	EQ.CM:	centimeter
	EQ.DM:	decimeter
	EQ.UM:	micron
	EQ.NM:	nanometer
	EQ.MIL:	mil
	EQ.IN:	inch
	EQ.FT:	foot
	EQ.YD:	yard
	EQ.A:	Angstrom
	EQ.MILE:	mile
	EQ.ROD:	rod
	EQ.LIGHTYEAR:	lightyear

VARIABLE	DESCRIPTION	
MASS	Mass units:	
	EQ.KG:	kilogram (default)
	EQ.G:	gram
	EQ.CENTIG:	centigram
	EQ.MG:	milligram
	EQ.MICROG:	microgram
	EQ.OUNCE:	ounce
	EQ.POUND:	pound
	EQ.POUNDAL:	poundal
	EQ.TON:	ton
	EQ.METRICTON:	metric ton
	EQ.SHORTTON:	short ton
	EQ.SLUG:	pound × second2 / foot
	EQ.AMU:	amu
TIME	Time units:	
	EQ.SEC:	second (default)
	EQ.MILLISEC:	millisecond
	EQ.MICROSEC:	microsecond
	EQ.NANOSEC:	nanosecond
	EQ.PICOSEC:	picosecond
	EQ.MIN:	minute
	EQ.HOUR:	hour
	EQ.DAY:	day
	EQ.WEEK:	week
	EQ.MONTH:	month
	EQ.YEAR:	year
TEMP	Temperature units:	
	EQ.K:	Kelvin (default)
	EQ.C:	Celsius

VARIABLE	DESCRIPTION
	EQ.F: Fahrenheit
	EQ.R: Rankine
CURRENT	Electric current units:
	EQ.AMPERE: ampere (default)
	EQ.MA: milliampere
	EQ.ABAMP: abampere
	EQ.STATSMP: statampere
	EQ.BIOT: Biot (same as abampere)
AMOUNT	Amount units:
	EQ.MOLE: moles (default)
LUMIN	Luminosity units:
	EQ.CANDELA: candela (default)
	EQ.VIOLLE: violle
	EQ.CANDLE_GER: Candle Germany
ANGLE	Angle units:
	EQ.RADIAN: radians (default)
	EQ.DEGREE: degrees
	EQ.DEGREE_MIN: degree minute
	EQ.DEGREE_SEC: degree second
	EQ.REV: revolutions

*UNIT_DERIVED

Purpose: Derive a new unit based upon products of powers of *UNIT default units: m, kg, sec, K, ampere, mole, candela, and radian. This derived unit is then made available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	UNITNAME							
Type	A							
Remarks	2, 4							

Card 2	1	2	3	4	5	6	7	8
Variable	EXP_LENG	EXPMASS	EXP_TIME	EXPTEMP	EXPCURR	EXPAMT	EXPLUMIN	EXPANGLE
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Remarks	1	1	1	1, 3	1	1	1	1

VARIABLE	DESCRIPTION
UNITNAME	Name of derived unit
EXP_LENG	Power of length unit
EXPMASS	Power of mass unit
EXP_TIME	Power of time unit
EXPTEMP	Power of temperature unit
EXPCURR	Power of electric current unit
EXPAMT	Power of amount unit
EXPLUMIN	Power of luminosity unit

VARIABLE	DESCRIPTION
EXPANGLE	Power of angle unit

Remarks:

1. **Excluding Fundamental Unit.** If the exponent of a given fundamental unit is zero, then that unit is not part of the derived unit.

2. **Validity.** In order to define a valid derived unit, at least one of the fundamental units must have its exponent be nonzero.

3. **Temperature in Derived Unit.** If temperature is involved in deriving a new unit, it must be converting from the Kelvin (K) temperature unit (without a shift).

4. **Availability.** This derived unit is made available for use with all unit systems setup by the user.

*UNIT_AMOUNT

Purpose: Specify a new user amount unit to make it available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	AMOUNT_UNIT		AMOUNT_SCALE					
Type	A		F					
Default	none		1.0					

VARIABLE	DESCRIPTION
AMOUNT_UNIT	Name of new amount unit
AMOUNT_SCALE	Scale factor to convert from this new unit amount to moles

Remarks:

1. **Conversion Factor.** The scale factor should be such that:

$$[\text{mole}] = \text{AMOUNT\_SCALE} \times \left[\text{AMOUNT\_UNIT}\right] .$$

*UNIT_ANGLE

Purpose: Specify a new user angle unit to make it available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	ANGLE_UNIT		ANGLE_SCALE					
Type	A		F					
Default	none		1.0					

VARIABLE	DESCRIPTION
ANGLE_UNIT	Name of new angle unit
ANGLE_SCALE	Scale factor to convert from this new angle unit to radians

Remarks:

1. **Conversion Factor.** The scale factor should be such that:

$$[\text{radians}] = \text{ANGLE\_SCALE} \times \left[\text{ANGLE\_UNIT}\right].$$

*UNIT_ELECTRIC_CURRENT

Purpose: Specify a new user electric current unit to make it available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	EC_UNIT		EC_SCALE					
Type	A		F					
Default	none		1.0					

VARIABLE	DESCRIPTION
EC_UNIT	Name of new electric current unit
EC_SCALE	Scale factor to convert from this new electric current unit to amperes

Remarks:

1. **Unit Conversion.** The scale factor should be such that:

$$[\text{ampere}] = \text{EC\_SCALE} \times \left[\text{EC\_UNIT}\right] .$$

*UNIT_LENGTH

Purpose: Specify a new user length unit to make it available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	LENGTH_UNIT		LENGTH_SCALE					
Type	A		F					
Default	none		1.0					

VARIABLE	DESCRIPTION
LENGTH_UNIT	Name of new length unit
LENGTH_SCALE	Scale factor to convert from this new length unit to meters

Remarks:

1. **Conversion Factor.** The scale factor should be such that:

$$[\mathrm{m}] = \mathrm{LENGTH\_SCALE} \times \left[\mathrm{LENGTH\_UNIT}\right] .$$

*UNIT_LUMINOUS_INTENSITY

Purpose: Specify a new user luminous intensity unit to make it available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	LI_UNIT		LI_SCALE					
Type	A		F					
Default	none		1.0					

VARIABLE	DESCRIPTION
LI_UNIT	Name of new luminous intensity unit
LI_SCALE	Scale factor to convert from this new luminous intensity unit to candela

Remarks:

1. **Unit Conversion.** The scale factor should be such that:

$$[\text{candela}] = \text{LI\_SCALE} \times \left[\text{LI\_UNIT}\right] .$$

*UNIT_MASS

Purpose: Specify a new user mass unit to make it available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	MASS_UNIT		MASS_SCALE					
Type	A		F					
Default	none		1.0					

VARIABLE	DESCRIPTION
MASS_UNIT	Name of new mass unit
MASS_SCALE	Scale factor to convert from this new mass unit to kilograms

Remarks:

1. **Conversion Factor.** The scale factor should be such that:

$$[\text{kg}] = \text{MASS\_SCALE} \times \left[\text{MASS\_UNIT}\right] .$$

*UNIT_SYSTEM

Purpose: Specify the user units for the current keyword input deck. These *UNIT cards are designed for when a solver and an external database to which the solver is connecting are in different units. It is also intended to be used for converting the units of data exchanged between solvers. Other applications are being planned.

For the built-in options for each type of unit, refer to *UNIT_DEFAULTS.

Card 1	1	2	3	4	5	6	7	8
Variable	UNITSYS							
Type	A							

Card 2	1	2	3	4	5	6	7	8
Variable	LENGTH	MASS	TIME	TEMP	CURRENT	AMOUNT	LUMIN	ANGLE
Type	A	A	A	A	A	A	A	A
Default	m	kg	sec	K	ampere	mole	candela	radian

VARIABLE	DESCRIPTION
UNITSYS	Name of new unit system
LENGTH	Length units
MASS	Mass units
TIME	Time units
TEMP	Temperature units
CURRENT	Electric current units
AMOUNT	Amount units
LUMIN	Luminosity units
ANGLE	Angle units

*UNIT_TEMPERATURE

Purpose: Specify a new user temperature unit to make it available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	TEMP_UNIT		TEMP_SCALE		TEMP_SHIFT			
Type	A		F		F			
Default	none		1.0		0.0			

VARIABLE	DESCRIPTION
TEMP_UNIT	Name of new temperature unit
TEMP_SCALE	Scale factor to convert from this new temperature unit to degrees Kelvin
TEMP_SHIFT	Shift to apply to a temperature in this new temperature unit before applying the TEMP_SCALE scaling to obtain degrees Kelvin

Remarks:

1. **Unit Conversion.** As the only unit specification that can include a shift, the new temperature unit must satisfy this relation, where [K] represents degrees Kelvin:

$$\left[\mathrm{K}\right] = \mathrm{TEMP\_SCALE} \times \left(\left[\mathrm{TEMP\_UNIT}\right] + \mathrm{TEMP\_SHIFT} \right)$$

*UNIT_TIME

Purpose: Specify a new user time unit to make it available for use in the current keyword input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	TIME_UNIT		TIME_SCALE					
Type	A		F					
Default	none		1.0					

VARIABLE	DESCRIPTION
TIME_UNIT	Name of new time unit
TIME_SCALE	Scale factor to convert from this new time unit to seconds

Remarks:

1. **Unit Conversion.** The scale factor should be such that:

$$[\text{sec}] = \text{TIME\_SCALE} \times \left[\text{TIME\_UNIT}\right] .$$

*USER

The *USER keyword cards are used to specify input for the user defined subroutines, including contact and boundary conditions. They are also used to smooth history data. The available keywords in this section are given in alphabetical order:

USER_INTERFACE_*OPTION

*USER_LOADING

*USER_LOADING_SET

*USER_NONLOCAL_SEARCH

USER_INTERFACE_*OPTION

Available options include:

CONTROL

FRICTION

FORCES

CONDUCTIVITY

Purpose: Define user defined input and allocate storage for user defined subroutines for the contact algorithms. See also *CONTROL_CONTACT.

The CONTROL option above allows the user to take information from the contact interface for further action; for example, stopping the analysis. A sample user subroutine is provided in Appendix F.

The FRICTION option may be used to modify the Coulomb friction coefficients in contact types 3, 5, or 10 (*CONTACT_SURFACE_TO_SURFACE, *CONTACT_NODES_TO_SURFACE, or *CONTACT_ONE_WAY_SURFACE_TO_SURFACE) and the 2D mortar contacts (*CONTACT_2D_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR and *CONTACT_2D_AUTOMATIC_SINGLE_SURFACE_MORTAR) according to contact information or a friction coefficient database. A sample user-defined friction subroutine is provided in Appendix G. For the subroutine to be called, the static friction coefficient FS on Card 2 of *CONTACT must be any nonzero value, and shell thickness offsets must be invoked in the contact by setting SHLTHK to 1 or 2 using *CONTROL_CONTACT or Opt. Card B in *CONTACT. The array length USRFRC in *CONTROL_CONTACT should be set to a value no less than the sum of the number of history variables NOC and the number of user-defined input parameters in *USER_INTERFACE_FRICTION. For Mortar contacts, the subroutine to call is `mortar_usrfrc`, found among the source routines in an object version.

The CONDUCTIVITY option is used to define heat transfer contact conductance properties for thermal contacts.

The FORCES option is used to collect contact nodal forces from specified contact ID list for user subroutines.

Card Summary:

Card 1a. Include this card if and only if the keyword option is CONTROL, FRICTION, or CONDUCTION.

IFID	NOC	NOCI	NHSV	NEHIS	MHSV		

Card 1a.1. Use as many cards as necessary to set NOCI variables.

UC1	UC2	UC3	UC4	UC5	UC6	UC7	UC8

Card 1b. Include this card if and only if the keyword option is FORCES.

NCONT							

Card 1b.1. Use as many cards as necessary to set NCONT variables.

CID1	CID2	CID3	CID4	CID5	CID6	CID7	CID8

Data Cards:

Card 1a	1	2	3	4	5	6	7	8
Variable	IFID	NOC	NOCI	NHSV	NEHIS	MHSV		
Type	I	I	I	I	I	I		
Default	none	none	none	0	0	0		

Initialization Cards. Use as many cards as necessary to set NOCI variables.

Card 1a.1	1	2	3	4	5	6	7	8
Variable	UC1	UC2	UC3	UC4	UC5	UC6	UC7	UC8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
IFID	Interface number
NOC	Number of history variables for interface. The number should not exceed the length of the array defined on *CONTROL_CONTACT. See Remark 1.
NOCI	Initialize the first NOCI history variables in the input. NOCI must be smaller or equal to NOC.

VARIABLE	DESCRIPTION
NHSV	Number of history variables per interface node (only for friction and conductivity interface). For Mortar contact it is the number of history variables per SURFA segment.
NEHIS	Flag for element (material) history data provided as input quantities in subroutine `usrfrc` (see comments there). EQ.0: A special choice of element history variables is provided, namely plastic strain, yield stress, and material directions. GT.0: Plastic strain and element history variables up to NEHIS-1 are provided in original order.
MHSV	Number of history variables per SURFB segment for Mortar contact, ignored for single surface Mortar contact
UC1	First user defined input parameter
UC2	Second user defined input parameter
⋮	⋮
UC[N]	Last user defined input parameter, where N = NOCI

Card 1b	1	2	3	4	5	6	7	8
Variable	NCONT							
Type	I							
Default	none							

Contact ID Cards. Use as many cards as necessary to set NCONT contact IDs.

Card 1b.1	1	2	3	4	5	6	7	8
Variable	CID1	CID2	CID3	CID4	CID5	CID6	CID7	CID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
NCONT	Number of contact IDs. LE.0: All contacts will be used.
CID1	First contact user ID
CID2	Second contact user ID
⋮	⋮
CID[N]	Last contact user ID, where N = NCONT.

Remarks:

1. **Interface Variables.** The (NOC) interface variables (of which NOCI are initialized) are passed as arguments to the user defined subroutine. See Appendix G for the full list of arguments passed to the subroutine.

2. **Segment Based Contact.** This keyword is not supported by segment-based contact which is invoked by setting SOFT = 2 on optional Card A of the *CONTACT card. It is, however, supported for Mortar contact.

*USER_LOADING

Purpose: Provide a means of applying pressure and force boundary conditions. The keyword *USER_LOADING activates this option. Input here is optional with the input being read until the next "*" keyword appears. The data read here is to be stored in a common block provided in the user subroutine, LOADUD. This data is stored and retrieved from the restart files.

Parameter Cards. Add one card for each input parameter. Include as many cards as needed. This input ends at the next keyword ("*") card.

Card 1…	1	2	3	4	5	6	7	8
Variable	PARM1	PARM2	PARM3	PARM4	PARM5	PARM6	PARM7	PARM8
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
PARM[N]	This is the N^{th} user input parameter.

*USER_LOADING_SET

Purpose: Provides a means to apply user-defined loading to a set of nodes or segments. Loading could be nodal force, body force, temperature distribution, and pressure on segment or beam.

Set Cards. Add a card for each set to which a load is applied. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	LTYPE	LCID	CID	SF1	SF2	SF3	IDULS
Type	I	A	I	I	F	F	F	I
Default	none	none	none	global	none	none	none	Seq. #

VARIABLE	DESCRIPTION
SID	ID of the set to which user-defined loading will be applied. Set type depends on the type of loading, see LTYPE.
LTYPE	Loading type: EQ."FORCEN": Force a will be applied to node set SID. The load is to be given in units of force. EQ."BODYFN": Body force density will be applied to node set SID. The load is to be given in units of force per volume. EQ."TEMPTN": Temperature will be assigned to node set SID. This option cannot be coexist with *LOAD_THERMAL_VARIABLE. In other word, users can only use either this option or *LOAD_THERMAL_VARIABLE to specify temperature distribution, not both of them, EQ."PRESSS": Pressure will be applied to segment set SID. The load is to be given in units of force per area. EQ."PRESSB": Pressure in units of force per length will be applied to beam set SID.
LCID	Load curve, a function of time. Its current value, crv, is passed to user subroutine LOADSETUD.

VARIABLE	DESCRIPTION
CID	Optional coordinate system along which scale factors SF_i is defined. Global system is the default system.
SF[i]	Scale factor of loading magnitude, when LTYPE
	LTYPE.EQ."FORCEN": SFi is the factor along i^{th} direction of CID. For example, set SF1 = 1. and the others to zero if the load is to be applied in the positive x-direction. This applies whether the global or a local coordinate system is used.
	LTYPE.EQ."BODYFN": See "EQ.FORCEN"
	LTYPE.EQ."PRESSS": SF1 is used as the scale factor, SF2 and SF3 are ignored,
	LTYPE.EQ."PRESSB": Scale factor along r, s, t axis of beam.
IDULS	Each USER_LOADING_SET can be assigned a unique ID, which is passed to user subroutine LOADSETUD and allows multiple loading definitions by using a single user subroutine, LOADSETUD. If no value is input, LS-DYNA will assign a sequence number to each USER_LOADING_SET based on its definition sequence.

Remarks:

*USER_LOADING_SET activates the loading defined in user subroutine LOADSETUD, part of dyn21.F. When both *USER_LOADING_SET and *USER_LOADING are defined, *USER_LOADING is only used to define user-defined parameters, PARM*n*; not to activate user subroutine LOADUD. Therefore only loading defined in LOADSETUD will be applied.

More than one loading definitions can be defined and assigned a unique ID, that enables multiple loading to be taken care of by a single subroutine, LOADSETUD, as shown below:

```
subroutine loadsetud(time,lft,llt,crv,iduls,parm)
c
c     Input (not modifiable)
c       x   : coordinate of node or element center
c       d   : displacement of node or element center
c       v   : velocity of node or element center
c       temp: temperature of node or element center
c       crv : value of LCID at current time
c     isuls : id of user_loading_set
c     parm: parameters defined in *USER_LOADING
c     Output (defined by user)
```

```
c       udl : user-defined load value
      include 'nlqparm'
C_TASKCOMMON (aux8loc)
      common/aux8loc/
     & x1(nlq),x2(nlq),x3(nlq),v1(nlq),v2(nlq),v3(nlq),
     & d1(nlq),d2(nlq),d3(nlq),temp(nlq),udl(nlq),tmp(nlq,12)
c
c    sample code
c    if (iduls.eq.100) then
c      do i=lft,llt
c       your code here
c        udl(i)=.........
c      enddo
c    elseif (iduls.eq.200) then
c      do i=lft,llt
c        udl(i)=.........
c      enddo
c    endif
      return
      end
```

*USER_NONLOCAL_SEARCH

Purpose: Interface for gathering the history data of specified elements that surround an element ("averaged" element) to average (or smooth) the history data of that element. The surrounding elements are determined using a user defined strategy. The type of averaging is also user specified. This keyword only works for solid elements. Note that all the averaged elements *must* be the *same material* and all the surrounding elements *must* also be the *same material*, but the averaged elements and the surrounding elements may be *different materials* from each other.

Card Summary:

Card 1. This card is required.

SSID	ASID	STYPE	ATYPE	R	SF1	SF2	SF3

Card 2. This card is required.

NFREQ	VOLTYPE	UTYPE	NUCONST	NUELHSV			

Card 2.1. Define ceil(NUCONST/8) of this card. NUCONST can not exceed 48, so only a maximum of 6 of this card can be defined.

P1	P2	P3	P4	P5	P6	P7	P8

Card 2.2. Define ceil(NUELHSV/8) of this card.

U1	U2	U3	U4	U5	U6	U7	U8

Card 3. Include this card as many times as needed. The next keyword ("*") card ends this input.

H1	H2	H3	H4	H5	H6	H7	H8

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	ASID	STYPE	ATYPE	R	SF1	SF2	SF3
Type	I	I	I	I	F	F	F	F
Default	none	none	none	none	none	1.0	1.0	1.0

VARIABLE	DESCRIPTION
SSID	Surrounding elements set ID (note that the surrounding elements can include averaged elements)
ASID	Averaged elements set ID
STYPE	ID type of SSID: EQ.0: Part set ID EQ.1: Part ID
ATYPE	ID type of ASID: EQ.0: Part set ID EQ.1: Part ID EQ.2: Solid set ID EQ.3: Solid ID
R	Search distance from the center of the averaged solid element
SF*i*	Scale factor for each search (**a**, **b**, **c**) direction (Default = 1.0).

Card 2	1	2	3	4	5	6	7	8
Variable	NFREQ	VOLTYPE	UTYPE	NUCONST	NUELHSV			
Type	I	I	I	I	I			
Default	1	1	none	none	none			

VARIABLE	DESCRIPTION
NFREQ	Number of cycles for collecting the history data (Default = 1).
VOLTYPE	Search geometry: EQ.1: Global axes (Default), EQ.2: Material axes (*ELEMENT_SOLID_ORTHO only)
UTYPE	User specified function type

VARIABLE	DESCRIPTION
NUCONST	Number of user defined parameters. NUCONST is limited to a maximum of 48.
NUELHSV	Number of user element history variables to be gathered. This is only needed if applied to user defined elements.

User Define Parameter Card. Define NUCONST parameters with this card. Include ceil(NUCONST/8) of this card. Only 48 parameters at most can be defined (6 cards).

Card 2.1	1	2	3	4	5	6	7	8
Variable	P1	P2	P3	P4	P5	P6	P7	P8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
P[N]	N^{th} user defined parameter (48 maximum)

User Element History Variable Location Card. Specify the locations of the user element history variables to be gathered. This card is only needed if applied to user defined elements. Define NUELHSV locations with this card. Include ceil(NUELHSV/8) of this card.

Card 2.2	1	2	3	4	5	6	7	8
Variable	U1	U2	U3	U4	U5	U6	U7	U8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
U[N]	Location of N^{th} user element history variable to be gathered

Material History Variable Location Card. Specify the locations of the material history variables to be gathered. Define 8 locations per card. Include as many cards as desired. This input ends at the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	H1	H2	H3	H4	H5	H6	H7	H8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
H[N]	Location of N^{th} material history variable to be gathered

Remarks:

*USER_NONLOCAL_SEARCH activates the user subroutines USER_NUNONL and USER_NUNONL_SMOOTH which are a part of dyn21.F. This keyword can be defined more than once. Each definition is assigned a unique ID which enables multiple instances of nonlocal data to be taken care of by a single user interface (see below). Each instance can use different history variables and have different averaging functions. The subroutine below indicates how this keyword interacts with the user subroutines.

```
      subroutine user_nunonl(nnon,ictl,rctl,auxvec,lochvh,
     . ixh,nwcon,x,iuhhv,uehh)

c nnon       : number of user defined *user_nonlocal_search cards
c
c Element information (I indicates integers and H memory pointers):
c ictl(1)    : I, set ID
c ictl(2)    : I, number of averaged solid elements
c ictl(3)    : H, 1:nelems                    , solid internal sorted ID
c                 nelems+1:nelems+1+(nelems+1), range of neighorbing elements
c ictl(14)   : H, neighboring element list in the local list
c ictl(15)   : H, number of surrounding solid elements under this card and its
c                 solid internal ID
c ictl(20)   : I, location of last local solid element
c ictl(25)   : H, user ID of the surrounding element (>0 exist on current processor)
c                                                    (<0 on remote processor)

Restart Input Data

In general three categories of restart actions are possible with LS-DYNA and are outlined in the following discussion:

1. A simple restart occurs when LS-DYNA was interactively stopped before reaching the termination time. Then, by specifying the R=**rtf** command line option on the execution line, LS-DYNA restarts the calculation from the termination point. The calculation will pick up at the specified termination time. See Execution Syntax in the Getting Started section. No additional input deck is required.

2. For small modifications of the input deck during the restart run, LS-DYNA offers a "small restart" capability which can

   a) reset termination time,

   b) reset output printing interval,

   c) reset output plotting interval,

   d) delete contact surfaces,

   e) delete elements and parts,

   f) switch deformable bodies to rigid,

   g) switch rigid bodies to deformable,

   h) change damping options.

   All modifications to the problem made with the restart input deck will be reflected in subsequent restart dumps. All the members of the file families are consecutively numbered beginning from the last member prior to termination.

   For a small restart run a *small input deck* replaces the standard input deck on the execution line which must have at least the following command line arguments:

   LS-DYNA I=**restartinput** R=**D3DUMP*nn***

   where **D3DUMP*nn*** (or whatever name is chosen for the family member) is the *n*th restart file from the last run where the data is taken. LS-DYNA automatically detects that a small input deck is used since the I=**restartinput** file may contain *only* the *restart* keywords (excluding *STRESS_INITIALIZATION):

   CHANGE_*OPTION

*CONTROL_DYNAMIC_RELAXATION

*CONTROL_SHELL

*CONTROL_TERMINATION

*CONTROL_TIMESTEP

*DAMPING_GLOBAL

DATABASE_*OPTION

DATABASE_BINARY_*OPTION

DELETE_*OPTION

*INTERFACE_SPRINGBACK_LSDYNA

RIGID_DEFORMABLE_*OPTION

STRESS_INITIALIZATION_*{OPTION} (full restart only)

TERMINATION_*OPTION

*TITLE

*KEYWORD

*CONTROL_CPU

DEFINE_*OPTION

SET_*OPTION

You must take care to avoid nonphysical modifications to the input deck; otherwise, complete nonsense may be the result.

3. If many modifications are desired, a *full restart* may be the appropriate choice. A full restart is selected by including a full model along with a *STRESS_INITIALIZATION keyword card and possibly other restart cards. As mentioned in the Restart Analysis subsection of the Getting Started portion of the manual, either all parts or some subset of parts can be made for the stress initialization.

Remarks:

1. In a full restart, only those nodes and elements defined in the full restart deck will be present in the analysis after the full restart is initiated. But as a

convenience, any of those nodes or elements can be deleted using the *DELETE command.

2. In a small restart, velocities of nodes come from the dump file by default, but those velocities can be changed using *CHANGE_VELOCITY_....

3. In a full restart, velocities of pre-existing nodes come from the dump file by default, but those velocities can be changed using *CHANGE_VELOCITY_.... To set the starting velocities for new nodes in a full restart, use *INITIAL_VELOCITY_....

4. Pre-existing contacts, in general, carry forward seamlessly using data from the d3dump (or d3full if MPP) database. It is important that the contact ID(s) in the full restart input deck match the contact ID(s) in the original input deck if the intent is for the contacts to be initialized using data from the d3dump/d3full database. EXCEPTION: In the special case of MPP, a *CONTACT_AUTOMATIC_GENERAL contact in the full restart input deck is treated as a brand new contact and is not initialized using data from d3full.

5. Parameters used in a restart input deck must be defined in that same restart input deck using *PARAMETER.

6. Only sets using element IDs and node IDs are permitted in a small restart deck; part IDs are not recognized. Sets referenced by other commands in a small restart deck must be defined in the small restart deck.

***CHANGE**_*OPTION*

Purpose: Change solution options.

Available options include:

BOUNDARY_CONDITION

CONTACT_SMALL_PENETRATION

CURVE_DEFINITION

OUTPUT

RIGIDWALL_GEOMETRIC

RIGIDWALL_PLANAR

RIGID_BODY_CONSTRAINT

RIGID_BODY_INERTIA

RIGID_BODY_STOPPERS

STATUS_REPORT_FREQUENCY

THERMAL_PARAMETERS

VELOCITY

VELOCITY_GENERATION

VELOCITY_NODE

VELOCITY_RIGID_BODY

VELOCITY_ZERO

Boundary Condition Cards. This card 1 format is for the ***BOUNDARY_CONDITION*** keyword option. Add one card for each boundary condition. This card imposes *additional* boundary conditions. It does not remove previously imposed conditions (for example, this option will not free a fixed node). This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NID	BCC						
Type	I	I						

VARIABLE	DESCRIPTION
NID	Nodal point ID, see also *NODE.
BCC	New translational boundary condition code: EQ.1: Constrained x displacement, EQ.2: Constrained y displacement, EQ.3: Constrained z displacement, EQ.4: Constrained x and y displacements, EQ.5: Constrained y and z displacements, EQ.6: Constrained z and x displacements, EQ.7: Constrained x, y, and z displacements.

Small Penetration Check Cards. This Card 1 format is for the ***CONTACT_SMALL_PENETRATION*** keyword option. Set one value for each contact surface ID where the small penetration check is to be turned on. The input terminates at the next keyword ("*") card. See the PENCHK variable in *CONTACT.

Card 1	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
IDn	Contact ID for surface number n

Load Curve Redefinition Cards. This Card 1 format is for the ***CURVE_DEFINITION*** keyword option. *The new load curve must contain the same number of points as the curve it replaces.* The curve should be defined according to the *DEFINE_CURVE section of the manual. This input terminates at the next keyword ("*") card. Offsets and scale factors are ignored.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID							
Type	I							

VARIABLE	DESCRIPTION
LCID	Load curve ID

ASCII Output Overwrite Card. This format applies to the ***OUTPUT*** keyword option.

Card 1	1	2	3	4	5	6	7	8
Variable	IASCII							
Type	I							

VARIABLE	DESCRIPTION
IASCII	Flag to control manner of outputting ASCII data requested by *DATABASE_*OPTION* commands in a full restart deck: EQ.0: Full restart overwrites existing ASCII output (default), EQ.1: Full restart appends to existing ASCII output.

Rigidwall Modification. The format for the ***RIGIDWALL_GEOMETRIC*** and ***RIGIDWALL_PLANAR*** cards is identical to the original cards (see *RIGIDWALL_GEOMETRIC and *RIGIDWALL_PLANAR), however there are restrictions on the entries that may be changed: only those entries that define the size and orientation of the rigid walls may be changed, but not any of the others (e.g., the type). A rigidwall may only be modified when doing a full restart.

Rigid Body Constraint Modification Cards. This format for Card 1 applies to the ***RIGID_BODY_CONSTRAINT*** keyword option. This option can change translation and

rotational boundary condition on a rigid body. This input ends at the next keyword ("*") card. See CONSTRAINTED_RIGID_BODIES.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	TC	RC					
Type	I	I	I					

VARIABLE	DESCRIPTION
PID	Part ID, see *PART.
TC	Translational constraint: EQ.0: No constraints, EQ.1: Constrained x displacement, EQ.2: Constrained y displacement, EQ.3: Constrained z displacement, EQ.4: Constrained x and y displacements, EQ.5: Constrained y and z displacements, EQ.6: Constrained z and x displacements, EQ.7: Constrained x, y, and z displacements.
RC	Rotational constraint: EQ.0: No constraints, EQ.1: Constrained x rotation, EQ.2: Constrained y rotation, EQ.3: Constrained z rotation, EQ.4: Constrained x and y rotations, EQ.5: Constrained y and z rotations, EQ.6: Constrained z and x rotations, EQ.7: Constrained x, y, and z rotations.

Card sets for *RIGID_BODY_INERTIA* keyword option. This option supports changing the mass and inertia properties of a rigid body. Include as many pairs of the following two cards as necessary. This input ends at the next keyword ("*") card. The inertia tensor

is specified relative to the coordinate system set in *MAT_RIGID at the start of the calculation, which is fixed in the rigid body and tracks the rigid body rotation.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	PID	TM					
Type	I	I	F					

Card 2	1	2	3	4	5	6	7	8
Variable	IXX	IXY	IXZ	IYY	IYZ	IZZ		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
ID	ID for this change inertia input.
PID	Part ID, see *PART.
TM	Translational mass.
IXX	I_{xx}, xx component of inertia tensor.
IXY	I_{xy}
IXZ	I_{xz}
IYY	I_{yy}
IYZ	I_{yz}
IZZ	I_{zz}

Card sets for the *RIGID_BODY_STOPPERS* keyword option. This option is for redefining existing stoppers. Include as many pairs of cards as necessary. This input terminates when the next keyword ("*") card is encountered. See *CONSTRAINED_RIGID_-

BODY_STOPPERS. Note that new stopper definitions cannot be introduced in this section. Existing stoppers can be modified.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	LCMAX	LCMIN	PSIDMX	PSIDMN	LCVMNX	DIR	VID
Type	I	I	I	I	I	I	I	I
Default	required	0	0	0	0	0	required	0

Card 2	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH						
Type	F	F						
Default	0.0	10^{28}						

VARIABLE	DESCRIPTION
PID	Part ID of lead rigid body, see *PART.
LCMAX	Load curve ID defining the maximum coordinate as a function of time: EQ.0: No limitation of the maximum displacement. New curves can be defined by the *DEFINE_CURVE within the present restart deck. (Not applicable for small deck restart).
LCMIN	Load curve ID defining the minimum coordinate as a function of time: EQ.0: No limitation of the minimum displacement. New curves can be defined by the *DEFINE_CURVE within the present restart deck. (Not applicable for small deck restart).
PSIDMX	Optional part set ID of rigid bodies that are constrained in the maximum coordinate direction to the lead rigid body. This option requires additional input by the *SET_PART definition.

VARIABLE	DESCRIPTION
PSIDMN	Optional part set ID of rigid bodies that are constrained in the minimum coordinate direction to the lead rigid body. This option requires additional input by the *SET_PART definition.
LCVMNX	Load curve ID which defines the maximum absolute value of the velocity that is allowed within the stopper: EQ.0: No limitation of the maximum velocity
DIR	Direction stopper acts in: EQ.1: x-translation EQ.2: y-translation EQ.3: z-translation EQ.4: arbitrary, defined by vector VID EQ.5: x-axis rotation EQ.6: y-axis rotation EQ.7: z-axis rotation EQ.8: Arbitrary, defined by vector VID
VID	Vector for arbitrary orientation of stopper. The vector must be defined by a *DEFINE_VECTOR within the present restart deck.
BIRTH	Time at which stopper is activated
DEATH	Time at which stopper is deactivated

Remarks:

The optional definition of part sets in minimum or maximum coordinate directions allows the motion to be controlled in an arbitrary direction.

D3HSP Interval Change Card. This card format applies to the ***STATUS_REPORT_FREQUENCY*** keyword option.

Card 1	1	2	3	4	5	6	7	8
Variable	IKEDIT							
Type	I							

VARIABLE	DESCRIPTION
IKEDIT	Problem status report interval steps in the D3HSP output file: EQ.0: Interval remains unchanged.

Card set for the *THERMAL_PARAMETERS* keyword option. This option is for changing the parameters used by a thermal or coupled structural/thermal analysis. See *CONTROL_THERMAL. Add the two following cards to the deck (they do not repeat).

Card 1	1	2	3	4	5	6	7	8
Variable	TS	DT	TMIN	TMAX	DTEMP	TSCP		
Type	I	F	F	F	F	F		

Card 2	1	2	3	4	5	6	7	8
Variable	REFMAX	TOL						
Type	I	F						

VARIABLE	DESCRIPTION
TS	Thermal time step code: EQ.0: No change, EQ.1: Fixed time step, EQ.2: Variable time step.
DT	Thermal time step on restart: EQ.0: No change.
TMIN	Minimum thermal time step: EQ.0: No change.
TMAX	Maximum thermal time step: EQ.0: No change.

VARIABLE	DESCRIPTION
DTEMP	Maximum temperature change in a thermal time step: EQ.0: No change.
TSCP	Time step control parameter (0.0 < TSCP < 1.0): EQ.0: No change.
REFMAX	Maximum number of reformations per thermal time step: EQ.0: No change.
TOL	Non-linear convergence tolerance: EQ.0: No change.

Node Set Velocity Card Sets. The formats for Cards 1 and 2 apply to the ***VELOCITY*** and ***VELOCITY_ONLY*** keyword options. These options are for setting velocity fields on node sets at restart. For each node set add one pair of the following cards. This input ends at the next keyword ("*") card. Undefined nodes (not listed on a set velocity card) will have their nodal velocities reset to zero if a *CHANGE_VELOCITY definition is encountered in the restart deck. However, if any of the *CHANGE_VELOCITY definitions have the keyword option ONLY appended, then only the specified nodes will have their nodal velocities modified.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID							
Type	I							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	VX	VY	VZ	VXR	VYR	VZR		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
NSID	Nodal set ID containing nodes for initial velocity (see Remark 1)
VX	Velocity in x-direction
VY	Velocity in y-direction
VZ	Velocity in z-direction
VXR	Rotational velocity about the x-axis
VYR	Rotational velocity about the y-axis
VZR	Rotational velocity about the z-axis

Remarks:

1. **Multiple Velocity Initializations for a Node.** If a node is initialized on more than one input card set, then the last set input will determine its velocity, unless it is specified on a *CHANGE_VELOCITY_NODE card.

2. **Undefined Nodes.** Undefined nodes will have their nodal velocities set to zero if a *CHANGE_VELOCITY definition is encountered in the restart deck.

3. **Zero Velocity.** If both *CHANGE_VELOCITY and *CHANGE_VELOCITY_ZERO cards are defined, then all velocities will be reset to zero.

Velocity Generation Cards. The velocity generation cards for the ***VELOCITY_GENERATION*** option are identical to the standard velocity generation cards (see *INITIAL_VELOCITY_GENERATION), and all parameters may be changed.

Nodal Point Velocity Cards. This format applies to the ***VELOCITY_NODE*** and ***VELOCITY_NODE_ONLY*** keyword options. These option support changing nodal velocities. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NID	VX	VY	VZ	VXR	VYR	VZR	
Type	I	F	F	F	F	F	F	
Default	none	0.	0.	0.	0.	0.	0.	

VARIABLE	DESCRIPTION
NID	Node ID
VX	Translational velocity in x-direction
VY	Translational velocity in y-direction
VZ	Translational velocity in z-direction
VXR	Rotational velocity about the x-axis
VYR	Rotational velocity about the y-axis
VZR	Rotational velocity about the z-axis

Remarks:

1. **Undefined Nodes.** Undefined nodes (not listed on a point velocity card) will have their nodal velocities reset to zero if a *CHANGE_VELOCITY_NODE definition is encountered in the restart deck. However, if any of the *CHANGE_VELOCITY or CHANGE_VELOCITY_NODE definitions have ONLY appended, then only the specified nodes will have their nodal velocities modified.

2. **Multiple Velocity Initializations for a Node.** If a node is initialized on more than one input card set, then the last set input will determine its velocity, unless it is specified on a *CHANGE_VELOCITY_NODE card.

3. **Zero Velocity.** If both *CHANGE_VELOCITY and *CHANGE_VELOCITY_ZERO cards are defined, then all velocities will be reset to zero.

Rigid Body Velocity Cards. This Card 1 format applies to the ***VELOCITY_RIGID_BODY*** keyword option. This option allows for setting the velocity components of a rigid body at restart. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	VX	VY	VZ	VXR	VYR	VZR	
Type	I	F	F	F	F	F	F	
Default	none	0.	0.	0.	0.	0.	0.	

VARIABLE	DESCRIPTION
PID	Part ID of rigid body
VX	Translational velocity in x-direction
VY	Translational velocity in y-direction
VZ	Translational velocity in z-direction
VXR	Rotational velocity about the x-axis
VYR	Rotational velocity about the y-axis
VZR	Rotational velocity about the z-axis

Remarks:

1. **Rotational Velocities.** Rotational velocities are defined about the center of mass of the rigid body.

2. **Undefined Rigid Bodies.** Rigid bodies not defined in this section will not have their velocities modified.

Restarting the Model at Rest. The ***VELOCITY_ZERO*** option resets the velocities to zero at the start of the restart. There are no data cards associated with *CHANGE_VELOCITY_ZERO.

*CONTROL_DYNAMIC_RELAXATION

Purpose: Define controls for dynamic relaxation.

Card 1	1	2	3	4	5	6	7	8
Variable	NRCYCK	DRTOL	DRFCTR	DRTERM	TSSFDR	IRELAL	EDTTL	IDRFLG
Type	I	F	F	F	F	I	F	I
Default	250	0.001	0.995	∞	TSSFAC	0	0.0	0
Remarks	1	1	1	1	1			1

VARIABLE	DESCRIPTION
NRCYCK	Number of iterations between convergence checks, for dynamic relaxation option
DRTOL	Convergence tolerance for dynamic relaxation option
DRFCTR	Dynamic relaxation factor
DRTERM	Optional termination time for dynamic relaxation. Termination occurs at this time or when convergence is attained.
TSSFDR	Scale factor for computed time step during dynamic relaxation. If zero, the value is set to TSSFAC defined on *CONTROL_TERMINATION. After converging, the scale factor is reset to TSSFAC.
IRELAL	Automatic control for dynamic relaxation option based on algorithm of Papadrakakis [1981]: EQ.0: not active, EQ.1: active.
EDTTL	Convergence tolerance on automatic control of dynamic relaxation.
IDRFLG	Dynamic relaxation flag for stress initialization: EQ.0: not active, EQ.1: dynamic relaxation is activated.

Remarks:

1. **Restart before Dynamic Relaxation Convergence.** If a dynamic relaxation relaxation analysis is being restarted at a point before convergence was obtained, then NRCYCK, DRTOL, DRFCTR, DRTERM and TSSFDR will default to their previous values, and IDRFLG will be set to 1.

2. **Restart from Normal Transient Analysis.** If dynamic relaxation is activated after a restart from a normal transient analysis, LS-DYNA continues the output of data as it would without the dynamic relaxation being active. This is unlike the dynamic relaxation phase at the beginning of the calculation when a separate database is not used. Only load curves that are flagged for dynamic relaxation are applied after restarting.

*CONTROL_SHELL

Purpose: Change failure parameters NFAIL1 and NFAIL4 if necessary. These parameters must be nonzero in the initial run.

Card 1	1	2	3	4	5	6	7	8
Variable								
Type								

Card 2	1	2	3	4	5	6	7	8
Variable						NFAIL1	NFAIL4	PSNFAIL
Type						I	I	I

VARIABLE	DESCRIPTION
NFAIL1	Flag to check for highly distorted under-integrated shell elements, print a message, and delete the element or terminate. Generally, this flag is not needed for one point elements that do not use the warping stiffness. A distorted element is one where a negative jacobian exists within the domain of the shell, not just at integration points. The checks are made away from the integration points to enable the bad elements to be deleted before an instability leading to an error termination occurs. This test will increase CPU requirements for one point elements. EQ.1: print message and delete element. EQ.2: print message, write d3dump file, and terminate GT.2: print message and delete element. When NFAIL1 elements are deleted, LS-Dyna writes the d3dump file and terminates. These NFAIL1 failed elements also include all shell elements that failed for other reasons than distortion. Before the d3dump file is written, NFAIL1 is doubled, so the run can immediately be continued if desired.

VARIABLE	DESCRIPTION
NFAIL4	Flag to check for highly distorted fully-integrated shell elements, print a message, and delete the element or terminate. Generally, this flag is recommended. A distorted element is one where a negative jacobian exists within the domain of the shell, not just at integration points. The checks are made away from the integration points to enable the bad elements to be deleted before an instability leading to an error termination occurs. EQ.1: print message and delete element. EQ.2: print message, write d3dump file, and terminate GT.2: print message and delete element. When NFAIL4 elements are deleted, LS-Dyna writes the d3dump file and terminates. These NFAIL4 failed elements also include all shell elements that failed for other reasons than distortion. Before the d3dump file is written, NFAIL4 is doubled, so the run can immediately be continued if desired.
PSNFAIL	Optional shell part set ID specifying which part IDs are checked by the NFAIL1, NFAIL4, and W-MODE options. If zero, all shell part IDs are included.

*CONTROL_TERMINATION

Purpose: Stop the job.

Card	1	2	3	4	5	6	7	8
Variable	ENDTIM	ENDCYC						
Type	F	I						

VARIABLE	DESCRIPTION
ENDTIM	Termination time: EQ.0.0: Termination time remains unchanged.
ENDCYC	Termination cycle. The termination cycle is optional and will be used if the specified cycle is reached before the termination time. EQ.0.0: Termination cycle remains unchanged.

Remarks:

This is a reduced version of the *CONTROL_TERMINATION card used in the initial input deck.

*CONTROL_TIMESTEP

Purpose: Set time step size control using different options.

Card	1	2	3	4	5	6	7	8
Variable	DUMMY	TSSFAC	ISDO	DUMMY	DT2MS	LCTM		
Type	F	F	I	F	F	I		

VARIABLE	DESCRIPTION
DUMMY	Dummy field, see Remark 1 below.
TSSFAC	Scale factor for computed time step. EQ.0.0: TSSFAC remains unchanged.
ISDO	Basis of time size calculation for 4-node shell elements. 3-node shells use the shortest altitude for options 0 and 1 and the shortest side for option 2. This field has no relevance to solid elements, which use a length based on the element volume divided by the largest surface area. EQ.0: characteristic length is given by $\frac{\text{area}}{\min(\text{longest side},\ \text{longest diagonal})}$. EQ.1: characteristic length is given by $\frac{\text{area}}{\text{longest diagonal}}$. EQ.2: based on bar wave speed and, $\max\left[\text{shortest side}, \frac{\text{area}}{\min(\text{longest side},\ \text{longest diagonal})}\right]$. WARNING: Option 2 can give a much larger time step size that can lead to instabilities in some applications, especially when triangular elements are used.
DUMMY	Dummy field, see Remark 1 below.

VARIABLE	DESCRIPTION
DT2MS	New time step for mass scaled calculations. Mass scaling must be active in the time zero analysis. EQ.0.0: DT2MS remains unchanged.
LCTM	Load curve ID that limits maximum time step size: EQ.0: LCTM remains unchanged.

Remarks:

1. **Dummy Fields.** This a reduced version of the *CONTROL_TIMESTEP used in the initial analysis. The dummy fields are included to maintain compatibility. If using free format input then a 0.0 should be entered for the dummy values.

*DAMPING_GLOBAL

Purpose: Define mass weighted nodal damping that applies globally to the deformable nodes.

Card	1	2	3	4	5	6	7	8
Variable	LCID	VALDMP						
Type	I	F						
Default	0	0.0						

VARIABLE	DESCRIPTION
LCID	Load curve ID (see *DEFINE_CURVE) which specifies the system damping constant vs. time: EQ.0: a constant damping factor as defined by VALDMP is used, GT.0: system damping is given by load curve LCID (which must be an integer). The damping force applied to each node is $f = -d(t)mv$, where $d(t)$ is defined by load curve LCID.
VALDMP	System damping constant, d (this option is bypassed if the load curve number defined above is nonzero).

***DATABASE**_*OPTION*

Purpose: Change the output interval for ASCII files. If a file is not specified in the restart deck, then the output interval for the file will remain unchanged.

Options for ASCII files include:

SECFORC	Cross section forces.
RWFORC	Wall forces.
NODOUT	Nodal point data.
ELOUT	Element data.
GLSTAT	Global data.
DEFORC	Discrete elements.
MATSUM	Material energies.
NCFORC	Nodal interface forces.
RCFORC	Resultant interface forces.
DEFGEO	Deformed geometry file.
SPCFORC	Set DT for SPC reaction forces.
SWFORC	Nodal constraint reaction forces (spot welds and rivets).
ABSTAT	Set DT for airbag statistics.
NODFOR	Set DT for nodal force groups.
BNDOUT	Boundary condition forces and energy
RBDOUT	Set DT for rigid body data.
GCEOUT	Set DT for geometric contact entities.
SLEOUT	Set DT for sliding interface energy.
JNTFORC	Set DT for joint force file.
SBTOUT	Set DT for seat belt output file.
AVSFLT	Set DT for AVS database.
MOVIE	Set DT for MOVIE.
MPGS	Set DT for MPGS.
TPRINT	Set DT for thermal file.

Card	1	2	3	4	5	6	7	8
Variable	DT							
Type	F							

VARIABLE	DESCRIPTION
DT	Time interval between outputs: EQ.0.0: Output interval is unchanged.

Remarks:

1. **File Output Termination.** To terminate output to a particular file, set DT to a high value.

2. **NODOUT Results.** If IACCOP = 2 was specified in *CONTROL_OUTPUT, the best results are obtained in the NODOUT file by keeping the same DT on restart. When DT is changed for NODOUT, oscillations may occur around the restart time. If DT is larger than initially specified in the original input file, more memory is required to store the time states for the averaging than was originally allocated. A warning message is printed, and the filtering is applied using the available memory. When DT is smaller than initially specified, more oscillations may appear in the output than earlier in the calculation because the frequency content of the averaged output increases as DT decreases.

***DATABASE_BINARY**_*OPTION*

Options for binary output files with the default names given include:

D3PLOT DT for complete output states.

D3THDT DT for time history data for element subsets.

D3DUMP Binary output restart files. Define output frequency in cycles

RUNRSF Binary output restart file. Define output frequency in cycles.

INTFOR DT for contact surface interface database.

Card	1	2	3	4	5	6	7	8
Variable	DT/CYCL							
Type	F							

VARIABLE	DESCRIPTION
DT	Time interval between outputs. EQ.0.0: Time interval remains unchanged.
CYCL	Output interval in time steps. EQ.0.0: Output interval remains unchanged.

***DELETE**_*OPTION1_OPTION2*

Available options for OPTION1 are:

ALECPL

CONTACT

CONTACT_2DAUTO

ENTITY

PART

ELEMENT_BEAM

ELEMENT_SHELL

ELEMENT_SOLID

ELEMENT_TSHELL

FSI

OPTION2 only works with *DELETE_PART. This option causes LS-DYNA to exclude the geometric and other element/node information of deleted parts in d3plot files after re-start which significantly reduces d3plot file size.

COMP

Purpose: Delete contact surfaces, ALE FSI couplings, parts, or elements by a list of IDs. There are two contact algorithms for two-dimensional problems: the line-to-line contact and the automatic contact defined by part IDs. Each uses their own numbering.

ID Cards. This card applies to the ALECPL, CONTACT, CONTACT_2DAUTO, ENTITY, FSI and PART options. Include as many cards as necessary to input desired IDs. This input ends at the next keyword ("*") card.

Card 1a	1	2	3	4	5	6	7	8
Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I

VARIABLE	DESCRIPTION
ID*n*	Contact ID/Coupling ID/Part ID. See Remarks.

Element Set Cards. This card applies to the four ELEMENT options. This input ends at the next keyword ("*") card.

Card 1b	1	2	3	4	5	6	7	8
Variable	ESID							
Type	I							

VARIABLE	DESCRIPTION
ESID	Element set ID, see *SET_SOLID, *SET_BEAM, *SET_SHELL, *SET_TSHELL.

Remarks:

The FSI option corresponds to ALE couplings defined with *CONSTRAINED_LAGRANGE_IN_SOLID. The ALECPL option corresponds to ALE couplings defined with *ALE_COUPLING_NODAL_*OPTION*. For CONTACT, FSI, and ALECPL options, a negative ID implies that the absolute value gives the contact surface/FSI/ALECPL coupling which is to be activated.

*INTERFACE_SPRINGBACK_LSDYNA

Purpose: Define a material subset for output to a stress initialization file dynain. The dynain file contains keyword commands that can be included in a subsequent input deck to initialize deformation, stress, and strain in parts. This file can be used, for example, to do an implicit springback analysis after an explicit forming analysis.

Part Set ID Cards.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID	NSHV						
Type	I	I						

Constraint Cards. Optional cards that list of nodal points that are constrained in the dynain file. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	NID	TC	RC					
Type	I	F	F					
Default	none	0.	0.					

VARIABLE	DESCRIPTION
PSID	Part set ID for springback, see *SET_PART.
NSHV	Number of shell or solid history variables (beyond the six stresses and effective plastic strain) to be initialized in the interface file. For solids, one additional state variable (initial volume) is also written. If NSHV is nonzero, the element formulations, calculational units, and constitutive models should not change between runs. If NHSV exceeds the number of integration point history variables required by the constitutive model, only the number required is written; therefore, if in doubt, set NHSV to a large number.
NID	Node ID

VARIABLE	DESCRIPTION
TC	Translational constraint: EQ.0: no constraints, EQ.1: constrained x displacement, EQ.2: constrained y displacement, EQ.3: constrained z displacement, EQ.4: constrained x and y displacements, EQ.5: constrained y and z displacements, EQ.6: constrained z and x displacements, EQ.7: constrained x, y, and z displacements.
RC	Rotational constraint: EQ.0: no constraints, EQ.1: constrained x rotation, EQ.2: constrained y rotation, EQ.3: constrained z rotation, EQ.4: constrained x and y rotations, EQ.5: constrained y and z rotations, EQ.6: constrained z and x rotations, EQ.7: constrained x, y, and z rotations.

RIGID_DEFORMABLE_*OPTION

Available options include:

CONTROL	
D2R	(Deformable to rigid part switch)
R2D	(Rigid to deformable part switch)

Purpose: Define parts to be switched from rigid to deformable and deformable to rigid in a restart. It is only possible to switch parts on a restart if part switching was activated in the time zero analysis. See *DEFORMABLE_TO_RIGID for details of part switching.

*RIGID_DEFORMABLE_CONTROL

Card	1	2	3	4	5	6	7	8
Variable	NRBF	NCSF	RWF	DTMAX				
Type	I	I	I	F				
Default	0	0	0	none				

VARIABLE	DESCRIPTION
NRBF	Flag to delete or activate nodal rigid bodies (see Remark 1): EQ.0: no change, EQ.1: delete, EQ.2: activate.
NCSF	Flag to delete or activate nodal constraint set (see Remark 2): EQ.0: no change, EQ.1: delete, EQ.2: activate.
RWF	Flag to delete or activate rigid walls: EQ.0: no change, EQ.1: delete, EQ.2: activate.
DTMAX	Maximum permitted time step size after restart.

Remarks:

1. **Nodal Rigid Bodies.** If nodal rigid bodies or generalized, weld definitions are active in the deformable bodies that are switched to rigid, then the definitions should be deleted to avoid instabilities.

2. **Nodal Constraint Set.** If nodal constraint/spot weld definitions are active in the deformable bodies that are switched to rigid, then the definitions should be deleted to avoid instabilities.

*RIGID_DEFORMABLE_D2R

Part ID Cards. Include one card for each part. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	LRB						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
PID	Part ID of the part which is switched to a rigid material.
LRB	Part ID of the lead rigid body to which the part is merged. If zero, the part becomes either an independent or lead rigid body.

***RIGID_DEFORMABLE_R2D**

Termination of this input is when the next "*" card is read.

Part ID Cards. Include one card for each part. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
PID	Part ID of the part which is switched to a deformable material.

*STRESS_INITIALIZATION_{OPTION}

This keyword causes a full deck restart. For a full deck restart the input deck must contain the full model. The stress initialization feature allows all or selected parts to be initialized from the previous calculation using data from the d3dump or runrsf databases.

The options that are available with this keyword are:

<BLANK>

DISCRETE

SEATBELT

Optional Part Cards. If no part cards are included in the deck then all parts, seatbelts and discrete parts in the new input deck that existed in the previous input deck (with or without the same part IDs) are initialized from the d3dump or runrsf database. Otherwise for each part to be initialized from the restart data include an addition card in format 1. This input terminates at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	PID0	PIDN						
Type	I	I						
Default	none	PIDO						

VARIABLE	DESCRIPTION
PIDO	Old part ID, see *PART.
PIDN	New part ID, see *PART: EQ.0: New part ID is the same as the old part ID.

Remarks:

If one or more of the above cards are defined, then discrete and seatbelt elements will not be initialized unless the additional option cards *STRESS_INITIALIZATION_DISCRETE and *STRESS_INITIALIZATION_SEATBELT are defined.

*STRESS_INITIALIZATION_DISCRETE

Initialize all discrete parts from the old parts. No further input is required with this card. This card is not required if *STRESS_INITIALIZATION is specified without further input.

*STRESS_INITIALIZATION_SEATBELT

Initialize all seatbelt parts from the old parts. No further input is required with this card. This card is not required if *STRESS_INITIALIZATION is specified without further input.

TERMINATION_*OPTION

Purpose: Stops the job depending on some displacement conditions.

Available options include:

NODE

BODY

Caution: The inputs are different for the nodal and rigid body stop conditions. The nodal stop condition works on the global coordinate position, while the body stop condition works on the relative global translation. The number of termination conditions cannot exceed the maximum of 10 or the number specified in the original analysis.

The analysis terminates for *TERMINATION_NODE when the current position of the node specified reaches either the maximum or minimum value (stops 1, 2 or 3), or picks up force from any contact surface (stop 4). For *TERMINATION_BODY the analysis terminates when the center of mass displacement of the rigid body specified reaches either the maximum or minimum value (stops 1, 2 or 3) or the displacement magnitude of the center of mass is exceeded (stop 4). If more than one condition is input, the analysis stops when any of the conditions is satisfied.

> **NOTE:** This input completely overrides the existing termination conditions defined in the time zero run.

Termination by other means is controlled by the *CONTROL_TERMINATION control card.

Card Summary:

Card 1a. This card is included if and only if the NODE keyword option is used.

NID	STOP	MAXC	MINC				

Card 1b. This card is included if and only if the BODY keyword option is used.

PID	STOP	MAXC	MINC				

Data Card Descriptions:

Node Cards. Include an additional card for each node with a termination criterion.

Card 1a	1	2	3	4	5	6	7	8
Variable	NID/PID	STOP	MAXC	MINC				
Type	I	I	F	F				
Default	none	none	↓	↓				

VARIABLE	DESCRIPTION
NID	Node ID
STOP	Stop criterion: EQ.1: global *x* direction, EQ.2: global *y* direction, EQ.3: global *z* direction, EQ.4: stop if node touches contact surface.
MAXC	Maximum (most positive) coordinate, options 1, 2 and 3 above only.
MINC	Minimum (most negative) coordinate, options 1, 2 and 3 above only.

Part Cards. Include an additional card for each part with a termination criterion.

Card 1b	1	2	3	4	5	6	7	8
Variable	NID/PID	STOP	MAXC	MINC				
Type	I	I	F	F				
Default	none	none	↓	↓				

VARIABLE	DESCRIPTION
PID	Part ID of rigid body

VARIABLE	DESCRIPTION
STOP	Stop criterion: EQ.1: global *x*-direction, EQ.2: global *y*-direction, EQ.3: global *z*-direction, EQ.4: stop if displacement magnitude is exceeded.
MAXC	Maximum (most positive) displacement, options 1, 2, 3 and 4: EQ.0.0: MAXC set to 10^{21}
MINC	Minimum (most negative) displacement, options 1, 2 and 3 above only: EQ.0.0: MINC set to -10^{21}

***TITLE**

Purpose: Define job title.

Card	1	2	3	4	5	6	7	8
Variable	TITLE							
Type	C							
Default	LS-DYNA USER INPUT							

VARIABLE	DESCRIPTION
TITLE	Heading to appear in a small restart's d3hsp file. This heading is not written to any other output file.

APPENDIX A: User-Defined Materials

GETTING STARTED WITH USER-DEFINED FEATURES

We begin with a general introduction to user-defined features. This section is valid for any user-defined feature described in the remaining appendices and serves as a practical guide to enable you to begin coding. We will specifically discuss the different methods for linking your user-defined subroutines to LS-DYNA. For a comprehensive overview of user-defined features and their applications, please refer to Erhart [2010], which can be seen as a complement to the present text.

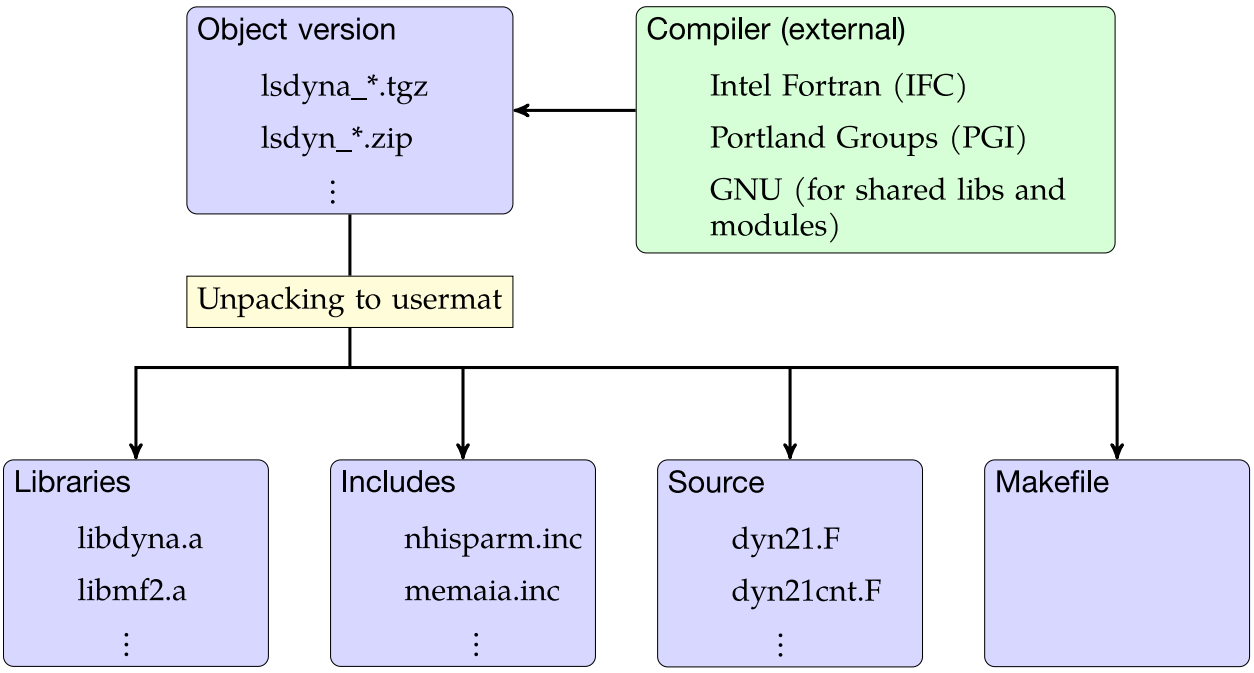

Figure 49-1. Conceptual overview of the usermat package

Download

First, download an *object version* of LS-DYNA for the computer architecture/platform of interest. This version is a compressed package (.tgz, .tar.gz, .zip) provided by Ansys or your local LS-DYNA distributor. The unpacked content contains not only a single binary executable but also a usermat directory, possibly including

- precompiled static object libraries (.a, .lib)
- Fortran source code files (.f, .F)
- include files (.inc)
- makefile

APPENDIX A

Choosing a version to download compatible with your computer environment in terms of architecture, operating system, and possible MPI implementation for MPP is essential. Selecting an appropriate version may not be obvious. For questions regarding the version, contact your LS-DYNA distributor. An object version does not require a special license but falls under the general LS-DYNA license agreement. Figure 49-1 gives a conceptual overview of the usermat package.

At this point we need to mention that presence of libraries and include files are made obsolete with the advent of modules, as to be explained below, but we start with the non-modular approach.

Static or Dynamic linking

To get something that is actually runnable it is necessary to *compile* the source code files and link the resulting object files either to a *shared object* (.so, .dll) or with the precompiled libraries to a binary executable. The former option requires a shared object version of the usermat package while the latter assumes a statically linked version, and this is thus a choice that needs to be made before retrieving the package. Working with shared objects is more flexible in the sense that a binary executable can be installed once and for all and the (small) shared object is dynamically linked at runtime as a plugin. Upon execution, LS-DYNA will look for the shared object file in directories specified by a library path that is usually set/edited in the run command script, and when found the shared object content is linked to the execution. On Linux this is governed by the environment variable LD_LIBRARY_PATH. The shared object is easily substituted, or the run command script can be edited to redirect the location of the shared object, and this facilitates portability when working on large projects. A statically linked version requires that the entire binary executable is generated at compile time and this option may be preferred if working on small projects or during the development phase.

Compiler and Compiling

The compilation is usually performed in the usermat (working) directory using a terminal window. The object version does not contain a compiler but it is assumed that the appropriate compiler is installed on your system and accessible from your working directory. To render compatibility between the precompiled libraries or binary executable and your compiled object files, the *appropriate* compiler is the (by LSTC) designated compiler with which the precompiled libraries or binary are readily compiled. As examples, on Linux this is typically either the Intel Fortran Compiler (IFC) on Red Hat or CentOS or Portland Groups Compiler (PGF) on SUSE, and on Windows it is the Intel Fortran Compiler (IFC) in combination with Microsoft Visual Studio (MSVS). For MPP you also need a wrapper for whatever MPI implementation you have installed, but again, consult your LS-DYNA distributor for detailed information.

To compile, execute 'make' in the terminal window and in most cases this will generate a shared object or binary executable depending on your type of LS-DYNA object version, and if not it comes down to interpreting error messages. A possible reason for failure is

that the makefile that comes with the usermat package does not contain appropriate compiler directives and requires some editing. This could range from trivial tasks like altering the path used to actually find the compiler on your system to more complex endeavors such as adding or changing compiler flags. An even worse scenario is that your operating system is not up-to-date and may require that the library content on your computer is somehow updated. Whatever the reason might be, any case is unique and the situation is preferably resolved by your computer administrator in collaboration with your LS-DYNA distributor.

Execution

When compiling a virgin instance of an object version, the generated executable *{xyz}dyna* in combination with a possible shared object *lib{xyz}dyna_{t}_{Y}.{Z}.so* makes up an exact replica of a non-object executable counterpart. It is only when the source code is modified that a customized version is generated. In the adopted binary and shared object naming convention above, *xyz* stands for *smp* or *mpp*, *t* is either *s* for single precision or *d* for double precision, *Y* is the base revision number for the LS-DYNA and *Z* is the corresponding release revision number. *Z* is always larger than *Y*. The binary and shared object may be left in the working directory, moved to some other location on your system or properly installed for execution on clusters by a queuing system. Obviously the way execution is performed is affected accordingly, and we don't claim to cover all these situations but leave this task to you and your computer administrator. While the executable may be renamed, a shared object should in general not be since this dynamic dependence is built into the executable. During the development phase it may be convenient to leave the binary in its place to facilitate debugging, but possibly move the shared object to the execution directory to not having to edit the library path for the executable to find it. Two Linux examples on how to run an input file are given in the following, one assuming an SMP static object version has been downloaded and the other an MPP shared object version. Let */path_to_my_source/usermat* be the complete path to the working directory and *in.k* be the name of the LS-DYNA keyword input file. If located in the *execution* directory, i.e., the directory containing *in.k*, the problem is run as

/path_to_my_source/usermat/lsdyna i = in.k

in the SMP case. For the MPP shared object case, you may copy the shared object file to the execution directory which is a default directory for executables to look for dynamic object files. Assuming the MPI software is platform-MPI, the input file could be run on 2 cores as

/path_to_platform-mpi/bin/mpirun –np 2 /path_to_my_source/usermat/mppdyna i = in.k

These two examples are only intended to indicate how to treat the compiled files and changes in details thereof are to be expected.

Coding

APPENDIX A

All subroutines for the user-defined features are collected in the files *dyn21.f* and *dyn21b.f* and are ready for editing using your favorite text editor. Mechanical user materials, user-defined loading, user defined wear and friction are contained in dyn21.f, while user defined elements and thermal user materials are in dyn21b.f, just to give a few examples. The prevailing programming language is Fortran 77, but many compilers support Fortran 90 and it may also be possible to write C code but this requires some manipulation of the makefile and function interfaces. Each individual feature is connected to one or a few keywords to properly take advantage of innovative coding. For user materials, this keyword is `*MAT_USER_DEFINED_MATERIAL_MODELS` and is described in detail below, and for user defined loads the corresponding keyword is `*USER_LOADING`. We refer to the individual keyword sections for details on their respective usage.

Module Concept

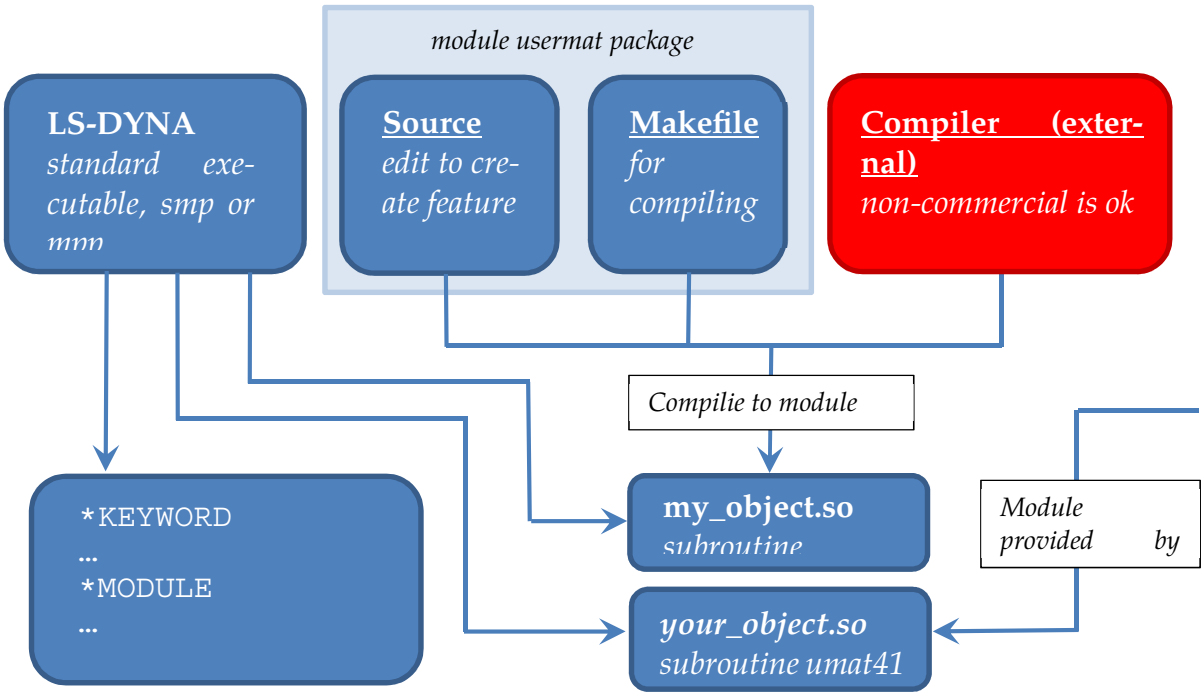
As of version R9 of LS-DYNA (MPP only) there is yet another way of approaching user defined features, namely through the concept of *modules*. The purpose is twofold:

1. To facilitate working with UDFs in that the content of the usermat package is significantly reduced and instead replaced by `*MODULE` keywords

2. To enhance flexibility when incorporating features delivered as shared objects by third parties

By way of 1, the usermat package only consists of a makefile and a few source code files, and in principle all the user needs to do is to (*i*) implement the feature of interest in the source code files, (*ii*) compile to a shared object using the makefile, and (*iii*) use the keyword input file to access the generated object. A shared object to be used in this way is henceforth called a *module*. One of two nice side effects coming out of this approach is that the restriction on the choice of compiler is alleviated, the source code files can be compiled with any valid fortran compiler as long as the generated module is linkable as a plug-in to LS-DYNA. The other is that the LS-DYNA executable need not be updated as new versions of the *module usermat package* is retrieved, the plug-in concept should still work[2]. To explain how LS-DYNA in practice access modulus and specific routines therein, and at the same time address 2 above, the *MODULE keyword requires some attention by means of an example.

[2] Currently a special "module" version is required to work with this approach, contact your local distributor for details.



In a standard version of LS-DYNA the keywords

```
*MODULE_PATH
*MODULE_LOAD
*MODULE_USE
```

are available, see the Section on *MODULE for further explanations than what is provided here. With reference to the picture above, we assume that *my_object.so* and *your_object.so* are two independently generated modules, and both are located in directory */path_to_modules*. We also assume that these two objects contain the same routines names, one of them being the source code for user material 41 (*subroutine umat41*). Without the present approach, it would be at least intricate to execute both of these two source codes in the same LS-DYNA executable and same keyword input. A simple way of dealing with this here is to use the following set of keywords

```
*MODULE_PATH
/path_to_modules
*MODULE_LOAD
$ MDLID               TITLE
myid                  my library
$ FILENAME
my_object.so
*MODULE_LOAD
$ MDLID               TITLE
yourid                your library
$ FILENAME
your_object.so
*MODULE_USE
$ MDLID
```

```
myid
$ TYPE                PARAM1                PARAM2
UMAT                  1001                  41
*MODULE_USE
$ MDLID
yourid
$ TYPE                PARAM1                PARAM2
UMAT                  1002                  41
*MAT_USER_DEFINED_MATERIAL_MODELS
$       MID         RO         MT
          1   7.85e-9       1001
…
*MAT_USER_DEFINED_MATERIAL_MODELS
$       MID         RO         MT
          2   7.85e-9       1002
…
*PART
first part
$       PID      SECID        MID
          1          1          1
*PART
second part
$       PID      SECID        MID
          2          2          2
```

The *MODULE_PATH lists the path(s) to the modules to be loaded, *MODULE_LOAD actually loads the module into LS-DYNA, and *MODULE_USE tells LS-DYNA how to access routines in the module. In this particular example, the rules (TYPE = UMAT) are that a user material *MAT_USER_. . . with MT set to 1001 (because PARAM1 = 1001) will execute subroutine umat41 (because PARAM2 = 41) in the module with id myid (because MDLID = myid) and in the same manner user material with MT set to 1002 will also execute subroutine umat41 but now in the module with id yourid. Hence we have made part 1 and part 2, in the same keyword input file, execute the *same* subroutine (by name) but in *different* modules. Obviously this generalizes to any number of modules by analogy, see *MODULE_USE for many more rules and yet another example.

GENERAL OVERVIEW OF USER-DEFINED MATERIALS

We now turn to the specific discussion of user-defined materials. You can simultaneously implement up to ten user subroutines to update the stresses in solids, shells, beams, discrete beams, and truss beams. This section serves as an introductory guide to implementing such a model. Note that the names of variables and subroutines below may differ from the actual ones depending on the platform and version of LS-DYNA.

When the keyword *MAT_USER_DEFINED_MATERIAL_MODELS is defined for a part in the keyword deck, LS-DYNA calls the subroutine usrmat with appropriate input

data for the constitutive update. This routine calls `urmathn` for 2D and 3D solid elements, `urmats` for 2D plane stress and 3D shell elements, `urmatb` for beam elements, `urmatd` for discrete beam elements, and `urmatt` for truss beam elements. You may modify these routines if necessary. These routines initialize the following data structures:

`sig(6)`	–	stresses in the previous time step
`eps(6)`	–	strain increments
`epsp`	–	effective plastic strain in the previous time step
`hsv(*)`	–	history variables in the previous time step, excluding plastic strain
`dt1`	–	current time step size
`temper`	-	current temperature
`failel`	–	flag indicating failure of element

A specific *scalar* material subroutine receives these data structures. Suppose you activate the vectorization flag (IVECT = 1 on the material card). In that case, the program stores variables in vector blocks of length `nlq`, with vector indexes ranging from `lft` to `llt`. This storage method allows for more efficient execution of the material routine. As an example, the data structures mentioned above are for the vectorized case exchanged for

`sig`*X*`(nlq)`	–	stresses in the previous time step
`d`*X*`(nlq)`	–	strain increments
`epsps(nlq)`	–	effective plastic strains in the previous time step
`hsvs(nlq,*)`	–	history variables in the previous time step
`dt1siz(nlq)`	-	current time step sizes
`temps(nlq)`	–	current temperatures
`failels(nlq)`	–	flags indicating failure of elements

where *X* ranges from 1 to 6 for the different components. Each entry in a vector block is associated with an element in the finite element mesh for a fixed integration point.

The number of entries in the history variables array (indicated by `*` above) matches the number of history variables requested on the material card (NHV). Hence the number NHV should equal the number of history variables excluding the effective plastic strain. We give effective plastic strain special treatment. All history variables, including the effective plastic strain, are initially zero. Furthermore, all user-defined material models require bulk and shear moduli for transmitting boundaries, contact interfaces, rigid body constraints, and time-step calculations. Thus, the length of the material constants array, `LMC`, must, generally, be increased by 2 for storing these parameters. In addition to the variables mentioned above, user-material routines may receive the following data, regardless of whether vectorization is used or not:

`cm(*)`	–	material constants array
`capa`	–	transverse shear correction factor for shell elements
`tt`	–	current time
`crv(lq1,2,*)`	–	array representation of curves defined in the keyword deck

Next, the previously mentioned element-specific routine calls a specific material routine, `umat`*XX* in the scalar case or `umat`*XX*`v` in the vector case. *XX* is a number between 41 and 50 and matches MT on the material card. You write the specific material subroutine. This subroutine should update the stresses and history variables to the current time. For shells and beams, your subroutine must also determine the strain increments in the directions of constrained zero stress. To be able to write different stress updates for distinct element types, your subroutine receives the following character string:

`etype` – character string that equals `solid`, `shell`, `beam`, `dbeam` or `tbeam`

A sample user subroutine of a hypoelastic material in the scalar case is provided below. This sample and the others below are from the dyn21.F file distributed with version R6.1.

Sample user subroutine 41

```
      subroutine umat41 (cm,eps,sig,epsp,hsv,dt1,capa,etype,tt,
     1 temper,failel,crv,nnpcrv,cma,qmat,elsiz,idele,reject)

```

ADDITIONAL FEATURES

Load curves and tables

If the material of interest requires load curves, predefined routines easily obtain curve and table data. For instance, your material implementation may need a curve defining yield stress as a function of effective plastic strain. For curves, call

```
      subroutine crvval(crv,nnpcrv,eid,xval,yval,slope)
```

or

```
subroutine crvval_v(crv,nnpcrv,eid,xval,yval,slope,lft,llt)
```

where the former routine works for scalar routines and the latter for vectorized. These subroutines have the following arguments:

- `crv` - the load curve array (available in material routine, just pass on)
- `nnpcrv` - curve data pointer (available in material routine, just pass on)
- `eid` - external load curve ID, meaning the load curve ID taken from the keyword deck
  - .GT.0: Use approximate representation of the curve
  - .LT.0: Use exact representation of the curve (with ID –`eid`)
- `xval` - abscissa value
- `yval` - ordinate value (output from routine)
- `slope` - slope of curve (output from routine)
- `lft` - first index of vector
- `llt` - final index of vector

where `xval`, `yval`, and `slope` are scalars in the scalar routine and vectors of length `nlq` in the vectorized routine. Note that `eid` should be passed as a float. A positive value for `eid` causes the routine to use an approximate representation of the curve. In contrast, a negative value causes the extraction to be made on the curve as it is defined in the keyword input deck.

For tables, we have two subroutines available for extracting values. The scalar version is

```
subroutine tabval(crv,nnpcrv,eid,dxval,yval,dslope,xval,slope)
```

and the vector version is

```
      subroutine
     1 tabval_v(crv,nnpcrv,eid,dxval,yval,dslope,lft,llt,xval,slope)
```

where

- `crv` - curve array (available in material routine, just pass on)
- `nnpcrv` - curve pointer (available in material routine, just pass on)
- `eid` - external table ID (data type real), i.e., table id taken from keyword deck
  - GT.0: Use approximate representation of the curve
  - LT.0: Use exact representation of curve (with ID –`eid`)
- `dxval` - abscissa value (x_2-axis)
- `yval` - ordinate value (y-axis, output from routine)
- `dslope` - slope of curve (dy/dx_2, output from routine)
- `xval` - abscissa value (x_1-axis)
- `slope` - slope of curve (dy/dx_1, output from routine)
- `lft` - vector index
- `llt` - vector index

In the scalar routine, `dxval`, `yval`, `dslope`, `xval`, and `slope` are all scalars, whereas, in the vector routine, they are vectors of length `nlq`. A positive and negative value of `eid` works in the same way for tables as it does for curves.

Local coordinate system

Invoke the local coordinate system option if the material model has directional properties, such as composite and anisotropic plasticity models. To do this, set IORTHO to 1 on the material card. A local coordinate requires two additional cards for the material with values for forming and updating the coordinate system. When invoked, the constitutive routine, `umat`*XX* or `umat`*XX*`v`, receives all the data in the local system. You do not transform the data to the global system since another routine performs the transformation unless your model requires the deformation gradient. See Deformation gradient for more details.

Temperature

Setting ITHERMAL to 1 on the material card for a material with thermal properties makes temperature available to your subroutine. The `temper` variable for a scalar and `temps` array for the vectorized implementation contain this data. For a coupled thermal-structural analysis, LS-DYNA solves the thermal problem first, making temperatures at the current time available in the user-defined subroutine. Note that LS-DYNA calculates the dissipated heat in the presence of plastic deformation. Thus, you do not include it in your subroutine. If the stress update requires the time derivative of the temperature, request a history variable that contains the temperature in the previous time step. Adding a backward finite difference estimate to your subroutine gives the time derivative.

Failure

Your material model may include failure, resulting in deleting elements that fulfill a failure criterion. To accomplish this, set IFAIL to 1 or a negative number on the material card. For a scalar implementation, the variable `failel` is set to `.true.` when a failure criterion is met. For a vectorized implementation, the corresponding entry in the `failels` array is set to `.true.`

Deformation gradient

For some material models, the stresses depend on the deformation gradient, **F**, instead of incremental strains. For instance, this dependency applies to hyperelastic and hyperplastic materials. To make the deformation gradient available for bricks and shells in the user-defined material subroutines, set IHYPER to 1 on the material card. LS-DYNA puts the deformation gradient components F_{11}, F_{21}, F_{31}, F_{12}, F_{22}, F_{32}, F_{13}, F_{23}, and F_{33} in the

history variables array in positions NHV+1 to NHV+9, that is, the positions right after the requested number of history variables.

For shell elements, the components of the deformation gradient are with respect to the co-rotational system for the element. Note that the user-defined material routine needs to properly update the third row of the deformation gradient, components F_{31}, F_{32}, and F_{33}. These components depend on the thickness strain increment, which must be determined so that the normal stress in the shell vanishes. For a given thickness strain increment `d3`, the following subroutines can determine these three components, `f31`, `f32` and `f33`:

```
subroutine compute_f3s(f31,f32,f33,d3)
```

for a scalar implementation and

```
subroutine compute_f3(f31,f32,f33,d3,lft,llt)
```

for a vector implementation. The first four arguments are scalars for the scalar routine and arrays of length `nlq` for the vector routine.

For hyperelastic materials, the user-defined subroutines can call push-forward operations. These routines are

```
subroutine push_forward_2(sig1,sig2,sig3,sig4,sig5,sig6,
      f11,f21,f31,f12,f22,f32,f13,f23,f33,lft,llt)
```

and

```
subroutine push_forward_2s(sig1,sig2,sig3,sig4,sig5,sig6,
      f11,f21,f31,f12,f22,f32,f13,f23,f33)
```

which perform push-forward operations on the stress tensor for the vectorized and scalar routines, respectively. In the latter subroutine, all arguments are scalars, whereas the corresponding entries in the vectorized routine are vectors of length `nlq`. The `sig1` to `sig6` are components of the stress tensor, and `f11` to `f33` are components of the deformation gradient.

Suppose you invoke the local coordinate system option (IORTHO = 1). In that case, the program transforms the deformation gradient into the local system with the following expression before passing it to the user-defined subroutine:

$$\bar{F}_{ij} = Q^s_{ki} F_{kj} \ .$$

Here Q^s_{ij} refers to a transformation between the current global and material frames. For IORTHO equal to 1, setting IHYPER equal to –1 results in the following transformation of the deformation gradient:

$$\bar{F}_{ij} = F_{ik} Q^r_{kj} \ .$$

Q^r_{ij} is the transformation between the reference global and material frames. For this latter option the spatial frame remains the global one, so the user-defined routine must express the stresses in this frame of reference upon exiting the routine. The suitable choice of IHYPER depends on the formulation of the material model.

For shells only, a particular option invoked by setting IHYPER to 3 causes LS-DYNA to compute the deformation gradient from the nodal coordinates in the global coordinate system. With this option, you must calculate the stress in the local system of interest. LS-DYNA passes a transformation matrix between the global and this local system to the user material routines (`qmat`). The columns in this matrix correspond to local basis vectors expressed in global coordinates. Your subroutine must compute the stress in this system. Note that the resulting deformation gradient may not be consistent with the theory for the element for your material because of how LS-DYNA calculates it. To account for thickness changes due to membrane straining, we provide the following subroutines:

```
subroutine usrshl_updatfs(f,t,s,e)
```

and

```
subroutine usrshl_updatfv(f,t,s,e,lft,llt)
```

for the scalar and vector versions. The subroutine recomputes the deformation gradient based on the thickness strain increment, `e`, and the nodal thicknesses, `t`. The history variables array stores the current nodal thicknesses immediately after the deformation gradient. Your subroutine must call this routine with these four values as `t`. This subroutine produces a deformation, `f`, and the new thicknesses, `s`. Your subroutine finds the strain increment, `e`, giving zero thickness stress through this subroutine. After obtaining zero thickness stress, your subroutine needs to store the new thicknesses, `s`, in the history variables array. To achieve this, copy the new thicknesses, `s`, to the location for the nodal thicknesses. We provide sample code in the object library.

Sample user subroutine 45

Here we provide an example of a user-defined material that requires the deformation gradient. Our user-defined subroutine models a Neo-Hookean material. With λ and μ being the Lame parameters in the linearized theory, the following gives the strain energy density for this material:

$$\psi = \frac{1}{2}\lambda(\ln(\det \mathbf{F}))^2 - \mu \ln(\det \mathbf{F}) + \frac{1}{2}\mu\left(\mathrm{tr}\left(\mathbf{F}^T\mathbf{F}\right) - 3\right) \ .$$

Thus, we can express the Cauchy stress as

$$\sigma = \frac{1}{\det \mathbf{F}}\left(\lambda \ln(\det \mathbf{F})\,\mathbf{I} + \mu\left(\mathbf{F}\mathbf{F}^T - \mathbf{I}\right)\right) \ .$$

```
      subroutine umat45 (cm,eps,sig,epsp,hsv,dt1,capa,
     . etype,time,temp,failel,crv,nnpcrv,cma,qmat,elsiz,idele,reject)

Implicit analysis

We also support user-defined material models with implicit analysis for solid, shell, thick shell, and Hughes-Liu beam elements. When you request implicit analysis in the input deck, LS-DYNA calls the subroutine `urtanh` for solids (and thick shell types 3, 5, and 7), `urtans` for shells (and thick shell types 1, 2, and 6), and `urtanb` for beams with appropriate input data for calculating the material tangent modulus. This subroutine then calls a user-defined subroutine for calculating the tangent modulus for your material: `utan`*`XX`* for the scalar implementation or `utan`*`XX`*`v` for the vectorized implementation. Again, *`XX`* is the number that matches MT on the material card. `utan`*`XX`* includes

`es(6,6)` – material tangent modulus

as an argument, while `utan`*`XX`* has the corresponding vector block

`dsave(nlq,6,6)` – material tangent modulus

as an argument. Your user-defined subroutine builds the tangent modulus matrix needed for assembling the tangent stiffness matrix. This matrix equals the zero matrix when entering the user-defined subroutine. The matrix must be symmetric. If you invoke the local coordinate system option for solids, it should be in this local system. For shell elements, it should be in the co-rotational system defined for the current shell element. All transformations back to the global system are made after exiting the user-defined subroutine.

The user-defined material routine (`umat`*`XX`* or `umat`*`XX`*`v`) includes the argument `reject` to improve convergence characteristics. To use this parameter, have your user-defined subroutine set it to `.true.` when a criterion declares the iteration unacceptable. For example, the plastic strain could increase too much in one step. If your material subroutine rejects the iteration, LS-DYNA prints a warning message that says, 'Material model rejected current iterate.' LS-DYNA then retries the step with a smaller time step. If chosen carefully (by way of experimenting), this feature may result in a good trade-off between the number of implicit iterations per step and the step size for overall speed.

If the material is hyperelastic, you can apply push-forward operations on the tangent modulus tensor with

```
      subroutine push_forward_4(dsave,
     .      f11,f21,f31,f12,f22,f32,f13,f23,f33,lft,llt)
```

or

```
      subroutine push_forward_4s(es,
     .      f11,f21,f31,f12,f22,f32,f13,f23,f33)
```

for the vector and scalar implementations, respectively. In the latter subroutine, all arguments are scalars, whereas the corresponding entries in the vectorized routine are vectors of length `nlq`. `f11` to `f33` are components of the deformation gradient.

Sample user-subroutine 42, tangent modulus

The following sample user subroutine illustrates how to implement the tangent stiffness modulus for the Neo-Hookean material covered in the Sample user subroutine 45 subsection of the Deformation gradient section. The material tangent modulus is for this material given by

$$\mathbf{C} = \frac{1}{\det \mathbf{F}} \left(\lambda \mathbf{I} \otimes \mathbf{I} + 2(\mu - \lambda \ln(\det \mathbf{F})\, \mathbf{I}) \right) \ .$$

```
      subroutine utan42(cm,eps,sig,epsp,hsv,dt1,capa,
     .     etype,tt,temper,es,crv)

APPENDIX A

User-defined materials with equations-of-state

The following example user-defined subroutine uses an equation-of-state (EOS). Unlike standard models, it updates only the deviatoric stress and assigns a value to PC, the pressure cut-off. The pressure cut-off limits the amount of hydrostatic pressure that can be carried in tension (that is, when the pressure is negative). The default value is zero. A large negative number will allow the material to carry an unlimited pressure load in tension. Typically, the pressure cut-off is a function of the current state of the material and varies with time. Thus, the material model subroutine needs to calculate it. We made the pressure cut-off a constant value for simplicity in this example. The named common block `eosdloc` stores the pressure cut-off array. Depending on the computing environment, compiler directives may be required (such as the task common directive in the example) for correct SMP execution.

In addition, the number of history variables, NHV, must be increased by 4 in the input file to allocate the extra storage required for the EOS. The first 4 variables in `hsvs` contain the storage. The user-defined material model must not alter it.

Post-processing a user-defined material

Post-processing a user-defined material is very similar to post-processing a regular LS-DYNA material. However, we would like to stress some aspects of post-processing, all dealing with how to post-process history variables.

First, LS-DYNA always writes the effective plastic strain to the d3plot database and thus need not be requested by you. LS-PREPOST treats it the same as for the result from any other LS-DYNA material.

NEIPH and NEIPS on *DATABASE_EXTENT_BINARY specify the number of additional history variables written to the d3plot database for solids and shells, respectively. For instance, if NEIPH (NEIPS) equals 2, LS-DYNA writes the first two history variables in the history variables array as history var#1 and history var#2 in the d3plot database. By setting NEIPH (NEIPS) equal to NHV, LS-DYNA outputs all history variables to the d3plot database. Furthermore, if the material model uses the deformation gradient (IHYPER = 1), you must request an additional nine variables to make it available for post-processing, meaning set NEIPH (NEIPS) equal to NHV+9. The deformation gradient becomes available in the d3plot database as history variables NHV+1 to NHV+9. Note that LS-DYNA outputs the deformation gradient in the co-rotational system for shells. If using the local coordinate system option (IORTHO = 1), LS-DYNA expresses the deformation gradient in this local system. Set NEIPH (NEIPS) equal to NHV+9+9(=NHV+18) to output the deformation gradient in the global system for bricks and co-rotational system for shells. LS-DYNA outputs these as history variables NHV+10 to NHV+18.

APPENDIX B: User-Defined Equation-of-State

You can supply your own subroutines to define equation-of-state (EOS) models in LS-DYNA. To invoke a user-defined EOS, you must

1. Write a user EOS subroutine called by the LS-DYNA user-defined EOS interface.
2. Create a custom executable that includes the EOS subroutine.
3. Invoke that subroutine by defining a part in the keyword input deck that uses *EOS_USER_DEFINED with the appropriate input parameters.

We provide subroutine `ueoslib` and sample subroutines `ueos21s` and `ueos21v` in Fortran source files. This text serves as an introductory guide to implementing such a model. Note that the names of variables and subroutines below may differ from the actual ones depending on the platform and the current version of LS-DYNA.

General overview

When you define *EOS_USER_DEFINED for a part, LS-DYNA calls the subroutine `ueoslib` with the appropriate input data for the EOS update. LS-DYNA calls this subroutine twice for each integration point in each element. The first call requires the EOS to calculate the bulk modulus, and the second call updates the pressure and internal energy. You may modify this routine if necessary. This routine initializes the following data structures used by a specific *scalar* material subroutine:

`iflag` – mode flag
- EQ.-1: for initializing EOS constants
- EQ.0: for calculating the bulk modulus
- EQ.1: for the pressure and energy update

`cb` – bulk modulus
`pnew` – the new pressure
`rho0` – reference density
`hist` – array of user-defined history variables, NHV in length
`specen` – internal energy per unit reference volume
`df` – volume ratio, V/V_0
`v0` – the initial volume
`dvol` – volume increment
`pc` – pressure cut-off

If you activate the *vectorization* flag (IVECT = 1) on the EOS card, this routine generally stores these variables in vector blocks of length `nlq`, with vector indices ranging from

lft to llt, which allows for more efficient execution of the EOS routine. The data structures mentioned above for the vectorized case are:

cb(nlq)	–	bulk modulus
pnew(nlq)	–	the new pressure
hist(nlq,*)	–	array of user-defined history variables with NHV columns
specen(nlq)	–	internal energy per unit reference volume
df(nlq)	–	volume ratio, V/V0
v0(nlq)	–	the initial volume
dvol(nlq)	–	volume increment
pc(nlq)	–	pressure cut-off

The value of nlq is set as a parameter in the include file nlqparm, included at the top of the subroutine, and varies between machines and operating systems. Each entry in a vector block is associated with an element in the finite element mesh for a fixed integration point. The number of entries in the history variables array (indicated by * above) matches the number of history variables requested on the material card (NHV). All history variables are initially zero and are initialized within the user-define EOS subroutine on the first time step, when the logical variable first, passed through the argument list, is .TRUE. Furthermore, all user-defined EOS models require a bulk modulus, cb, for transmitting boundaries, contact interfaces, rigid body constraints, and time step calculations. In addition to the variables mentioned above, the following data can be supplied to the user-defined material routines, regardless of whether vectorization is used or not:

eosp(*)	–	array of material constants from the input file
tt	–	current time
crv(lq1,2,*)	–	array representation of curves defined in the keyword deck.

A user-defined EOS subroutine, ueos*XX*s in the scalar case or ueos*XX*v in the vector case, will be called for parts that point to *EOS_USER_DEFINED in the input deck. The letters *XX* represent a number between 21 and 30 that matches the input variable EOST in the *EOS_USER_DEFINED keyword. During the initialization phase, LS-DYNA calls the user-define EOS subroutine with iflag set to -1 to permit the initialization of constants in the user-defined EOS subroutine. Although fewer than 48 constants may be read into the array eosp during the input, you may use all 48 within the EOS subroutines. The user-defined subroutine should calculate the bulk modulus when iflag = 0 and update the pressure, internal energy, and history variables when iflag = 1.

See Appendix A for a discussion about using curves (*DEFINE_CURVE).

Example and Discussion

Here we provide a sample scalar user-defined subroutine for a Gruneisen EOS. Its vector counterpart immediately follows it. We close this section with a discussion about implementation and common pitfalls.

Scalar subroutine

```
      subroutine ueos21s(iflag,cb,pnew,hist,rho0,eosp,specen,
     &                   df,dvol,v0,pc,dt,tt,crv,nnpcrv,first)
      include 'nlqparm'
c
c***  example scalar user implementation of the Gruneisen EOS
c
c***  variables
c          iflag ----- =0 calculate bulk modulus

Implementation discussion

The Gruneisen EOS implemented in the example subroutines has the same form as *EOS_GRUNEISEN, EOS form 4. Its update of the pressure and the internal energy is typical for an EOS that is linear in the internal energy,

$$P = A(\rho) + B(\rho)E\ ,$$

where A and B correspond to the variables `a` and `b` in the example subroutines, and E is `specen`. Integrating the energy equation with the trapezoidal rule gives

$$E^{n+1} = E^n + \frac{1}{2}(\sigma'^n + \sigma'^{n+1})\Delta\varepsilon - \frac{1}{2}(P^n + q^n + P^{n+1} + q^{n+1})\frac{\Delta V}{V_0}$$

where the superscripts refer to the time step, ΔV is the change in the volume associated with the Gauss point and V_0 is the reference volume. Collecting all the energy

contributions on the right-hand side except for the contribution from the new pressure gives a simple linear relationship between the new internal energy and pressure,

$$E^{n+1} = \tilde{E} - \frac{P^{n+1}\Delta V}{2V_0}.$$

The value of `specen` passed to `ueosXX` for the pressure and energy update corresponds to $\tilde{E}$. Substituting this relation into the EOS and solving for the new pressure gives:

$$P^{n+1} = \frac{A\rho^{n+1} + B\rho^{n+1}\tilde{E}}{1 + \frac{B\Delta V}{2V_0}} .$$

The final update of the new energy is calculated using the updated pressure. For a more general EOS, the nonlinear equation for the new pressure,

$$P^{n+1} = P\left(\rho^{n+1}, \tilde{E} - \frac{P^{n+1}\Delta V}{2V_0}\right)$$

is solved iteratively using Newton iteration or successive substitution.

The pressure cut-off, `pc`, limits the amount of pressure that can be generated by tensile loading, `pnew=max(pnew,pc)`. Its value is usually specified in the *MAT input, such as *MAT_JOHNSON_COOK. It is not enforced outside the EOS subroutines. Thus, you determine whether to enforce the pressure cut-off in `ueosXX`. To impose the pressure cut-off, apply it before the final update to the internal energy; otherwise, the energy will be incorrect.

Calculating the bulk modulus is similar to updating the pressure and energy. Since the bulk modulus calculation always precedes the pressure update, the values may be saved in a common block during the bulk modulus calculation to reduce the cost of the pressure update. The arrays that store the values in the vectorized subroutines should be dimensioned by `nlq`.

A common pitfall is using the wrong internal energy when implementing an EOS from a paper or book. Three internal energies are commonly used: the energy per unit mass, e_M, the energy per unit current volume, e_V, and the energy per unit reference volume, E. LS-DYNA always uses the energy per unit reference volume. Some helpful relations for converting between the EOS in the literature and the variables in LS-DYNA are

$$e_V = E\frac{V_0}{V} = \frac{\text{specen}}{\text{df}}$$
$$e_M = E\frac{V_0}{M} = \frac{\text{specen}}{\text{rho0}}$$
$$\rho = \rho_0\frac{V_0}{V} = \frac{\text{rho0}}{\text{df}}$$

APPENDIX C: User Defined Element Interface for Solids and Shells

This appendix describes the user-defined element interface for solids and shells. The interface can accommodate either an integrated or a resultant element. For the integrated element, you supply two matrices defining the kinematical properties of the element. You also determine whether to use standard LS-DYNA hourglass stabilization, a user-defined stabilization, or no stabilization in the absence of zero-energy modes (see IHGF on *SECTION_SHELL/SOLID). The number and locations of the integration points are arbitrary, meaning you define them. For the resultant/discrete element formulations, you implement the force and stiffness assembly. For both element formulations, history variables can be associated with the elements. In both cases, if desired, the element may have more than the conventional 3 (for bricks) and 6 (for shells) degrees-of-freedom per node (see Extra Degrees-Of-Freedom).

Algorithm Outline

We implemented user-defined, integrated elements in the same way as standard LS-DYNA elements aside from additionally calling user routines for setting up the matrices of interest. In the end, LS-DYNA constructs the gradient-displacement matrix, B_{ijkK}, with the property that

$$B_{ijkK}u_{kK} = \frac{\partial v_i}{\partial x_j} \ ,$$

where

$u_{kK} =$ Vector of velocity nodal degrees-of-freedom

$\frac{\partial v_i}{\partial x_i} =$ Velocity gradient

Moreover, the numerical integration requires the input of J, the determinant of the Jacobian matrix that determines the mapping from the isoparametric to the physical domain. Your subroutine determines the gradient-displacement matrix and either the Jacobian matrix or the determinant of the Jacobian matrix, depending on the definition of ITAJ. From these expressions, the symmetric part of the velocity gradient determines the strain, and the corresponding antisymmetric part determines the spin. LS-DYNA, then, evaluates the stresses with a specified constitutive model. From the stresses, it obtains the internal forces with

$$f_{kK} = \int \sigma_{ij} B_{ijkK} dV \ ,$$

where σ_{ij} are the stresses. LS-DYNA calculates the geometric and material tangent stiffnesses through

$$K_{iIjJ}^{\text{mat}} = \int C_{klmn} B_{kliI} B_{mnjJ} dV$$

and

$$K_{iIjJ}^{\text{geo}} = \int \sigma_{mn} B_{kmiI} B_{knjJ} dV$$

where C_{klmn} is the tangent modulus for the material. LS-DYNA evaluates the integrals using user-defined quadrature and J.

For user-defined hourglass control, you must provide the corresponding internal force and stiffness contribution in a separate user routine.

With resultant elements, you provide the force and stiffness matrix directly for the entire element.

Invoking User-Defined Elements

To invoke a user-defined element, you must do the following:

1. Write a user element subroutine that defines the kinematics or kinetics of the element.

2. Create a custom executable that includes these subroutines.

3. Invoke the element by specifying this subroutine on the corresponding *SECTION card with ELFORM (101 through 105).

We provide you with the dummy subroutines for the user-defined elements in a FORTRAN source file for you to modify, along with the necessary object files to compile a new executable. Contact Ansys or your local distributor for information about obtaining these files and what compiler/version to use for your specific platform. Up to five user elements can simultaneously be used for bricks and shells (i.e., ten). This text is an introductory guide to implementing such an element.

Integrated Elements
To activate a user-defined element, set ELFORM to a number between 101 and 105 and NIPP/NIP to a value greater than 0 on Card 5/3 of the *SECTION_SHELL/SOLID definition. By doing so, LS-DYNA calls the following user subroutine to determine the kinematics of the elements:

```
subroutine uXXX_bYYY(bmtrx,gmtrx,gjac,...
⋮
dimension bmtrx(nlq,3,3,*),gmtrx(nlq,3,3),gjac(*)
```

where `XXX` is substituted for `shl` for a shell section and `sld` for a solid section, and `YYY` is the value of ELFORM in *SECTION_SHELL/SOLID.

Your choice of ITAJ on *SECTION_SHELL/SOLID determines how to set up these matrices in your subroutine. If ITAJ = 0, set the isoparametric gradient-displacement matrix

and the Jacobian matrix. The user subroutine represents these matrices with the arrays `bmtrx` and `gmtrx`, respectively. Here, the first index corresponds to the LS-DYNA block loop index, where `nlq` is the block size. For a more convenient notation in this discussion, we assign a correspondence between the arrays `gmtrx` and `bmtrx` in the subroutines to matrices/tensors as:

`gmtrx(*,i,j)` - g_{ij}
`bmtrx(*,i,j,k)` - b_{ijk}

Your subroutine should determine these matrices should so that at the current integration point:

$$g_{ij} = \frac{\partial x_i}{\partial \xi_j}$$

$$b_{ijk} u_k = \frac{\partial v_i}{\partial \xi_j} \Delta t$$

In the above, we assume summation over repeated indices. We use the following notation:

$x_i(\xi_1, \xi_2, \xi_3, t)$ = i^{th} component of the current position vector at the isoparametric coordinate (ξ_1, ξ_2, ξ_3) and time t.

$v_i(\xi_1, \xi_2, \xi_3, t)$ = i^{th} component of the velocity vector at the isoparametric coordinate (ξ_1, ξ_2, ξ_3) and time t.

Δt = current time step

u_k = k^{th} component of generalized local displacements

ξ_i = i^{th} component of the isoparametric coordinate ranging from -1.0 to 1.0

For shells, ILOC on *SECTION_SHELL specifies the coordinate system for the variables. ILOC = 0 sets the coordinate system to the LS-DYNA local coordinate system (`ILOC=0`), while ILOC = 1 sets it to the global coordinate system. LS-DYNA passes the coordinate system transformation matrix to the user routines, where the columns represent the local unit base vectors. The resulting strains must always be in the local coordinate system for the constitutive evaluations.

For no extra degrees-of-freedom (see Extra Degrees-Of-Freedom), the following formula gives the index k in the displacement expression:

$$k = n(m-1) + d \ ,$$

where $n = 3$ if only translational degrees-of-freedom are present (typical for solids) and $n = 6$ if rotational degrees-of-freedom are present (typical for shells), m is the local node number (m = 1,2,...), and d is the degree of freedom. The translational degrees-of-freedom correspond to $d \leq 3$ and the rotational degrees-of-freedom to $4 \leq d \leq 6$.

If ITAJ = 1, your subroutine sets up the physical gradient-displacement matrix and the Jacobian determinant. The user subroutines represent these by the arrays `bmtrx` and `gjac`, respectively. Again, we assign a correspondence between the arrays `gjac` and `bmtrx` in the subroutines to matrices/tensors as follows

```
        gjac(*) - J
bmtrx(*,i,j,k) - b_ijk
```

Your subroutine should determine these matrices should so that at the current integration point:

$$J = \det \frac{\partial x_i}{\partial \xi_j}$$

$$b_{ijk} u_k = \frac{\partial v_i}{\partial x_j} \Delta t$$

To set up these matrices, LS-DYNA passes a set of additional auxiliary variables to the user-defined element subroutines. These variables include the isoparametric coordinates, the element thickness, the shape function values, and the derivatives of the shape functions. Again, for shells, LS-DYNA expresses these variables in either the local or global coordinate system depending on your choice of ILOC. For more information on these variables, see the comments in the subroutines.

The integrated elements can use up to 100 integration points (in the plane for shells) at arbitrary locations. You must specify these integration points in terms of isoparametric coordinates and weights (see Card 5.1 for *SECTION_SHELL and Card 4 for *SECTION_-SHELL). The isoparametric coordinates should range from –1 to 1, and the weights should sum up to 4 for shells and 8 for solids.

You may need to incorporate hourglass stabilization to suppress zero energy modes. To do this, set IHGF > 0 in *SECTION_SHELL/SOLID. IHGF = 1 sets automatically using the LS-DYNA hourglass routines. For IHGF = 2 or 3, you must provide hourglass force and stiffness in a specific user-defined routine. If IHGF = 3, physical stabilization becomes available since LS-DYNA passes the resultant material tangent moduli to the hourglass routine to provide the material's current membrane, bending, and coupled membrane-bending stiffness. With C_{ij} denoting the material tangent modulus in matrix form, we express the resultant tangent moduli as

$$\bar{C}^0_{ij} = \int C_{ij}\, dV \qquad \text{(membrane)}$$
$$\bar{C}^1_{ij} = \int z^1 C_{ij}\, dV \quad \text{(membrane} - \text{bending)}$$
$$\bar{C}^2_{ij} = \int z^2 C_{ij}\, dV \quad \text{(bending)}$$

where z is the thickness coordinate for shells. For solids, LS-DYNA only passes the first resultant modulus. In this case, the array has 21 entries corresponding to the subdiagonal terms of the 6 by 6 resultant matrix. For the matrix, index (i, j) in the material tangent

modulus matrix, where $i \geq j$, the following gives the index I of the array passed to the routine:

$$I = i(i-1)/2 + j$$

In other words, the subdiagonal terms are stored row-wise in the array. For shells, LS-DYNA passes all three moduli in the local coordinate system, where each array has 15 entries corresponding to the subdiagonal terms of the 5 by 5 resultant matrices. We eliminated the through-thickness direction by assuming plane stress. The formula for the array indices transformation above holds.

The subroutine for user-defined hourglass control is called

```
subroutine uXXX_eYYY(force,stiff,ndtot,...
⋮
dimension force(nlq,*),stiff(nlq,ndtot,*)
```

where again `XXX` is substituted for `shl` for a shell section and `sld` for a soli section, and `YYY` is the value of ELFORM in *SECTION_SHELL/SOLID. The variables in the subroutine correspond to the force and stiffness as

`force(*,i)` - f_i

`stiff(*,i,j)` - K_{ij}

The indices correspond to node and degree-of-freedom numbers in the same way as for the displacements. For shells, ILOC on *SECTION_SHELL specifies the coordinate system for the force and stiffness. The variable `ndtot` gives the total number of degrees-of-freedom for the element ($4 \times (6 + n_{\text{xdof}})$ for shells and $8 \times (3 + n_{\text{xdof}})$ for solids). This subroutine has the property parameters and history variables associated with the element as input. You specify the property parameters on *SECTION_SHELL/SOLID. Each user-defined element can have no more than 40 property parameters and 100 history variables. You must update the history variables in this routine.

Resultant/Discrete Elements

By setting NIPP/NIP equal to 0 in *SECTION_SHELL/SOLID, LS-DYNA assumes a resultant/discrete element formulation. For this option, you provide force and stiffness in the same user-defined routine as for the user-defined hourglass control, that is, subroutine `uXXX_eYYY` where `XXX` is substituted for `shl` for a shell-section and `sld` for a solid-section, and `YYY` is the value of ELFORM in *SECTION_SHELL/SOLID. Thus, IHGF > 0 on *SECTION_SHELL/SOLID (hourglass stabilization) is incompatible with this option. Because you provide the force and stiffness, LS-DYNA does not call a material subroutine to update stresses and history variables. Instead, this user-defined element subroutine updates the stresses and history variables.

Nevertheless, you need to define *MAT_ELASTIC as the material for the corresponding part with suitable values of Young's modulus and Poisson's ratio. LS-DYNA calculates the time step and determines the contact stiffness with these material properties. Again, LS-DYNA passes the property parameters and history variables to the routine. It also

passes the thickness of the elements for shells. For the shell thickness update option (ISTUPD > 0 on *CONTROL_SHELL), you need to update the thicknesses in this routine.

The stiffness matrix assembled in the element routines can be input as nonsymmetric if and only if LCPACK = 3 on *CONTROL_IMPLICIT_SOLVER, that is if LS-DYNA uses the nonsymmetric solver to update the Newton iterates.

Additional Features of User-Defined Elements

Here we will provide a short description of the additional features associated with user-defined elements.

Nodal Fiber Vectors
If a user-defined shell element formulation requires the nodal fiber vectors, set IUNF to 1 on the *SECTION_SHELL card. With this option, the element routines process the nodal fiber vectors, which can be used as input to the user-defined routines for determining the b_{ijk}, g_{ij}/J, f_i and K_{ij} tensors/matrices. If IUNF ≠ 1, LS-DYNA assumes that the fiber direction is always normal to the plane of the shell. LS-DYNA expresses these nodal fiber vectors in either the local or global system, depending on your choice of ILOC on *SECTION_SHELL. See comments in the user subroutines for more information.

Extra Degrees-Of-Freedom
Exotic element formulations may require extra degrees-of-freedom per node beside the translational (and rotational) degrees-of-freedom. You can specify up to 15 extra degrees-of-freedom per node for user-defined elements. Note that if your element requires more than three extra degrees-of-freedom per node, you must increase NXDOFUE in the file nhisparm.inc to the corresponding value. This parameter is, by default, set to 3. We chose this value to limit the default sizes of common blocks and heaps. Note that NXDOFUE does not set the number of extra degrees-of-freedom per node for your element. It just sets the limit for allocation. To specify the number, you set NXDOF on *SECTION_SHELL/SOLID. We recommend setting NXDOFUE equal to NXDOF if possible.

We implemented the extra degrees-of-freedom per node so that LS-DYNA creates *a scalar node for every three extra degrees-of-freedom* associated with an actual node. Scalar nodes are dummy nodes linked to a node on an element. In other words, LS-DYNA automatically creates ceil(NXDOF/3) scalar nodes. With *NODE_SCALAR_VALUE and *ELEMENT_SOLID/SHELL_DOF, you can associate some of the extra degrees-of-freedom with a scalar node ID of your choice. This association is optional as LS-DYNA will create the scalar nodes regardless of using these keywords. It helps with setting boundary conditions and can be used to specify initial conditions, which will be discussed in more depth below. With *NODE_SCALAR_VALUE, you select the node ID associated with up to three degrees-of-freedom and then associate this scalar node with the real node using *ELEMENT_SOLID/SHELL_DOF. However, using this method, only one related

is associated with each real node. Thus, if you have more than three extra degrees-of-freedom, you cannot associate a scalar node for all the degrees-of-freedom.

We have implemented two methods for setting initial conditions. With the first method, you set the initial conditions in the first step of the user subroutine, while with the second method, you use *NODE_SCALAR_VALUE and *ELEMENT_SOLID/SHELL_DOF. We generally recommend the first method. The second method, however, is helpful if you want a node number associated with the extra degrees-of-freedom and want to apply boundary conditions to a degree-of-freedom. With the second method, you can set the initial values of up to three degrees-of-freedom per scalar node. Note that this method can only initialize up to three extra degrees-of-freedom per node because you can only associate one scalar node to each actual node. As an example:

```
*NODE_SCALAR_VALUE
$    NID              V1              V2              V3     NDF
      11             1.0                                     1
      12             1.0                                     1
      13             1.0                                     1

```

defines an element with one extra degree-of-freedom per node. The initial value of the corresponding degree-of-freedom is 1.0, and it is unconstrained. Recall that NXDOF on *SECTION_SHELL specifies the actual number of extra degrees-of-freedom. Thus, if you set NXDOF to 4 and use *NODE_SCALAR_VALUE as in the previous example, you would still need to initialize three more degrees-of-freedom in the user subroutine.

The array `xdof` contains the current values of these extra variables. LS-DYNA passes `xdof` to the user routines for setting up the correct kinematical properties. See comments in the routines for more information. The formula for the displacement index changes to

$$k = (n + n_{\text{xdof}})(m - 1) + d$$

where n_{xdof} is the number of extra degrees-of-freedom, n is the number of normal degrees-of-freedom, and m is an index for the node. The extra degrees-of-freedom for each node corresponds to $n + 1 \leq d \leq n + n_{\text{xdof}}$.

For dynamic simulations, the mass corresponding to these extra degrees-of-freedom may be defined by either:

- *ELEMENT_INERTIA or *ELEMENT_MASS, or
- the subroutine `uXXX_mYYY` for `XXX` equal to `sld` or `shl` and `YYY` between 101 and 105.

For solid elements with the subroutine method for specifying mass, XNOD on *SECTION_SOLID indicates the interpretation of the input mass. By default (XNOD = 0), the mass is interpreted as per extra degree-of-freedom. By setting XNOD to 1, the mass is

interpreted as nodal, which means you can specify the mass for the scalar node. The mass for the scalar node is then divided equally among the degrees-of-freedom associated with that scalar node.

Section Keywords

The following is a list of keywords that apply to the user-defined elements.

The *SECTION_SHELL Card
Add Card 5 with the accompanying optional cards, Cards 5.1 and 5.2, of *SECTION_-SHELL to the keyword input deck if you invoke the user-defined shell element option.

Additional Card for ELFORM = 101,102,103,104 or 105

Card 5	1	2	3	4	5	6	7	8
Variable	NIPP	NXDOF	IUNF	IHGF	ITAJ	LMC	NHSV	ILOC
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

Include NIPP cards according to the following format.

Card 5.1	1	2	3	4	5	6	7	8
Variable	XI	ETA	WGT					
Type	F	F	F					

Define LMC property parameters using 8 parameters per card.

Card 5.2	1	2	3	4	5	6	7	8
Variable	P1	P2	P3	P4	P5	P6	P7	P8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
ELFORM	GT.100.AND.LT.106: User-defined shell
NIPP	Number of in-plane integration points for user-defined shell (0 if resultant element). Up to 100 allowed.
NXDOF	Number of extra degrees-of-freedom per node for user-defined shell
IUNF	Flag for using nodal fiber vectors in user-defined shell EQ.0: Nodal fiber vectors are not used. EQ.1: Nodal fiber vectors are used
IHGF	Flag for using hourglass stabilization (NIPP is greater than 0): EQ.0: Hourglass stabilization is not used. EQ.1: LS-DYNA hourglass stabilization is used. EQ.2: User-defined hourglass stabilization is used. EQ.3: Same as 2, but the resultant material tangent moduli are passed.
ITAJ	Flag for setting up finite element matrices (NIPP is greater than 0) EQ.0: Set up matrices with respect to the isoparametric domain EQ.1: Set up matrices with respect to the physical domain
LMC	Number of property parameters
NHSV	Number of history variables
ILOC	Coordinate system option: EQ.0: Pass all variables in the LS-DYNA local coordinate system EQ.1: Pass all variables in the global coordinate system
XI	First isoparametric coordinate
ETA	Second isoparametric coordinate
WGT	Isoparametric weight
P*i*	i^{th} property parameter

For more information on the variables, consult the previous sections in this appendix.

The *SECTION_SOLID Card

Add Card 3 with the accompanying optional cards, Cards 4 and 5, of *SECTION_SOLID to the input deck if you invoke the user-defined solid element option.

Additional card for ELFORM = 101,102,103,104 or 105

Card 3	1	2	3	4	5	6	7	8
Variable	NIP	NXDOF	IHGF	ITAJ	LMC	NHSV	XNOD	
Type	I	I	I	I	I	I	I	
Default	0	0	0	0	0	0	0	

Include NIP cards according to the following format.

Card 4	1	2	3	4	5	6	7	8
Variable	XI	ETA	ZETA	WGT				
Type	F	F	F	F				

Define LMC property parameters using 8 parameters per card.

Card 5	1	2	3	4	5	6	7	8
Variable	P1	P2	P3	P4	P5	P6	P7	P8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
ELFORM	GT.100.AND.LT.106: User-defined solid
NIP	Number of integration points for user-defined solid (0 if resultant element)
NXDOF	Number of extra degrees-of-freedom per node for user-defined solid

VARIABLE	DESCRIPTION
IHGF	Flag for using hourglass stabilization (NIP > 0): EQ.0: Hourglass stabilization is not used. EQ.1: LS-DYNA hourglass stabilization is used. EQ.2: User-defined hourglass stabilization is used. EQ.3: Same as 2, but the resultant material tangent moduli are passed.
ITAJ	Flag for setting up finite element matrices (NIP > 0): EQ.0: Set up matrices with respect to the isoparametric domain. EQ.1: Set up matrices with respect to the physical domain.
LMC	Number of property parameters
NHSV	Number of history variables
XNOD	Controls how the mass of extra degrees-of-freedom is interpreted when defined using user subroutine. EQ.0: The mass is defined per degree of freedom. EQ.1: The mass is defined as a nodal mass, where each scalar node has three extra degrees-of-freedom. See Extra Degrees-Of-Freedom.
XI	First isoparametric coordinate
ETA	Second isoparametric coordinate
ZETA	Third isoparametric coordinate
WGT	Isoparametric weight
P*i*	i^{th} property parameter

For more information on the variables, consult the previous sections in this appendix.

Sample User Shell Element 101 (Belytschko-Tsay shell)

We can write the geometry of the Belytschko-Tsay element in local coordinates as:

$$x_i = (x_{iI} + \frac{t}{2}\xi_3\delta_{i3})N_I(\xi_1,\xi_2)$$
$$v_i = (v_{iI} + \frac{t}{2}\xi_3 e_{ij3}\omega_{jI})N_I(\xi_1,\xi_2)$$

where

$x_{iI} =$ i^{th} component of the coordinate of node I

$v_{iI} =$ i^{th} component of the translational velocity of node I

$\omega_{jI} =$ j^{th} component of the rotational velocity of node I

$t =$ thickness of the element

$e_{ijk} =$ permutation tensor

$N_I =$ shape function localized at node I

$\delta_{i3} =$ Kronecker delta

Taking the derivative of these expressions with respect to the isoparametric coordinate yields:

$$\frac{\partial x_i}{\partial \xi_1} = (x_{iI} + \frac{t}{2}\xi_3\delta_{i3})\frac{\partial N_I}{\partial \xi_1}$$
$$\frac{\partial x_i}{\partial \xi_2} = (x_{iI} + \frac{t}{2}\xi_3\delta_{i3})\frac{\partial N_I}{\partial \xi_2}$$
$$\frac{\partial x_i}{\partial \xi_3} = \frac{t}{2}\delta_{i3}$$

and

$$\frac{\partial v_i}{\partial \xi_1} = (v_{iI} + \frac{t}{2}\xi_3 e_{ij3}\omega_{jI})\frac{\partial N_I}{\partial \xi_1}$$
$$\frac{\partial v_i}{\partial \xi_2} = (v_{iI} + \frac{t}{2}\xi_3 e_{ij3}\omega_{jI})\frac{\partial N_I}{\partial \xi_2}$$
$$\frac{\partial v_i}{\partial \xi_3} = \frac{t}{2}e_{ij3}\omega_{jI}N_I$$

respectively. Using these expressions, we can implement the element as a user-defined shell as follows.

```
      subroutine ushl_b101(bmtrx,gmtrx,gjac,
     1     xi,eta,zeta,

To use the element for a part, we add the following section input to the keyword deck:

```
*SECTION_SHELL
$    SECID    ELFORM
         1       101
$       T1        T2        T3        T4

$     NIPP     NXDOF      IUNF      IHGF
         1         0         0         1
$       XI       ETA       WGT
        0.        0.        4.
```

Sample User Solid Element 101 (constant stress solid)

We can express the geometry for the constant stress solid as:

$$x_i = x_{iI} N_I(\xi_1, \xi_2, \xi_3)$$
$$v_i = v_{iI} N_I(\xi_1, \xi_2, \xi_3)$$

where

$x_{iI} =$ i^{th} component of the coordinate of node I

$v_{iI} =$ i^{th} component of the translational velocity of node I

$N_I =$ shape function localized at node I

Taking the derivative of these expressions with respect to the isoparametric coordinate yields:

$$\frac{\partial x_i}{\partial \xi_1} = x_{iI} \frac{\partial N_I}{\partial \xi_1}$$
$$\frac{\partial x_i}{\partial \xi_2} = x_{iI} \frac{\partial N_I}{\partial \xi_2}$$
$$\frac{\partial x_i}{\partial \xi_3} = x_{iI} \frac{\partial N_I}{\partial \xi_3}$$

and

$$\frac{\partial v_i}{\partial \xi_1} = v_{iI} \frac{\partial N_I}{\partial \xi_1}$$
$$\frac{\partial v_i}{\partial \xi_2} = v_{iI} \frac{\partial N_I}{\partial \xi_2}$$
$$\frac{\partial v_i}{\partial \xi_3} = v_{iI} \frac{\partial N_I}{\partial \xi_3}$$

respectively. Using these expressions, we can implement the element as a user-defined solid as follows.

```
      subroutine usld_b101(bmtrx,gmtrx,gjac,
     1     xi,eta,zeta,

         0.        0.        0.       8.0
```

Examples

We present three test examples. Our first example is a simple tension-compression test of a solid cylinder. Figure 51-1 shows the geometry. We used the sample implementations of user elements and compared the results and performance with standard LS-DYNA elements. As for the computational efficiency, we note that the performance is worse. We expected this decrease in performance because we sought a user-friendly interface that came at the expense of performance. The implicit performance compares well with the other elements in LS-DYNA.

The second example is a combined bending and stretching simulation with the geometry shown in Figure 51-2. We ran the problem with the user element implementations and compared the results and performance with standard LS-DYNA elements. We saw the same tendencies as for the solid elements.

The third example is an impact between a solid bar and a shell beam. Both parts are modeled with user-defined elements. The results were similar to the ones obtained by substituting the sections for standard LS-DYNA sections, but the simulation time was about 3-4 times longer.

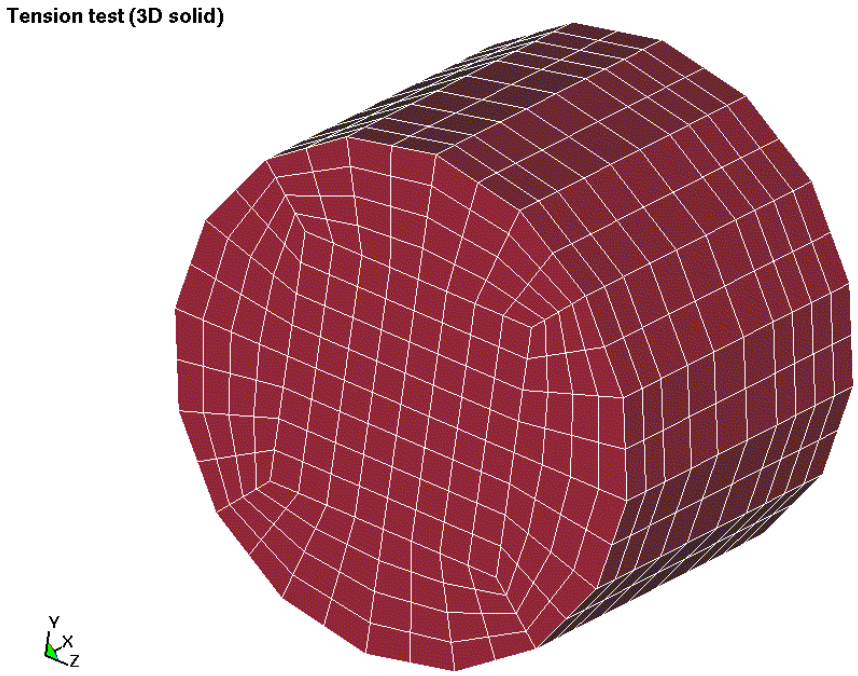

Figure 51-1. Solid mesh for user element test.

Figure 51-2. Shell mesh for the user element test.

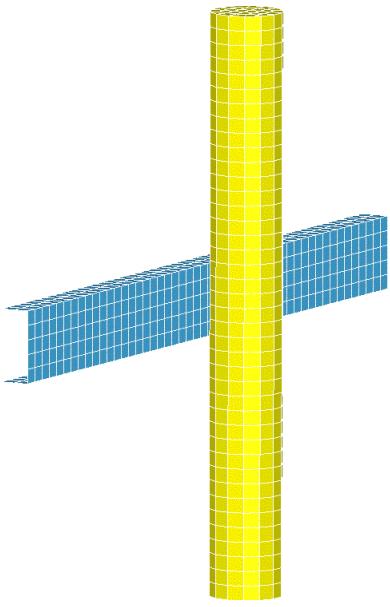

Figure 51-3. Impact between a user-defined shell and user-defined solid part.

APPENDIX D: User Defined Airbag Sensor

The addition of a user sensor subroutine into LS-DYNA is relatively simple. The sensor is mounted on a rigid body which is attached to the structure. The motion of the sensor is provided in the local coordinate system defined for the rigid body in the definition of material model 20–the rigid material. When the user defined criterion is met for the deployment of the airbag, a flag is set and the deployment begins. All load curves relating to the mass flow rate versus time are then shifted by the initiation time. The user subroutine is given below with all the necessary information contained in the comment cards.

```
      subroutine airusr (rbu,rbv,rba,time,dt1,dt2,param,hist,itrnon,
     . rbug,rbvg,rbag,icnv)
c

c*************************************************************
c
c     user subroutine to initiate the inflation of the airbag
c
c     variables
c
c     displacements are defined at time n+1 in local system
c     velocites are defined at time n+1/2 in local system
c     accelerations are defined at time n in local system
c
c         rbu(1-3) total displacements in the local xyz directions
c         rbu(3-6) total rotations about the local xyz axes
c         rbv(1-3) velocities in the local xyz directions
c         rbv(3-6) rotational velocities about the local xyz axes
c         rba(1-3) accelerations in the local xyz directions
c         rba(3-6) rotational accelerations about the local xyz axes
c         time is the current time
c         dt1 is time step size at n-1/2
c         dt2 is time step size at n+1/2
c         param is user defined input parameters
c         hist is user defined history variables
c         itrnon is a flag to turn on the airbag inflation
c         rbug,rbvg,rbag, are similar to rbu,rbv,rba but are defined
c                         globally.
c         icnv is the airbag ID
c
c     the user subroutine sets the variable itrnon to:
c
c           itrnon=0 bag is not inflated
c           itrnon=1 bag inflation begins and this subroutine is
c                    not called again
c
      include 'iounits.inc'
      dimension rbu(6),rbv(6),rba(6),param(25),hist(25),
     . rbug(6),rbvg(6),rbag(6)
c
      itrnon=0
      ra=sqrt(rba(1)**2+rba(2)**2+rba(3)**2)
      if (ra.gt.param(1)) then
        itrnon=1
```

APPENDIX D

```
        write(iotty,100) time
        write(iohsp,100) time
        write(iomsg,100) time
      endif
 100  format (' Airbag activated at time ',1pe10.3)
c
      return
      end
```

APPENDIX E: User Defined Solution Control

You can control the I/O, monitor the energies and other solution norms of interest, and shut down the problem whenever you please with user subroutine `uctrl1` in dyn21.F. The arguments are defined in the listing provided below. This subroutine is called each time step and does not need any control card to operate.

```
      subroutine uctrl1 (numnp,ndof,time,dt1,dt2,prtc,pltc,frci,prto,
     . plto,frco,vt,vr,at,ar,ut,ur,xmst,xmsr,irbody,rbdyn,usrhv,
     . messag,totalm,cycle,idrint,mtype,lrb,nrba,rbcor,x,rbv,nrbn,
     . nrb,xrb,yrb,zrb,axrb,ayrb,azrb,dtx,nmmat,rba,fvalnew,fvalold,
     . fvalmid,fvalnxt)
c

APPENDIX G: User Defined Interface Friction and Conductivity

An easy-to-use user contact interface is provided in LS-DYNA where you can define the frictional coefficients (static and dynamic) as well as contact heat transfer conductance as functions of contact pressure, relative sliding velocity, separation and temperature. To be able to use this feature, an object version of the LS-DYNA code is required, and you must write your own Fortran (or C) code to define the contact parameters of interest.

The object version of LS-DYN comes with various text files in which user subroutines can be included. The subroutines of interest are

```
subroutine usrfrc(fstt,fdyn,...)
```

for defining the frictional coefficients fstt (static) and fdyn (dynamic) and

```
subroutine usrhcon(h,...)
```

for defining the heat transfer contact conductance, *h*. Subroutines `usrfrc` and `usrhcon` are dyn21cnt.F and dyn21.F. Due to the significant change in characteristics between the regular node-to-surface contact and segment-to-segment Mortar contact, the subroutine

```
subroutine mortar_usrfrc(…)
```

in dyn21cnt.F is intended for usage with Mortar contact. This routine is supposed to return the coefficient of friction for the current contact state and is in this sense very similar to the other routine. For explanation of all arguments, we refer to the source code.

We emphasize at this point that the user friction interface for non-Mortar differs between LS-DYNA (SMP) and MPP-DYNA (MPP), for reasons that have to do with how the contacts are implemented in general. In LS-DYNA (SMP) you are required not only to define the frictional coefficients but also to assemble and store contact forces and history, whereas in MPP-DYNA (MPP) only the frictional coefficients have to be defined. For Mortar contact, the same routine is called for both SMP and MPP, and only one frictional coefficient needs to be defined.

For the friction interface (SMP and MPP) you may associate history variables with each contact node (or segment for Mortar contact). Unfortunately, the user friction interface is currently not supported by all available contacts in LS-DYNA and MPP-DYNA, but it should cover the most interesting ones among others, *CONTACT_(FORMING_)NODES_TO_SURFACE, *CONTACT_(FORMING_)SURFACE_TO_SURFACE, *CONTACT_(FORMING_)ONE_WAY_SURFACE_TO_SURFACE and all Mortar contacts. Upon request by customers, additional contact types can be supported.

One of the arguments to the user contact routines is the curve array `crv`, also available in the user material interface. Note that when using this array, the curve identity must

be converted to an internal number or the subroutine `crvval` may be utilized. For more information, see Appendix A on user materials.

For definition of user contact parameters, you must define the keywords

*USER_INTERFACE_FRICTION

or

*USER_INTERFACE_CONDUCTIVITY

The card format for these two keywords is identical and can be found in other sections in this manual.

There is an alternate route to defining the conductivity parameters for a user defined thermal contact. On the *CONTACT_..._THERMAL_FRICTION optional card the parameter FORMULA may be set to a negative number. This will automatically create a user defined conductivity interface and invoke reading of –FORMULA contact parameters immediately following the card including the FORMULA parameter. Note that FORMULA is related to NOC and NOCI in the *USER_INTERFACE_CONDUCTIVITY keyword as

$$-\text{FORMULA} = \text{NOC} = \text{NOCI}.$$

Note that the pressure is automatically computed for each user conductivity interface, meaning the keyword *LOAD_SURFACE_STRESS is not necessary.

A sample friction subroutine for the non-Mortar case is provided below for SMP, for Mortar contact we refer to the source code for an example.

```
      subroutine usrfrc(nosl,time,ncycle,dt2,intr,areat,xt,yt,zt,
     . lsv,ix1,ix2,ix3,ix4,arear,xx1,xx2,xx3,stfn,stf,fni,
     . dx,dy,dz,fdt2,ninput,ua,side,iisv5,niisv5,n1,n2,n3,fric1,
     . fric2,fric3,fric4,bignum,fdat,iseg,fxis,fyis,fzis,ss,tt,
     . ilbsv,stfk,frc,numnp,npc,pld,lcfst,lcfdt,temp,temp_bot,
     . temp_top,isurface)

APPENDIX H: User Defined Thermal Material Model

The addition of a thermal user material routine into LS-DYNA is fairly straightforward. The thermal user material is controlled using the keyword *MAT_THERMAL_USER_-DEFINED, which is described at the appropriate place in the manual.

The thermal user material can be used alone or in conjunction with any given mechanical material model in a coupled thermal-mechanical solution. A heat-source can be included and the specific heat updated so that it possible to model e.g. phase transformations including melt energy.

If for the same part (shell or solid elements) both a thermal and mechanical user material model is defined then the two user material models have (optionally) read access to each other's history variables. If the integration points of the thermal and mechanical elements not are coincident then interpolation or extrapolation is used when reading history variables. Linear interpolation or extrapolation using history data from the two closest integration points is used in all cases except when reading history variables from the thick thermal shell (THSHEL = 1 on *CONTROL_SHELL). For the latter thermal shell, the shape functions of the element are used for the interpolation or extrapolation.

The thermal user materials are thermal material types 11-15. These thermal user material subroutines are defined in file dyn21.f as subroutines thumat11, … , thumat15. The latter subroutines are called from the subroutine thusrmat. The source code of subroutine thusrmat is also in file dyn21.f. Additional useful information is available in the comments of subroutines thusrmat, thumat12, and umat46 that all reside in the source file dyn21.f

Thermal history variables

Thermal history variables can be used by setting NVH greater that 0. Thermal history variables are output to the tprint file, see *DATABASE_TPRINT.

Interchange of history variables with mechanical user material

In a coupled thermo-mechanical solution there is for each mechanical shell, thick shell, or solid element a corresponding thermal element. A pair consisting of a mechanical and a corresponding thermal element both have integration points and possibly history variables. The mechanical and thermal elements do not necessarily have the same number of integration points.

By setting IHVE to 1, a thermal user material model can read, but not write, the history variables from a mechanical user material model and vice versa.

APPENDIX H

If the locations of the points where the history variables are located differ between the mechanical and thermal element differ interpolation or extrapolation is used to calculate the history value. More information is available in the comments to the subroutines thusrmat and thumat11.

Limitations:

Currently there are a few limitations of the thermal user material implementation. LS-DYNA will in most cases give an appropriate warning or error message when such a limit is violated. The limitations include:

1. Option IHVE.EQ.1 is only supported for a limited range of mechanical elements:
   a) Solid elements: ELFORM = 1, 2, 10, 13.
   b) Shell elements: ELFORM = 2, 3, 4, 16. Note that user-defined integration rules are not supported.
2. Thermal history variables limitations:
   a) Thermal history variables are not output to d3plot.
3. The thermal solver includes not only the plastically dissipated energy as a heat source but also wrongly the elastic energy. The latter however is in most cases not of practical importance.

Example source code:

Example source code for thermal user material models is available in thumat11 and thumat12 as well as in umat46. Note that there is space for up to 64 material parameters in r_matp (material parameter array) but only 32 can be read in from the *MAT_THERMAL_USER_DEFINED card. The material parameters in r_matp(i), i = 41-64, which are initially set to 0.0, may be used by the user to store additional data.

Subroutine crvval evaluates load curves. Note that when using crvval the load curves are first re-interpolated to 100 equidistant points. See Appendix A for more information on subroutine crvval.

Following is a short thermal user material model. The card format is in this case, if enabling orthotropic conduction, and with sample input in SI-units:

***MAT_THERMAL_USER_DEFINED**

Card 1	1	2	3	4	5	6	7	8
Variable	MID	RO	MT	LMC	NVH	AOPT	IORTHO	IHVE
Type	21	7800.0	12.0	6.0	3.0	0.0	1.0	0.0

Card 2	1	2	3	4	5	6	7	8

APPENDIX I: Occupant Simulation Including the Coupling to the CAL3D and MADYMO programs

INTRODUCTION

LS-DYNA is coupled to occupant simulation codes to generate solutions in automotive crashworthiness that include occupants interacting with the automotive structure. In such applications LS-DYNA provides the simulation of the structural and deformable aspects of the model and the OSP (Occupant Simulation Program) simulates the motion of the occupant. There is some overlap between the two programs which provides flexibility in the modeling approach. For example, both the OSP and LS-DYNA have the capability of modeling seat belts and other deformable restraints. The advantage of using the OSP is related to the considerable databases and expertise that have been developed in the past for simulating dummy behavior using these programs.

The development of the interface provided us a number of possible approaches. The approach selected is consistent with our philosophy of providing the most flexible and useful interface possible. This is important because the field of non-linear mechanics is evolving rapidly and techniques which are used today are frequently rendered obsolete by improved methodologies and lower cost computing which allows more rigorous techniques to be used. This does make the learning somewhat more difficult as there is not any single procedure for performing a coupling.

One characteristic of LS-DYNA is the large number of capabilities, particularly those associated with rigid bodies. This creates both an opportunity and a difficulty: LSDYNA3D has many ways approximating different aspects of problems, but they are frequently not obvious to users without considerable experience. Therefore, in this Appendix we emphasize modeling methods rather than simply listing capabilities.

THE LS-DYNA/OCCUPANT SIMULATION PROGRAM LINK

Coupling between the OSP and LS-DYNA is performed by combining the programs into a single executable. In the case of CAL3D, LS-DYNA calls CAL3D as a subroutine, but in the case of MADYMO, LS-DYNA is called as a subroutine. The two programs are then integrated in parallel with the results being passed between the two until a user defined termination time is reached.

The OSP and LS-DYNA have different approaches to the time integration schemes. The OSP time integrators are based on accurate implicit integrators which are valid for large time steps which are on the order of a millisecond for the particular applications of

interest here. An iterative solution is used to ensure that the problem remains in equilibrium. The implicit integrators are extremely good for smoothly varying loads; however, sharp nonlinear pulses can introduce considerable error. An automatic time step size control which decreases the time step size quickly restores the accuracy for such events. The LS-DYNA time integrator is based on an explicit central difference scheme. Stability requires that the time step size be less than the highest frequency in the system. For a coarse airbag mesh, this number is on the order of 100 microseconds while an actual car crash simulation is on the order of 1 microsecond. The smallest LS-DYNA models have at least 1,000 elements. Experience indicates that the cost of a single LS-DYNA time step for a small model is at least as great as the cost of a time step in the OSP. Therefore, in the coupling, the LS-DYNA time step is used to control the entire simulation including the OSP part. This approach has negligible cost penalties and avoids questions of stability and accuracy that would result by using a subcycling scheme between the two programs.

LS-DYNA has a highly developed rigid body capability which is used in different parts of automobile crash simulation. In particular, components such as the engine are routinely modeled with rigid bodies. These rigid bodies have been modified so that they form the basis of the coupling procedure in LS-DYNA to the OSP.

Please contact the technical support team (https://support.ansys.com) for instructions to download and run LS-DYNA executables coupled with Madymo.

AIRBAG MODELING

Modeling of airbags is accomplished by use of shell or membrane elements in conjunction with a control volume (see *AIRBAG_*OPTION*) and possibly a single surface contact algorithm to eliminate interpenetrations during the inflation phase (see *CONTACT_*OPTION*). The contact types showing an "a" in front are most suited for airbag analysis. Current recommended material types for the airbags are:

1. *MAT_ELASTIC (Type 1, Elastic)
2. *MAT_COMPOSITE_DAMAGE (Type 22, layered orthotropic elastic for composites)
3. *MAT_FABRIC (Type 34, fabric model for folded airbags)

Model 34 is a "fabric" model which can be used for flat bags. As a user option this model may or may not support compression.

The elements which can be used are as follows:

1. Belytschko-Tsay quadrilateral with 1 point quadrature. This element behaves rather well for folded and unfolded cases with only a small tendency to

hourglass. The element tends to be a little stiff. Stiffness form hourglass control is recommended.

2. Belytschko-Tsay membrane. This model is softer than the normal Belytschko-Tsay element and can hourglass quite badly. Stiffness form hourglass is recommended. As a better option, the fully integrated Belytschko-Tsay membrane element can be chosen.

3. C0 Triangular element. The C0 triangle is very good for flat bag inflation and has no tendency to hourglass.

4. The best choice is a specially developed airbag membrane element with quadrilateral shape. This is an automatic choice when the fabric material is used.

As an airbag inflates, a considerable amount of energy is transferred to the surrounding air. This energy transfer decreases the kinetic energy of the bag as it inflates. In the control volume logic, this is simulated either by using either a mass weighted damping option or a back pressure on the bag based on a stagnation pressure. In both cases, the energy that is absorbed is a function of the fabric velocity relative to a rigid body velocity for the bag. For the mass weighted case, the damping force on a node is proportional to the mass times the damping factor times the velocity vector. This is quite effective in maintaining a stable system, but has little physical justification. The latter approach using the stagnation pressure method estimates the pressure needed to accelerate the surrounding air to the speed of the fabric. The formula for this is:

$$P = \text{Area} \times \alpha \times \left[\left(\vec{V}_i - \vec{V}_{cg}\right) \cdot \hat{n}\right]^2$$

This formula accomplishes a similar function and has a physical justification. Values of the damping factor, α, are limited to the range of 0 to 1, but a value of 0.1 or less is more likely to be a good value.

COMMON ERRORS

1. Improper airbag inflation or no inflation.

The most common problem is inconsistency in the units used for the input constants. An inflation load curve must also be specified. The normals for the airbag segments must all be consistent and facing outwards. If a negative volume results, this can sometimes be quickly cured by using the "flip" flag on the control volume definition to force inward facing normals to face outwards.

2. Excessive airbag distortions.

Check the material constants. Triangular elements should have less distortion problems than quadrilaterals. Overlapped elements at time zero can cause locking to occur in the contact leading to excessive distortions. The considerable

energy input to the bag will create numerical noise and some damping is recommended to avoid problems.

3. The dummy passes through the airbag.

A most likely problem is that the contacts are improperly defined. Another possibility is that the models were developed in an incompatible unit system. The extra check for penetration flag if set to 1 on the contact control cards variable PENCHK in the *CONTACT_... definitions may sometimes cause nodes to be prematurely released due to the softness of the penalties. In this case the flag should be turned off.

4. The OSP fails to converge.

This may occur when excessively large forces are passed to the OSP. First, check that unit systems are consistent and then look for improperly defined contacts in the LS-DYNA input.

5. Time step approaches zero.

This is almost always in the airbag. If elastic or orthotropic (*MAT_ELASTIC or *MAT_COMPOSITE material 1 or 22) is being used, then switch to fabric material *MAT_FABRIC which is less time step size sensitive and use the fully integrated membrane element. Increasing the damping in the control volume usually helps considerably. Also, check for “cuts” in the airbag where nodes are not merged. These can allow elements to deform freely and cut the time step to zero.

APPENDIX J: Interactive Graphics Commands

NOTE: The former Appendix J has been removed due to obsolescence.

APPENDIX K: Interactive Material Model Driver

INTRODUCTION

The interactive material model driver in LS-DYNA allows calculation of the material constitutive response to a specified strain path. Since the constitutive model subroutines in LS-DYNA are directly called by this driver, the behavior of the constitutive model is precisely that which can be expected in actual applications. In the current implementation the constitutive subroutines for both shell elements and solid elements can be examined.

INPUT DEFINITION

The material model driver is invoked when no *NODE or *ELEMENT commands are present in a standard LS-DYNA input file. The number of material model definitions should be set to one, the number of load curves should be nine, and the termination time to the desired length of the driver run. The complete state dump interval as given in *DATABASE_BINARY_D3PLOT serves as the time step to be used in the material model driver run. Plotting information is saved in core for the interactive plotting phase.

The input deck typically consists only of *KEYWORD, *DATABASE_BINARY_D3PLOT, *CONTROL_TERMINATION, one each of *PART/*MAT/*SECTION, and nine load curves (*DEFINE_CURVE) describing the strain path. These nine curves define the time history of the displacement gradient components shown in Table 59-1.

The velocity gradient matrix, L_{ij}, is approximated by taking the time derivative of the components in Table 59-1. If these components are considered to form a tensor S_{ij} , then

$$L_{ij}(t) = \frac{S_{ij}(t) - S_{ij}(t_{k-1})}{(t - t_k)}$$

and the strain rate tensor is defined as

$$d_{ij} = \frac{L_{ij} + L_{ij}^t}{2}$$

and the spin tensor as

$$\omega_{ij} = \frac{L_{ij} - L_{ij}^t}{2}$$

Load Curve Number	Component Definition
1	$\frac{\partial u}{\partial x}$
2	$\frac{\partial v}{\partial y}$
3	$\frac{\partial w}{\partial z}$
4	$\frac{\partial u}{\partial y}$
5	$\frac{\partial v}{\partial x}$
6	$\frac{\partial u}{\partial z}$
7	$\frac{\partial w}{\partial x}$
8	$\frac{\partial v}{\partial z}$
9	$\frac{\partial w}{\partial y}$

Table 59-1. Load Curve Definitions versus Time

INTERACTIVE DRIVER COMMANDS

After reading the input file and completing the calculations, LS-DYNA gives a command prompt to the terminal. A summary of the available interactive commands is given below. An on-line help package is available by typing HELP. Only available in Unix and Linux.

ACCL	Scale all abscissa data by f. Default is f = 1.
ASET amin omax	Set min and max values on abscissa to amin and amax, respectively. If amin = amax = 0, scaling is automatic.
CHGL n	Change label for component n. LS-DYNA prompts for new label.

CONTINUE	Re-analyze material model.
CROSS c_1 c_2	Plot component c_1 versus c_2.
ECOMP	Display component numbers on the graphics display: EQ.1: x-stress, EQ.2: y-stress, EQ.3: z-stress, EQ.4: xy-stress, EQ.5: yz-stress, EQ.6: zx-stress, EQ.7: effective plastic strain, EQ.8: pressure, EQ.9: von Mises (effective) stress, EQ.10: 1st principal deviatoric stress, EQ.11: 2nd principal deviatoric stress, EQ.12: 3rd principal deviatoric stress, EQ.13: maximum shear stress, EQ.14: 1st principal stress, EQ.15: 2nd principal stress, EQ.16: 3rd principal stress, EQ.17: ln (v/v0), EQ.18: relative volume, EQ.19: v0/v - 1.0, EQ.20: 1st history variable, EQ.21: 2nd history variable. Adding 100 or 400 to component numbers 1-16 yields strains and strain rates, respectively.
FILE name	Change pampers filename to name for printing.
GRID	Graphics displays will be overlaid by a grid of orthogonal lines.
NOGRID	Graphics displays will not be overlaid by a grid of orthogonal lines.
OSCL	Scale all ordinate data by f. Default is f = 1.
OSET omin omax	Set min and max values on ordinate to omin and omax, respectively. If omin = omax = 0, scaling is automatic.

PRINT	Print plotted time history data into file "pampers." Only data plotted after this command is printed. File name can be changed with the "file" command.
QUIT, END, T	Exit the material model driver program.
RDLC m n r_1 z_1 ... r_n z_n	Redefine load curve m using n coordinate pairs (r_1,z_1) (r_2,z_2),...(r_n,z_n).
TIME c	Plot component c versus time.
TV n	Use terminal output device type n. LS-DYNA provides a list of available devices.

Presently, the material model drive is implemented for solid and shell element material models. The driver does not yet support material models for beam elements.

Use the keyword *CONTROL_MPP_MATERIAL_MODEL_DRIVER and run the input deck only on one processor if a distributed memory executable (MPP) is used.

Beginning with Release R11, it is possible to use the material model driver in batch mode. That means if a file called "mmd.bat" exists in the working directory, then the commands contained therein get executed sequentially without opening an interactive command prompt. Supported commands are print, cross, time, and quit. Example for contents of "mmd.bat" to get effective stress versus plastic strain in a file called "sigeps" and effective stress versus time in "sigtim" is given here (read format '(a8,2x,2e10.0)'):

```
print
sigeps
cross              9          7
print
sigtim
time               9
quit
```

APPENDIX L: VDA Database

VDA surfaces describe the surface of geometric entities and are useful for the simulation of sheet forming problems. The German automobile and automotive supplier industry (VDA) has defined the VDA guidelines [VDA 1987] for a proper surface definition used for the exchange of surface data information. In LS-DYNA, this format can be read and used directly. Some files have to be provided for proper linkage to the motion of the correlation parts/materials in LS-DYNA.

Linking is performed via names. To these names surfaces are attached, which in turn can be linked together from many files externally to LS-DYNA. Thus, arbitrary surfaces can be provided by a preprocessor and then can be written to various files. The so-called VDA file given on the LS-DYNA execution line via V = **vda** contains references to all other files. It also contains several other parameters affecting the treatment in the contact subroutines; see below.

The procedure is as follows. If VDA surfaces are to be used, the file specified by **vda** must have the following form. The file is free formatted with blanks as delimiters. Note that the characters "}" and "{" must be separated from the other input by spaces or new lines. The **vda** file may contain any number of input file specifications of the form:

```
file afile bfile {
        alias definitions
}
alias definitions
followed by optional runtime parameters and a final end statement.
```

The file, **afile,** is optional, and if given must be the name of an ASCII input file formatted in accordance with the VDA Surface Interface Definitions as defined by the German automobile and automotive supply industry. **bfile** is required, and is the name of a binary VDA file. In a first run **afile** is given and **bfile** is created. In any further run, if the definitions have not changed, **afile** can be dropped and only **bfile** is needed. The purpose of **bfile** is that it allows for much faster initialization if the same VDA surfaces are to be used in a future LS-DYNA run.

If **afile** is given, **bfile** will always be created or overwritten. The alias definitions are used for linking to LS-DYNA and between the various surface definitions in the files defined by **afile** and **bfile.**

The alias definitions are of the form

```
alias name { el1 el2 ... eln }
```

where **name** is any string of up to 12 characters, and el1,...,eln are the names of VDA elements as specified in **afile**. The list of elements can be empty, in which case all the SURF and FACE VDA elements in **afile** will be used. Care should be taken to ensure that the alias **name** is unique, not only among the other aliases, but among the VDA element

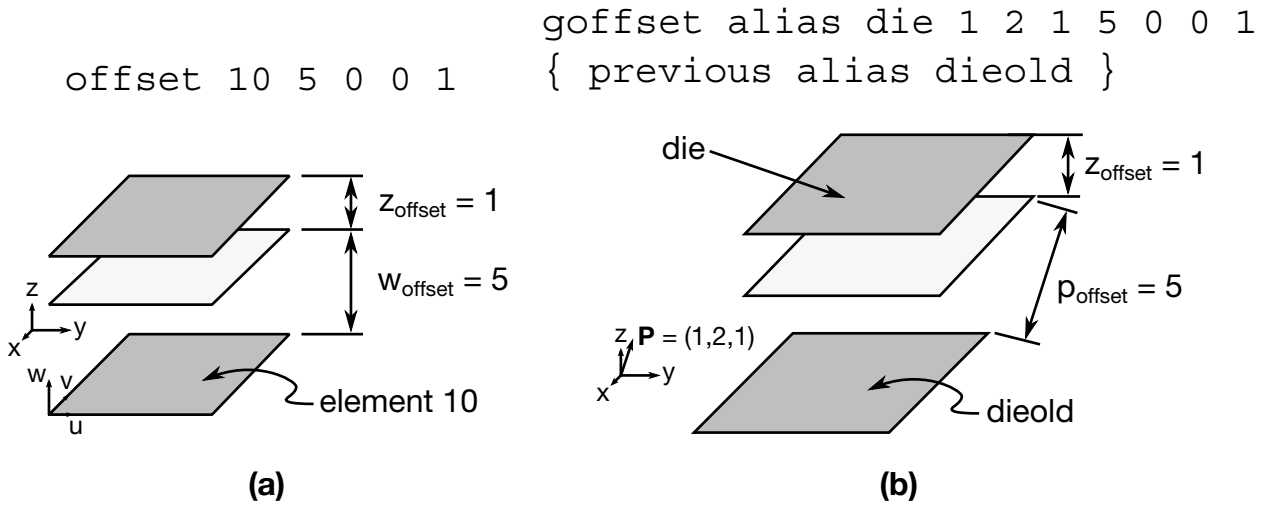

Figure 60-1. (a) a schematic illustration of offset version 1, and (b) is a schematic illustration of offset version 2.

names in **afile**. This collection of VDA elements can later be indicated by the alias **name**. In particular, **name** may appear in later alias definitions.

Often it is required that a punch or die be created by a simple offset. This can be achieved in the **vda** files in two ways, either on VDA elements directly, or on parts defined by aliases. This feature offers great capability in generating and using surface data information.

Offset Version 1

As an option, the keyword **offset** may appear in the alias list which allows a new surface to be created as a normal offset (plus translation) of a VDA element in the file. The keyword **offset** my be applied to VDA elements only, not aliases. The usage of **offset** follows the form

offset elem **normal x y z**

where **normal** is the amount to offset the surface along the normal direction, and **x**,**y**,**z** are the translations to be applied. The default normal direction is given by the cross product of the local u and v directions on the VDA surface, taken in that order. **normal** can be negative.

Offset Version 2

Frequently, it is convenient to create a new alias **name** by offsetting and translating an existing **name**. The keyword **goffset** provides this function:

goffset **alias name xc yc zc normal x y z** { previous **alias name** }

where **normal**, **x**, **y**, and **z** are defined as in the offset keyword. A reference point $\mathbf{x_c}$, $\mathbf{y_c}$, and $\mathbf{z_c}$ defines a point in space which determines the normal direction to the VDA surface, which is a vector from the origin to $P(x_c,y_c,z_c)$. See example below.

Finally, several parameters affecting the VDA surface iteration routines can be reset in the file **vda**. These parameters, and their default values in square brackets [ ], are:

gap [5.0] The maximum allowable surface gap to be filled in during the iterations. Points following the surface will effectively extend the edges of surfaces if necessary to keep them from falling through cracks in the surface smaller than this. This number should be set as small as possible while still allowing correct results. In particular, if your VDA surfaces are well formed (having no gaps), this parameter can be set to 0.0. The default value is 5.0.

t**rack** [2.0] A point must be within this distance of contact to be continually tracked. When a point not being tracked comes close to a surface, a global search is performed to find the near surface point. While a point is being tracked, iterations are performed every cycle. These iterations are much faster, but if the point is far away it is faster to occasionally do the global search. The default value is 2.0.

t**rack2** [5.0] Every VDA surface is surrounded by a bounding box. When a global search needs to be performed but the distance from a point to this box is > t**rack2**, the actual global search is not performed. This will require another global search to be performed sooner than if the actual distance to the surface were known, but also allows many global searches to be skipped. The default value is 5.0.

ntrack [4] The number of VDA surfaces for which each point maintains actual distance information. A global lower bound on distance is maintained for all remaining surfaces. Whenever the point moves far enough to violate this global lower bound, all VDA surfaces must have the global search performed for them. Hence, this parameter should be set to the maximum number of surfaces that any point can be expected to be near at one time (the largest number of surfaces that come together at one point). Setting **ntrack** higher will require more memory but result in faster execution. If **ntrack** is too low, performance may be unacceptably slow. The default value is 4.0.

toroid [.01] Any surface with opposing edges which are within distance [t] of each other is assumed to be cylindrical. Contacts occurring on one edge can pass to the adjacent edge. The default value is 0.01.

converge [.01] When surface iterations are performed to locate the near point, iteration is continued until convergence is detected to within this distance (all VDA coordinates are in mm). The default value is 0.01.

iterate [8] Maximum number of surface iterations allowed. Since points being tracked are checked every cycle, if convergence fails it will be tried again next cycle, so setting this parameter high does not necessarily help much. On the other hand, a point converging to a crease in the VDA surface (a crease between patches with discontinuous derivative, for example) may bounce back and forth between patches up to this many times, without actually moving. Hence, this value should not be too large. The default value is 8.

el_size [t mx mn]

Controls the generation of elements where:

t = surface tolerance for mesh generation,
mx = maximum element size to generate,
mn = minimum element size to generate.

The default values are [0.25 100. 1.0]

aspect [s1 s2] Controls the generation of elements where:

s1 = maximum difference in aspect ratio between elements generated in neighboring VDA patches,
s2 = maximum aspect ratio for any generated element.

The default values are [1.5 4.0]

cp_space [10] Determines the spacing around the boundaries of parts at which the size of elements is controlled. In the interior of the part, the element size is a weighted function of these control points as well as additional control points in the interior of the region. If there are too few control points around the boundary, elements generated along or near straight boundaries, but between control points, may be too small. The default value is 10.

meshonly The existence of this keyword causes LS-DYNA to generate a file containing the mesh for the VDA surfaces and then terminate.

onepatch The existence of this keyword causes LS-DYNA to generate a single element on each VDA patch.

somepatch [n] Like onepatch, but generates an element for 1 out of every [n] patches.

Example for file V = **vda**. It contains the following data:

```
file vda1 vda1.bin {
        alias die {
                sur0001
                sur0003
                offset fce0006 1.5 0 0 120
        }
        alias holder1 { sur008 }
}
file vda2 vda2.bin {
        alias holder2 { sur003 }
}
alias holder { holder1 holder2 }
ntrack 6
gap 0.5

end
```

Explanation:

vda1	This file contains the surfaces/face elements sur0001,sur0003, fce0006, and sur0008.
alias die face	Combines the surface/face elements sur0001, sur0003, and the offsetted fce0006 to a global surface.
alias holder1	Defines the surface/face element sur0008 as holder1.
vda2	This file contains the surface/face element sur0003.
alias holder2	Defines the surface/face element sur0003 as holder2.
alias holder	Combines the surfaces holder1 and holder2 into a combined surface holder.
ntrack 6	For each point the actual distances to 6 VDA surfaces are maintained.
gap 0.5	Surface gaps of 0.5mm or less are filled.
end	Closes reading of this file.

APPENDIX M: Commands for Two-Dimensional Rezoning

NOTE: The former Appendix M has been removed due to obsolescence.

APPENDIX N: Rigid-Body Dummies

The two varieties of rigid body dummies available in LS-DYNA are described in this appendix. These are generated internally by including the appropriate *COMPONENT keyword. A description of the GEBOD dummies begins on this page and the HYBRID III family on page N.7.

GEBOD Dummies

Rigid body dummies can be generated and simulated within LS-DYNA using the keyword *COMPONENT_GEBOD. Physical properties of these dummies draw upon the GEBOD database [Cheng et al. 1994] which represents an extensive measurement program conducted by Wright-Patterson AFB and other agencies. The differential equations governing motion of the dummy are integrated within LS-DYNA separate from the finite element model. Interaction between the dummy and finite element structure is achieved using contact interfaces (see *CONTACT_GEBOD).

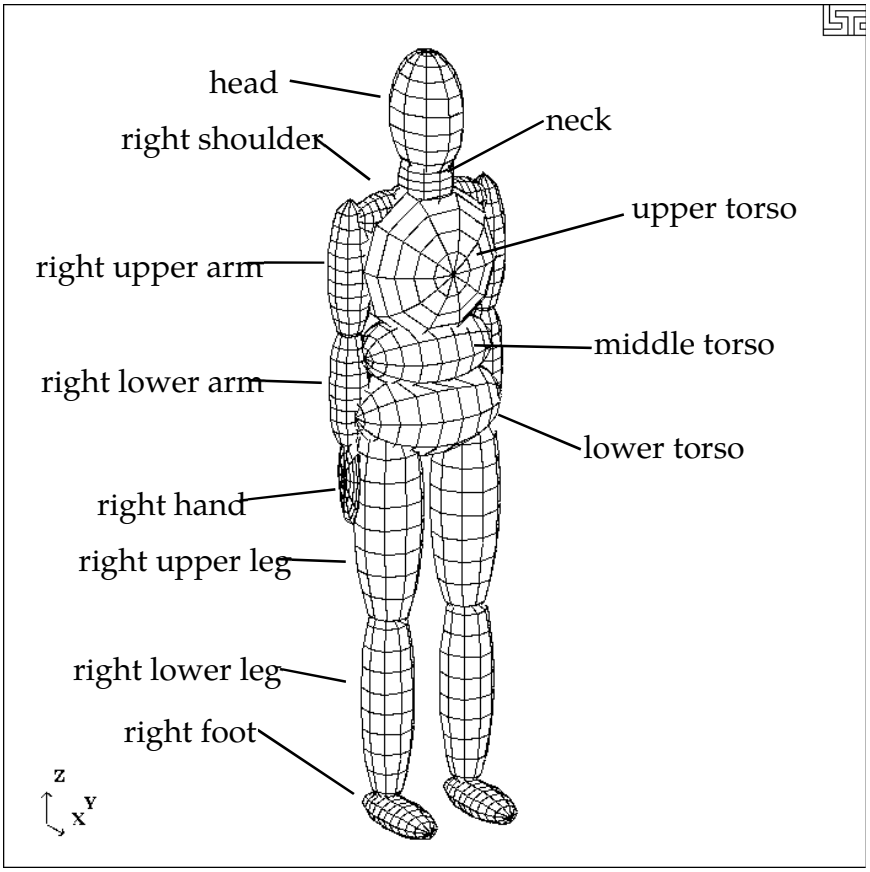

Figure 62-1. 50th percentile male dummy in the nominal position.

APPENDIX N

The dynamical system representing a dummy is comprised of fifteen rigid bodies (segments) and include: lower torso, middle torso, upper torso, neck, head, upper arms, forearms/hands, upper legs, lower legs, and feet. Ellipsoids are used for visualization and contact purposes. Shown in Figure 62-1 is a 50th percentile male dummy generated using the keyword command *COMPONENT_GEBOD_MALE. Note that the ellipsoids representing the shoulders are considered to be part of the upper torso segment and the hands are rigidly attached to the forearms.

Each of the rigid segments which make up the dummy is connected to its neighbor with a joint which permits various relative motions of the segments. Listed in the Table 62-2 are the joints and their applicable degrees of freedom.

Joint Name	Degree(s) of Freedom		
	1st	2nd	3rd
pelvis	lateral flexion (x)	forward flexion (y)	torsion (z)
waist	lateral flexion (x)	forward flexion (y)	torsion (z)
lower neck	lateral flexion (x)	forward flexion (y)	torsion (z)
upper neck	lateral flexion (x)	forward flexion (y)	torsion (z)
shoulders	abduction-adduction (x)	internal-external rotation (z)	flexion-extension (y)
elbows	flexion-extension (y)	n/a	n/a
hips	abduction-adduction (x)	medial-lateral rotation (z)	flexion-extension (y)
knees	flexion-extension (y)	n/a	n/a
ankles	inversion-eversion (x)	dorsi-plantar flexion (y)	medial-lateral rotation (z)

Table 62-2. Joints and associated degrees of freedom. Local axes are in parentheses.

Orientation of a segment is effected by performing successive right-handed rotations of that segment relative to its parent segment - each rotation corresponds to a joint degree of freedom. These rotations are performed about the local segment axes and the sequence is given in Table 62-2. For example, the left upper leg is connected to the lower torso by the left hip joint; the limb is first abducted relative to lower torso, it then undergoes lateral rotation, followed by extension. The remainder of the lower extremity (lower leg and foot) moves with the upper leg during this orientation process.

By default all joints are assigned stiffnesses, viscous characteristics, and stop angles which should give reasonable results in a crash simulation. One or all default values of a joint may be altered by applying the *COMPONENT_GEBOD_JOINT_*OPTION* command to the joint of interest. The default shape of the resistive torque load curve used by all joints is shown in Figure 62-6. A scale factor is applied to this curve to obtain the proper stiffness relationship. Listed in Table 62-3 are the default values of joint characteristics for dummies of all types and sizes. These values are given in the English system of units;

the appropriate units are used if a different system is specified in card 1 of *COMPONENT_GEBOD_*OPTION*.

joint degrees of freedom	load curve scale factor (in·lbf)	damping coef. (in·lbf·s/rad)	low stop angle (degrees)	high stop angle (degrees)	neutral angle (degrees)
pelvis - 1	65000	5.77	-20	20	0
pelvis - 2	65000	5.77	-20	20	0
pelvis - 3	65000	5.77	-5	5	0
waist - 1	65000	5.77	-20	20	0
waist - 2	65000	5.77	-20	20	0
waist - 3	65000	5.77	-35	35	0
lower neck - 1	10000	5.77	-25	25	0
lower neck - 2	10000	5.77	-25	25	0
lower neck - 3	10000	5.77	-35	35	0
upper neck - 1	10000	5.77	-25	25	0
upper neck - 2	10000	5.77	-25	25	0
upper neck - 3	10000	5.77	-35	35	0
l. shoulder - 1	100	5.77	-30	175	0
r. shoulder - 1	100	5.77	-175	30	0
shoulder - 2	100	5.77	-65	65	0
shoulder - 3	100	5.77	-175	60	0
elbow - 1	100	5.77	1	-140	0
l. hip - 1	10000	5.77	-25	70	0
r. hip - 1	10000	5.77	-70	25	0
hip - 2	10000	5.77	-70	70	0
hip - 3	10000	5.77	-140	40	0
knee - 1	100	5.77	-1	120	0
l. ankle - 1	100	5.77	-30	20	0
l. ankle - 1	100	5.77	-20	30	0
ankle - 2	100	5.77	-20	45	0
ankle - 3	100	5.77	-30	30	0

Table 62-3. Default joint characteristics for all dummies.

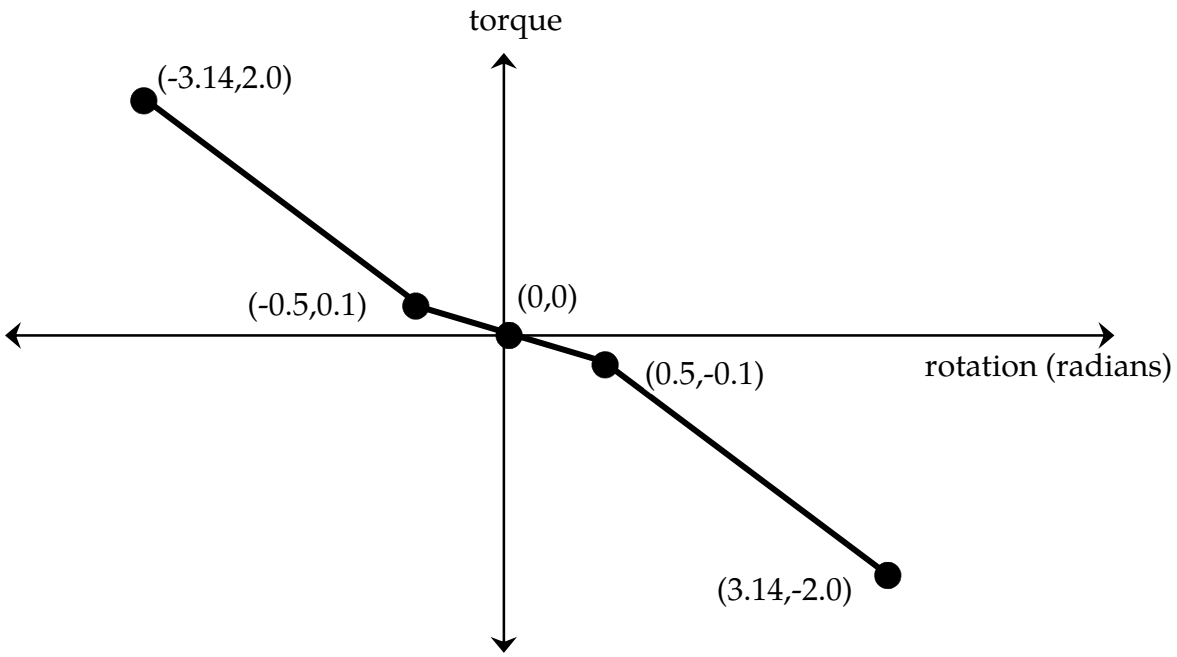

Figure 62-4 Characteristic torque curve shape used by all joints.

The dummy depicted in Figure 62-1 appears in what is referred to as its "nominal" position. In this position the dummy is standing upright facing in the positive x direction and the toe-to-head direction points in positive z. Additionally, the dummy's hands are at the sides with palms facing inward and the centroid of the lower torso is positioned at the origin of the global coordinate system. Each of the dummy's segments has a local coordinate system attached to it and in the nominal position all of the local axes are aligned with the global axes.

When performing a simulation involving a *COMPONENT_GEBOD dummy, a positioning file named "gebod.*did*" must reside in the directory with the LS-DYNA input file; here the extension *did* is the dummy ID number, see card 1 of *COMPONENT_GEBOD_*OPTION*. The contents of a typical positioning file is shown in Table 62-5; it consists of 40 lines formatted as (59a1,e30.0). All of the angular measures are input as degrees, while the lower torso global positions depend on the choice of units in card 1 of *COMPONENT_GEBOD_*OPTION*. Setting all of the values in this file to zero yields the so-called "nominal" position.

Table 62-5. Typical contents of a dummy positioning file.

lower torso	centroid global x position	0.0
lower torso	centroid global y position	0.0
lower torso	centroid global z position	0.0
total body	global x rotation	0.0
total body	global y rotation	-20.0
total body	global z rotation	180.0

pelvis	lateral flexion	+ = tilt right	0.0
pelvis	forward flexion	+ = lean fwd	0.0
pelvis	torsion	+ = twist left	0.0
waist	lateral flexion	+ = tilt right	0.0
waist	forward flexion	+ = lean fwd	0.0
waist	torsion	+ = twist left	0.0
lower neck	lateral flexion	+ = tilt right	0.0
lower neck	forward flexion	+ = nod fwd	0.0
lower neck	torsion	+ = twist left	0.0
upper neck	lateral lexion	+ = tilt right	0.0
upper neck	forward flexion	+ = nod fwd	0.0
upper neck	torsion	+ = twist left	0.0
left shoulder	abduction-adduction	+ = abduction	30.0
left shoulder	internal-external rotation	+ = external	-10.0
left shoulder	flexion-extension	- = fwd raise	-40.0
right shoulder	abduction-adduction	- = abduction	-30.0
right shoulder	internal-external rotation	- = external	10.0
right shoulder	flexion-extension	- = fwd raise	-40.0
left elbow	flexion-extension	+ = extension	-60.0
right elbow	flexion-extension	+ = extension	-60.0
left hip	abduction-adduction	+ = abduction	0.0
left hip	medial-lateral rotation	+ = lateral	0.0
left hip	flexion-extension	+ = extension	-80.0
right hip	abduction-adduction	- = abduction	0.0
right hip	medial-lateral rotation	- = lateral	0.0
right hip	flexion-extension	+ = extension	-80.0
left knee	flexion-extension	+ = flexion	50.0
right knee	flexion-extension	+ = flexion	50.0
left ankle	inversion-eversion	+ = eversion	0.0
left ankle	dorsi-plantar flexion	+ = plantar	0.0
left ankle	medial-lateral rotation	+ = lateral	0.0
right ankle	inversion-eversion	- = eversion	0.0
right ankle	dorsi-plantar flexion	+ = plantar	0.0
right ankle	medial-lateral rotation	- = lateral	0.0

In Figure 62-6 the 50th percentile male dummy is shown in a seated position and some of its joints are labeled. The file listed in Table 62-5 was used to put the dummy into the position shown. Note that the dummy was first brought into general orientation by setting nonzero values for two of the lower torso local rotations. This is accomplished by performing right-handed rotations successively about local axes fixed in the lower torso, the sequence of which follows: the first about local x, next about local y, and the last about local z. The dummy in Figure 62-6 was made to pitch backward by setting "total

body global y rotation" equal to -20. Setting the "total body global z rotation" equal to 180 caused the dummy to rotate about the global z-axis and face in the -x direction.

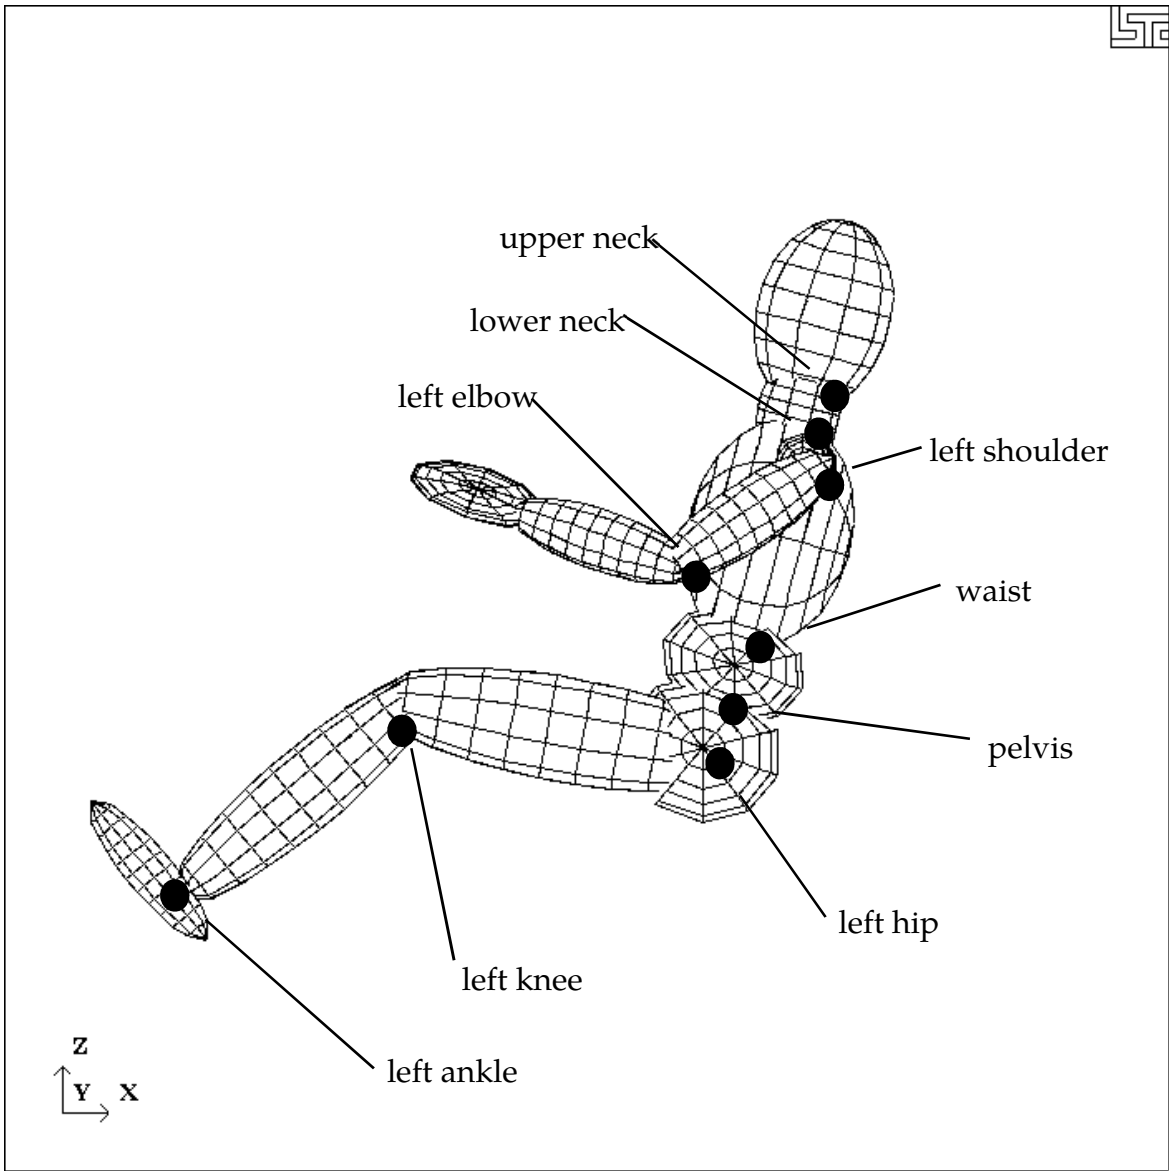

Figure 62-6. Dummy seated using the file listed in Table 62-5.

HYBRID III Dummies

A listing of applicable joint degrees of freedom of the Hybrid III dummy is given below.

Joint Name	Degree(s) of Freedom		
	1st	2nd	3rd
lumbar	flexion (y)	torsion (z)	
lower neck	flexion (y)	torsion (z)	
upper neck	flexion (y)	torsion (z)	
shoulders	flexion-extension (y)	abduction-adduction (x)	n/a
elbows	flexion-extension (y)	n/a	n/a
wrists	flexion-extension (x)	n/a	n/a
hips	abduction-adduction (x)	medial-lateral rotation (z)	flexion-extension (y)
knees	flexion-extension (y)	n/a	n/a
ankles	inversion-eversion (x)	medial-lateral rotation (z)	dorsi-plantar flexion (y)
sternum	translation (x)	rotation (y)	rotation (z)
knee sliders	translation (z)		

Table 62-7. Joints and associated degrees of freedom. Local axes are in parentheses.

Joint springs of the *COMPONENT_HYBRIDIII dummies are formulated in the following manner.

$$
\begin{aligned}
T &= a_{\mathrm{lo}}(q - q_{\mathrm{lo}}) + b_{\mathrm{lo}}(q - q_{\mathrm{lo}})^3, && q \le q_{\mathrm{lo}} \\
T &= a_{\mathrm{hi}}(q - q_{\mathrm{hi}}) + b_{\mathrm{hi}}(q - q_{\mathrm{hi}})^3, && q \ge q_{\mathrm{hi}} \\
T &= 0, && q_{\mathrm{lo}} < q < q_{\mathrm{hi}}
\end{aligned}
$$

Where,

T is the joint torque
q is the joint generalized coordinate
a_{lo} and b_{lo} are the linear and cubic coefficients, respectively, for the low regime
a_{hi} and b_{hi} are the linear and cubic coefficients, respectively, for the high regime
q_{lo} and q_{hi} are the activation values for the low and high regimes, respectively

APPENDIX O: LS-DYNA MPP User Guide

This is a short user's guide for the MPP version of LS-DYNA. For a general guide to the capabilities of LS-DYNA and a detailed description of the input, consult the LS-DYNA User's Manual. If you have questions about this guide, find errors or omissions in it, please email https://support.ansys.com.

Supported Features

Most LS-DYNA features are available for MPP. Those that are not supported are being systematically added. Unless otherwise noted here, all options of LS-DYNA are supported by MPP/LS-DYNA.

The following are *unsupported* features:

*BOUNDARY_THERMAL_WELD

*BOUNDARY_USA_SURFACE

*CONTACT_1D

*DATABASE_AVS

*DATABASE_MOVIE

*DATABASE_MPGS

*LOAD_SUPERPLASTIC_OPTION

*USER

*TERMINATION_NODE

Contact Interfaces

MPP/LS-DYNA uses a completely redesigned, highly parallel contact algorithm. The contact options currently *unsupported* include:

*CONTACT_FORCE_TRANSDUCER_CONSTRAINT

Because these options are all supported via the new, parallel contact algorithms, slight differences in results may be observed as compared to the serial and SMP versions of LS-

DYNA. Work has been done to minimize these differences, but they may still be evident in some models.

For each of the supported types of contact, the keyword option MPP can be used. Adding this keyword option triggers the reading of a new control card immediately following the keyword (unless an ID card is included). See the section on *CONTACT for details of the parameters and their meanings.

Output Files and Post-Processing

For performance reasons, many of the ASCII output files normally created by LS-DYNA have been combined into a new binary format used by MPP/LS-DYNA. When running MPP/LS-DYNA, this output is written only in binary format, irrespective of the setting of the variable BINARY in *DATABASE_*OPTION*. There is a post-processing program l2a, which reads the binary database of files and produces as output the corresponding ASCII files. The new binary files will be created in the directory specified as the global directory in the pfile (see section pfile). The files (up to one per processor) are named binout*nnnn*, where *nnnn* is replaced by the four-digit processor number. To convert these files to ASCII, simply feed them to the l2a program like this:

l2a binout*

LS-PREPOST can read the binout files directly, so conversion is not required; it is provided for backward compatibility.

The *supported* ASCII files are:

*DATABASE_SECFORC

*DATABASE_RWFORC

*DATABASE_NODOUT

*DATABASE_NODOUTHF

*DATABASE_ELOUT

*DATABASE_GLSTAT

*DATABASE_DEFORC

*DATABASE_MATSUM

*DATABASE_NCFORC

*DATABASE_RCFORC

*DATABASE_SPCFORC

*DATABASE_SWFORC

*DATABASE_DEFGEO

*DATABASE_CURVOUT

*DATABASE_ABSTAT

*DATABASE_NODOFR

*DATABASE_BNDOUT

*DATABASE_GCEOUT

*DATABASE_RBDOUT

*DATABASE_SLEOUT

*DATABASE_JNTFORC

*DATABASE_SBTOUT

*DATABASE_SPHOUT

*DATABASE_TPRINT

Some of the normal LS-DYNA files will have corresponding collections of files produced by MPP/LS-DYNA, with one per processor. These include the d3dump files (new names = d3dump.*nnnn*), the messag files (now mes*nnnn*) and others. Most of these will be found in the local directory specified in the pfile.

The format of the d3plot file has not been changed. It will be created in the global directory, and can be directly handled with your current graphics post-processor.

Parallel Specific Options

There are a few new command line options that are specific to the MPP version of LS-DYNA.

In the serial and SMP versions of LS-DYNA, the amount of memory required to run the problem can be specified on the command line by adding "memory=*XXX*", where *XXX* is the number of words of memory to be allocated. For the MPP code, this will result in each processor allocating *XXX* words of memory. If pre-decomposition has not been performed, one processor must perform the decomposition of the problem. This can require substantially more memory than will be required once execution has started. For this reason, there is a second memory command line option, "memory2=*YYY*." If used

together with adding "memory=*XXX*," the decomposing processor will allocate *XXX* words of memory, and all other processors will allocate *YYY* words of memory.

For example, in order to run a 250,000 element crash problem on 4 processors, you might need memory=80m and memory2=20m. To run the same problem on 16 processors, you still need memory=80m, but can set memory2=6m. The value for *memory2* drops nearly linearly with the number of processors used to run the program, which works well for shared-memory systems.

See the "Memory" subsection of the "Linear Equation Solver" section in Appendix P, "Implicit Solver," for additional remarks pertaining to memory for implicit analyses.

The full deck restart capability is supported by the MPP version of LS-DYNA, but in a manner slightly different than the SMP code. Each time a restart dump file is written, a separate restart file is also written with the base name d3full. For example, when the third restart file d3dump03 is written (one for each processor, d3dump03.0000, d3dump03.0001, etc), there is also a single file written named d3full03. This d3full file (or alternately the runfull file, which is written at the interval specified in *DATABASE_BINARY_RUNRSF) is required in order to do a full deck restart in MPP instead of a d3dump or runrsf file. In order to perform a full deck restart with the MPP code, you first must prepare a full deck restart input file as for the serial/SMP version. Then, instead of giving the command line option r = d3dump03 for example, you would use the special option n = d3full03. The presence of this command line option tells the MPP code that this is a restart, not a new problem, and that the file d3full03 contains the geometry and stress data from the previous run.

PFILE

There is a new command line option: p = pfile. pfile contains MPP specific parameters that affect the execution of the program. The file is split into sections, with several options in each section. Currently, these sections: directory, decomposition, contact, and general are available. First, here is a sample pfile:

```
directory {
        global rundir
        local /tmp/rundir
}
contact {
        inititer 3
}
```

The file is case insensitive and has a free format input. The sections and options currently supported are:

directory:

Holds directory specific options.

transfer_files

If this option is given, then processor 0 will write all output and restart files to the **global** directory (see "global" below), and scratch files to the **local** directory. All other processors will write all data to their **local** directory. At normal termination, all restart and output files will be copied from the processor specific **local** directories to the **global** directory. Also, if this is a restart from a dump file, the dump files will be distributed to the processors from the **global** directory. With this option enabled, there is no need for the processors to have shared access to a single disk for output – all files will be transferred as needed to and from the **global** directory.
Default = disabled

global *path*

Path to a directory where program output should be written. If **transfer_files** is not given, this directory needs to be accessible to all processors – otherwise it is only accessed by processor 0. This directory will be created if necessary.
Default = current working directory

global_message_files

If this option appears, the message files are written in the global directory rather than the local directory
Default = disabled (message files go in the local directory)

local *path*

Path to a processor specific local directory for scratch files. This directory will be created if necessary. This should be a local disk on each processor, for performance reasons.
Default = global path

rmlocal

If this option, which is not available for the Windows OS, is given and **transfer_files** is active, the program attempts to clean up the **local** directories on each processor. In particular, it deletes files that are successfully transferred back to the **global** directory and removes the **local** directory if it was created. It will not delete any files if there is a failure during file copying, nor will it delete directories it did not create.
Default = disabled

repository *path*

Path to a safe directory accessible from processor 0. This directory will be created if necessary. This is intended to be used as a safekeeping/backup of files during

execution and should only be used if **transfer_files** is also given. If this directory is specified, then the following actions occur:

- At program start up, any required files (d3dump, binout, etc) that cannot be located in the **global** directory are looked for in the **repository** for copying to the **local** processor directories.
- Important output files (d3dump, runrsf, d3plot, binout and others) are synchronized to the repository regularly. That is, every time one of these files is updated on the node local or the global directories, a synchronized copy is updated in the repository.

The intention is that the repository be on a redundant disk, such as NAS, to allow restarting the problem if a hardware failure should occur on the machine running the problem. It must be noted that some performance penalty must be paid for the extra communication and I/O. Effort has been made to minimize this overhead, but this option is not recommended for general use.
Default = unspecified

decomposition:

Holds decomposition specific options.

file_*option filename*
The name of the file that holds the decomposition information. If ***option*** is unset, this file will be created in the current working directory if it does not exist. If set, ***option*** can be entered as ***READ*** or ***WRITE***. When ***READ*** is used, LS-DYNA expects you to place the pre-decomposition file in the working directory. The job will be terminated if the file is not presented. When ***WRITE*** is used, LS-DYNA will create the file. The job will be terminated if the pre-decomposition file is in the working directory. If **file_*option*** is not specified, MPP/LS-DYNA will perform the decomposition.
Default = None

numproc *n*
The problem will be decomposed for n processors. If $n > 1$ and you are running on 1 processor, or if the number of processors you are running on does not evenly divide n, then execution terminates immediately after decomposition. Otherwise, the decomposition file is written, and execution continues. For a decomposition only run, both **numproc** and **file** should be specified.
Default = the number of processors you are running on

method *name*
Currently, there are two decomposition methods supported, namely *rcb* and *greedy*. Method *rcb* is Recursive Coordinate Bisection. Method *greedy* is a simple

neighborhood expansion algorithm. The impact on overall runtime is problem dependent, but *rcb* generally gives the best performance.
Default = rcb

region rx ry rz sx sy sz c2r s2r 3vec mat
See the section below on Special Decompositions for details about these decomposition options.

show
If this option appears in the decomposition section, the d3plot file is doctored so that the decomposition can be viewed with the post processor. Displaying material 1 will show that portion of the problem assigned to processor 0, and so on. The problem will not actually be run, but the code will terminate once the initial d3plot state has been written.

outdecomp *itype*
If this option appears in the decomposition section, the decomposition is written to the output file decomp_parts.lsprepost for itype = 1 or decomp_parts.ses for itype = 2. The d3plot file is not changed, and the problem will run normally.

rcblog *filename*
This option is ignored unless the decomposition method is *rcb*. A record is written to the indicated file recording the steps taken during decomposition. This is an ASCII file giving each decomposition **region** (see the section on Special Decompositions) and the location of each subdivision for that **region**. Except for the addition of this decomposition information, the file is otherwise equivalent to the current pfile. Thus it can be used directly as the pfile for a subsequent problem, which will result in a decomposition as similar as possible between the two runs. For example, suppose a simulation is run twice, but the second time with a slightly different mesh. Because of the different meshes the problems will be distributed differently between the processors, resulting in slightly different answers due to roundoff errors. If an rcblog is used, then the resulting decompositions would be as similar as possible.

vspeed
If this option is specified, a brief measurement is taken of the performance of each processor by timing a short floating point calculation. The resulting information is used during the decomposition to distribute the problem according to the relative speed of the processors. This might be of some use if the cluster has machines of significantly different speed.

automatic
If this option is given, an attempt is made to automatically determine a reasonable decomposition, primarily based on the initial velocity of nodes in the model. Use of the **show** option is recommended to verify a reasonable decomposition.

APPENDIX O

aledist
Distribute ALE elements to all processors.

ctcost *id1,id2,…,sf*
Apply a scale factor to the partition weight of all elements defined in the surfa and surfb sides in the list of contacts. A prefix of "a," or "b," can be added before "id1" to apply different scale factors to the surfa or surfb sides, respectively. Repeat this option as desired.

dcmem *n*
It may be in some cases that the memory requirements during the first phase of decomposition are too high. If that is found to be the case (if you get out of memory errors during decomposition phase 1), then this may provide a work around. Specifying a value *n* here will cause some routines to process the model in blocks of *n* items, when normal processing would read the whole set (of nodes, elements, whatever) all at once. This will reduce memory requirements at the cost of greater communication overhead. Most users will not need this option. Values in the range of 10,000 to 50,000 would be reasonable.

dunreflc
Time dependent load curves are usually applied to the following boundary or loading conditions on each node. By default, those curves are copied to all MPP subdomain without checking for the presence of that node in the domain or not. The curves are evaluated every cycle and may consume substantial CPU time. This command will remove curves which are not referenced in the MPP subdomain for the following keywords.

*BOUNDARY_PRESCRIBED_MOTION_NODE

*LOAD_NODE

*LOAD_SHELL_ELEMENT

*LOAD_THERMAL_VARIABLE_NODE

timing_start *n*
Begin timing of element calculations on cycle *n*. The appearance of this option will trigger the generation of a file named DECOMP_TIMINGS.OUT during normal termination. This file will contain information about the actual time spent doing element calculations, broken down by part.

timing_end *n*
End timing of element calculations on cycle *n*. A reasonable value is probably **timing_start** + 50 or 100.

timing_file *filename*
The file filename is assumed to be the output file DECOMP_TIMINGS.OUT from a previous run of this or a similar model. The computational cost of each part that appears in this file is then used during the decomposition instead of the built-in internal value for that part. Matching is based strictly on the user part ID. The first two lines of the file are skipped and only the first two entries on each of the remaining lines are relevant (the part ID and the cost per element).

transform_keyword
Including this option will cause global decomposition transformations to apply to all the decomposition regions created by the decomposition keywords _PARTS_-DISTRIBUTE, _PARTSET_DISTRIBUTE, _ARRANGE_PARTS, and _CONTACT_-DISTRIBUTE. If this option is not given, these regions are decomposed without any coordinate transformation applied.

contact:

This section has been largely replaced by the MPP keyword option on the normal contact card. The remaining useful options are:

alebkt *n*
Sets the bucket sort frequency for FSI (fluid structure interaction) to once every *n* cycles.
default = 50

non_blocking
The non-blocking algorithm applies to groupable contacts. With this option, data for contact is pack/unpacked before the element loop. With this option, the contact cost is considered along with the element cost for better load balancing.

general:

Holds general options.

lstc_reduce
If this option appears, our own reduce routine is used to get consistent summation of floating point data among processors. See also, *CONTROL_MPP_IO_LSTC_-REDUCE which has the same effect.

nodump
If this option appears, all restart dump file writing will be suppressed: d3dump, runrsf, d3full and runfull files will not be written.

nofull
If this option appears, writing of d3full and runfull (full deck restart) files will be suppressed.

nod3dump
If this option appears, writing of d3dump and runrsf files will be suppressed.

runrsfonly
If this option appears, writing of d3dump files will not occur – runrsf files will be written instead. Any time a d3dump *or* runrsf file would normally be written, a runrsf file will be written.

swapbytes
If this option appears, the d3plot and interface component analysis files are written in swapped byte ordering.

nobeamout
Generally, whenever a beam, shell, or solid element fails, an element failure report is written to the d3hsp and message files. This can generate a lot of output. If this option appears, the element failure report is suppressed.

Special Decompositions:

These options appear in the "decomposition" section of the pfile and are only valid if the decomposition method is *rcb*. The *rcb* decomposition method works by recursively dividing the model in half, each time slicing the current piece of the model perpendicularly to one of the three coordinate axes. It chooses the axis along which the current piece of the model is longest. The result is that it tends to generate cube shaped domains aligned along the coordinate axes. This is inherent to the algorithm but is often not the behavior desired.

This situation is addressed by providing a set of coordinate transformation functions which are applied to the model before it is decomposed. The resulting deformed geometry is then passed to the decomposition algorithm, and the resulting domains are mapped back to the undeformed model. As a simple example, suppose you wanted rectangular domains aligned along a line in the *xy*-plane, 30 degrees from the *x*-axis, and twice as long along this line as in the other two dimensions. If you applied these transformations:

```
sx 0.5
rz -30
```

then you would achieve the desired effect.

Furthermore, it may be desirable for different portions of the model to be decomposed differently. It is now possible to specify different regions of the model to be decomposed

with different transformations. The general form for a special decomposition would look like this:

```
decomposition {
        region { <region specifiers> <transformation> <grouping> }
        region { <region specifiers> <transformation> <grouping> }
        <transformation>
}
```

Where the region specifiers are logical combinations of **box**, **sphere**, **cylinder**, **parts**, and **silist**.
The transformation is a series of **sx**, **sy**, **sz**, **rx**, **ry**, **rz**, **c2r**, **s2r**, **3vec**, and **mat**. The grouping is either **lumped**, **together**, **nproc**, or empty. The portion of the model falling in the first region will be decomposed according to the given transformation. Any remaining part of the model in the second region will then be treated, and finally anything left over will be decomposed according to the final transformation. Any number of regions may be given, including 0. Any number of transformations may be specified. They are applied to the region in the order given.

The region specifiers are:

box xmin xmax ymin ymax zmin zmax
A box with the given extents

sphere xc yc zc r
The sphere centered at (x_c, y_c, z_c) with radius r. If r is negative, it is treated as infinite.

cylinder xc yc zc ax ay az r d
A cylinder with center at (x_c, y_c, z_c) with radius r, extending out in the direction of (a_x, a_y, a_z) for a distance of d. If d is 0, the cylinder is infinite in both directions.

parts n1 n2 n3 n4….
All parts whose user ID matches one of the given values are included in the region. Any number of values may be given.

partsets n1 n2 n3 n4….
All partsets whose user ID matches one of the given values will have all of their parts included in the region. Any number of values may be given.

silist n1 n2 n3 n4….
All elements involved in a contact interface whose user ID matches one of the given values are included in the region.

APPENDIX O

The transformations available are:

local
This is only useful in conjunction with the *CONTROL_MPP_PFILE keyword option, when used inside a file included via *INCLUDE_TRANSFORM. At this point in the region processing, a transformation is inserted to invert the transformation used by *INCLUDE_TRANSFORM. The effect is that if this option appears before any other transformation options, all those options (and the subsequent decomposition) are performed in the coordinate system of the include file itself, not the global coordinate system.

sx t
Scale the current x coordinates by t.

sy t
Scale the current y coordinates by t.

sz t
Scale the current z coordinates by t.

rx t
Rotate around the current x axis by t degrees.

ry t
Rotate around the current y axis by t degrees.

rz t
Rotate around the current z axis by t degrees.

txyz x y z
Translate by (x, y, z).

mat m11 m12 m13 m21 m22 m23 m31 m32 m33
Transform the coordinates by matrix multiplication:

$$\text{Transformed Coordinates} = \begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = \begin{bmatrix} m_{11} & m_{12} & m_{13} \\ m_{21} & m_{22} & m_{23} \\ m_{31} & m_{32} & m_{33} \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

3vec v11 v12 v13 v21 v22 v23 v31 v32 v33
Transform the coordinates by the inverse of the transpose matrix:

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} v_{11} & v_{21} & v_{31} \\ v_{12} & v_{22} & v_{32} \\ v_{13} & v_{23} & v_{33} \end{bmatrix} \begin{bmatrix} x' \\ y' \\ z' \end{bmatrix}$$
$$= \mathbf{V}^{\mathrm{T}} \times \text{transformed coordinates}$$

This appears complicated, but in practice is very intuitive: instead of decomposing into cubes aligned along the coordinate axes, *rcb* will decompose into

parallelepipeds whose edges are aligned with the three vectors (v_{11}, v_{12}, v_{13}), (v_{21}, v_{22}, v_{23}), and (v_{31}, v_{32}, v_{33}). Furthermore, the relative lengths of the edges of the decomposition domains will correspond to the relative lengths of these vectors.

C2R x0 y0 z0 vx1 vy1 vz1 vx2 vy2 vz2

The part is converted into a cylindrical coordinate system with origin at (x_0, y_0, z_0), cylinder axis (v_{x1}, v_{y1}, v_{z1}) and $\theta = 0$ along the vector (v_{x2}, v_{y2}, v_{z2}). You can think of this as tearing the model along the (v_{x2}, v_{y2}, v_{z2}) vector and unwrapping it around the (v_{x1}, v_{y1}, v_{z1}) axis. The effect is to create decomposition domains that are "cubes" in cylindrical coordinates: they are portions of cylindrical shells. The actual transformation is:

$$\text{new}(x, y, z) = \text{cylindrical coordinates}(r, \theta, z)$$

Knowing the order of the coordinates is important if combining transformations, as in the example below.

S2R x0 y0 z0 vx1 vy1 vz1 vx2 vy2 vz2

Just like the above, but for spherical coordinates. The (v_{x1}, v_{y1}, v_{z1}) vector is the $\phi = 0$ axis.

$$\text{new}(x, y, z) = \text{spherical coordinates}(\rho, \theta, \phi)$$

The grouping qualifier is:

lumped

Group all elements in the region on a single processor. If this qualifier is not given, the elements in the region are distributed across all processors.

together

Group all elements in the region as one "super" element and join decomposition together with other remaining parts. This qualifier works like "lumped" to keep all elements in the region on a single processor. It also assigns them on the same processor with their neighboring elements with load balanced. In general, this qualifier is recommended over "lumped."

nproc *n frstp*

This region will be distributed to n processors which usually is a subset of **numproc** and starting from rank **frstp**. If **frstp** is not given, the code will select the n least costly processors from **numproc** automatically.

Examples:

rz 45

will generate domains rotated -45° around the z-axis.

C2R 0 0 0 0 0 1 1 0 0

will generate cylindrical shells of domains. They will have their axis along the vector (0,0,1), and will start at the vector (1,0,0). Note that the part will be cut at (1,0,0), so no domains will cross this boundary. If there is a natural boundary or opening in your part, the $\theta = 0$ vector should point through this opening. Note also that if the part is, say, a cylinder 100 units tall and 50 units in radius, after the C2R transformation the part will fit inside the box: $x = [0,50]$, $y = [0, 2\pi)$, $z = [0,100]$. In particular, the new y coordinates (θ) will be very small compared to the other coordinate directions. It is therefore likely that every decomposition domain will extend through the complete transformed y-direction. This means that each domain will be a shell completely around the original cylinder. If you want to split the domains along radial lines, try this pair of transformations:

C2R 0 0 0 0 0 1 1 0 0
SY 5000

This will do the above C2R, but then scale y by 5000. This will result in the part appearing to be about 30,000 long in the y-direction, long enough that every decomposition domain will divide the part in this (transformed) y-direction. The result will be decomposition domains that are radial "wedges" in the original part.

General combinations of transformations can be specified, and they are applied in order:

SX 5 SY .2 RZ 30

will scale x, then y, and then rotate.

A more general decomposition might look like:

```
decomposition { rx 45 sz 10
    region { parts 1 2 3 4 5 and sphere 0 0 0 200 lumped }
    region { box 0 100 –1.e+8 1.e+8 0 500 or sphere 100 0 200 200 rx 20 }
}
```

This would take elements that have user ID 1, 2, 3, 4, or 5 for their part *and* that lie in the sphere of radius 200 centered at (0,0,0), and place them all on one processor.

Then, any remaining elements that lie in the given box *or* the sphere of radius 200 centered at (100,0,200) would be rotated 20° in the x-direction and then decomposed across all processors. Finally, anything remaining would be rotated 45° in the x-direction, scaled 10 in the z-direction, and distributed to all processors. In general, region qualifiers can be combined using the logical operations *and*, *or*, and *not*. Grouping using parentheses is also supported.

Execution of MPP/LS-DYNA

MPP/LS-DYNA runs under a parallel environment provided by the hardware vendor. The execution of the program therefore varies from machine to machine. On some platforms, command line parameters can be passed directly on the command line. For others, the use of the names file is required. The names file is supported on all systems.

The serial/SMP code supports the use of the SIGINT signal (usually Ctrl-C) to interrupt the execution and prompt for user input, generally referred to as "sense switches." The MPP code also supports this capability. However, on many systems a shell script or front end program (generally "mpirun") is required to start MPI applications. Pressing Ctrl-C on some systems will kill this process, and thus kill the running MPP-DYNA executable. As a workaround, there are two ways to issue this sense-switch:

1. Create a file called D3KIL with the desired sense switch in it. LS-DYNA checks for this file every 100 cycles and executes this sense-switch.

2. When the MPP code begins execution, it creates a file bg_switch in the current working directory. This file contains the following single line:

   ssh -x <machine name> kill -INT <PID>

   where < machine name > is the hostname of the machine on which the root MPP-DYNA process is running, and <PID> is its process ID. Thus, simply executing this file will send the appropriate signal and prompt the user to enter the desired sense switch. Alternatively, a file with name switch can be created where the desired sense switch is included in the file. When bg_switch is executed, the desired 'sense switch' is applied.

Here is a simple table to show how to run the program on various platforms. Of course, scripts are often written to mask these differences.

Platform	Execution Command
DEC Alpha	dmpirun –np n mpp-dyna
Fujitsu	jobexec –vp n –mem m mpp-dyna
Hitachi	mpirun –np n mpp-dyna

APPENDIX O

Platform	Execution Command
HP	mpp-dyna –np n
IBM	#!/bin./ksh export MP_PROC=n export MP_LABELIO=no export MP_EUILIB=us export MPI_EUIDEVICE=css0 poe mpp-dyna
NEC	mpirun –np n mpp-dyna
SGI	mpirun –np n mpp-dyna
Sun	tmrun –np n mpp-dyna

In the above, **n** is the number of processors, **mpp-dyna** is the name of the MPP/LS-DYNA executable, and **m** is the MB of real memory.

APPENDIX P: Implicit Solver

Introduction

The terms implicit and explicit refer to time integration algorithms. In the explicit approach, internal and external forces are summed at each node point, and a nodal acceleration is computed by dividing by nodal mass. The solution is advanced by integrating this acceleration in time. The maximum time step size is limited by the Courant condition, producing an algorithm which typically requires many relatively inexpensive time steps.

While explicit analysis is well suited to dynamic simulations such as impact and crash, it can become prohibitively expensive to conduct long duration or static analyses. Static problems, such as sheet metal springback after forming, are one application area for implicit methods. In the implicit method, a global stiffness matrix is computed, inverted, and applied to the nodal out-of-balance force to obtain a displacement increment. The advantage of this approach is that time step size may be selected by the user. The disadvantage is the large numerical effort required to form, store, and factorize the stiffness matrix. Implicit simulations therefore typically involve a relatively small number of expensive time steps.

In a dynamic implicit simulation these steps are termed *time steps*, and in a static simulation they are *load steps*. Multiple steps are used to divide the nonlinear behavior into manageable pieces, to obtain results at intermediate stages during the simulation, or perhaps to resolve a particular frequency of motion in dynamic simulations. In each step, an equilibrium geometry is sought which balances dynamic, internal and external forces in the model. The *nonlinear equation solver* performs an iterative search using one of several Newton based methods. *Convergence* of this iterative process is obtained when norms of displacement and/or energy fall below user-prescribed tolerances. Within each implicit iteration there is a *line search* performed for enhancing robustness of the procedure.

The implicit analysis capability was first released in Version 950. Initially designed for metal forming springback simulation, this new capability allowed static stress analysis. Version 970 added many additional implicit features, including new element formulations for linear and modal analysis. A milestone in implicit was the advent of Version 971 in which implicit analysis was carried over to MPP and thus allowed much larger problems to be solved, and from there it has evolved extensively to presently contend well among competitive softwares. Still, it can be a gruesome task to set up an implicit input problem that runs all the way to completion with acceptable results, especially when contacts are involved. The purpose of this text is to explain keywords of interest and suggest values of important parameters in order to give users tools for developing own solution strategies to these kinds of problems.

APPENDIX P

A prerequisite for running implicit is to use a double precision version of LS-DYNA, and a machine with a significant amount of memory. A theoretical overview of implicit can be found in the LS-DYNA Theory Manual.

Nonlinear Implicit Analysis

Activating Implicit Analysis

The keyword *CONTROL_IMPLICIT_GENERAL is used to activate the implicit method, and in principle it is sufficient to set

IMFLAG = 1
DT0 = some reasonable initial time step.

The initial time step should be chosen small enough to resolve the frequency spectrum of interest and/or provide decent convergence properties, but large enough to benefit from an implicit analysis. With no other implicit options, this converts an explicit input deck to a static implicit input deck with a constant time step throughout the simulation and the problem will terminate upon convergence failure. Time stepping strategies to prevent this are discussed below.

Singularities and Eigenvalue Analysis

The first concern in implicit analysis is to prevent singularities in the stiffness matrix, otherwise the chance of succeeding is close to none. The major cause of a singular stiffness matrix is the presence of rigid body modes in a static problem which can be revealed in an eigenvalue analysis. This is done by using *CONTROL_IMPLICIT_EIGENVALUE and setting

NEIG = number of modes to extract.

First, run an eigenvalue analysis and extract (if practically possible) enough modes to see all the rigid body modes just to get an impression of the properties of the model. The frequencies are in the output text file eigout and the mode shapes can be animated in the binary output file d3eigv using LS-PrePost. Some rigid body modes may come as a surprise and should be constrained. A typical example of this is a beam that is free to rotate around its own axis. Other rigid body modes are a consequence of the nature of the problem and cannot be constrained without destroying the connection to reality. An example of this could be components that are to be constrained with contacts but are initially free to move. There are several strategies to deal with these latter rigid body modes; some are discussed in the context of contacts but here dynamics is used.

Dynamics and Intermittent Eigenvalue Analysis

Dynamics alleviates singular rigid body modes and is activated on *CONTROL_IMPLICIT_DYNAMICS by setting

IMASS = 1 or a negative number.

If the purpose is to solve a dynamic problem in the first place, then just use IMASS = 1 and don't bother about the other parameters; otherwise some other strategy is necessary. The idea is start with a dynamic analysis until the rigid modes have been constrained by contacts at which point dynamics is turned off. The simplest way of doing this is to set

TDYBIR = 0
TDYDTH = time when contacts have been established and rigid body modes are constrained
TDYBUR = time after TDYDTH for fading out dynamics between TDYDTH and TDYBUR.

If the dynamic results are of no interest but just a way to proceed to the static solution, then it is recommended to use numerical damping to prevent unnecessary oscillations, that is, set

GAMMA = 0.6
BETA = 0.38.

This should be enough to start up most problems of interest. A restriction with this is that when dynamics has been turned off it cannot be turned on again. If this is necessary for some reason, then a negative number of IMASS should be used to control dynamics through a load curve.

If it is hard to deduce how to choose the time when to turn off dynamics, the use of intermittent eigenvalues may be of great help. By setting

NEIG = a negative number

on *CONTROL_IMPLICIT_EIGENVALUE the user may extract eigenvalues at given time points during a nonlinear simulation and deduce from that if all rigid body modes have been eliminated.

The Geometric Stiffness Contribution

Stiffness singularities may also occur during a simulation due to a complex global phenomenon involving the stress state and geometry. For instance, slender components with compressive stresses could give rise to zero eigenvalues, commonly known as buckling. The mathematical explanation for these kinds of singularities is that the material and geometric stiffness contributions cancel out, and for this reason the geometric contribution to the stiffness matrix in LS-DYNA is optional. It is activated by putting

IGS = 1

on *CONTROL_IMPLICIT_GENERAL. Most often singularities due to this contribution have a negative effect on convergence although it sometimes helps. It is recommended to leave this as default and turn it on if other strategies fail. A controlled way of getting past singular points of this type is to use so called arc length methods for which the geometric stiffness should be turned on. This way of dealing with the problem is discussed in the Theory Manual.

BFGS or Full Newton

The nonlinear solver parameters are set on *CONTROL_IMPLICIT_SOLUTION where the solver type is specified as

NSOLVR = nonlinear or linear implicit analysis option.

By default, a nonlinear BFGS solution strategy is used when the stiffness matrix is reformed every 11th iteration and a maximum of 15 reformations is allowed (for a linear solution set NSOLVR = 1). These parameters are set by

ILIMIT = iterations between reforming stiffness matrix
MAXREF = maximum number of stiffness reformations

on *CONTROL_IMPLICIT_SOLUTION. Reforming the stiffness matrix is computationally expensive but stabilizes the solution procedure, and the best strategy in this context is very much problem dependent. The recommendation is to start with the default strategy and if necessary, change them. For hard problems decrease ILIMIT while for problems that converge well increase ILIMIT. For really bad problems switch to full Newton (the safe bet) by for instance setting

ILIMIT = 1
MAXREF = 30.

Keep the maximum number of reformations reasonably low or otherwise it may take an unnecessary amount of time just to reach convergence failure.

Convergence

Tolerances

Convergence is based on changes in displacements, energies and optionally residual forces, and the tolerance levels are set by

DCTOL = Relative displacement tolerance
ECTOL = Relative energy tolerance
RCTOL = Relative residual tolerance
ABSTOL = Absolute tolerance
DMTOL = Maximum displacement tolerance
EMTOL = Maximum energy tolerance
RMTOL = Maximum residual tolerance

on *CONTROL_IMPLICIT_SOLUTION. The tolerances on the left are based on Euclidian norms of the involved vectors, whereas the ones on the right are based on maximum norms. The maximum norm tolerances are optional and should be activated if increased accuracy is desired at the price of more implicit iterations. To keep things simple, the discussion that follows pertains only to the Euclidian norm tolerances.

By default, the progress of the equilibrium search is shown to the screen. The box below shows a typical iteration sequence, where the norms of displacement and energy are displayed. When these norms are reduced below user prescribed tolerances (default 0.001 and 0.01, respectively), the iteration process is said to have *converged*, and the solution proceeds to the next time step. The message files, messag in SMP and mesxxxx in MPP, typically contain a whole lot more information that will be dealt with further in output diagnostics and convergence issues.

```
BEGIN static time step     3
============================================================
               time =  1.50000E-01
  current step size =  5.00000E-02
Iteration:   1     *|du|/|u| =  3.4483847E-01     *Ei/E0 =  1.0000000E+00
Iteration:   2     *|du|/|u| =  1.7706435E-01     *Ei/E0 =  2.9395439E-01
Iteration:   3     *|du|/|u| =  1.6631174E-03     *Ei/E0 =  3.7030904E-02
Iteration:   4     *|du|/|u| =  9.7088516E-05     *Ei/E0 =  9.6749731E-08
```

Premature Convergence

The last of these parameters (ABSTOL) overrides the other three (DCTOL, ECTOL, RCTOL) in the sense that if the residual force is small enough, convergence is detected regardless of if the other three criteria are fulfilled or not. It has been seen that this sometimes give rise to so called *premature convergence*, converged states are not *really* converged in the sense that the residual norm is small enough. This gives bad results and it is usually recommended to tighten this tolerance to 10^{-20} to prevent this. On the other hand, if the problem is very hard this may prevent convergence to the extent that going back to the default is more or less necessary. It is difficult to give a general recommendation that holds for every problem.

As for the other three parameters, the one that usually comes into practice is the displacement criterion DCTOL. The energy criterion ECTOL is often easy to fulfill and the residual criterion is disabled by default and there may be no reason to activate this (that is unless a completely different strategy is used, or if convergence issues arise). Using the default values on all three is usually good enough to give acceptable results in decent time. For problems with poor convergence, the question of tightening or relaxing these parameters (that is the displacement convergence criterion) is up for debate. It is tempting to believe that relaxing the constraints will give better convergence which may or may not be true. Sloppy convergence criteria may once again result in premature convergence, and this will have a negative effect on the subsequent steps. The general recommendation would have to be to leave these unchanged, and be aware that relaxing them may not result in getting further in the implicit simulation.

Using Residual Tolerance

A novel strategy that seems to make sense and works well for some problems is to only use tolerances on residual forces RCTOL. This relies on the degree of nonlinearity of the simulation model being moderate, but it could be well worth trying. The first thing to do would be to set DCTOL and ECTOL to large numbers to disable them while setting RCTOL to a relatively small number (start with 0.01 and see how that works out). This must be complemented with an absolute tolerance on the residual forces to get past the initial stages where the residual forces are small enough to not fulfill the relative tolerance. To do this, set ABSTOL to a negative number, which is a different absolute criterion compared to setting it to a positive number. Now, this number is very problem dependent as this says that convergence is attained as soon as the Euclidian norm of the residual force vector is smaller than the absolute value of ABSTOL. It goes without saying that this requires running the problem for a few steps to monitor the residual norm in the message files as described below; this should give an indication on how to determine the ABSTOL value.

Convergence Norms

The degrees of freedom encountered in an LS-DYNA simulation are either *translational* or *rotational,* where the latter comes from the presence of beams and shells. Historically, convergence check is on norms of the translational degrees of freedom only, which is unsettling because rotational residual forces (moments) are equally important in an implicit simulation. It is therefore recommended to use

NLNORM = choice of convergence norms

on *CONTROL_IMPLICIT_SOLUTION to change this default (which is = 2). While NLNORM = 3 will incorporate residual degrees of freedom separately and is a more satisfying approach, the recommended option is to use NLNORM = 4 or a negative number. NLNORM = 4 will treat the entire force and displacement vector, respectively, as one complete mathematical vector and the convergence norms and scalar products used for checks are simply the Euclidian norms of these vectors. To make the displacement and residual norms unit consistent, a scale factor l, corresponding to a characteristic element size in the model, is introduced and accounted for when computing the norms. This means for instance that displacements are summed to l length unit times angular increments, and moments are summed to l length unit times forces. For NLNORM = 4 the scale factor is echoed to the output files and screen. If the internally calculated value is inappropriate for some reason, it may be convenient to use NLNORM = -(length scale) to supersede this scale factor.

Time Stepping Strategies

By default, LS-DYNA will terminate when a step fails to converge. This is unfortunate since it may just be that the step is too large to achieve convergence and taking smaller steps would solve this problem. Instead of starting all over with a smaller step size, set

IAUTO = 1 to activate automatic time stepping

on *CONTROL_IMPLICIT_AUTO. When the problem fails to converge LS-DYNA will with this option go back to the previously converged state and retry with a smaller step size. If the problem converges well, the step size is increased for subsequent steps. This process of backing up and retrying difficult steps lends much persistence to the analysis and is often the only procedure for solving highly nonlinear problems short of adjusting the step size manually. We recommend always turning automatic time stepping on.

Another parameter worth mentioning in this context is

DTMAX = Max time step allowed, or a negative number

on the same card. This is the maximum step size possible and should be chosen to not lose necessary information in the results, such as resolving frequencies, contacts and non-linear material response to a satisfactory degree. A negative value of this parameter will give the maximum step size as a function of the simulation time and allows for hitting key points that are of interest. The user may for instance look for the peak stress for a certain external load and hitting the point in time when this happens is crucial. It also allows for taking smaller steps during critical stages in the simulation without wasting resources away from these stages.

Line Search

A good line search strategy is crucial in solving nonlinear implicit problems; without it only simple problems would be solvable. There are a few line search options available and these are activated by

LSMTD = Line search method

on *CONTROL_IMPLICIT_SOLUTION. The default method is based on minimizing a potential energy along the search direction and at the same time keeping track of the residual force magnitude. It also detects when a BFGS step results in negative initial energy which causes the stiffness matrix to be reformed for robustness (this can only happen when the stiffness matrix has negative eigenvalues). Line search type 2 is based on residual forces and is more robust than the others; the drawback is that it typically results in too small steps and is not practically useful. Line search type 3 is very similar to type 4, but it does not track the residual force or avoid negative volumes to the same extent. In sum, there is no practical reason for choosing methods 1 through 3. Worth mentioning is however line search type 5 which combines the energy and residual method in a stricter sense. That is, it minimizes the potential energy just like type 4, but it only allows the residual norm to double at each implicit iteration. This has shown to be robust but slow in convergence and is to be used for problems that have difficulties converging with the default line search strategy. This has had a huge impact on the treatment of rubber models for instance. An interesting combination is to use line search method 5 together with the strategy of converging based on residual forces only.

Finally, the line search tolerance

LSTOL = Line search tolerance

on *CONTROL_IMPLICIT_SOLUTION is fine as it is; don't change it.

Output

As previously mentioned, the output to the message file is more extensive than that to the screen/stdout. To novice or average implicit users this information may be more than can be digested at first and this section may be skipped, but with experience the output can become really useful when running into convergence issues. For this discussion it is important to distinguish between different *types* of iterations, and we use the term *time/load step* to mean the actual advance in simulation time, *implicit iteration* to indicate points in the iterative solution procedure where a new search direction is obtained (corresponding to either Newton or BFGS) and *line search iteration* to indicate the search for an optimal step size along a given search direction. We begin by showing a typical iteration output for when NLPRINT = 3 following by a numbered list explaining the content.

Referring to the superscripts at the beginning of the lines in the excerpt above, and taking them in order of appearance, we have at

1. Beginning a *dynamic* implicit time/load step, the goal is to get to a given time point (in this case 2.5849E-01 using a step size of 1.58489E-01). Implicit time/load steps are either dynamic, *static* or *semidnmc*, where the last one indicates a transition phase between dynamics and statics.

2. A *Newton* implicit iteration is performed, meaning that a full reformation of the stiffness matrix has just been made. Other implicit iterations can be either a *linear* if at the first iteration of a time/load step, or *BFGS* if the implicit iteration corresponds to a quasi-Newton step.

3. Initial norms are displayed at the beginning of each implicit iteration; these numbers are used as reference for the line search algorithm when checking line search convergence.

4. Detailed initial norms are displayed, separating out translational/rotational as well as nodal/rigid body Euclidian/max norms. The node number and rigid body attaining the global maximum norms are displayed and can be used to spot critical points in the model. In this particular case node 440984 and part 4000024 would be the likely candidates for trouble.

5. A full step along the search direction is taken, as a candidate for the next implicit iteration.

6. Norms for the full step is displayed. The line search algorithm compares these with the ones from 3 to deduce if the line search convergence criterion is fulfilled.

7. Line search is in this case needed, and information for further iterates along the search direction is displayed in analogy to previous line search iterates. If no line search had been needed, the string *Line search is skipped* would have been displayed.

8. The way line search is performed, each line search iteration narrows in on the optimal step and the bounds within which the optimal step is sought is continuously displayed. The size of this interval becomes smaller and smaller with increasing number of line search iterations, but convergence should preferably be attained before it tends to zero.

9. Line search converged here in 2 iterations; as a rule of thumb the number of iterations for line search should be about 10 or less. For critical steps one might accept 20 iterations but that should be among the exceptions. If the string *Line search did not converge* is displayed, that is an indication of something being terribly wrong.

10. After each implicit iteration, *Max relative step* indicates how large steps have been taken during line search so far. It also indicates how well prescribed motion is approximated where a value of 1 is perfect. For values below 1 and in the presence of non-zero prescribed motion, convergence will not be accepted even though all norms are within prescribed tolerances. This will instead issue the warning *Convergence prevented due to unfulfilled boundary conditions* and iterations continue.

11. Diagnostics for iteration 5 is displayed; similar numbers as shown during line search but in another format. Furthermore, the initial norms here refer to the initial norms from the beginning of the implicit time/load step and not from the beginning of the implicit iteration. This table can be used to deduce how close the implicit time/load step is at converging. The single important number for comfortably assessing the accuracy of an implicit iterate is the residual norm, currently displayed as 1.258E+00 (bold-faced in the table), since this should be small for good results.

At equilibrium, the output ends with a summary on how convergence was achieved. It may look like

```
Convergence detected as a combination of
      1.Ratio of euclidian displacement
         Value =   2.3417E-03 vs Tolerance =  2.5000E-3
      2.Ratio of euclidian energy
         Value =   3.2269E-08 vs Tolerance =  1.0000E-2
```

which tells us that the ratio of displacement was below DCTOL = 2.5E-3 and the ratio of energy was below ECTOL = 1E-2. If other criteria are satisfied, these will be listed as well.

So, with NLPRINT = 3 information from every force evaluation is given, including type of step taken, the line search step size, the potential energy value used in line search and the magnitude of the residual force. A point is made here, already touched upon and will be repeated, and it is the following: the nonlinear implicit solver is solving for zero residual force, so basically the number observed for the magnitude of the residual force should be small upon convergence (bold-faced in the table). If it is not, then the convergence is premature, and the results may not be correct and subsequent steps are in danger. What "small" means in this context is hard to say since this depends on units as well as loads and geometry of the problem, but a good sign is that the residual force does not grow by more than the external loads in the problem do. Another thing to observe is how the line search is doing; if the line search starts needing many iterations and very large variations in the residual force along the search direction is observed, then it is likely that something in the model is causing this behavior. A safe bet is that contact states are changed along the line search direction causing discontinuities in the residual force and indicates that some remodeling has to be done.

APPENDIX P

We will come back to this section when discussing convergence problems and strategies to prevent them.

Linear Equation Solver

General

Within each equilibrium iteration, a linear system of equations of the form $\mathbf{K}\Delta\mathbf{u} = \mathbf{R}$ must be solved. To do this, the stiffness matrix **K** is factorized and applied to the out-of-balance load or residual **R**, yielding a displacement increment $\Delta\mathbf{u}$. Storing and solving this linear system represents a large portion of the memory and CPU costs of an implicit analysis. LS-DYNA uses a multi-frontal sparse direct solver. For a problem with N number of nodes, the number of operations and memory storage is asymptotically proportional to $N^{3/2}$ and $NlogN$, respectively. This should give a ballpark indication on the growth when increasing the size of a given model. It must be stressed, however, that it is *a priori* difficult to predict the actual value of these numbers as they are highly dependent on the problem solved, in particular on the nodal connectivity through elements and contacts.

We here focus on the memory, and the purpose is twofold. First it is a documentation of the memory diagnostics that is written to the output message files (messag in SMP and mesxxxx in MPP) of LS-DYNA for the linear solvers. The level of information is regulated by the

LPRINT = Linear solver diagnostics level

input parameter on *CONTROL_IMPLICIT_SOLVER, and this text will cover LPRINT = 2 as the information for higher values is of no particular interest to others than developers. Second it should help understanding the interrelationship between the size of a model, and the memory required to obtain a solution. We emphasize however that different classes of problems most likely require different guidelines (shell and solid structures typically result in different matrix topologies for instance) and to this end the user is left at earning this experience on his own.

Memory

The memory is specified and reported in terms of *words*, where 1 word is equivalent to 8 bytes in double precision arithmetic. To simplify things, a word can in this context be seen as the equivalent of a real number or an integer. For implicit calculations the executable is only provided in double precision.

When starting a simulation, the user typically specifies the *static* memory, for instance in SMP

```
ls-dyna i = in.k memory = 200m
```

meaning that LS-DYNA tries to allocate 200 Mwords for storing statically allocated data. In MPP, the physical memory is distributed among processes and this option applies to each individual process. In MPP there is also an option to add a second memory flag, for instance

```
mpp-dyna i = in.k memory = 1000m memory2 = 200m
```

and this means that 200 Mwords are allocated for each process while 1000 Mwords is allocated on the first process to handle everything up to the point when the model data has been distributed among all the involved processes. The memory size may also be specified on *KEYWORD.

Beginning with LS-DYNA version R11.0.0, more and more of the statically allocated memory is being moved to dynamically allocated memory. For explicit simulation, the will allow real time adaptivity and dynamic load balancing. Implicit has migrated all of the linear algebra storage (matrices, factorization) to dynamically allocated storage. This vastly simplifies the specification of memory and memory2 for implicit jobs.

If the model is initially explicit, the following message will be printed:

```
Memory required to process keyword: 38147436
```

For this case memory = 39m should be used on the command line.

For SMP, implicit will require an additional $(19 + 2 \times \text{ILIMIT}) \times (6 \times \text{NUMNP})$ words of memory for a transient nonlinear simulation where ILIMIT is specified on *CONTROL_-IMPLICIT_SOLUTION (default of 11; for modal or linear analysis ILIMIT = 0) and NUM-NP is the number of nodes in the model. To approximate the minimum value of memory needed to run the implicit analysis using SMP, one could add this additional value to the "Memory required to process keyword". In practice, one doesn't need to go to the trouble of calculating the required memory since the code will tell you what is needed as explained below.

For MPP, the nodes will be distributed across p processors, so a rough estimate of the addition to memory will reduced by $1/p$.

For an actual implicit execution look for

ALERT

which will tell you exactly the setting to use.

When a certain feature requires a slot in the memory, this is reported in the output text files, for instance as

```
contracting memory to    2306940 d 696365    implicit friction
expanding   memory to    2306955 d 696365    joints
```

The first number in each line above is the current value of statically allocated memory. The second number (following the "d") is the current value of dynamically allocated memory.

In the example above, the static memory pointer after having allocated for implicit friction is at 2306940; allocating the joints reserves 15 words and the static memory pointer is incremented accordingly. So the memory used up to this point is roughly 2.3 Mwords for this particular process. At the end of the initialization a memory report is written and can look like

```
S t o r a g e   a l l o c a t i o n
Memory required to begin solution      :     929 k
Linear Alg dynamically allocated memory:     196 k
Additional dynamically allocated memory:    2285 k
                                  Total:    3409 k
```

The total amount of memory used up to this point is roughly 3.5 Mwords, which is partitioned in the static memory specified and *dynamic* memory. Whenever a memory violation occurs, for instance when trying to allocate more memory than physically available or if more memory needs to be specified, LS-DYNA terminates with appropriate error information. The dynamic memory for the linear solver is allocated thereafter, which is the topic for the next section.

Linear Solver Memory Consumption

For LPRINT = 2, some memory information is given in the output files, and this is here presented in order of execution, thus as they appear in the files. We repeat that this is the information obtained in the message files and is thus referring to the memory consumption for this particular process if MPP is considered. For the sake of completeness we also cover the diagnostics related to the CPU time for the involved stages in the linear solution.

The last statically allocated memory for implicit is reserved and reported as

```
expanding   memory to    125081 d 2652145 matrix assembly allocation
```

After this allocation all remaining memory is dynamically allocated. All storage for the linear algebra modules is dynamically allocated. Typically this will be a 3 phase process of symbolical factorization, numeric factorization, and numeric solve.

Before the symbolic factorization takes place, current information on the system matrix and workspace reserved for implicit is reported

```
local number of rows      =             68490
local size of matrix      =           2338945
```

The first number refers to the number of independent degrees of freedom in the model, meaning the number of rows in the system matrix, and the second to the number of non-zero entries before factorization takes place, that is, after assembly.

The symbolic factorization is now performed and information on the CPU time for doing this together with the estimated size of the factorized matrix is reported.

```
CPU: symbolic factor      =          0.200
WCT: symbolic factor      =          0.203
storage currently in use  =        1038915
storage needed            =       12913838
factor speedup            =     1.9197E+00
solve  speedup            =     1.9378E+00
est.  factor nonzeroes    =     5.1432E+07
est.  factor operations   =     1.2099E+11
est.  total factor nz.    =     9.9666E+07
est.  max.  factor op.    =     1.2099E+11
est.  total factor op.    =     2.3293E+11
est.  max.  factor nz.    =     5.1432E+07
```

The first two rows reports the CPU and wall clock time for doing the symbolic factorization in terms of seconds. The next two are storage requirements for the symbolic factorization, of which the latter is the memory reserved for this. After this we have estimations of the speedup in the factorization and subsequent solve of the linear system of equations; this is a report from an MPP run on 2 processors. The last lines refer to the estimated requirement for storing and factorizing the system matrix and distinguish between the local, total and maximum number of each of these two entries. This allows for determining the memory scaling in the case of an MPP run.

Now LS-DYNA is in the position of reserving space for the factorization of the system matrix, and a report on the storage needed for this is given.

```
symbolic storage        1 =           1038915
in-core numeric  storg  1 =          62762269
out-of-core num.  storg 1 =          13168676
```

Here basically the same information is repeated, except for a slight increment in order to account for potential penalty when doing the actual factorization. The first is again the memory reserved for the symbolic factorization and the other two are the memory required to perform an in-core and out-of-core factorization, respectively. If the memory available is not sufficient for doing an in-core factorization, LS-DYNA warns about this and attempts to do an out-of-core factorization, which means that the hard disk is used to store information during factorization.

At this point a redistribution of the system matrix is performed and a short report is given on this

```
symbolic storage        2 =           1038915
in-core numeric  storg  2 =          68238926
out-of-core num.  storg 2 =          11553502
```

Now the actual factorization takes place and a report from this is given where the information of interest is

```
CPU: factorization        =            59.025
WCT: factorization        =            50.151
act.  factor nonzeroes    =       5.1236E+07
act.  factor operations   =       1.2092E+11
act.  max.  factor nz.    =       5.1236E+07
act.  max.  factor op.    =       1.2092E+11
act.  total factor nz.    =       9.9666E+07
act.  total factor op.    =       2.3293E+11
```

which basically is the same information as from the symbolic factorization except that now it is the actual instead of the estimated values that is reported.

Finally, the forward and backward substitutions are allocated for and performed. The information given is

```
symbolic storage        3 =          1038915
in-core numeric storg   3 =         68299122
out-of-core num.  storg 3 =         16476693
CPU: numeric solve        =            0.191
WCT: numeric solve        =            0.194
```

More information is available with the command line options DIAG = 1 (memory) and IMPCON = 1 (time stamps).

Elements and Materials

Implicit Accuracy

Implicit and explicit analysis differ in many respects. An important one is that the deformation during a single step is much larger in implicit than a typical one in explicit. In the context of elements and materials, the demand for stronger objectivity and higher accuracy in implicit is obvious. The notion of implicit executing the same algorithms as a corresponding explicit analysis is therefore not adopted in general. This can optionally be further extended, using

IACC = 1 to increase implicit accuracy

on *CONTROL_ACCURACY will make selected elements strongly objective and enhance the accuracy for selected materials. For instance finite rotations will be represented exactly and fully iterative plasticity adopted. In addition, the flag applies to tied contacts as will be elaborated on below. Currently the following elements are supported for this option

Solid elements -2,-1,1,2

Shell elements 4,-16,16,23,24
Beam elements 1,2,9

and materials 24 and 123 use fully iterative plasticity.

Contacts

Contacts are probably among the hardest features to treat in a nonlinear implicit simulation. They are divided into the categories *tied* (bilateral) and *sliding* (unilateral) contact, and the characteristics of the two are quite different. Tied contacts are most often applied as constraints, only sometimes using a penalty formulation, and are fairly easy to deal with as they are only moderately nonlinear. In contrast, sliding contacts are exclusively implemented as penalty contacts and hard to deal with because of the unilateral condition. While the number of contacts, see *CONTACT, in LS-DYNA is abundant, we will here only present the few contacts that make most sense to use in implicit.

Tied Contacts

Tied contacts in implicit analysis should be accompanied with the implicit accuracy option. This restriction essentially reduces the number of relevant contacts to six. These six contacts are

*CONTACT_TIED_NODES_TO_SURFACE
*CONTACT_TIED_NODES_TO_SURFACE_CONSTRAINED_OFFSET
*CONTACT_TIED_NODES_TO_SURFACE_OFFSET
*CONTACT_TIED_SHELL_EDGE_TO_SURFACE
*CONTACT_TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET
*CONTACT_TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET

The first and fourth of these project the nodes on the tracked side to the reference surface, while the rest are offset contacts for which nodes will remain in place. The fourth, fifth and sixth constrain rotations while the others do not. The third and sixth are penalty-based, while the others are constraint-based. In sum, these six contacts cover most reasonable scenarios.

The implicit accuracy option will in this context make these six tied contact strongly objective, and built-in intelligence will detect whether nodes contain rotations to constrain or not. A nice feature with the latter is that torsion is automatically applied with physical consistency. Thus, it is no problem to use single beams to model spot welds between solid elements. When using the same connection technique between shells, the beam axial rotational degrees of freedom will be constrained to the translational degrees of the

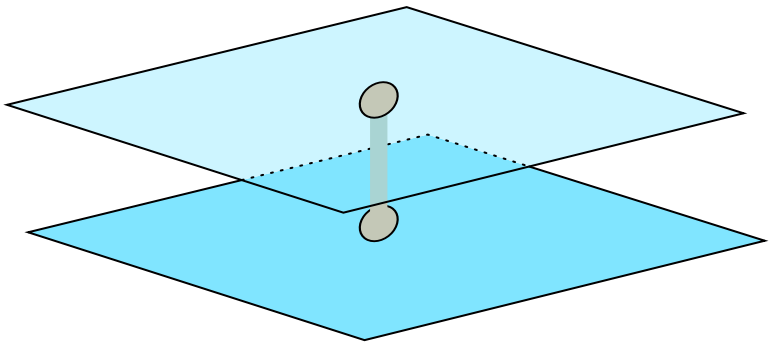

Figure 64-1. Modeling spotwelds by connecting a beam element to two shell elements.

shells, avoiding the relatively weak (and non-physical) drilling degree of freedom. This situation is depicted in Figure 64-1.

The choice of contact depends on the situation, but from a conceptual point of view it should be alright to use *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET for most cases. The only problem then would be if complicated geometry results in termination from overconstraining, for which a switch to the corresponding penalty version *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET is motivated. See General Remarks in the *CONTACT section of the LS-DYNA keyword manual for more information.

Sliding Contact

In this section we will discuss Mortar contact as this seems to be the best implicit contact algorithm when considering a combination of speed, accuracy and robustness. Mortar contact features smoothness and continuity that is highly appreciated in implicit analysis but is expensive enough to not be recommended for explicit analysis. Many other contact algorithms are supported for implicit analysis and execute faster than the Mortar contact, but this is often seen when IGAP flag is set to the default. This flag manipulates the stiffness matrix to the extent that accuracy may be deteriorated. If used, the results should be thoroughly checked. For Mortar contact IGAP has a different meaning as will be described IGAP. See General Remarks for *CONTACT_OPTION in the LS-DYNA keyword manual for more information.

Basics

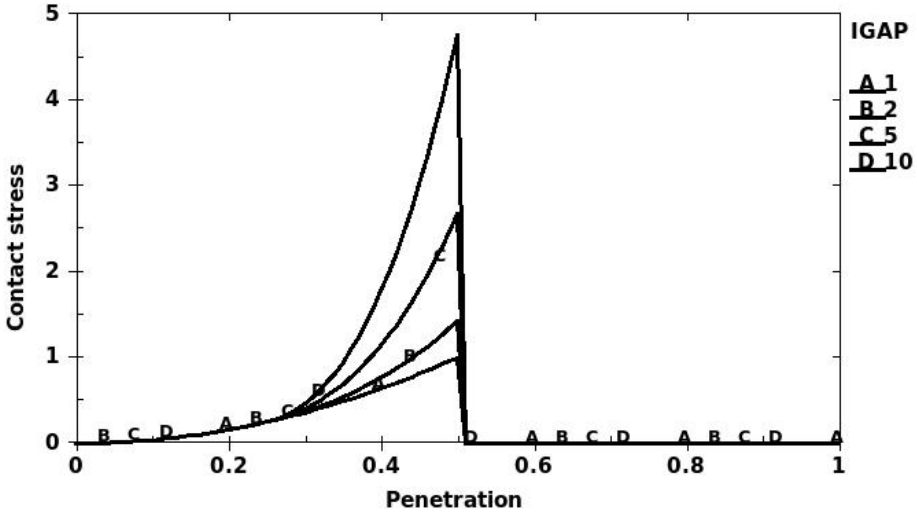
Mortar contact is activated by typically appending the suffix MORTAR to automatic single surface, automatic surface-to-surface or forming surface-to-surface keywords. It can also be run as tied and tiebreak contacts. All Mortar contacts are segment-to-segment and penalty-based. The tied and tiebreak contacts are always offset, meaning the tie occurs on the outer surfaces of shells and not on the mid-surfaces. For automatic contacts, edge contact with flat edges is always active. It possesses features that are of particular interest to implicit and are not available for other contacts. It is supported in both SMP and MPP, but the keyword option MPP does not apply. The SOFT flag does not apply. To summarize it is a contact algorithm especially intended for implicit analysis.

Recommendations

For Mortar forming contact the rigid tools must be meshed so that the normal vectors are directed towards the blank. Contacts from above and below the blank must be separated into two or more interfaces because contact can only occur from one side of the blank for a given contact interface. Rigid shells on the tracked side have no contact thickness. This is not the case for automatic Mortar contacts. For these contacts, there are no restrictions on the mesh and even rigid shells have contact thickness. For all Mortar contacts, part or part set based tracked and reference sides are recommended but not mandatory. If the two sides in the contact interface have different stiffnesses, use the weak part as the tracked side to get the best possible implicit convergence behavior. The single surface Mortar contact automatically takes care of this.

Characteristics

The contact pressure in Mortar contact is a parabolic function of the penetration in combination with a cubic stiffening phase. In short, the contact stiffness depends on the tracked side material and a characteristic length of the tracked side segment. The characteristic length for shells is the shell thickness and for solids is a median of the edges in the tracked side of the contact interface. The maximum penetration allowed is given as 95% of the average characteristic lengths on reference and tracked sides. For solids the definition of the characteristic length may cause the stiffness to become unnecessarily high if some elements are much smaller than most, so stiffness adjustments may be necessary. Furthermore, the characteristic length also determines the maximum penetration as well as the search radius for finding contact pairs; for this reason, the characteristic length can optionally be increased by assigning it on PENMAX on optional card B. In most cases it is expected that default value (= 0.0) for this parameter will suffice.



IGAP

The contact stiffness is parabolic with respect to penetration up to a penetration depth corresponding to half of the maximum penetration. For IGAP = 1 it will remain parabolic

for even larger penetrations, but the user may increase IGAP which means that the contact will stiffen for larger penetrations. In fact it will become cubic according to the picture above. The purpose of increasing IGAP could be to prevent the penetration from becoming larger than the maximum allowed penetration, because if convergence is attained with penetrations larger than this value this contact will be released in subsequent steps and the simulation is likely destroyed. Penetrations of this depth are likely to cause discontinuities along line searches and other discouraging phenomena. The user may of course scale the stiffness by increasing SFSA but this also scales the stiffness for small penetrations and probably has a negative effect on convergence.

Output for Debugging

Just as for implicit in general, information is always a good thing to have when convergence starts deteriorating and considering the release of contact in the previous section, it would be interesting to know if penetrations are large enough for this to be a potential danger. First, initial penetrations are always reported in the message file(s), including the maximum penetration and how initial penetrations are to be handled. The latter depends on the value of the IGNORE flag and this is dealt with below. In addition, by setting

MINFO = 1

on *CONTROL_OUTPUT, LS-DYNA will report the absolute maximum penetration as well as the maximum penetration in percentage after each equilibrium. If the relative maximum penetration reaches above 99% a warning message is printed as this particular contact is close to being released. The output is exemplified in the following.

```
     Contact sliding interface          1
     Number of contact pairs          527

     Maximum penetration is  0.2447797E+00 between
     elements     306774 and     306672

     Maximum relative penetration is  0.2266694E+02 % between
     elements     306742 and     306733

     Contact sliding interface          2
     Number of contact pairs        16209

     Maximum penetration is   0.5027643E+00 between
     elements     219492 and      94935

     Maximum relative penetration is  1.0366694E+02 % between
     elements     219492 and      94935
 *** Warning Penetration is close to maximum before release
```

This percentage value should ideally be kept below some 90% to have some sort of comfort margin. There are three ways to reduce maximum relative penetrations, and these are *(i)* to increase IGAP, *(ii)* to increase PENMAX for solids or *(iii)* to increase SFSA.

Initial Penetrations

As mentioned above, initial penetrations are always reported in the message file(s), including the maximum penetration and how initial penetrations are to be handled. The IGNORE flag governs the latter and the options are listed below.

IGNORE < 0	Same functionality as the corresponding absolute value but contact between segments belonging to the same part is ignored completely.
IGNORE = 0	Initial penetrations will give rise to initial contact stresses, meaning the tracked contact surface is not modified. *This is not available for Mortar but listed for the sake of completeness*.
IGNORE = 1	Initial penetrations will be tracked, that is, the tracked contact surface is translated to the level of the initial penetrations and subsequently follows the reference contact surface on separation until the unmodified level is reached.
IGNORE = 2	Initial penetrations will be ignored, meaning the tracked contact surface is translated to the level of the initial penetrations, optionally with an initial contact stress governed by MPAR1 (*this is the default*).
IGNORE = 3	Initial penetrations will be removed over time, that is, the tracked contact surface is translated to the level of the initial penetrations and pushed back to its unmodified level over a time determined by MPAR1.
IGNORE = 4	Same as IGNORE = 3, but it allows for large penetrations by also setting MPAR2 to at least the maximum initial penetration.

The use of IGNORE depends on the problem. If no initial penetrations are present, there is no need to use this parameter at all. If penetrations are relatively small in relation to the maximum allowed penetration, then IGNORE = 1 or IGNORE = 2 seems to be the appropriate choice. For IGNORE = 2 the user may specify an initial contact stress small enough to not significantly affect the physics, but large enough to eliminate rigid body modes and thus singularities in the stiffness matrix. The intention with this is to constrain loose parts that are initially close but not in contact by pushing out the contact surface using SFSAT and applying the IGNORE = 2 option. It is at least good for debugging problems with many singular rigid body modes. IGNORE = 3 is the Mortar interference counterpart, used for instance if there is a desire to fit a rubber component in a structure. With this option the contact surfaces are restored linearly in time from the beginning of the simulation to the time specified by MPAR1. A drawback with IGNORE = 3 is that initial penetration must be smaller than half the characteristic length of the contact or otherwise they will not be detected in the first place. For this reason, IGNORE = 4 was introduced where initial penetrations may be of arbitrary size, but it requires that the user provides crude information on the level of penetration of the contact interface. This is done in MPAR2 which must be larger than the maximum penetration or otherwise and error termination will occur. IGNORE = 4 only applies to solid elements at the moment.

When eliminating penetrations by simulation for models with many parts, some parts may contain thin members that cause spurious self-contacts. These may be difficult to work around by only adjusting contact parameters, but fortunately there is rarely any loss of generality in ignoring contact within parts completely since those are usually not of interest in such a context. The option IGNORE < 0 was implemented for this purpose and is a way to approach this problem.

Damping
Damping can be activated in dynamic implicit analysis using VDC. A problem with contact damping in implicit is that the time step is usually large enough to not resolve the time in contact to get the desired damping effect. Therefore, it is not recommended to use damping.

Troubleshooting Convergence Problems

Convergence of the nonlinear equilibrium iteration process presents one of the greatest challenges to using the implicit mode of LS-DYNA. At risk of repeating what has already been mentioned, below are some useful troubleshooting approaches.

Eigenvalue Analysis

Many convergence problems in static implicit analysis are caused by unconstrained rigid body modes. These are created when an insufficient number of constraints are applied to the model, or when individual model parts are left disconnected. Eigenvalue analysis is an excellent diagnostic tool to check for these problems, both initially and at critical points in the simulation. The procedure for performing an eigenvalue analysis was discussed above.

D3Iter Plot Database

To diagnose convergence trouble which develops in the middle of a simulation, get a picture of the deformed mesh. Adjust the d3plot output interval to produce an output state after every step leading up to the problematic time. An additional binary plot database named d3iter is available which shows the deformed mesh during each equilibrium iteration. This output is activated by

D3ITCTL = 1 to activate d3iter plot database

on *CONTROL_IMPLICIT_SOLUTION. View this database using LS-PrePost to detect abnormal displacements. The problem may become obvious, especially as deformation is magnified. If not, there is yet another flag to activate to get the residual forces into both this database as well as d3plot for fringing. Setting

RESPLT = 1 to get residual data to binary databases

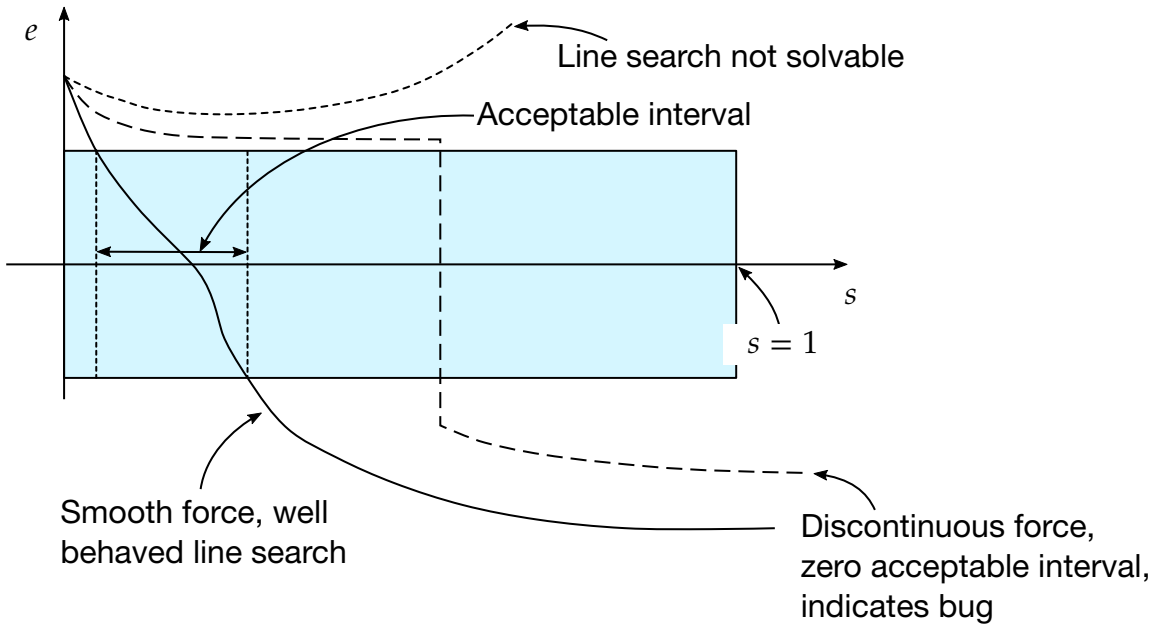
on *DATABASE_EXTENT_BINARY will do just that. With this option the residual forces are output to the d3plot and d3iter databases for fringing under the *NdV* menu. This is a great tool for locating areas in the model where the residual forces are not being reduced to a satisfactory level and take appropriate actions.

Taking Advantage of ASCII Information

If requested through NLPRINT = 3 on *CONTROL_IMPLICIT_SOLUTION and MINFO = 1 on *CONTROL_OUTPUT, a lot can be drawn from the information in the message file(s). This may be considered as a piece of advanced topic but may become useful in due time.

Residual Norm

Starting with the nonlinear output diagnostics, the following basic principle should be held in mind; *if the residual norm is zero, the problem is solved*. So it all comes down to make this number (11) small enough to trust the results. Therefore, we suggest monitoring the residual norm and interpreting it as an indicator of whether the convergence characteristics is good. Hopefully you would see this number decrease with implicit iterations and finally reach a relatively small number at convergence. Although it may (and will) increase on occasion, the trend should be a decreasing one. If this is a problem from the get-go, and you checked the model integrity through eigenvalue analysis and common practice, it may be that a feature is not properly supported in implicit.



Line Search

Another thing to look at is the line search convergence (9), as the relatively loose line search convergence tolerance should render a reasonably small number of line search iterations. A rule of thumb would be less than 10, at most 20. If more is used, or if the line search does not converge, there may be something in the model causing a jump in the residual forces. This is not supposed to happen in implicit and may suggest a bug.

APPENDIX P

Either of the two following scenarios for a feature discontinuity (and many line search iterations) is possible

- The line search step size becomes ridiculously small, and the current residual norm (7) is not approaching the initial one (3).
- The interval in which the optimal step is to be found (8) becomes ridiculously small, and the residual norm on the left and right interval points are not approaching each other. This situation is depicted in the figure above (dashed line).

Many line search iterations can of course be due to high nonlinearities but if the above is observed it should probably be investigated, for instance by trying to identify model features that may be causing the bad behavior. If it is obvious that a discontinuity exist, like if the step size goes down to ~1^{-100} or the interval size becomes zero, and it is not due to a model error, please send a bug report.

Stretching for Convergence

If the problem runs fine for a significant number of load/time steps with subsequent convergence issues, then the information received up to this point may be used intelligently and suggest a different (unorthodox) implicit strategy. To justify the approach, we begin by recalling that the convergence is detected by the following numbers becoming small; $d = \|\Delta \boldsymbol{u}\|$ (displacement norm), $r = \|\boldsymbol{R}\|$ (residual norm) and $e = \left|\boldsymbol{R}^T \Delta \boldsymbol{u}\right|$ (energy norm). But all these numbers are linked through the linear system of equations, $\boldsymbol{K}\Delta \boldsymbol{u} = \boldsymbol{R}$, so if $\boldsymbol{K}$ reasonably "nice" at all times it doesn't matter which numbers we use for detecting convergence. A mathematical way to state this is; if the condition number of $\boldsymbol{K}$ is "good," then all the norms are equivalent throughout the solution process. An intuitive statement would be to say that the problem is only moderately nonlinear, and convergence is usually never a problem. *But*, what happens if the properties of $\boldsymbol{K}$ are not that nice, or if $\boldsymbol{K}$ shifts character every time it is reformed? This is sort of saying that the problem is highly nonlinear, for instance due to frequent change of contact state or onsets/offsets of plasticity. In those cases the equivalence between d and r is lost, and typically an oscillatory behavior of the displacement norm is observed *even though the residual norm is reducing*, which in turn may lead to potential convergence problems just because the displacement criterion cannot be satisfied. Or equally bad, it could lead to premature convergence just by the coincidence that the displacement norm happens to become small. In those cases we essentially want to come up with a strategy where the displacement criterion is taken out of the convergence check and instead detect convergence based on residual only.

So assume we have say 10 converged states, after which the convergence problems begin. Then we can look at what the residual norm is for each of these converged states (11). For instance, we may see the sequence

Step 1, residual norm 2859
Step 2, residual norm 1581

Step 3, residual norm 2119
Step 4, residual norm 2511
Step 5, residual norm 11570
Step 6, residual norm 4904
Step 7, residual norm 3586
Step 8, residual norm 3157
Step 9, residual norm 3315
Step 10, residual norm 2825.

For each of these steps we may validate the results, by post-processing contact force curves, checking force/moment balance etc., in LS-PrePost, and usually there is a correlation between "good results" and small residual norms. Step 5 above is for instance an outlier and may be associated with a prematurely converged step, something that can be confirmed or rejected from looking at the result. The goal with these observations is to establish a reasonable residual norm for which we can safely say that the results are good, and the numbers above indicates that 3000 may be a good candidate. The strategy is then to simply put DCTOL = 10^{-16} to ignore the displacement and set ABSTOL = -3000, which means we can be assured that convergence will not be detected until the residual norm is below 3000. We "know" from having learned about the problem that this will yield good results. It should be mentioned that this may not work if the character (force level) changes significantly later on in the simulation, as 3000 then may not be the number we would trust.

Contacts
Continuing with the contact output, a general rule is that there should be *no* warnings of large penetrations and preferably the maximum relative penetration should be below 90%. These numbers can be monitored after each load/time step. If large penetrations occur, either increase IGAP or contact stiffness, whatever makes most sense, but first make sure that the converged step is *really* converged (no premature convergence) by monitoring the residual forces and checking results as indicated above.

Checklist

So, to summarize

- Activate implicit by setting IMFLAG = 1 on *CONTROL_IMPLICIT_GENERAL
    - Set DT0 to a reasonable initial time step
- Check possible singularities in an eigenvalue analysis by requesting NEIG eigenvalues on *CONTROL_IMPLICIT_EIGENVALUE
    - Find a way to constrain spurious modes

- Initially use dynamic analysis if rigid body modes are present in a static problem by setting IMASS = 1 on *CONTROL_IMPLICIT_DYNAMICS
    - Use TDYBIR, TDYDTH and TDYBUR
    - Use numerical damping by putting GAMMA = 0.6 and BETA = 0.38
- Only activate geometric stiffness contribution as a last resort, except for arc length methods
- Use default BFGS parameters ILIMIT and MAXREF on *CONTROL_IMPLICIT_-SOLUTION
    - Increase or decrease ILIMIT based on convergence characteristics
    - Use full Newton (ILIMIT = 1) for hard problems
    - Keep MAXREF to a reasonably low number
- Use default convergence tolerances DCTOL, ECTOL and RCTOL on *CONTROL_IMPLICIT_SOLUTION
    - ABSTOL may be set to 10^{-20} to prevent premature convergence
    - Relaxing DCTOL may not necessarily result in better convergence
    - Future strategy may be to focus on residual
- Activate automatic time stepping on *CONTROL_IMPLICIT_AUTO
    - Set DTMAX to a number that resolves features of interest
        - Contacts
        - Material nonlinearities
        - Frequencies
- Use default line search method on *CONTROL_IMPLICIT_SOLUTION
    - Switch to LSMTD = 5 if hard problem (typically rubbers)
    - Don’t change LSTOL
- Use at least NLPRINT = 2 on *CONTROL_IMPLICIT_SOLUTION to get convergence diagnostics into log files
    - Use NLPRINT = 3 to thoroughly track the residual norm and monitor line search behavior if debugging model is necessary
- Use *CONTROL_IMPLICIT_SOLVER only in special occasions
- Set D3ITCTL = 1 on *CONTROL_IMPLICIT_SOLUTION to get a database with Newton iterates when debugging a model

    - Complement this with RESPLOT = 1 on *DATABASE_EXTENT_BINARY to get the possibility to fringe the residual force vector

- For forming Mortar contact, make sure

    - Tools are oriented towards the blank
    - Contact on top and bottom of blank are separated among contact interfaces

- Use part (set) definitions of SURFA and SURFB in Mortar contact
- Always use weak part as SURFA (tracked) in a Mortar contact definition to get best possible convergence
- Set SAST to a reasonable characteristic length for SURFA side consisting of solid elements

    - With this option, separate solids and shells into different contact interfaces in order to not manipulate the contact thickness for shells

- If penetrations are large, activate penetration diagnostics on *CONTROL_CONTACT
- To avoid release of contact pairs, either

    - Increase stiffness scaling factor SFSA
    - Increase IGAP for progressive stiffness increase
    - Increase SAST for solids while at the same time increasing SFSA

- Use IGNORE appropriately to deal with initial penetrations

    - Check initial penetrations in messag file

- Don’t use contact damping

APPENDIX Q: User Defined Weld Failure

The addition of a user weld failure subroutine into LS-DYNA is relatively simple. The UWELDFAIL subroutine is called every time step when OPT = 2 is specified in MAT_-SPOTWELD. As data, the identification number for the spotweld material, six constants specified in the input by thfe locations NRR through MTT, the radius of the cross section of the spotwelds, the current time, and the current values of the resultants for the spotwelds, which are stored in array STRR, are passed to the subroutine. The subroutine loops over the welds from LFT through LLT, and sets the values of the failure flag array FLAG.

APPENDIX R: User Defined Cohesive Model

The addition of a user cohesive material subroutine into LS-DYNA is relatively simple. The UMATiC subroutine is called every time step where i ranges from 41 to 50. Input for the material model follows the *MAT_USER_DEFINED_MATERIAL definition. The user has the option of providing either a scalar or vectorized subroutine. As discussed in the Remarks for the user-defined material, the first two material parameters are reserved to specify how the density is treated and the number of integration points required for the failure of the element.

The cohesive model calculates the tractions on the mid-surface of the element as a function of the differences of the displacements and velocities of the upper (defined by nodes 5-6-7-8) and lower surfaces (defined by nodes 1-2-3-4). The displacements, velocities, and the calculated tractions are in the local coordinate system of the element, where the first two components of the vectors are in the plane of the mid-surface and the third component is normal to the mid-surface.

A stiffness must also be calculated by the user for the explicit time step calculation in LS-DYNA. This stiffness must provide an upper bound on the stiffness in all three directions.

The material fails at an integration point when `ifail=.true`. For an element to be deleted from the calculation, the number of integration points specified by the second material parameter must fail. If the second parameter is zero, elements cannot fail regardless of the specification of IFAIL in the user-defined material input. For example, the user may choose to reject an implicit step is the displacement increment is too

For implicit analysis, the subroutine is called with `maketan=.true.` and the user must provide the elastic moduli in the three local directions in the respective diagonal terms of the `dsave` array. The parameter `reject`, if set to `.true.` by the user, will signal to LS-DYNA that the current implicit iteration is unacceptable. For example, the user may choose to reject an implicit step if the traction changes too much from the last time step. In this situation, LS-DYNA will print a warning message `Material model rejected current iterate' and retry the step with a smaller time step. If chosen carefully (by way of experimenting), this may result in a good trade-off between the number of implicit iterations per step and the step size for overall speed.

The following example is a vectorized model with two elastic constants and failure:

```
      subroutine umat41c(idpart,cm,lft,llt,fc,dx,dxdt,aux,ek,
     & ifail,dt1siz,crv,nnpcrv,nhxbwp,cma,maketan,dsave,ctmp,elsiz,
     & reject,ip,nip)
      include 'nlqparm'

APPENDIX S: User Defined Boundary Flux

A user defined boundary flux interface is provided in LS-DYNA where it is possible to define the thermal heat flux (power per surface area) in or out of a surface segment as an arbitrary function of temperature and history. The user may associate history variables with each individual flux interface and also use load curves.

The user flux interface is invoked using the keyword *BOUNDARY_FLUX_*OPTION.* This is accomplished with the parameter NHISV. When it is defined with a value greater than 0, the user subroutine

```
subroutine usrflux(fl,flp,…)
```

is called to compute the flux (`fl`) defined as heat (energy) per time and per surface area.

Other parameters that are passed to the user flux subroutine include the segment nodal temperatures at the previous (T_0) and current time (T_1), the segment nodal coordinates and the time integration parameter α. Also, the current thermal simulation time t, the time step Δt and average segment temperature (T_α) at time $t+\alpha\Delta t$ is provided together with the curve array for accessing defined load curves in the keyword input file. For computing load curve values, note that load curve IDs need to be transformed to internal numbers or the subroutine crvval should be used, see the appendix on user defined materials for details.

The segment coordinates available in the subroutine are such that the outward normal vector follows the well-known right-hand rule, thus segments corresponding to the lower surface of thick thermal shells are reversed before passed to the subroutine. For shells in general, the segment connectivity should follow the connectivity of the actual shell element to avoid problems.

Optionally, the user may define the derivative of the flux `fl` with respect to the average segment temperature (T_α) at time $t+\alpha\Delta t$, `flp`. This value is used in the nonlinear thermal solver for assembling the correct stiffness matrix and must be set by the user. If possible, it is recommended to use a value that reflects the nonlinearity of the flux model, otherwise the value 0 should be used.

An array of history variables, identical with the input parameters defined in the keyword input file, are passed to the subroutine that can be updated with time or kept constant throughout the simulation. An example of usage would be to integrate the flux with time to keep track of the dissipated energy per surface area in order to simulate the effects of spray cooling in hot-stamping.

```
      subroutine usrflux(fl,flp,x,tnpl,tnl,nodes,
```

```
     .     alpha,atime,atemp,dt,time,fhsv,nfhsv,crv)

APPENDIX T: Metal Forming Glossary

A TYPICAL DRAW DIE ENGINEERING PROCESS

Clay models of a new vehicle are scanned and the outer shell surfaces are created in a design studio. Body-in-white engineers and designers are responsible to create all the inner parts and various structure and underbody parts. Flanges are created on outer surface parts to be joined with the inner panels. These parts are typically created in the car axis; with global X-axis runs from the front to the back along the car's center line, global Y-axis from the driver side to the passenger side and Z-axis going straight up.

During the clay design and shaping, simultaneous and multidisciplinary engineering may be practiced involving divisions/departments from design, engineering and manufacturing. Material suppliers may also be involved in this stage for consultation if advanced materials are to be applied. Multidisciplinary involvement in this early stage of a vehicle development allows manufacturing engineers to capture any part designs with "no make" conditions that would be costly if they were allowed to proceed to a later stage; while design envelopes can be pushed to their maximum potential within the state-of-art manufacturing capabilities.

During the advance feasibility phase, parts from the design studio are processed quickly to go through an engineering process involving mainly the process engineer and FEA simulation engineer. Addendum and binder are roughly built in order to conduct a reliable draw die simulation. The exact process eventually would be used to build the die may not yet be established, therefore similar processes from knowledge base are used as references. Rarely are secondary dies (all dies except draw die) simulated. The main task here is to provide some quick assessment of the part's manufacturability through fast design/engineering iterations.

During the hard die design and construction phase, stamping manufacturing processes (some in three dimensional) are established, by referring to existing knowledge base, with necessary modifications needed for the current part design, and with the limits of manufacturing equipment such as press type, shut height, maximum tonnage and automation, etc. The stamping process includes the number of dies (to make a complete part of the final shape), part tipping, draw height, trimming (direct or aerial), flanging, springback compensation requirements, etc. Not all areas of the part may be formed to its final shape in one draw die. Some involve redraw die if one area of the part is especially deep compared to the rest of the part, which may otherwise cause uncontrollable wrinkles, splits, or exceed the draw height limit without the redrawing. Some areas of the part (which may have "undercut" or "die locked" conditions) may be unfolded to the addendum, then trimmed and flanged in a flanging die later. A typical example of such can be found along the hood line of a fender outer. There may be multiple trimming and flanging dies, since not all areas of the drawn panel may be feasible for trimming or flanging all in one trim or flanging die.

*APPENDIX T

Referring to Figure 68-1, a typical draw die development process flow for an outer part is illustrated. The part is tipped from the global car axis to a 'draw die' axis, which takes into account of balancing the internal draw angles over the entire part, and minimizing the overall draw height, etc. Hem flanges are unfolded off the part breakline (Figure 68-1) in one of the following ways:

1)Tangent extension of the part surface,
2)Horizontal surface,
3)Vertical down-standing surface,
4)Any angled surface between horizontal and vertical surface,
5)To the addendum surfaces to be designed; in this case, the unfolding will happen after the addendum design is complete.

Flange unfold must take into account the trimming condition later in the trim dies. Direct trim represents the trim steel going down in a draw direction (vertical); while aerial (cam) trim steel covers all other directions, driven by a 'cam driver' driven further by the vertical downward motion of the trim die. There are specific trim angle requirements for direct and aerial trim operations. Next, the part boundary is smoothed, filling up any gaps, holes and sharp features. The boundary will likely be modified later during the addendum build. Binder is created, based on the unfolded part boundary and overall part curvature. A developable binder surface, which consists of planes, cylindrical surfaces or a combination of both, is preferred; however, in some cases a doubly curved binder surface (undevelopable surface) must be designed for the purpose of reducing the draw depth at critical locations for material utilization, alleviating thinning, or both. Theoretical punch opening line (P.O. line, Detail #2 in Figure 68-1) can be offset from the smoothed part boundary in the plane normal to the draw axis, projected to the binder surface in the draw direction; some smoothing of the P.O. lines may be required. Generally, the finished P.O. lines should be consisted of mostly straight lines and radii, with generous transition among corners. P.O. lines do not follow tight corners, avoiding formation of wrinkles during the draw. In addition, design of P.O. lines must take into consideration the material utilization issue, especially in the blank sizing critical locations. Once P.O. lines design is complete, binder surfaces inside of the P.O. are trimmed and the remaining binder surface design is sent for binder closing simulation. Given a blank initial shape, simulation of the binder closing action can determine the quality of the binder design. Typically, for exterior outer panels, no buckles or wrinkles are allowed during the closing; for inner panels, some wrinkles are acceptable, or even desirable, depending on the part shape. Lower punch/post support may be introduced to reduce the draw height, alleviate thinning, or remove the initial blank drape into the binder cavity. Based on the binder closing simulation results, unacceptable binder design is sent back for rework, and the satisfactory binder design proceeds into the next step of addendum build, which is used to fill the space between the part boundary and binder surface. It is noted that the P.O. lines may need to be adjusted during the addendum design. The trimming condition may also be affected and modified during the addendum design. Next, draw simulation ensues, assessing the overall formablity of the draw design. If quality targets are not achieved in the simulation, the process may go

all the way back to the tipping for redesign/reprocess; otherwise successful simulation will direct the draw surface design to the next stage of draw die structure design.

TYPES OF DRAW DIES

There are many different types of draw dies used to punch the part to their intended shape, as shown in Figure 68-2. They basically can be divided into either single action or double action dies. Specifically (names may vary among different companies),

1)Air draw – Single action. It is a 3-piece die system with 1 piece upper (cavity) and 2-piece (binder and punch/post) lowers. The upper cavity (driven by press ram) moves down in one action to close with the lower binder, and then closes with the lower punch to draw the part to the home position. The lower binder is either sitting on an air cushion through pins that go through the press bed, or directly on nitrogen cylinders arranged uniformly between the bottom of the binder structure and the press bed; the punch is fixed onto the press bed. This is the most popular draw type, mainly because of its speed and efficiency. Its limitation includes a maximum draw height of 10".

2)Toggle draw – Double action. It is a 3-piece die system with 2-piece upper (binder and punch) and 1 piece (cavity) lower. Upper binder, driven by the outer ram of the press, moves down to clamp the blank with the lower cavity; then the upper punch, driven down by the inner ram, closes with the lower cavity to complete the draw. Since this adds another action, it is slower than the air draw; however, this type of draw die is well suited to control the wrinkles created during the forming of difficult part, such as liftgate and door inner. Furthermore, this type of draw has a relatively large draw height, which is limited only by the press.

3)Air draw with pressure pad – Single action. This is very similar to 1), except an additional pressure pad, driven by nitrogen cylinders mounted on the upper die structure, closes first with the lower punch, then the entire upper comes down to finish the draw. This is similar to 1) in efficiency.

4)Stretch Draw (four piece) – Double action. It is a 4-piece die system with 2-piece uppers (upper binder and punch) and 2-piece lowers (lower binder and cavity). Upper binder moves down to close with lower binder, moving together for a certain distance (up to 2"), then upper punch comes down to completely close with lower cavity. Finally the binders move down together to their home position. This process is not used as often as 1), 2) and 3), however, it is very capable in forming difficult inner parts, especially those prone for wrinkles, such as liftgate inner, door inner and floor pan. Since there is a 'pre-stretch' action with the binders clamping the blank and moving down together, strain path change in the part during the forming is expected. This is the slowest draw type.

5)Crash Form Die – Single action. It is a 2-piece die system with no upper or binders. Upper and lower tool takes the same shape, with upper moving down to close with the lower tool. This is obviously a very simple die, which can handle simple

parts, with not too much draw depth variation (near constant draw depth all around).

TYPES OF FLANGING DIES

There are three types of flanging dies, as shown in Figure 68-3. All three types have a fixed lower (trim) post upon which the drawn (or partially trimmed part) is sitting, and a pressure pad (or multiple pads) which holds the part (which is loaded onto the post in a vertical direction) in place against the post. In a direct flanging process, the flanging steel (Figure 68-3) moves vertically down to 'wipe' or 'bend' the part to its flanged position. In an aerial flanging process, the flanging steel moves to form the flanges in an angle rather than the vertical direction. The steel is held by the cam slide, driven by a cam driver which in turn is driven by the trim die's downward movement. Since the finished flange forms a 'die lock' condition, meaning the flanged part will not be able to be lifted (retract) out of the trim die into the next die (or station), the filler cam (Figure) is moved horizontally out of the way so the part can be lifted up and out. Once the part is removed, the filler cam moves back into its home position ready for the next drawn panel to be loaded. In the rotary cam flanging process, the filler cam is called a 'rotor', which rotates out of the way for the flanged part to be lifted up and out. Some parts of the rotary cam flanging design are a patented process. In comparison to the conventional cam flanging, rotary flanging has the advantage of being very compact.

TYPES OF HEMMING DIES

There are two types of hemming dies, as shown in Figure 68-4. Both processes have a fixed hemming bed, on which the flanged outer part is loaded; the inner panel is then loaded onto the outer panel; proper clamps are applied to hold tight the panels together and in place. In press (or table top) hemming, a pre-hemming tool is moved to form the flange into a halfway position, followed by the final hemming tool pressing down on the flange against the inner and outer panels to its final position. Many different shapes of hem tips can be achieved, as shown in the figure. In roller hemming, a pre-roller moves in a three dimensional curvilinear path following the hem tip, to form the flange partially. This is followed by a final roller, moving in another three dimensional path, to finish the hem shape. In the hemming of complex or high-end parts, many passes (rollers) are needed to achieve high quality hem surfaces. Similarly, with the design of different roller shapes, many shapes of hem tips can be achieved.

Appendix V: How to Read Card Summaries

LST has written the LS-DYNA manual an encyclopedic reference for LS-DYNA. The first goal of the manual is to fully document all features and their corresponding input structures. Secondly, we have structured the manual so that any chunk of keyword input can be quickly interpreted. As of R11 we have introduced a new standard format aimed at making the manual even more useful for *quickly* interpreting keyword input. The definitions below, which are provided for clarity, are followed by a lengthy discussion of this new format.

Definitions: Decks, Cards, and Keywords

1. **Decks.** The text file containing the LS-DYNA input is called *the input deck.* The term *deck* is historical in origin, originally referring to actual punch-cards.

2. **Cards.** Each line of the input file is called a *card*, as in a punch-*card.* Taken together the *cards* comprise the *deck*.

3. **Keywords.** A typical input deck consists of two kinds of cards: (1) keyword cards and (2) data cards. Keyword cards are easily recognized by the "*"-character in the first column followed directly by a (case insensitive) *keyword*. These cards form the skeleton of the deck. LS-DYNA treats each keyword card as a kind of command (or function or subroutine) for which the arguments are passed with data cards.

4. **Keyword Options.** Each keyword card consists of a base keyword combined with option words. Option words are appended to the base keyword using underscores. For example, to invoke the *node* keyword with the *merge* option one would include a card (a line) consisting of the text "*NODE_MERGE" where the "*"-character is in the first column. We have, for clarity, adopted a convention of capitalizing (the case insensitive) keywords.

Introduction to Card Summaries

The keyword manual (the enormous PDF you're looking at) is organized by keyword. As mentioned in item 3 above, keywords are like subroutines (or functions, if you program in C). Like subroutines, keywords take input. Unlike subroutines, keyword input is not divided into a fixed number of strongly-typed fields. For instance, for a given keyword the number of fields and their data types can, and often does, depend on what is contained in the input itself. Keyword input is, then, best described by flow chart.

APPENDIX V

After processing a keyword card all cards until the next keyword card are treated as the keyword's input. Collectively, these cards are called the *data cards*. Most of the LS-DYNA manual is devoted to describing how each keyword interprets the contents of its data cards (the flowchart mentioned in the previous paragraph). *Beginning in 2018 (R11), new and updated entries to the manual will contain a section called "card summary" that expresses the structure of the keyword's data in a concise and standardized format*. We hope that these summaries will be simple enough that you can understand them without reading this document.

Motivation for Introducing the Card Summary Section.

1. **"Optional" Cards/Blank Cards.** Traditionally, some data cards have been called *optional* and others have been called *required*. This can be confusing. Some examples of frequently asked questions are:

   Can the second optional card be omitted? The answer is: not if you intend to include the third optional card.

   Can I add blank lines to make my deck more human-readable? The answer is "no" because LS-DYNA interprets blank lines as data. For instance, each data card after a *NODE is expected to contain a node definition. A blank card is interpreted as an invalid node definition.

2. **Branching (and Switch Constructs).** Often the format of the next data cards depends on what was in the preceding cards or on the options applied to the keyword. Sometimes the branching can be complicated. We have adopted a compact convention to express branching in the *card summaries*.

3. **Repeated Cards (DO/FOR Loops Constructs).** There has been confusion over the meaning of the *card number* as presented in traditional manual entries. In some cases, a data card's card number indicates its position relative to the keyword; in other cases, the card number serves as a kind of format identifier. Iterated cards, however, make the line-number interpretation impossible without saying something like *Card n*, where *n* is an integer, and we almost never do that. Card summaries clear up this confusion.

4. **Default Values.** When a field is blank or set to 0, then LS-DYNA applies a default value. The meaning of "0" for objects like node sets can be confusing and, in the past, hasn't been explicitly spelled out. As part of the format revamp we are adopting new conventions for ambiguous cases.

"Optional" Cards (How LS-DYNA Parses Blank Lines).

When LS-DYNA reads an input deck some data cards contain fields having no default value. These data cards are said to be *required*; LS-DYNA will error terminate when required cards are missing. In contrast, data cards consisting entirely of fields that have default values can, generally, be left blank. Such cards are called *optional.*

The details of the algorithm for processing optional cards are subtle, but the application of optional cards is nonetheless mostly intuitive. An *optional card* is only optional in the sense that if *all the cards* that come after it are also optional, then the card can be omitted, but *only* if *all* the subsequent cards *are also omitted*. For example, if a keyword has three optional data cards and some of the values on the third optional card need to be changed from their default values, then the two previous optional cards must be included, at the very least, as blank lines. Note that there are a very small number of irregular cases where an omitted card is treated differently from a blank card; such special cases are documented when they appear.

Example:

The example below illustrates some of the subtleties involved in deciding when to omit an optional card. In this example, two rigid wall cylinders are defined with a single instance of the *RIGIDWALL_GEOMETRIC_CYLINDER_ID_DISPLAY_MOTION keyword by including two sets of data cards, one for each cylinder. The DISPLAY option activates an optional data card. Since two cylinders are being defined, the DISPLAY data card must be included, at least as a blank line, for the first cylinder; otherwise, LS-DYNA will read the first line for the second cylinder as new defaults for the DISPLAY option data card causing an error termination due to format mismatch. The last card included in the input below for the second cylinder is *not* the DISPLAY data card. For this case, it does not have to be input since it is optional and no further data cards follow. A blank line may be included for the second DISPLAY data card, but is not necessary, and excluding it makes no difference.

```
      ⋮
*RIGIDWALL_GEOMETRIC_CYLINDER_ID_DISPLAY_MOTION
$ first cylinder
$       ID
       100
$     nsid    nsidex     boxid     birth     death
                 0         0     0.000     0.000
$       xt        yt        zt        xh        yh        zh      fric
-20.000000     0.000-50.000000-21.000000     0.000-50.000000     0.000
$   radcyl    lencyl
 20.000000 30.000000
$     lcid       opt        vx        vy        vz
        99         0     0.000  1.000000     0.000
$
$ Blank line for card data associated with DISPLAY. This blank line is necessary since
$ 2 card sets are being used even though this card is optional.  If the blank line was
$ not included, then LS-DYNA would read 101 as the DISPLAY data card line which would
$ lead to an error termination
$

$ second cylinder
```

```
101
                    0          0     0.000     0.000
-20.000000     0.000 10.000000-21.000000     0.000 10.000000     0.000
 20.000000 30.000000
          2                0.000  1.000000     0.000
$ No blank line is needed here since this is the last card set and the DISPLAY data
$ card is optional.
*control_contact
       ⋮
```

The Structure of Manual Entries.

The following table compares traditional entries to summary table formatted entries:

Old Format (no summary table)		Summary Table Format	
1.	The entry begins with a "purpose" statement	1.	No change.
2.	The purpose statement is followed by an explanation of options, if there are any. Sometimes the purpose statement and option sections are reversed.	2.	No change.
3.		3.	Summary table
4.	Several small tables of between 2 and 4 rows are included, roughly, one for each type of data card. Each table contains a short note about how many times its repeated.	4 & 5.	Each card table is followed directly by a short variable list. Generally, each branching is represented by a *different* card table.
5.	These tables are followed by a single long "variable list table," which defines the meaning of all the fields on all of the preceding tables. Branching is mostly explained in the variable list.		
6.	Lastly, manual entries often contain a "remarks" section.	6.	No change.

As indicated in the above table, the differences between the two formats are confined to items 3, 4, and 5. The traditional format, when applied to keywords with large data sets suffers a few drawbacks which the summary table format addresses:

1. For keywords having many data cards (> 5) the variable lists may be several pages removed from the original data card. In the summary table format a data card's fields are explained right after the data card.

2. The entire set of data card tables, itself, may span several pages. Ideally, it should be on one page so that a user can look at a single page when trying to interpret his input deck. The card summary table is compact (and more likely to fit on one page) and contains enough information to match each field in an input deck to the name of the field in the manual.

3. In cases where the meaning of a data card's field depends on previous data cards, the traditional format puts the branching explanations entirely in the variable list. Interpreting an input deck then requires lots of page flipping. Moreover, since groups of fields often branch together, the same branching verbiage is often repeated in field after field requiring you to read each-and-every repetition in case one field works differently from the others, which sometimes happens.

   In the card summary format branching is explained in the summary table and sometimes repeated on the card representations. Since the fields are explained after the card, the branching is *not* generally dealt with in the variable lists.

Summary Table Format

The summary table itself consists of two rows per data card (see Example 1 directly below). The first row consists of pseudo-code containing an identifier for the card type, the logic used to determine when a data card is included, and the logic used to determine how many times it is repeated. The second row represents the data card's fields following the convention from the traditional manual entry.

The summary tables will, for the most part, adhere to the conventions described below.

1. Cards are labeled as "Card [identifier]". In the simplest case, the identifier is an integer. See Example 1.

2. In the case of a group of mutually exclusive cards (or sets of cards), the variants are expressed by adding a letter onto the identifier. Letters increment alphabetically. See Example 2.

3. Cards that are grouped together (in contrast to ones that are mutually exclusive) are indicated by adding a "*.n*" onto the base identifier, where *n* is the card number with the first card in the group being numbered "1". This construct is analogous to increasing indention in python or nesting with curly braces in C. See Example 3.

4. Cards with italicized names are optional. See Example 2.

APPENDIX V

Example 1.

The data cards for the *RIGIDWALL_PLANAR keyword have neither exclusive branches or conditional sets. The cards are, therefore, numbered linearly. To the extent there is branching, it is only to include extra data cards as options are appended to the keyword.

ID Card. First data card of the card set if the ID keyword option is used in the keyword name. Otherwise Card 1 is the first data card.

ID							

Card 1. This card is required.

NSID	NSIDEX	BOXID	OFFSET	BIRTH	DEATH	RWKSF	

Card 2. This card is required.

XT	YT	ZT	XH	YH	ZH	FRIC	WVEL

Card 3. This card is included only if the ORTHO option is used.

SFRICA	SFRICB	DFRICA	DFRICB	DECAYA	DECAYB		

Card 4. This card is included only if the ORTHO option is used.

NODE1	NODE2	D1	D2	D3			

Card 5. This card is included only if the FRICTION option is used.

XHEV	YHEV	ZHEV	LENL	LENM			

Card 6. This card is included only if the MOTION option is used.

MASS	V0						

Card 7. This card is included only if the FORCES option is used.

SOFT	SSID	N1	N2	N3	N4		

For the *RIGIDWALL_PLANAR_MOTION_FORCES_ID keyword the summary table is interpreted as

ID	ID							
1	NSID	NSIDEX	BOXID	OFFSET	BIRTH	DEATH	RWKSF	
2	XT	YT	ZT	XH	YH	ZH	FRIC	WVEL
6	MASS	V0						
7	SOFT	SSID	N1	N2	N3	N4		

For the *RIGIDWALL_PLANAR_ORTHO_FRICTION keyword the summary table is interpreted as

1	NSID	NSIDEX	BOXID	OFFSET	BIRTH	DEATH	RWKSF	
2	XT	YT	ZT	XH	YH	ZH	FRIC	WVEL
3	SFRICA	SFRICB	DFRICA	DFRICB	DECAYA	DECAYB		
4	NODE1	NODE2	D1	D2	D3			
5	XHEV	YHEV	ZHEV	LENL	LENM			

Example 2.

Card 1. This card is required.

NEIG	CENTER	LFLAG	LFTEND	RFLAG	RHTEND	EIGMTH	SHFSCL

Card 2. Card 2 and beyond are optional. If Card 3a or 3b are included, then Card 2 must be included; Card 2 can be a blank line in this case, so default values are used.

ISOLID	IBEAM	ISHELL	ITSHELL	MSTRES	EVDUMP	MSTRSCL	

Card 3a. Card 3a is read only when EIGMTH = 101. It is optional.

IPARM1	IPARM2	IPARM3	IPARM4	RPARM1			

Card 3b. Card 3b is read only when EIGMTH = 102. It is optional.

IPARM1	IPARM2			RPARM1	RPARM2		

APPENDIX V

Example 3.

ID Card. First data card of the card set if the ID keyword option is used in the keyword name. Otherwise Card 1 is the first data card.

RWID	HEADING

Card 1. This card is required.

NSID	NSIDEX	BOXID	BIRTH	DEATH			

Card 2. This card is required.

XT	YT	ZT	XH	YH	ZH	FRIC	

Card 3a. This card is included only for the FLAT shape.

XHEV	YHEV	ZHEV	LENL	LENM			

Card 3b. This card is included only for the PRISM shape.

XHEV	YHEV	ZHEV	LENL	LENM	LENP		

Card 3c. This card is included only for the CYLINDER shape.

RADCYL	LENCYL	NSEGS					

Card 3c.1. NSEGS instances of this card are included only for the CYLINDER shape.

VL	HEIGHT						

Card 3d. This card is included only for the SPHERE shape.

RADSPH							

Card 4. This card is required if the MOTION keyword option is used.

LCID	OPT	VX	VY	VZ			

Card 5. This card is read only if the DISPLAY keyword option is used. It is optional and may be omitted unless more than one card set is being read in; if more than one card set is being used, then at least a blank line must be included for all but the last card set. If not input, the defaults will be used.

PID	RO	E	PR	↓			

Default Values for Data Cards.

The keyword reader always, with a vanishingly small number of exceptions, fills in blank fields with the value 0. LS-DYNA, then replaces the value of 0 with *the default value*. The default value row of a keyword card table adheres to the following conventions:

1. Often, the row of default values is missing from the keyword card tables. In this case see the variable list following the table (or after the tables for traditional format) for information about default values.

2. A "↓" character indicates that the default value is explained in the variable list. This, likely, indicates that the explanation involves more content than the table can accommodate.

3. If the field is required, then the default value is written as *none*.

4. The symbol {∅} indicates an empty set.

5. "Rem *n*" where *n* is an integer indicates that the field is explained in a remark.

6. If the default value is listed as being 0, then one of two things is being described: (1) the default value is *actually* 0, or (2) the table is indicating the tautological, namely, that the keyword reader fills blank fields with zero, which always happens for every field. In the second case the meaning of zero is almost always explained within the variable list. Going forward, LST will try to avoid this second case.

Appendix W: Acoustic Volume Element and Spectral Element Solvers

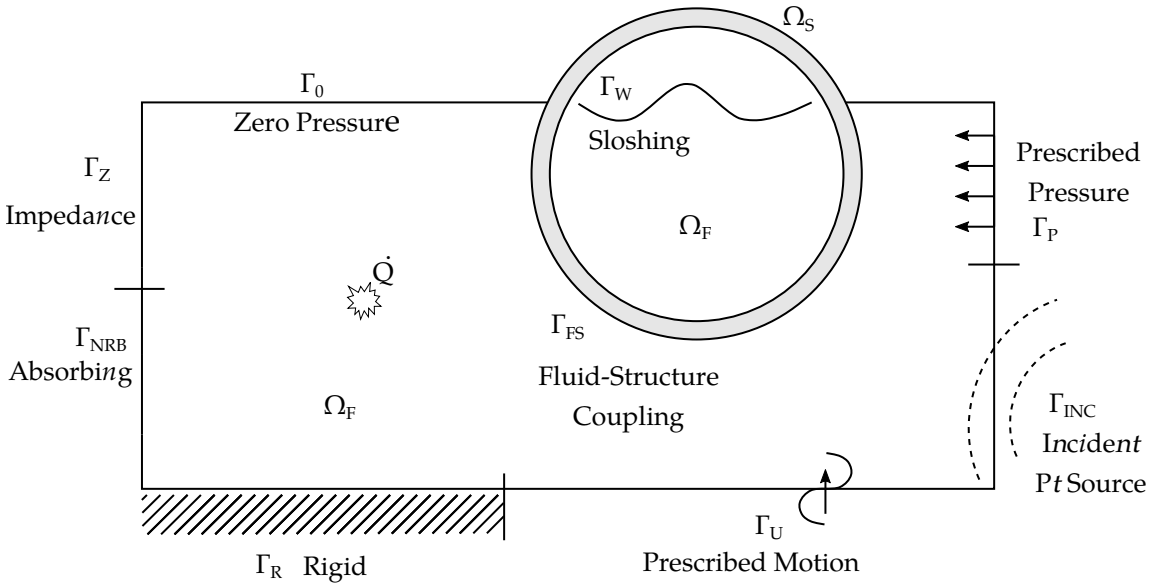

Figure 72-1. Sketch of the structural-acoustic system

Explicit Transient Acoustic Iso-parametric Element Solutions

The longstanding and default solution path for transient acoustic solutions in LS-DYNA uses low-order iso-parametric finite elements. It is capable of treating shock-induced cavitation and uses the displacement potential as the fundamental nodal unknown. This is the approach used if neither *CONTROL_IMPLICIT_SSD_DIRECT nor *CONTROL_ACOUSTIC_SPECTRAL is used.

Boundary condition treatment is summarized in Table 72-1. This solution path uses an inverted boundary condition strategy that may be confusing to analysts familiar with potential formulations. Kinematic boundary conditions are interpreted as if the formulation were a Lagrangian, displacement-based model like *MAT_ELASTIC. Thus, fluid faces that are constrained with nodal displacement constraints are rigid, sliding faces. Fluid faces that are left free are pressure release or zero pressure faces. And fluid faces that are merged with structural nodes are coupled faces. Structural coupling when there is fluid on both sides of a shell element requires *BOUNDARY_ACOUSTIC_COUPLING or *BOUNDARY_ACOUSTIC_COUPLING_MISMATCH. Non-reflecting and absorbing boundaries use either *BOUNDARY_NON_REFLECTING or the perfectly matched layer of *MAT_PML_ACOUSTIC.

APPENDIX W

Model Parameters	Keywords
Material Properties, Ω_F	*MAT_ACOUSTIC
Structural Coupling, Γ_{FS}	Merge fluid and structural nodes on one side *BOUNDARY_ACOUSTIC_COUPLING *BOUNDARY_ACOUSTIC_COUPLING_-MISMATCH
Prescribed Boundary Motion, Γ_U	No support
Prescribed Boundary Pressure, Γ_P	*LOAD_SEGMENT_SET
Rigid Boundary, Γ_R	*BOUNDARY_SPC
Impedance Boundary, Γ_Z	*BOUNDARY_ACOUSTIC_IMPEDANCE
Absorbing Boundary, Γ_{NRB}	*BOUNDARY_NON_REFLECTING *MAT_PML_ACOUSTIC
Zero Pressure Boudnary, Γ_{NRB}	Leave these nodes unconstrained
Small Amplitude Wave Boundary, Γ_W	No support
Internal Point Source, $\dot{Q}$	No support

Table 72-1. Keywords for explicit transient acoustic iso-parametric finite element solutions

Explicit Transient Acoustic Spectral Element Solutions

The spectral acoustic elements in LS-DYNA invoked with *CONTROL_ACOUSTIC_SPECTRAL use higher-order interpolants based on Legendre polynomials. The elements converge exponentially and support integration orders from 2 to 15. They are especially recommended for ultrasonic wave propagation. These elements have internal degrees-of-freedom (invisible to users). These degrees-of-freedom are generated automatically based on the integration order chosen. You may change the integration order and accuracy of the solution without remeshing.

For the explicit solution to the transient, fluid-structure interaction problem with acoustic spectral elements, the following nonsymmetric system is solved at every time step:

$$\begin{bmatrix} M_{ss} & 0 \\ -\rho c^2 T_{fs}^T & M_{ff} \end{bmatrix} \begin{bmatrix} \ddot{u} \\ \ddot{p} \end{bmatrix} + \begin{bmatrix} W_{ss} & 0 \\ 0 & W_{ff} \end{bmatrix} \begin{bmatrix} \dot{u} \\ \dot{p} \end{bmatrix} + \begin{bmatrix} K_{ss} & T_{fs} \\ 0 & K_{ff} \end{bmatrix} \begin{bmatrix} u \\ p \end{bmatrix} = \begin{bmatrix} r_s \\ r_f \end{bmatrix}$$

Here M_{ss}, W_{ss}, and K_{ss} are the structural mass, damping and stiffness. M_{ff}, W_{ff}, and K_{ff} are the equivalent matrices for the fluid. T_{fs} is the fluid-structure coupling matrix. Vector u is the structural displacements, and p is the pressure. The time step used is the smallest stable time step in either of the acoustic or structural domains. The applicable keywords are summarized by Table 72-2.

Model Parameters	Keywords
Material Properties, Ω_F	*MAT_ACOUSTIC *MAT_ACOUSTIC_DAMP
Structural Coupling, Γ_{FS}	*BOUNDARY_ACOUSTIC_COUPLING_-SPECTRAL
Weak Structural Coupling, Γ_{FS}	*INTERFACE_ACOUSTIC *BOUNDARY_ACOUSTIC_INTERFACE
Prescribed Boundary Motion, Γ_U	*BOUNDARY_ACOUSTIC_PRESCRIBED_-MOTION
Prescribed Boundary Pressure, Γ_P	*BOUNDARY_ACOUSTIC_PRESSURE_-SPECTRAL
Rigid Boundary, Γ_R	This is a natural condition
Impedance Boundary, Γ_Z	*BOUNDARY_ACOUSTIC_IMPEDANCE
Absorbing Boundary, Γ_{NRB}	*BOUNDARY_ACOUSTIC_NON_RE-FLECTING
Zero Pressure Boudnary, Γ_{NRB}	*BOUNDARY_ACOUSTIC_FREE_SURFACE
Small Amplitude Wave Boundary, Γ_W	*BOUNDARY_ACOUSTIC_FREE_SURFACE
Internal Point Source, $\dot{Q}$	*LOAD_ACOUSTIC_SOURCE

Table 72-2. Keywords for explicit transient acoustic spectral element solutions

The perfectly matched layer of *MAT_ACOUSTIC_PML is not currently supported in spectral acoustic element solutions.

For post-processing, pressure-time histories are written with *DATABASE_ACE-OUT and *DATABASE_HISTORY_ACOUSTIC. Plot states for the user's mesh are written to the D3PLOT file. The integration point used for those plot states is derived from the closest spectral pressure degree-of-freedom.

APPENDIX W

Implicit Direct Steady State Acoustic FE Solutions

For the direct solution to the forced vibration problem with acoustic fluid coupling, a complex symmetric system of equations is solved. This starts with

$$\begin{bmatrix} M_{ss} & 0 \\ 0 & M_{ff} \end{bmatrix} \begin{bmatrix} \ddot{u} \\ \ddot{q} \end{bmatrix} + \begin{bmatrix} W_{ss} & T_{fs} \\ T_{fs}^T & W_{ff} \end{bmatrix} \begin{bmatrix} \dot{u} \\ \dot{q} \end{bmatrix} + \begin{bmatrix} K_{ss} & 0 \\ 0 & K_{ff} \end{bmatrix} \begin{bmatrix} u \\ q \end{bmatrix} = \begin{bmatrix} r_s \\ r_f \end{bmatrix}$$

Here M_{ss}, W_{ss}, and K_{ss} are the structural mass, damping and stiffness. M_{ff}, W_{ff}, and K_{ff} are the equivalent matrices for the fluid. T_{fs} is the fluid-structure coupling matrix. Vector u contains the displacements of structural nodes. Vector q contains the integral of the pressure, that is, the fluid nodal pressure equals $\dot{q}$.

Assuming $u = \overline{U_s} e^{i\omega t}$, $q = \overline{\Phi_f} e^{i\omega t}$, and $r_{f/s} = \overline{F_{f/s}} e^{i\omega t}$, the assembled system of equations becomes complex

$$\begin{bmatrix} -\omega^2 M_{ss} + i\omega W_{ss} + \overline{K_{ss}} & i\omega T_{fs} \\ i\omega T_{fs}^T & -\omega^2 \overline{M_{ff}} + i\omega \overline{W_{ff}} + \overline{K_{ff}} \end{bmatrix} \begin{bmatrix} \overline{U_s} \\ \overline{\Phi_f} \end{bmatrix} = \begin{bmatrix} \overline{F_s} \\ F_f \end{bmatrix}$$

Submatrices K_{ss}, M_{ff}, W_{ff}, and K_{ff} may also be complex and may be frequency dependent. This is the system that is solved for every forcing frequency with *CONTROL_IMPLICIT_SSD_DIRECT.

Appendix X: Multistage Analysis

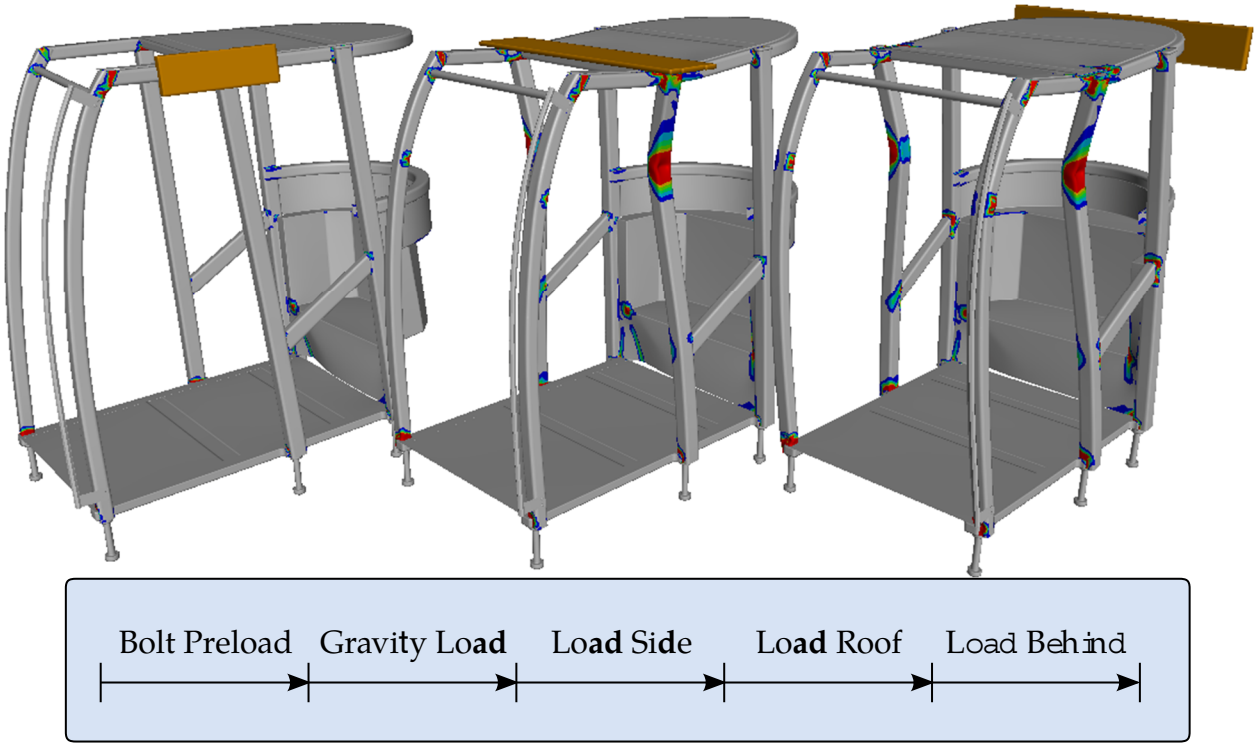

Figure 73-1. Example of Roll-Over Protection Systems simulation with Bolt Preload and Gravity Load

WHY USE STAGES

A typical LS-DYNA simulation is a boundary value problem with initial conditions. It is solved from an initial time 0 (zero) to an appropriate end time T. The initial configuration is usually assumed to be *stress free*, which basically means that all internal variables in all active features are trivially initialized. If the application is sufficiently complex, setting up the input can be cumbersome. The resulting simulation can also be difficult to tackle. In those situations, we can divide the entire problem into several *stages.* A stage is associated with an isolated and well-defined phase of the real physical process. In this sense, a stage naturally defines a *standard* analysis in the following ways:

- No birth or death time in any feature[3]
- Few and simple boundary conditions
- Only implicit or only explicit with no switching between

[3] The only exception is turning on and off dynamics in implicit, which is regarded as a stabilization technique for solving implicit static analyses. See Appendix P for details.

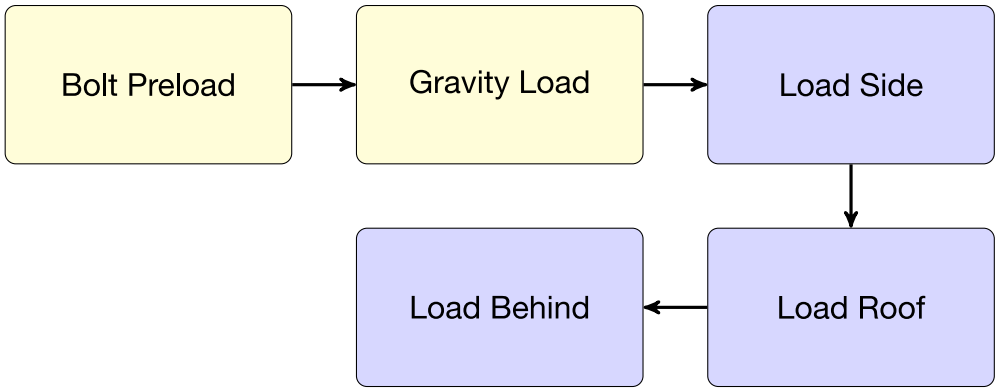

Figure 73-2. Flowchart of how to separate the ROPS test simulation into 5 stages

- Using well defined loadings with simple curves

Each stage is itself a boundary value problem with initial conditions. The only caveat is that the initial configuration may now be *prestressed* because of what occurred in the previous stage. In other words, internal variables must be propagated from the previous stage in order to make sense of future results. Apart from this, each stage can be executed and investigated separately instead of having to complete the entire simulation in a single run.

Example of Splitting into Stages:

To make things less abstract, consider the simple example of a hypothetical cab design subjected to a *ROPS (Roll-Over Protective Systems)* test, ISO requirement 3471, as depicted in Figure 73-1. The legal requirements state conditions for sequential quasi-static loads from the *side*, the *roof* and *behind*, which are graphically illustrated. To make things a little more interesting, we add *bolt preload* and *gravity load* before applying the external loads. Assume for the sake of simplicity that the entire process takes 10 seconds. As indicated, completing the entire simulation in one single run would require everything to be set up accordingly, with the potential risk of having to restart from the beginning in case of execution failure.

The alternative is to identify the 5 stages. Assuming each stage takes 2 seconds, you then set up a separate input for all of them. You run these input files sequentially in the order they apply. Figure 73-2 illustrates this method for setting up the simulation. For the moment we don't worry about the problem of inheriting the internal variables but instead think of what advantages this approach might bring:

- If the simulation fails, restart can be made from the last successful stage instead of rerunning the entire simulation. Thus, turnaround time decreases.
- Some stages may require only a subset of the entire model. Thus, this method reduces simulation time.

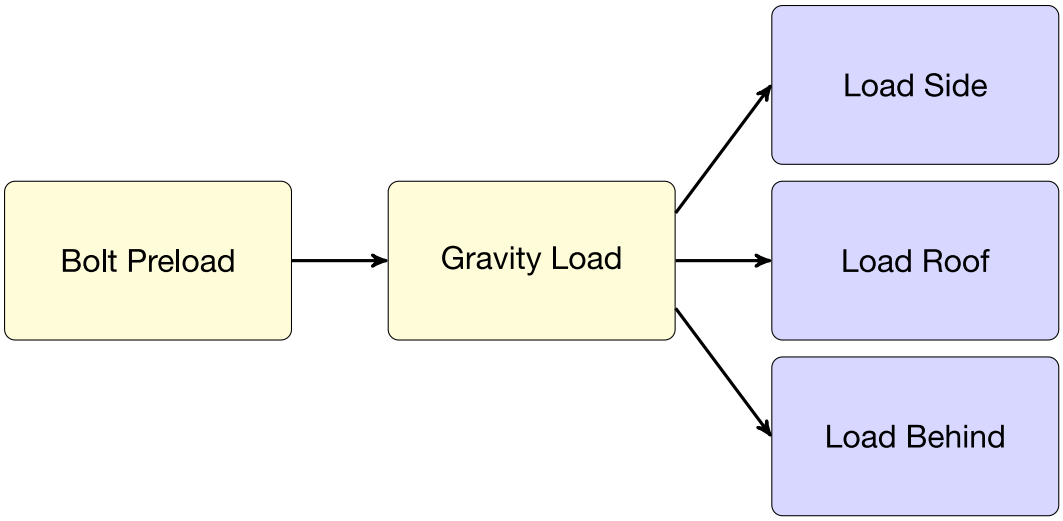

Figure 73-3. Flowchart of a multiple case staged analysis

- Some parts can be rigid during stages, saving simulation time.
- Data from a stage can be reused for many different types of simulations, such as different load cases and eigenvalue analyses.
- A prestressed component can be duplicated in subsequent stages.

So far, we only considered the situation where the stages are executed sequentially, and each case depends on the results of the previous. It is, however, easily seen that a *multiple case* analysis with preloads fits within this framework. Assume, for instance, that you want the response from each of the three external loads *independently*, but with the effect from both bolt preload and gravity load. This situation is illustrated in Figure 73-3. The only difference is that internal variables resulting from the gravity load is imported to each of the three different load cases. The three load cases can be executed in parallel if you have sufficient computer resources.

Simulating a particular stage is on the one hand rather straightforward, but we are left to explain how internal variables are exported from one stage and imported to the next. Although the principles are simple and much can be figured out from logical reasoning, certain situations and features call for a more thorough explanation. With this appendix, we intend to provide the basics and then meticulously go through each feature and situation that requires a more in-depth treatment. We will also explain how all stages can be simulated seamlessly without manual interaction, which is handy if submitting overnight runs.

THE "DYNAIN" APPROACH

The "dynain" approach is a well-known concept among experienced LS-DYNA users, especially in the forming simulation community. The common usage is to output

geometry and stresses of a blank from a forming simulation to a file called dynain, and then include this file in a subsequent simulation, such as springback. This is the simplest form of a multistage analysis, that is, porting stress between two simulations. Here we describe this approach for general situations.

Formats:

The first thing to observe is that the format of a dynain file can be one out of three: *ascii, binary* or *lsda* format.

1. The *ascii* format is popular because you can open it in a text editor and, thereby, inspect and edit the file. It is not, however, capable of representing the full *system state* of a particular simulation result. The *system state* is not only stresses and strains, but everything that is needed to seamlessly continue the process without losing any information. In particular, it requires the state from the contacts, like friction history and information from tied contacts.

2. The *binary* format is not used extensively and is therefore of no interest here.

3. The format we want to use for multistage analysis is the *lsda* format, since it handles most of the internal variables for obtaining an acceptable result. From now on we will refer to the file as the dynain.lsda file.

LSDA format:

The dynain.lsda file is in a sense "just" a regular keyword file. It is bound to the rules and regulations for that particular reader.

It is generated by LS-DYNA from a previous run, but the content is whatever you may find in any other keyword file, such as nodes, elements, initial stresses, etc. It can be included from any other keyword file. Given this prerequisite, and that you are familiar with the keyword format, much of what is about to be presented will make sense from your own experience.

It may contain keywords that are not available in the ascii format. These keywords are for representing the system state as accurately as possible. In particular, it contains stabilization forces and contact history. These are yet to be documented, but the lsda format does not currently have documentation, so this is not a showstopper.

Finally, it is a high-level *binary* format. The content is organized like a file system. To process it, you need an lsda *reader*. Both LS-PrePost and LS-DYNA have built-in lsda readers, but at this moment LS-PrePost is not able to *interpret* all the data correctly. We have an external reader called *ioq*, that can be used to parse through the hierarchical structure of the file with standard linux commands such as *cd, ls* and *cat*. This reader cannot

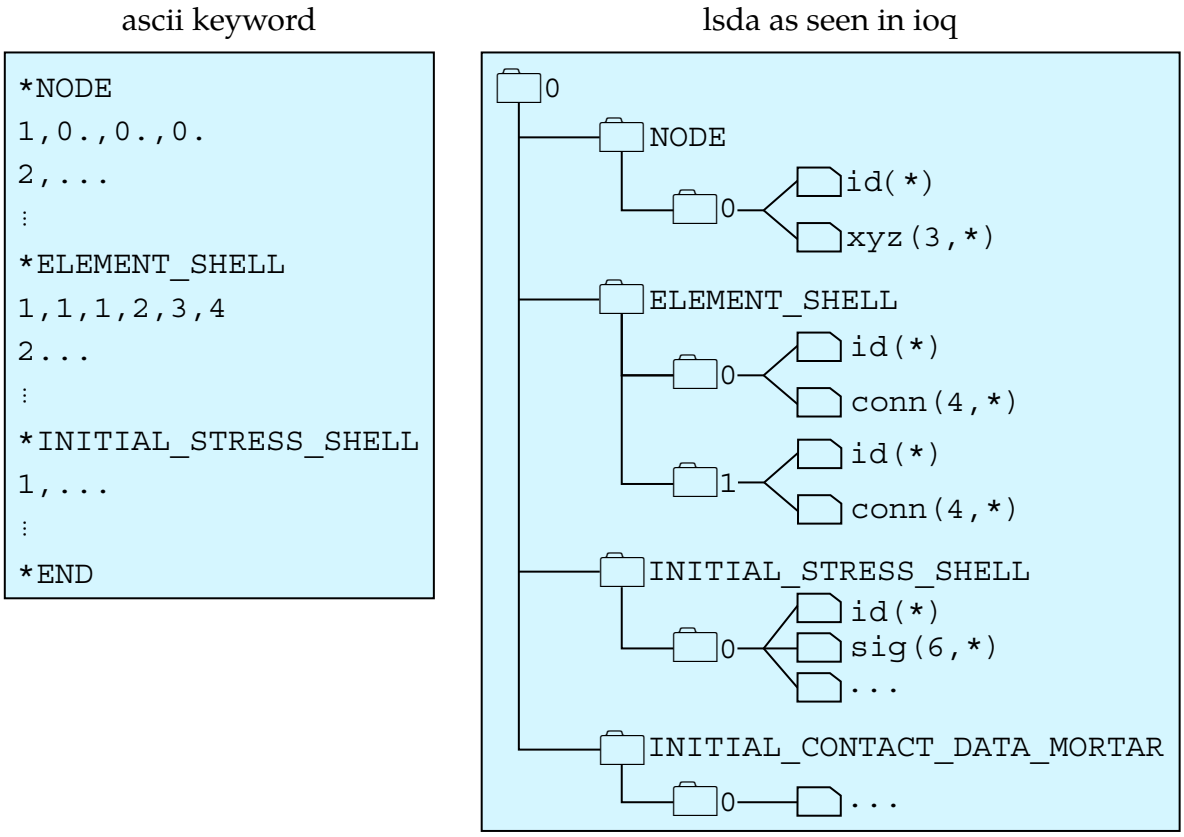

Figure 73-4. Comparison of the structure of *ascii* and *lsda* formats for the dynain file

edit the file. Figure 73-4 schematically illustrates the contents of a dynain file for the ascii and lsda formats, respectively. Note that the enumerations "0" and "1" for some directories are for organizational purposes. We also highlight that the lsda file may contain keywords not supported by the ascii format (here exemplified by INITIAL_CONTACT_-DATA_MORTAR).

Discussion

Juggling many stages soon becomes overwhelming. We recommend giving each stage a *job ID*, which will put a prefix on the dynain.lsda (and all other output) files so that you can distinguish one stage from another. One may either use jobid=A on the command line when executing the stage, or use

```
*KEYWORD_ID
A
```

in the main input file to make sure the dynain.lsda file will be named A.dynain.lsda to indicate that this is data from stage *A*. Using *CASE statements is another way of organizing the stages. *CASE will be described later.

Remember that dynain.lsda *represents* the keyword format in a different way than its ascii counterpart, but that it is nevertheless processed by the keyword reader and should be seen as a natural inclusion to a standard keyword input file. A strong argument in favor of this approach, when compared to other multistage functionalities, is *repeatability*. By restricting all inputs to be keyword and be processed by the same reader facilitates maintenance of the software and thus reduces the risk of i/o problems and related bugs. Stages are advantageous since they constitute a *simple* keyword input. With stages, we can avoid complexities associated with activating/deactivating, switching, using complicated curves and other forms of out-of-the-box solutions that are not part of main stream simulations.

This being said, the dynain approach is by no means trivially understood and failsafe, especially without an appropriate graphical user interface (GUI) to aid the user. But with the right information and tools at hand, it is a powerful framework to deal with complicated processes. We now intend to provide this information and present the tools for dealing with multistage analyses. We refer to Figure 73-5 to enhance understanding. In particular, we will meticulously go through the details for exporting data from one stage and importing this data to the next.

EXPORTING DATA

Referring to Figure 73-5, assume that we are about to simulate stage *B*, represented by the main keyword file B.k together with include files generated by previous *A* stage(s). For the sake of simplicity, we assume that only dynain.lsda files are included, and B.k is the only ascii file. The keyword required for exporting the results from stage *B* for use in a subsequent stage is *INTERFACE_SPRINGBACK_LSDYNA. It should be part of the input in B.k. A more detailed description of this keyword can be found elsewhere in the keyword manual, but here we provide a recommended setup and discuss the various parameters.

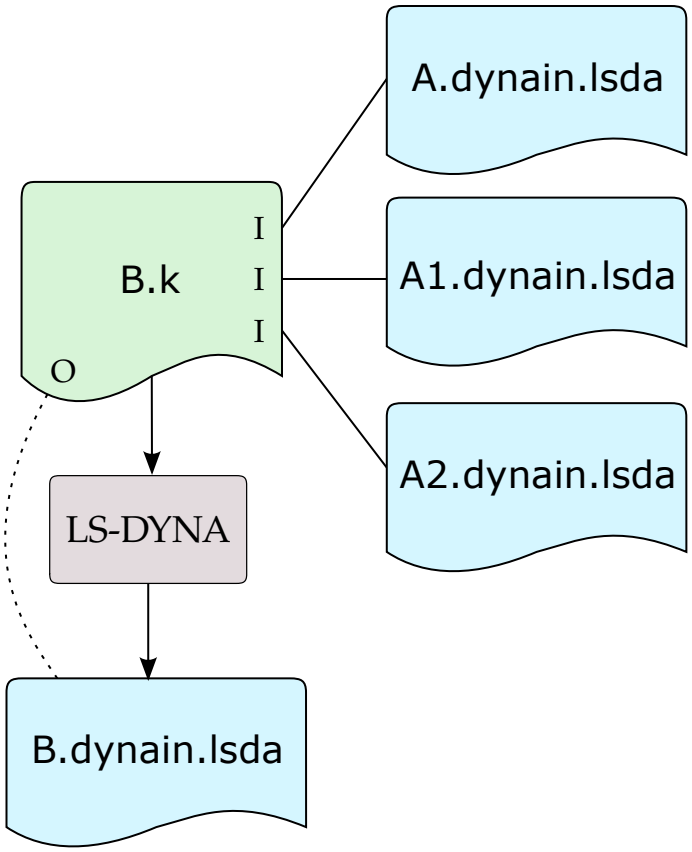

Figure 73-5. Basic schematic of including dynain.lsda files from previous stages in stage *B*. The I in the B.k box stands for an instantiation of *INCLUDE. In this case, A.dynain.lsda, A1.dynain.lsda, and A2.dynain.lsda are output by previous stages and are included in stage *B*. The O in the figure stands for output through *INTERFACE_SPRINGBACK_LSDYNA. With this keyword in the input deck for stage *B*, LS-DYNA exports B.dynain.lsda.

Outputting Data with *INTERFACE_SPRINGBACK_LSDYNA

In the two tables below, we list the needed input in the data cards for *INTERFACE_-SPRINGBACK_LSDYNA with recommended below. In this section we will give motivation for the recommended values of each of the variables.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID	NSHV	FTYPE				RFLAG	
Value	999	999	3				1	

APPENDIX X

Card 2	1	2	3	4	5	6	7	8
Variable	OPTC				NDFLAG	CFLAG	HFLAG	
Value	OPTCARD				1	1	1	

PSID = 999
We recommend reserving 999 (or some other favorite number) as the ID for a part set (see *SET_PART) containing parts to be carried over from stage *B* to stage *C*. The resulting B.dynain.lsda file will have the nodes with coordinates and elements with stresses/forces for *at least* those particular parts at the end of the simulation. More nodes will be output (see discussion of NDFLAG below) but not more elements.

Note that none of the *PART, *SECTION, and *MAT keywords are output to the B.dynain.lsda file. They must be inserted in the main file C.k for stage *C* or the simulation will error terminate. Using the same section and material for the same part throughout the entire process is convenient and often sufficient *but not mandatory*. For instance, when going from a quasi-static implicit stage to a dynamic explicit stage, you may want to switch from a fully integrated element formulation to a formulation with hourglass control. In this case, the stresses will be mapped onto the new integration point configuration, resulting in loss of accuracy. In rare situations you might want to alter the material as well. This situation is discussed in conjunction with NSHV below.

We *strongly* recommend associating part, node and element numbers with the actual physical components and their material locations throughout the process. By this, we mean that if a particular node number or element number is used for a certain material point or region, then the same number should *not* be reused for some *other* material point or region. For instance, say that we have a forming simulation where the tools have node numbers between 1 and 100000, and the blank between 100001 and 200000. Then you decide to only output the blank to the dynain.lsda file because the tools are no longer of importance. In the next stage you want to mount the blank onto a vehicle as part of the construction process, where some *new* parts are introduced to act as the rest of the car. It is tempting to reuse node numbers 1 through 100000 since these numbers are "available" again. You should use new numbers and *not* reuse the numbers because you will eventually run into trouble with duplicated nodes. The same recommendation applies to element and part numbers.

Selecting parts for PSID is difficult since it presupposes knowledge of what will be performed next. Any part that is *not* included in PSID can in general not be reintroduced without resetting stresses and history. Parts that *are* in PSID *will* be included in the next stage no matter what. But what if the situation demands that some parts are of interest in one particular branch of a continuation, and some other parts of interest in another? You might, for instance, want to do several sub-model analyses on disjoint components

given the stresses from a global gravity load. You might also forget to include a certain part that you need. You can always output all parts with:

```
*SET_PART_LIST_GENERATE
999
1,99999999
```

and then *exclude* some parts when importing the data in the subsequent analysis. This strategy might lead to a large dynain.lsda file, but it is convenient. We will discuss it further when dealing with importing data, specifically in the section Excluding Parts in Subsequent Stages g.

NSHV = 999
You should set NSHV to a "large" number to include all history variables for the elements contained in the part set PSID above. 999 should be enough assuming no material has no more than 999 history variables. We assume that the material models used for a particular element in stages *B* and *C* are not necessarily the same but *compatible.*

Compatible material models are those for which the mapping of stresses and history variables make physical sense. It is difficult to know which ones *are* compatible without consulting expertise. Generally, we only recommend switching from rigid to some deformable material model. This switch is useful when the deformation of some parts can be neglected for some stages. These parts can be defined as rigid until the stage of interest begins. All the stresses and histories for these parts will be trivially initialized. Note that we do not recommend switching a deformable part to a rigid part. A part that is deformable for some duration and then switched to rigid will be *reset* in terms of stress and history variables.

FTYPE = 3
Setting FTYPE = 3 causes the output dynain file to be in lsda format, which is what we *always* want.

RFLAG = 1
For any feature that depends on the referential coordinates, you need to set RFLAG to 1. Hyperelastic materials require this setting because the stress depends on the deformation gradient. This setting also affects the calculation of initial quantities that are important for the outcome of a simulation. For other features, setting RFLAG to 1 does not do any harm. It does ensure that *any* stage has the coordinates from the start of the *first* stage for the referential coordinates. As a result, hyperelastic stresses remain continuous throughout the process.

Hyperelastic materials may use a special reference geometry with either *INITIAL_AIRBAG_REFERENCE_GEOMETRY (shells) or *INITIAL_FOAM_REFERENCE_GEOMETRY (solids). When these keywords determine the reference geometry for selected materials in the first stage, then this section of the input *must* be copied to the main file for all remaining stages, and the materials in question must refer to this data (see REF on

the corresponding material cards). These two keywords are *not* ported through the dynain.lsda file. If they are not included in the input for each stage, the hyperelastic stresses will depend on the *actual* reference coordinates in the first stage, assuming RFLAG is set to 1. We will continue this discussion later when dealing with importing data, specifically in the section Deformation Gradient and Stress Update.

NDFLAG = 1
As mentioned earlier, by default, only the nodes and elements belonging to parts in PSID are output to the dynain.lsda file. This behavior is not always sufficient for adequately continuing a process. For instance, some nodes could be part of nodal rigid bodies or interpolation constraints without being associated to *any* part. The updated locations and orientations of these nodes also need to be carried over between stages. Setting NDFLAG = 1 will make sure that *all* nodes are output to the dynain.lsda file. As long as you follow the practice of not reusing a used node, there should be no reason to not *always* set this. Nodes that for some reason are not hooked up to parts or connectors in remaining stages will simply be constrained or massless and should not affect the outcome of the simulation.

CFLAG = 1
This flag is for output of contact history and tied contact pairs. It should *always* be set to not lose any such information. When this flag is active, *all supported* contacts will be output to the dynain.lsda file, regardless of which ones will be of interest in later stages. The philosophy behind this decision is the same as for elements and nodes discussed above. When importing the data, we simply discard everything that is not hooked up to contact entities in later simulations.

Note that the *CONTACT card itself will *not* be output to the dynain.lsda file, only the segments and their associated data. Therefore, you must copy and paste these lines from one main input file to the next in order for simulations to work properly. The pasting can be done with modifications in ways that will be apparent when we discuss importing data, specifically in the section Contact.

Because of the abundance of contact formulations in LS-DYNA, the flag applies only to *some* regular and *some* tied contacts. We will discuss these two classes of formulations separately, starting with regular (non-tied) contacts.

The flag is supported for *all* Mortar contacts, but none of the other contact algorithms. The multiple stage approach is in a sense limited to applications where Mortar contact is the preferred choice or is good enough. In situations, where for instance an implicit gravity load is to be followed by a crash simulation, you may need to switch from mortar to a (faster) contact at the expense of losing contact stress history.

The output is organized in chunks of the form *{contact segment ID, data for this segment}* or *{contact node ID, data for this node}*, depending on the type of contact. Since Mortar contact

is a segment-to-segment contact, we only have the former situation at the moment. We will only discuss this situation in the following.

The *contact segment ID* is uniquely defined as the pairing *{contact ID, segment node IDs}*, where *contact ID* is simply the identity of the contact given through the option _ID on the *CONTACT card. To properly map the data, you must specify a contact ID *and* use the same identity for the same contact in subsequent stages. The *segment node IDs* are the node numbers as given by you in the input file, reordered so that the smallest number comes first. The mapping of data occurs when a matching *contact segment ID* is found in the dynain.lsda file and among the actual contacts in the input file.

The *data for this segment* is currently specific to the contact of choice. The format is of little interest to the user. It simply contains enough information for properly migrating the state of the contact between stages, and the mapping is performed with no sophistication. It is, for instance, not possible to map data between different *types* of contacts, which essentially means that the same contact type must be used throughout the entire process. There are *some* allowed operations for changing the behavior of the contact between stages. The section concerning contact in importing data will discuss these allowed operations.

Our implementation for tied contacts follows similar conventions. For instance, the *CONTACT card must be copied between main files for the simulations to work properly. Before delving into further details, we need to elaborate on the extent of support for various tied contact formulations. Explicit and implicit tied contacts are in general different formulations which adds some complications. Explicit tied contacts are *incrementally* objective while implicit are *strongly* objective. Because of this, the internal variables used for keeping track of the tied stress logic is different, and it is nontrivial to map between the two. We added IACC = 2 on *CONTROL_ACCURACY to unite the tied contact formulations. IACC = 2 allows for switching between explicit and implicit with no loss of information. It ensures that the implicit contacts are executed even for explicit analysis. We, therefore, recommend always setting IACC to 2 for multiple stage analysis. If IACC = 1, internal variables are not properly ported. The actual *pairs* will be ported correctly, but the forces/stresses that have been built up during a stage will not be correct in subsequent stages. As an alternative, you could always set IACC to 0 for which the explicit contacts will be executed even for implicit analysis. IACC set to 0 should also be used if all stages are explicit.

The output to the dynain.lsda file for a tied contact is chunks in the form *{contact ID, node ID, segment node IDs, data}*. As before, *contact ID* is from the option _ID on *CONTACT. *{node ID, segment node IDs}* are the tied contact pairs in user node numbers. The *data* field constitutes the internal variables needed for computing the tied contact forces. As soon as a contact using a specific *contact ID* occurs in the dynain.lsda file, the tied contact pairs for that particular contact are generated solely from the information given therein, and *no* new tied contact pairs are generated even if the logic for tying is fulfilled. All mortar

tied contacts are also supported, for which the chunks are instead in the form *{contact ID, segment node IDs, segment node IDs, data}* since the tying occurs between segments and not nodes and segments. Except for this, the same treatment applies.

HFLAG = 1
By default, internal variables associated with *integration points*, such as stresses and material related history, are ported between stages. Stabilization forces, such as drilling and hourglass forces, may depend on their own internal variables. These variables may also need to be transferred for a complete description of the system state. We recommend setting HFLAG to 1 to deal with these internal variables. We will proceed to discuss the two mentioned types of stabilization.

In implicit analysis, *drilling* stabilization is on by default, otherwise shell elements would suffer from incompleteness. Usually, everything is taken care of automatically. If all stages are implicit, we can end the discussion here. If the implicit analysis is followed by an explicit analysis, the drilling stabilization will be turned *off* in the latter since explicit drilling resistance is by default handled through the rotational inertia of the shell element nodes. This transition results in loss of equilibrium. In practice this may not mean much, but, if you are picky, you can deal with this by using DRCPSID on *CONTROL_SHELL to invoke drilling stabilization even in explicit analyses. Doing so for all shell parts leads to force continuity between the implicit and explicit stages.

For elements with reduced integration (shells or solids), stiffness based *hourglass* stabilization may be invoked to complete the element. These hourglass models update the internal forces in a similar fashion to how the integration point stresses are incremented. These forces need to be output to the dynain.lsda file. To maintain equilibrium, all stages need to keep the same element formulation and hourglass model. Otherwise, these forces will be lost in the transition. Again, this may be of little practical importance, but nevertheless a good thing to know.

Boundary Conditions

Before discussing the importing of data from the previous stage, we need to emphasize that the two lines

```
*INTERFACE_SPRINGBACK_EXCLUDE
BOUNDARY_SPC_NODE
```

must be present in all stage files. Otherwise, the boundary conditions are inherited from the previous stage. With these lines, we are free to use whatever boundary conditions we like for each stage.

IMPORTING DATA

Let's assume stage *B* has been completed. Then, to import stage *B*'s data for stage *C*, add the lines

```
*INCLUDE
B.dynain.lsda
```

to the main file C.k. Assuming no conflict (that is, all element and node numbers are unique), you can include several files, each resulting from separate previous runs

```
*INCLUDE
B.dynain.lsda
B1.dynain.lsda
B2.dynain.lsda
…
```

You can also include the same file several times, but the data must be transformed differently for each include so that again there are no conflicts

```
*INCLUDE
B.dynain.lsda
*INCLUDE_TRANSFORM
B.dynain.lsda
*INCLUDE_TRANSFORM
…
```

Adding these lines is in principle how importing data works with the catch that the include files need to be complemented with accompanying *PART, *SECTION, *MAT, *CONTACT, etc. cards in the main file C.k to render a sensible continuation of the process. In this section we lay out the details concerning which keywords need to be reinserted into C.k and which ones appear in the include file B.dynain.lsda from the previous stage.

Excluding Parts in Subsequent Stages:

First, let's continue the discussion about PSID = 999 from the section on Outputting Data with *INTERFACE_SPRINGBACK_LSDYNA. Recall that only the parts specified in this particular part set in B.k are output to the B.dynain.lsda file. This requirement could be a problem if the parts to be used in subsequent stages are not known *a priori*, or if you want to perform several sub-modelling analyses using data from the same previous run. We previously indicated that you may output *all* parts and then use only those of interest in subsequent stages. This strategy will circumvent this conundrum. For it to work you will need to include *CONTROL_LSDA in the main file C.k. For details we refer to the corresponding keyword description elsewhere in the manual, but its application is best explained through a simple example.

For the sake of simplicity, assume that stage *B* consists merely of three parts, enumerated from 1 to 3. By include the following in B.k,

```
*SET_PART_LIST
999
1,2,3
```

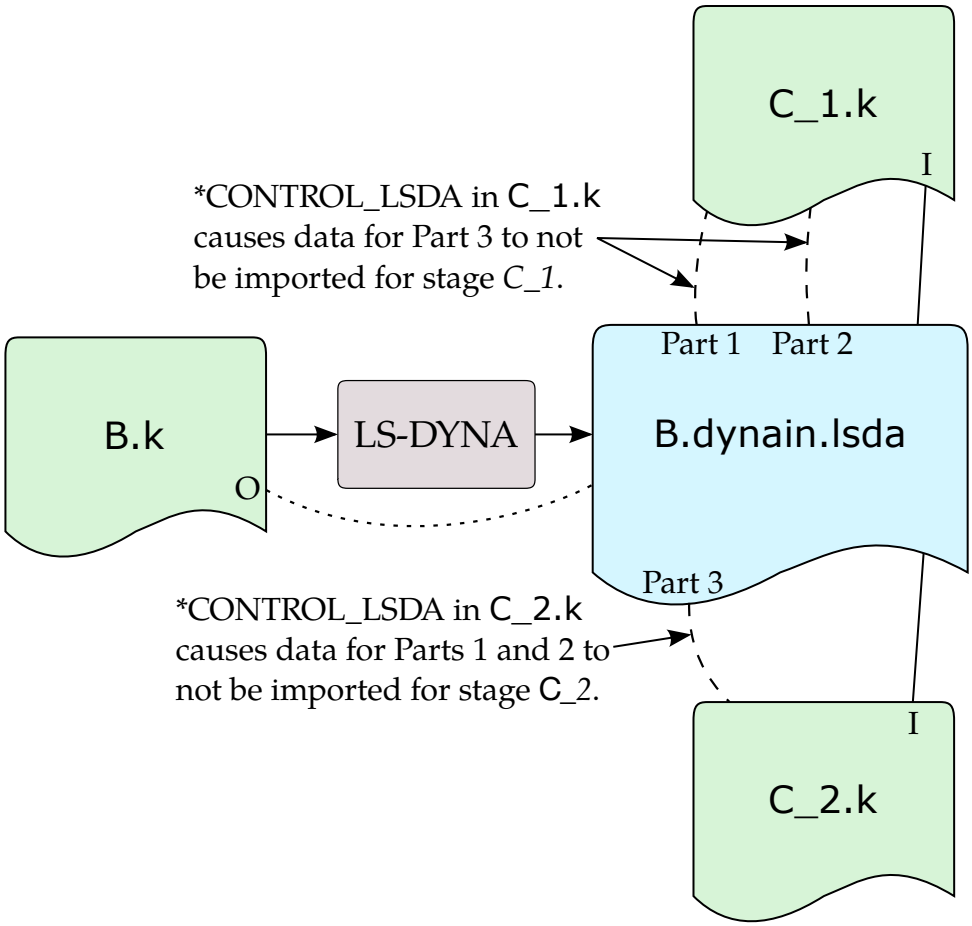

Figure 73-6. Illustration of how parts can be excluded in subsequent analyses. In this example. Stage *B* contains the full model. For stage *C_1* Part 3 is excluded from the analysis due to *CONTROL_LSDA while for stage *C_2* Parts 1 and 2 are excluded.

```
*INTERFACE_SPRINGBACK_LSDYNA
999,…
*PART
Part 1
1,1,1
*PART
Part 2
2,2,2
*PART
Part 3
3,3,3
```

LS-DYNA will output all three parts to B.dynain.lsda, including their respective nodal positions and integration point data.

We can now in one particular continuation, say stage *C_1*, insert

```
*CONTROL_LSDA
$ Number of parts to exclude
1
$ Part to exclude
3
*PART
```

```
Part 1
1,1,1
*PART
Part 2
2,2,2
```

into C_1.k to actually use only parts 1 and 2. And in another, say stage *C_2*, insert

```
*CONTROL_LSDA
$ Number of parts to exclude
2
$ Parts to exclude
1,2
*PART
Part 3
3,3,3
```

into C_2.k to use only part 3.

This approach is illustrated graphically in Figure 73-6. Note that the *PART card for the active parts need to be reinserted in each continuation.

Changing Element and Material Types:

Just as the *PART card is needed in a continuation, the *SECTION and *MAT cards are needed as well. In almost every situation you would just copy them from the previous stage, assuming things can proceed without sacrificing execution speed or accuracy. In rare cases, you may want to change element formulation or maybe even material model.

The element formulation is preferably changed when switching from an explicit stage to an implicit stage, or vice versa. Fully integrated elements (such as type -16) enhance accuracy in implicit without significant speed penalty while reduced integration elements make explicit computationally efficient while maintaining sufficient accuracy. For example, stage *B* may have

```
*CONTROL_IMPLICIT_GENERAL
1,1.0
*SECTION_SHELL
1,-16
1.,1.,1.,1.
```

in *B.k*, and stage *C* continues the process with

```
*CONTROL_IMPLICIT_GENERAL
0
*SECTION_SHELL
1,2
1.,1.,1.,1.
```

in *C.k*. The stresses from elements of type -16 in stage *B* will be averaged in the plane for use in the type 2 shells of stage *C*, leading to loss of accuracy. Had it been the other way around, the single point stress in the Belytschko-Tsay shell would be scattered to the four in-plane integration points of the fully integrated shell, impacting the accuracy of the transition. We recommend maintaining section properties between stages as much as possible.

We do not recommend switching materials either in general. As mentioned in the discussion of NSHV = 999 under Outputting Data with *INTERFACE_SPRINGBACK_LS-DYNA, you *may* use a rigid material for a subset of parts during the first few stages, and then switch them to a deformable material when loaded accordingly. Switching back to a rigid material later will rigidize the parts in the deformed state, causing you to lose the internal variables. You must decide if losing this information for subsequent stages is acceptable.

Inertia Properties of Rigid Bodies:

Concerning the *PART card, the particular keyword *PART_INERTIA needs special attention. Again, recall that LS-DYNA will interpret the keyword as written which is a problem if the inertia properties are provided in global coordinates. Consider a rigid body that initially has a center of mass located at

$$\mathbf{x}_c = \begin{pmatrix} 5 \\ 0 \\ 0 \end{pmatrix}$$

and an inertia tensor along the global axes

$$\mathbf{I}_c = \begin{pmatrix} 3 & & \\ & 2 & \\ & & 1 \end{pmatrix}.$$

The part input for this body would be

```
*PART_INERTIA
Global inertia
1
…
$ XC YC ZC TM
5,0,0,1
$ IXX IXY IXZ IYY IYZ IZZ
3,0,0,2,0,0,1
$ No velocities
…
```

Now, if the body translates a distance 1 in the global x direction and rotates 90 degrees about this axis during the first stage, then the rigid body properties at the end of the simulation are

$$\mathbf{x}_c = \begin{pmatrix} 6 \\ 0 \\ 0 \end{pmatrix}$$

and

$$\mathbf{I}_c = \begin{pmatrix} 3 & & \\ & 1 & \\ & & 2 \end{pmatrix}.$$

Consequently, if the *PART_INERTIA card is copied between stages as we have recommended, the inertia properties will always take the values from the beginning of the entire process, resulting in apparent errors. The strategy for circumventing this is to define

inertia properties with respect to local positions and a local coordinate system that follows the motion of the body. To do this, put a node at the center of mass and let NODEID refer to this node. Also, set IRCS = 1, and let CID refer to a coordinate system defined by nodes attached to the rigid body in question. The nodes needed for NODEID and CID can be defined by *CONSTRAINED_EXTRA_NODES. The keywords for the example above would be

```
*PART_INERTIA
Local inertia
1
…
$ XC YC ZC TM IRCS NODEID
,,,1,1,999
$ IXX IXY IXZ IYY IYZ IZZ
3,0,0,2,0,0,1
$ No velocities

$ XL YL ZL XLIP YLIP ZLIP CID
0,0,0,0,0,0,99
*NODE
999,5,0,0
9999,6,0,0
99999,5,1,0
*CONSTRAINED_EXTRA_NODES_NODE
1,999
1,9999
1,99999
*DEFINE_COORDINATE_NODES
99,999,9999,99999
```

The above is for the first stage. In all remaining stages the nodes will be contained in corresponding dynain.lsda files, while the other cards are copied between stages.

The same method must be used for *CONSTRAINED_NODAL_RIGID_BODY_INERTIA which has the same keyword data (except the coordinate system in input in field CID2) and *ELEMENT_INERTIA which can similarly be defined using a coordinate system based on nodal coordinates. In sum, care should be taken when simulating components with the INERTIA option.

Deformation Gradient and Stress Update:

As we discussed previously in the RFLAG = 1 section, we recommend always setting RFLAG to 1 on *INTERFACE_SPRINGBACK_LSDYNA. This flag mainly affects materials that somehow employs the deformation gradient for the stress update. All materials have their own set of history variables that are used for computing stresses. We loosely call a material *hyperelastic* if the deformation gradient or stretch tensor is an essential part of the history content and needed for computing the stress.

The deformation gradient can be computed in two different ways, governed by FMATRX on *CONTROL_SOLID. For FMATRX = 1 it is numerically incremented based on the strain and spin rate while for FMATRX = 2 it is computed directly as a relation between the current and reference configurations. In the FMATRX = 1 case, nothing needs to be

known about the reference configuration. Consequently, RFLAG would not be needed to migrate between stages. It would be just like a *hypoelastic* material situation where everything is incrementally updated. Nevertheless, we strongly recommend using RFLAG = 1 as a template. For FMATRX = 2, the reference configuration needs to be the same throughout the entire process. Keeping RFLAG = 1 will ensure that it will always be the one from the very first stage. Note that if FMATRX = 1 in one stage and FMATRX = 2 in the next, the stress will slightly change at the transition. This discrepancy is because FMATRX = 1 will have numerical errors associated with the updates while FMATRX = 2 will completely ignore the stored deformation gradient and recompute it directly. Conversely, FMATRX = 2 in the first stage followed by FMATRX = 1 in the next will *not* cause a change in stress since the stored deformation gradient from the first stage will be used directly in the next.

Hyperelastic materials can use the keyword *INITIAL_FOAM_REFERENCE_GEOMETRY for the reference configuration. Using this keyword will override any other reference configuration for computing initial and current deformation gradients. Therefore, it needs to be copied between stages if used to maintain consistency in the way the deformation gradient is computed/incremented.

The discussion above pertains to solid elements. For shells and beams the deformation gradient is in general numerically incremented, except for fabric materials (*MAT_FABRIC). For fabric materials the discussion is slightly modified. For instance, no corresponding FMATRX flag exists. The deformation gradient is computed based on the reference geometry from the first stage. Also, instead of *INITIAL_FOAM_REFERENCE_GEOMETRY, you would use *INITIAL_AIRBAG_REFERENCE_GEOMETRY which again overrides any other reference configuration definition. Nevertheless, always use RFLAG = 1.

Contact:

As discussed in the CFLAG = 1 section, contact histories are ported for a selection of contacts when CFLAG is 1 on *INTERFACE_SPRINGBACK_LSDYNA. The *CONTACT card itself, for the contact with a given ID, must be explicitly included in the keyword file in the continuing simulation. Recall that the dynain.lsda file contains the contact history for all supported contact types from the previous simulation. To read this information, the *CONTACT card ID must match the ID for the history data in the file must match. As discussed earlier, involved contact segments must also match in the sense of having the same user nodal IDs. Let's discuss some hypothetical situations beginning with the penalty contacts.

In a common scenario, the contact definition in subsequent runs is identical to the first run, using the same contact ID, same number of contact segments, and same corresponding user nodal IDs. We *are*, however, allowed to deviate from this restriction. For instance, if a part is added to the subsequent simulation, this part may be included in the

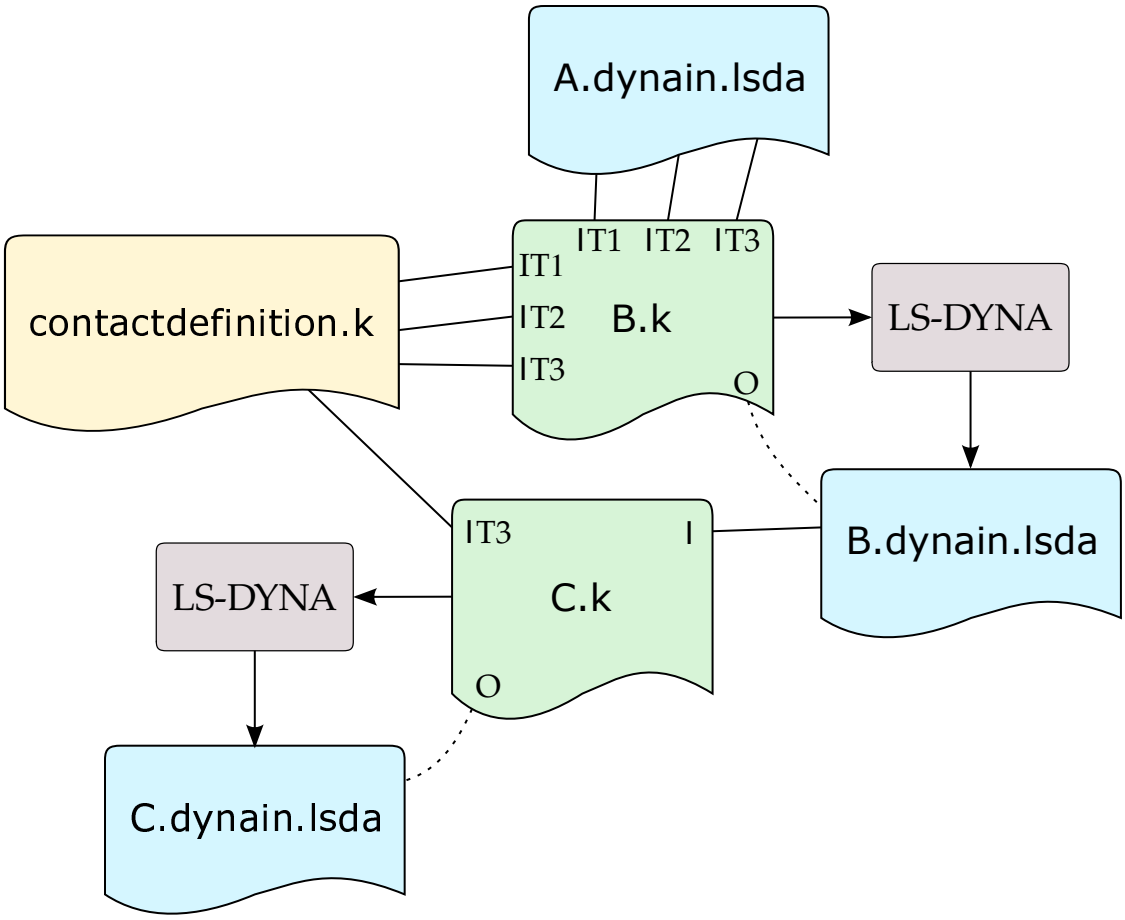

Figure 73-7. Example of including a component several times with transformations. In this example the component from stage *A* is included in Stage *B* three times. Because the same file is being included several times, you must use the keyword *INCLUDE_TRANSFORM. IT*i* indicates a *INCLUDE_TRANSFORM with TRANID *i*. The contact definition must also be included for each component with the same corresponding TRANIDs. For subsequent stage *C*, if we only want the third component, then we include the contact definition again with TRANID = 3. B.dynain.lsda does not need to be transformed since it already contains the transformed component.

contact. This additional part will render additional segments for which there will be a clean sheet of history variables. These segments may come into new contact situations while the other segments will have their history inherited. We can also consider removing a part from the model and consequently from the contact. Any remaining segments that *were* in contact with the deleted part will be given no contact force and will be reset in terms of history variables. Finally, you can change the contact stiffness scale factor SFSA if needed.

For tied contacts, there aren't many exceptions to the rule of keeping the contact as is. Departing from the same contacts tends to result in situations for which the behavior is ambiguous. The mortar tied contacts offer some interesting switch options that may be

worth discussing. For instance, you can execute a stage using the keyword *CONTACT_..._MORTAR_TIED_WELD. This contact essentially starts off as a regular, non-tied contact but will tie segments based on weld conditions as a result of the simulation. During the next stage, the keyword may be changed to *CONTACT_..._MORTAR_TIED, or *CONTACT_..._TIEBREAK_MORTAR, assuming the welding part of the process is now done. The segments that were tied during the first stage are inherited to the next and the behavior will for the remaining process be just as for a regular tied or tiebreak contact.

Sometimes you need to include the same dynain.lsda file several times with different transformations using *INCLUDE_TRANSFORM. For instance, a small, preloaded component may be spatially distributed in a larger assembly. This feature is supported for the state of contact, including ID and nodal offsets, but it requires that *all* segments in contact are transformed as a unified rigid body. Note also that you need a *CONTACT card for each included file where the ID is transformed as the ID in the dynain.lsda file. If many such transformations are required, you can put the contact definition in a separate file and include that the same way as the dynain.lsda file. Figure 73-7 illustrates the case where a component is simulated in stage *A* and distributed in three instances for stage *B*. Note the treatment of the contact definition.

The keyword syntax in B.k would be

```
*INCLUDE_TRANSFORM
A.dynain.lsda
…
$TRANID
1
*INCLUDE_TRANSFORM
A.dynain.lsda
…
$TRANID
2
*INCLUDE_TRANSFORM
A.dynain.lsda
…
$TRANID
3
*INCLUDE_TRANSFORM
contactdefinition.k
…
$TRANID
1
*INCLUDE_TRANSFORM
contactdefinition.k
…
$TRANID
2
*INCLUDE_TRANSFORM
contactdefinition.k
…
$TRANID
3
```

The contact definition file is the same as when simulating stage *A*, just copied between stages. In stage *C*, assume we just want to keep the third component, meaning that we

only need to keep the contact definition for that particular contact. The syntax in C.k would then be

```
*INCLUDE
B.dynain.lsda
*INCLUDE_TRANSFORM
contactdefinition.k
…
$TRANID
3
```

Note that the included dynain.lsda file needs no transformation since it already has the transformed quantities from the first transformation between stages *A* and *B*. This hypothetical example should provide insight into the interrelation between the resulting dynain.lsda files and main keyword ascii files. It should all make sense when recalling the basics of the keyword format.

Stabilization Forces:

Porting stabilization forces is done more or less automatically. the only concern is the compatibility between implicit and explicit. Following the discussion earlier (HFLAG = 1), we recommend invoking drilling restraints with DRCPSID on *CONTROL_SHELL, even for explicit analysis. Furthermore, using hourglass type 6 for solid elements and type 4 for shell elements is also a good practice. It would lead to continuity in the stabilization forces between stages. Departing from these recommendations may not be a terrible thing to do, but you should be aware of the possible consequences.

CASES

So far we have assumed that you execute runs sequentially and manually. Sometimes simulating all stages in a single run is convenient. For instance, suppose you need to submit an overnight run where you want all stages to be simulated, and you want to take advantage of multistage capability for reasons to be given. The keyword *CASE allows you to do setup a multistage simulation in a single run. Here we exemplify this usage by reconsidering the example at the beginning of this Appendix, the ROPS test. We emphasize that this problem may be set up in many equivalent ways. We will present here merely a suggested organization of files that should serve as a reasonable template. To shorten this section, we will skip the "gravity load" and the "load from behind" for this discussion.

The main process file would contain the definition of all cases (= stages), the card for writing the dynain.lsda file and perhaps other data that is common for all stages. It would look something like

```
*KEYWORD
$
$ Meta data for cases
$
*CASE
1,BoltPreload
```

```
*CASE
3,LoadSide
*CASE
4,LoadRoof
$
$ First case is defined all in ascii
$
*CASE_BEGIN_1
*INCLUDE
BoltPreload.k
*CASE_END_1
$
$ Remaining cases define bulk in ascii,
$ and includes the state from previous dynain.lsda file
$
*CASE_BEGIN_3
*INCLUDE
LoadSide.k
BoltPreload.dynain.lsda
*CASE_END_3
*CASE_BEGIN_4
*INCLUDE
LoadRoof.k
LoadSide.dynain.lsda
*CASE_END_4
$
$ Output "everything" to dynain.lsda
$
*INTERFACE_SPRINGBACK_LSDYNA
…
*INTERFACE_SPRINGBACK_EXCLUDE
BOUNDARY_SPC_NODE
$
$ Mounting of the cab, present in all stages
$
*BOUNDARY
…
*END
```

We then need to define each of the cases. We will start with the bolt preload. The bolt preload is the "easy" load case since it does not involve any inclusions of data from previous stages. Without further ado, BoltPreload.k would look something like

```
*KEYWORD
*TITLE
Bolt preload
$
$ Part data for the cab
$
*PART
…
*PART_INERTIA
…
*SECTION
…
*MAT
…
$
$ Nodes and elements for the cab
$
*NODE
…
*ELEMENT_...
…
$
$ Potential other cards required for the cab
```

```
$
*ELEMENT_MASS
…
*ELEMENT_INERTIA
…
*CONTACT_...
…
*CONSTRAINED_...
…
$
$ The specific load case follows
$
*INITIAL_STRESS_SECTION
…
*DATABASE_CROSS_SECTION
…
*END
```

We will not write out the details. You should imagine the general content of the cab model.

We then set up the load from the side assuming the bolt preload is already finished and the corresponding BoltPreload.dynain.lsda contains everything we now know it contains. The keyword file LoadSide.k needs to contain the complementary information as well as the impactor from the side and associated data. The input file would look like

```
*KEYWORD
*TITLE
Side load
$
$ Part data for the side impactor
$
*PART

1000,…
*SECTION
…
*MAT
…
$
$ Motion of the side impactor
$
*BOUNDARY_PRESCRIBED_MOTION_RIGID
1000,…
$
$ Geometry for the side impactor
$
*NODE
…
*ELEMENT
…
$
$ Contact between the side impactor and cab
$
*CONTACT_..._ID
1000,…
…
$
$ Data for the cab is exactly as in bolt preload,
$ except for nodes and elements which are in the
$ BoltPreload.dynain.lsda file
$
…
*END
```

We will highlight a few things. First, the nodes and elements for the cab are all in the dynain.lsda file, so they do not need to be copied over. Second, keywords like *ELEMENT_MASS/INERTIA and *CONSTRAINED_NODAL_RIGID_BODY/INTERPOLATION are to be seen as integrated components of the cab that are *not* written to the dynain.lsda file. These cards refer to quantities that are either updated between stages (nodes) or invariant to any deformation (masses). Therefore, these need to be copied.

Starting the third stage, we tend to get even more fancy because now we not only introduce the roof impactor but need to take out the side impactor. The LoadRoof.k would look like

```
*KEYWORD
*TITLE
Roof load
$
$ Ignore impactor from side in dynain.lsda file,
$ also taking out all of its part and contact data
$
*CONTROL_LSDA
1
1000
$
$ Part data for the roof impactor
$
*PART

2000,…
*SECTION
…
*MAT
…
$
$ Motion of the roof impactor
$
*BOUNDARY_PRESCRIBED_MOTION_RIGID
2000,…
$
$ Geometry for the roof impactor
$
*NODE
…
*ELEMENT
…
$
$ Contact between the roof impactor and cab
$
*CONTACT_..._ID
2000,…
…
$
$ Data for the cab is exactly as in side load,
$ except for nodes and elements which are now in the
$ LoadSide.dynain.lsda file
$
…
*END
```

In principle, this example defines one simulation run in three steps. You may wonder why this is better than defining all in one simulation. Assume you start this simulation overnight, and in the morning you can post-process the results for each of the three cases.

What if the first two stages were successful, and the third stage failed? Well, then you can simply make the modifications necessary in LoadRoof.k that you think takes care of whatever mistakes you made in the first place, and then redefine the main process file as

```
*KEYWORD
$
$ Meta data for cases, first two already successful
$
*CASE
4,LoadRoof
$
$ and we can start directly on the roof load
$
*CASE_BEGIN_4
*INCLUDE
LoadRoof.k
LoadSide.dynain.lsda
*CASE_END_4
*INTERFACE_SPRINGBACK_LSDYNA
…
*INTERFACE_SPRINGBACK_EXCLUDE
BOUNDARY_SPC_NODE
$
$ Mounting of the cab, present in all stages
$
*BOUNDARY
…
*END
```

You can submit this run without having to rerun the first two stages.

Multistage processes also allow you to cleanly organize a process compared to defining everything in a single input with birth/death times, deformable to rigid cards, implicit/explicit switches, complicated curves, etc. Admittedly, either way you do it manipulating text files in text editors is not the way to go. This appendix should be seen as an introductory guide for setting up and troubleshooting this kind of problem. An ultimate goal would be to do the setup in a high-level GUI where much of what has been presented in here as "recommendations" or "requirements" are dealt with automatically.

APPENDIX Y: LS-DYNA HYBRID User Guide

This is a short user's guide for the hybrid version of LS-DYNA.

INTRODUCTION

Since the LS-DYNA code was first introduced in the early nineties, continuous improvements have been made to the code to meet the needs of engineers who are using the code for increasingly complex applications. As this complexity has increased from purely structural problems to multi-physics problems and modeling details have raised the number of elements and solution variables, the performance of the code on multi-processor computers and computer clusters has become even more important. Calculation times have also risen with the use of more complex material models, multiple contacts, coupling between different modeling approaches, smaller element sizes, and more expensive element formulations. Contemporaneous to the increasing complexity of features and models, the increases in processor performance and the design of sophisticated clusters and networks have opened new possibilities for the solution of complex analysis models in a more acceptable timeframe. In order for software to take advantage of these increasingly common computational environments with multiple cores and compute clusters, parallel programming methods that enable the software to calculate portions of the model in parallel on several processors are required.

LS-DYNA offers two parallel programming models. SMP (Symmetric Multi-Processing), which originated from the serial code and uses OpenMP® directives to split the threads thereby enabling them to be run on multiple cores; and MPP (Massively Parallel Processing), which uses a message passing protocol to exchange information between the cores on a board or over the network. The SMP parallel programming model runs on computers with multiple identical cores with the cores and memory connected via a bus that is shared between all cores. The MPP programming model first performs a decomposition of the problem (domain decomposition) and then distributes the sub-domains to different cores using MPI (Message Passing Interface) protocol for communications between the subdomains during calculation. These sub-domains use their own exclusive part of memory and exchange data that is needed on other cores via MPI protocol. The MPP model is, therefore, not restricted to hardware where all cores have access to the same memory. This is important when using compute clusters, where an arbitrary number of cores are gathered and connected via a network. For the MPI protocol, messages can be passed between cores on one motherboard or over the network, which provides the opportunity to build clusters of single compute nodes connected via a network.

The LS-DYNA MPP version is scalable over a wide range of core counts and can reduce calculation wall clock times dramatically. While the MPI protocol connects all cores,

increasing the number of cores rapidly increases the network load, which has a negative impact on the performance and scalability. The LS-DYNA HYBRID version takes advantage of a combined SMP and MPP programming model to address this issue.

LS-DYNA HYBRID VERSION

In general, LS-DYNA HYBRID combines SMP and MPP parallel programming models to reduce wall clock time when using an increasing number of cores. Additionally, the LS-DYNA HYBRID version can be used (in a specific setup) to obtain consistent outputs for different core counts. "Output" is meant here to be the various result quantities obtained from binary or ASCII format result files, e.g., the value of specific node displacements for a node in a specific coordinate direction at a specific time.
In the following section, performance, and scalability as well as output consistency are discussed for the LS-DYNA HYBRID version. This includes the discussion of basic characteristics of the LS-DYNA SMP and LS-DYNA MPP versions since the LS-DYNA HYBRID version is a combination of these two programming models.

PERFORMANCE AND SCALABILITY

One of the main measures of performance is the elapsed wall clock time $T_{elapsed}$, which can be split up as follows:

for LS-DYNA SMP:	$T_{elapsed} = T_{computation}$	$+ T_{IO} + T_{overhead}$
for LS-DYNA MPP:	$T_{elapsed} = T_{computation} + T_{communication}$	$+ T_{IO}$
for LS-DYNA HYBRID:	$T_{elapsed} = T_{computation} + T_{communication}$	$+ T_{IO} + T_{overhead}$

where $T_{computation}$ is the actual time the cores do operations on the problem and T_{IO} is the time needed to perform the Input / Output operations to the hard disk. $T_{overhead}$ is related to the OpenMP® thread overhead in the SMP programming model. This thread overhead is related to the time needed to manage and create threads in the SMP programming model that also includes managing the memory for these threads and delays due to mismatches in computational time between threads. $T_{communication}$ is the time which is required by the MPI protocol to exchange data between different cores.

If the number of cores is increased for an MPP application, the performance and scalability may not also increase as would be expected. In MPP applications, communication is done between all cores used for the calculation. If the core count increases, the time needed for the communication $T_{communication}$ increases. If the amount of data exchanged via MPI protocol hits the bandwidth of the network connections, communication speed decreases rapidly, and when the time used for communication becomes dominant, the analysis fails to scale.

To keep the core count constant, but reduce the MPI communication, the LS-DYNA HYBRID version combines SMP and MPP parallel programming models. In the LS-DYNA HYBRID programming model a portion of the MPP ranks are replaced by an SMP process (the SMP process contains all SMP threads). The SMP calculations can use several cores, while the MPI protocol communicates only between the SMP processes, which reduce the amount of communication when compared to a pure MPP run.

OUTPUT CONSISTENCY

The drawback of having different parallel programming models is that some of the code subroutines for LS-DYNA keywords such as the *CONTACT, *ALE, *AIRBAG, *BOUNDARY, *CONSTRAINED keywords are different, while others such as the *ELEMENT and *MAT keywords are, for the most part, the same code. This discrepancy leads to different computed output for LS-DYNA SMP, LS-DYNA MPP and LS-DYNA HYBRID versions compared to each other.

Additional differences can be seen for all three parallel programming methods when using different core counts. The order of summation of result vectors depends on the number of cores used to compute them. Due to round off errors, the result of this summation is order dependent, which shows up as different output for different core counts. Methods to avoid or suppress these differences in output are discussed for the three parallel programming models in the next paragraphs.

When running LS-DYNA SMP versions, there is a consistency flag available that enforces the order of the summation of certain result vectors, thereby maintaining output numerical consistency when using different core counts. There is, however, a time penalty of about 10-15% of the wall clock time for this LS-DYNA SMP consistency option.

When running LS-DYNA MPP versions, there are numerical variations due to round off errors during the summation of certain result vectors. Using double precision, a finer mesh, or avoiding instabilities in the model, may help reduce these numerical variations. Unfortunately, a consistency flag option for MPP would increase wall clock time. Certain MPI protocols sum up the result vectors on the cores that belong to one compute node first and then sum up all results from the compute nodes connected via the network. If the compute nodes have different core counts, this could end up with different results even for constant core counts. To avoid this effect, the “lstc_reduce” option in pfile should be set.

The LS-DYNA HYBRID version inherits the merits and limits from both programming models, SMP and MPP that it was derived from. Using LS-DYNA HYBRID without the LS-DYNA SMP consistency flag would show differences in output when using different core counts for the SMP threads, as would different MPP processors counts show differences in the computed output. However, for the LS-DYNA HYBRID version, using the merits of the consistency flag for SMP threads and keeping the MPP processors constant,

output consistency is maintained for varying SMP thread counts. This enables a consistent output if the number of MPP processors is kept constant and the SMP thread count varies.

SUPPORTED FEATURES

For a list of supported features please refer to "Appendix O MPP User Guide" of this manual.

CONTACT INTERFACES

LS-DYNA HYBRID uses the parallel contact algorithm of LS-DYNA MPP. For supported and unsupported contact options please refer to "Appendix O MPP User Guide" of this manual.

OUTPUT FILES AND POST-PROCESSING

For performance reasons, many of the ASCII output files normally created by LS-DYNA have been combined into a binary format. For further information on the available output files formats please refer to "Appendix O MPP User Guide" of this manual.

PARALLEL SPECIFIC OPTIONS

For memory options and restart capabilities please refer to "Appendix O MPP User Guide" of this manual

PFILE

LS-DYNA HYBRID uses the same pfile definitions as LS-DYNA MPP. For details on these definitions please refer to "Appendix O MPP User Guide" of this manual.

EXECUTION OF LS-DYNA HYBRID

LS-DYNA HYBRID, as well as LS-DYNA MPP, uses a message passing interface to communicate between several MPP ranks. The message passing interface is not part of the LS-DYNA implementation. A third party MPI product software is needed to execute LS-DYNA HYBRID when more than one MPP rank is used. There are several MPI products available and LSTC provides LS-DYNA HYBRID executables for all major implementations of the MPI standard.

For the execution syntax of the MPI product, please refer to the user documentation of this product. In the following paragraphs <MPI-EXE> is used to identify the run command for the MPI product and "-np" is used as a flag to the MPI product executable to specify the number of MPP ranks.

The generic example for an execution syntax for LS-DYNA HYBRID is:

<MPI-EXE> -np < number of MPP ranks > <LS-DYNA HYBRID name > ncpu = - < number of OpenMP threads > <general LS-DYNA command line options >

The number of MPP ranks are specified in the same way as for LS-DYNA MPP versions. In addition to this specification, the OpenMP threads per MPP rank must specified as well. This is done in the same way as for the LS-DYNA SMP version, via the command line option "ncpu=". It is strongly recommended to use a negative number here to activate the SMP consistency flag.

APPENDIX Y
