INTRODUCTION

CHRONOLOGICAL HISTORY

DYNA3D originated at the Lawrence Livermore National Laboratory [Hallquist 1976]. The early applications were primarily for the stress analysis of structures subjected to a variety of impact loading. These applications required what was then significant computer resources, and the need for a much faster version was immediately obvious. Part of the speed problem was related to the inefficient implementation of the element technology which was further aggravated by the fact that supercomputers in 1976 were much slower than today's PC. Furthermore, the primitive sliding interface treatment could only treat logically regular interfaces that are uncommon in most finite element discretizations of complicated three-dimensional geometries; consequently, defining a suitable mesh for handling contact was often very difficult. The first version contained trusses, membranes, and a choice of solid elements. The solid elements ranged from a one-point quadrature eight-noded element with hourglass control to a twenty-noded element with eight integration points. Due to the high cost of the twenty node solid, the zero energy modes related to the reduced 8-point integration, and the high frequency content which drove the time step size down, higher order elements were all but abandoned in later versions of DYNA3D. A two-dimensional version, DYNA2D, was developed concurrently.

A new version of DYNA3D was released in 1979 that was programmed to provide near optimal speed on the CRAY-1 supercomputers, contained an improved sliding interface treatment that permitted triangular segments and was an order of magnitude faster than the previous contact treatment. The 1979 version eliminated structural and higher order solid elements and some of the material models of the first version. This version also included an optional element-wise implementation of the integral difference method developed by Wilkins et al. [1974].

The 1981 version [Hallquist 1981a] evolved from the 1979 version. Nine additional material models were added to allow a much broader range of problems to be modeled including explosive-structure and soil-structure interactions. Body force loads were implemented for angular velocities and base accelerations. A link was also established from the 3D Eulerian code, JOY [Couch, et. al., 1983] for studying the structural response to impacts by penetrating projectiles. An option was provided for storing element data on disk thereby doubling the capacity of DYNA3D.

The 1982 version of DYNA3D [Hallquist 1982] accepted DYNA2D [Hallquist 1980] material input directly. The new organization was such that equations of state and constitutive models of any complexity could be easily added. Complete vectorization of the

material models had been nearly achieved with about a 10 percent increase in execution speed over the 1981 version.

In the 1986 version of DYNA3D [Hallquist and Benson 1986], many new features were added, including beams, shells, rigid bodies, single surface contact, interface friction, discrete springs and dampers, optional hourglass treatments, optional exact volume integration, and VAX/ VMS, IBM, UNIX, COS operating systems compatibility, that greatly expanded its range of applications. DYNA3D thus became the first code to have a general single surface contact algorithm.

In the 1987 version of DYNA3D [Hallquist and Benson 1987] metal forming simulations and composite analysis became a reality. This version included shell thickness changes, the Belytschko-Tsay shell element [Belytschko and Tsay, 1981], and dynamic relaxation. Also included were non-reflecting boundaries, user specified integration rules for shell and beam elements, a layered composite damage model, and single point constraints.

New capabilities added in the 1988 DYNA3D [Hallquist 1988] version included a cost effective resultant beam element, a truss element, a C^0 triangular shell, the BCIZ triangular shell [Bazeley et al. 1965], mixing of element formulations in calculations, composite failure modeling for solids, noniterative plane stress plasticity, contact surfaces with spot welds, tie break sliding surfaces, beam surface contact, finite stonewalls, stonewall reaction forces, energy calculations for all elements, a crushable foam constitutive model, comment cards in the input, and one-dimensional slidelines.

By the end of 1988 it was obvious that a much more concentrated effort would be required in the development of this software if problems in crashworthiness were to be properly solved; therefore, Livermore Software Technology Corporation was founded to continue the development of DYNA3D as a commercial version called LS-DYNA3D which was later shortened to LS-DYNA. The 1989 release introduced many enhanced capabilities including a one-way treatment of slide surfaces with voids and friction; cross-sectional forces for structural elements; an optional user specified minimum time step size for shell elements using elastic and elastoplastic material models; nodal accelerations in the time history database; a compressible Mooney-Rivlin material model; a closed-form update shell plasticity model; a general rubber material model; unique penalty specifications for each slide surface; external work tracking; optional time step criterion for 4-node shell elements; and internal element sorting to allow full vectorization of right-hand-side force assembly.

During the last ten years, considerable progress has been made as may be seen in the chronology of the developments which follows.

Capabilities added in 1989-1990:

- arbitrary node and element numbers,

- fabric model for seat belts and airbags,
- composite glass model,
- vectorized type 3 contact and single surface contact,
- many more I/O options,
- all shell materials available for 8 node thick shell,
- strain rate dependent plasticity for beams,
- fully vectorized iterative plasticity,
- interactive graphics on some computers,
- nodal damping,
- shell thickness taken into account in shell type 3 contact,
- shell thinning accounted for in type 3 and type 4 contact,
- soft stonewalls,
- print suppression option for node and element data,
- massless truss elements, rivets – based on equations of rigid body dynamics,
- massless beam elements, spot welds – based on equations of rigid body dynamics,
- expanded databases with more history variables and integration points,
- force limited resultant beam,
- rotational spring and dampers, local coordinate systems for discrete elements,
- resultant plasticity for C^0 triangular element,
- energy dissipation calculations for stonewalls,
- hourglass energy calculations for solid and shell elements,
- viscous and Coulomb friction with arbitrary variation over surface,
- distributed loads on beam elements,
- Cowper and Symonds strain rate model,
- segmented stonewalls,
- stonewall Coulomb friction,
- stonewall energy dissipation,
- airbags (1990),
- nodal rigid bodies,
- automatic sorting of triangular shells into C^0 groups,
- mass scaling for quasi static analyses,
- user defined subroutines,

- warpage checks on shell elements,
- thickness consideration in all contact types,
- automatic orientation of contact segments,
- sliding interface energy dissipation calculations,
- nodal force and energy database for applied boundary conditions,
- defined stonewall velocity with input energy calculations,

Capabilities added in 1991-1992:

- rigid/deformable material switching,
- rigid bodies impacting rigid walls,
- strain-rate effects in metallic honeycomb model 26,
- shells and beams interfaces included for subsequent component analyses,
- external work computed for prescribed displacement/velocity/accelerations,
- linear constraint equations,
- MPGS database,
- MOVIE database,
- Slideline interface file,
- automated contact input for all input types,
- automatic single surface contact without element orientation,
- constraint technique for contact,
- cut planes for resultant forces,
- crushable cellular foams,
- urethane foam model with hysteresis,
- subcycling,
- friction in the contact entities,
- strains computed and written for the 8 node thick shells,
- "good" 4 node tetrahedron solid element with nodal rotations,
- 8 node solid element with nodal rotations,
- 2 × 2 integration for the membrane element,
- Belytschko-Schwer integrated beam,
- thin-walled Belytschko-Schwer integrated beam,
- improved TAURUS database control,

- null material for beams to display springs and seatbelts in TAURUS,
- parallel implementation on Crays and SGI computers,
- coupling to rigid body codes,
- seat belt capability.

Capabilities added in 1993-1994:

- Arbitrary Lagrangian Eulerian brick elements,
- Belytschko-Wong-Chiang quadrilateral shell element,
- Warping stiffness in the Belytschko-Tsay shell element,
- Fast Hughes-Liu shell element,
- Fully integrated thick shell element,
- Discrete 3D beam element,
- Generalized dampers,
- Cable modeling,
- Airbag reference geometry,
- Multiple jet model,
- Generalized joint stiffnesses,
- Enhanced rigid body to rigid body contact,
- Orthotropic rigid walls,
- Time zero mass scaling,
- Coupling with USA (Underwater Shock Analysis),
- Layered spot welds with failure based on resultants or plastic strain,
- Fillet welds with failure,
- Butt welds with failure,
- Automatic eroding contact,
- Edge-to-edge contact,
- Automatic mesh generation with contact entities,
- Drawbead modeling,
- Shells constrained inside brick elements,
- NIKE3D coupling for springback,
- Barlat's anisotropic plasticity,
- Superplastic forming option,

- Rigid body stoppers,
- Keyword input,
- Adaptivity,
- First MPP (Massively Parallel) version with limited capabilities.
- Built in least squares fit for rubber model constitutive constants,
- Large hysteresis in hyperelastic foam,
- Bilhku/Dubois foam model,
- Generalized rubber model,

Capabilities added in 1995:

- Belytschko - Leviathan Shell
- Automatic switching between rigid and deformable bodies.
- Accuracy on SMP machines to give identical answers on one, two or more processors.
- Local coordinate systems for cross-section output can be specified.
- Null material for shell elements.
- Global body force loads now may be applied to a subset of materials.
- User defined loading subroutine.
- Improved interactive graphics.
- New initial velocity options for specifying rotational velocities.
- Geometry changes after dynamic relaxation can be considered for initial velocities..
- Velocities may also be specified by using material or part ID's.
- Improved speed of brick element hourglass force and energy calculations.
- Pressure outflow boundary conditions have been added for the ALE options.
- More user control for hourglass control constants for shell elements.
- Full vectorization in constitutive models for foam, models 57 and 63.
- Damage mechanics plasticity model, material 81,
- General linear viscoelasticity with 6 term prony series.
- Least squares fit for viscoelastic material constants.
- Table definitions for strain rate effects in material type 24.
- Improved treatment of free flying nodes after element failure.

- Automatic projection of nodes in CONTACT_TIED to eliminate gaps in the surface.
- More user control over contact defaults.
- Improved interpenetration warnings printed in automatic contact.
- Flag for using actual shell thickness in single surface contact logic rather than the default.
- Definition by exempted part ID's.
- Airbag to Airbag venting/segmented airbags are now supported.
- Airbag reference geometry speed improvements by using the reference geometry for the time step size calculation.
- Isotropic airbag material may now be directly for cost efficiency.
- Airbag fabric material damping is specified as the ratio of critical damping.
- Ability to attach jets to the structure so the airbag, jets, and structure to move together.
- PVM 5.1 Madymo coupling is available.
- Meshes are generated within LS-DYNA3D for all standard contact entities.
- Joint damping for translational motion.
- Angular displacements, rates of displacements, damping forces, etc. in JNTFORC file.
- Link between LS-NIKE3D to LS-DYNA3D via *INITIAL_STRESS keywords.
- Trim curves for metal forming springback.
- Sparse equation solver for springback.
- Improved mesh generation for IGES and VDA provides a mesh that can directly be used to model tooling in metal stamping analyses.
- Capabilities added in 1996-1997 in Version 940:
- Part/Material ID's may be specified with 8 digits.
- Rigid body motion can be prescribed in a local system fixed to the rigid body.
- Nonlinear least squares fit available for the Ogden rubber model.
- Least squares fit to the relaxation curves for the viscoelasticity in rubber.
- Fu-Chang rate sensitive foam.
- 6 term Prony series expansion for rate effects in model 57-now 73
- Viscoelastic material model 76 implemented for shell elements.
- Mechanical threshold stress (MTS) plasticity model for rate effects.
- Thermoelastic-plastic material model for Hughes-Liu beam element.

- Ramberg-Osgood soil model
- Invariant local coordinate systems for shell elements are optional.
- Second order accurate stress updates.
- Four noded, linear, tetrahedron element.
- Co-rotational solid element for foam that can invert without stability problems.
- Improved speed in rigid body to rigid body contacts.
- Improved searching for the a_3, a_5 and a10 contact types.
- Invariant results on shared memory parallel machines with the *a_n* contact types.
- Thickness offsets in type 8 and 9 tie break contact algorithms.
- Bucket sort frequency can be controlled by a load curve for airbag applications.
- In automatic contact each part ID in the definition may have unique:
    - Static coefficient of friction
    - Dynamic coefficient of friction
    - Exponential decay coefficient
    - Viscous friction coefficient
    - Optional contact thickness
    - Optional thickness scale factor
    - Local penalty scale factor
- Automatic beam-to-beam, shell edge-to-beam, shell edge-to-shell edge and single surface contact algorithm.
- Release criteria may be a multiple of the shell thickness in types a_3, a_5, a10, 13, and 26 contact.
- Force transducers to obtain reaction forces in automatic contact definitions. Defined manually via segments, or automatically via part ID's.
- Searching depth can be defined as a function of time.
- Bucket sort frequency can be defined as a function of time.
- Interior contact for solid (foam) elements to prevent "negative volumes."
- Locking joint
- Temperature dependent heat capacity added to Wang-Nefske inflator models.
- Wang Hybrid inflator model [Wang, 1996] with jetting options and bag-to-bag venting.
- Aspiration included in Wang's hybrid model [Nusholtz, Wang, Wylie, 1996].
- Extended Wang's hybrid inflator with a quadratic temperature variation for heat capacities [Nusholtz, 1996].

- Fabric porosity added as part of the airbag constitutive model.
- Blockage of vent holes and fabric in contact with structure or itself considered in venting with leakage of gas.
- Option to delay airbag liner with using the reference geometry until the reference area is reached.
- Birth time for the reference geometry.
- Multi-material Euler/ALE fluids,
    - 2nd order accurate formulations.
    - Automatic coupling to shell, brick, or beam elements
    - Coupling using LS-DYNA contact options.
    - Element with fluid + void and void material
    - Element with multi-materials and pressure equilibrium
- Nodal inertia tensors.
- 2D plane stress, plane strain, rigid, and axisymmetric elements
- 2D plane strain shell element
- 2D axisymmetric shell element.
- Full contact support in 2D, tied, sliding only, penalty and constraint techniques.
- Most material types supported for 2D elements.
- Interactive remeshing and graphics options available for 2D.
- Subsystem definitions for energy and momentum output.
- Boundary element method for incompressible fluid dynamics and fluid-structure interaction problems.

Capabilities added during 1997-1998 in Version 950:

- Adaptive refinement can be based on tooling curvature with FORMING contact.
- The display of drawbeads is now possible since the drawbead data is output into the D3PLOT database.
- An adaptive box option, *DEFINE_BOX_ADAPTIVE, allows control over the refinement level and location of elements to be adapted.
- A root identification file, ADAPT.RID, gives the parent element ID for adapted elements.
- Draw bead box option, *DEFINE_BOX_DRAWBEAD, simplifies drawbead input.
- The new control option, CONTROL_IMPLICIT, activates an implicit solution scheme.

- 2D Arbitrary-Lagrangian-Eulerian elements are available.
- 2D automatic contact is defined by listing part ID's.
- 2D r-adaptivity for plane strain and axisymmetric forging simulations is available.
- 2D automatic non-interactive rezoning as in LS-DYNA2D.
- 2D plane strain and axisymmetric element with 2x2 selective-reduced integration are implemented.
- Implicit 2D solid and plane strain elements are available.
- Implicit 2D contact is available.
- The new keyword, *DELETE_CONTACT_2DAUTO, allows the deletion of 2D automatic contact definitions.
- The keyword, *LOAD_BEAM is added for pressure boundary conditions on 2D elements.
- A viscoplastic strain rate option is available for materials:
    - *MAT_PLASTIC_KINEMATIC
    - *MAT_JOHNSON_COOK
    - *MAT_POWER_LAW_PLASTICITY
    - *MAT_STRAIN_RATE_DEPENDENT_PLASTICITY
    - *MAT_PIECEWISE_LINEAR_PLASTICITY
    - *MAT_RATE_SENSITIVE_POWERLAW_PLASTICITY
    - *MAT_ZERILLI-ARMSTRONG
    - *MAT_PLASTICITY_WITH_DAMAGE
    - *MAT_PLASTICITY_COMPRESSION_TENSION
- Material model, *MAT_PLASTICITY_WITH_DAMAGE, has a piecewise linear damage curve given by a load curve ID.
- The Arruda-Boyce hyper-viscoelastic rubber model is available, see *MAT_-ARRUDA_BOYCE.
- Transverse-anisotropic-viscoelastic material for heart tissue, see *MAT_-HEART_-TISSUE.
- Lung hyper-viscoelastic material, see *MAT_LUNG_TISSUE.
- Compression/tension plasticity model, see *MAT_PLASTICITY_COMP-RESSION_TENSION.
- The Lund strain rate model, *MAT_STEINBERG_LUND, is added to Steinberg-Guinan plasticity model.
- Rate sensitive foam model, *MAT_FU_CHANG_FOAM, has been extended to include engineering strain rates, etc.

- Model, *MAT_MODIFIED_PIECEWISE_LINEAR_PLASTICITY, is added for modeling the failure of aluminum.
- Material model, *MAT_SPECIAL_ORTHOTROPIC, added for television shadow mask problems.
- Erosion strain is implemented for material type, *MAT_BAMMAN_DAMAGE.
- The equation of state, *EOS_JWLB, is available for modeling the expansion of explosive gases.
- The reference geometry option is extended for foam and rubber materials and can be used for stress initialization, see *INITIAL_FOAM_REFERENCE_GEOMETRY.
- A vehicle positioning option is available for setting the initial orientation and velocities, see *INITIAL_VEHICLE_KINEMATICS.
- A boundary element method is available for incompressible fluid dynamics problems.
- The thermal materials work with instantaneous coefficients of thermal expansion:
    - *MAT_ELASTIC_PLASTIC_THERMAL
    - *MAT_ORTHOTROPIC_THERMAL
    - *MAT_TEMPERATURE_DEPENDENT_ORTHOTROPIC
    - *MAT_ELASTIC_WITH_VISCOSITY
- Airbag interaction flow rate versus pressure differences.
- Contact segment search option, [bricks first optional]
- A through thickness Gauss integration rule with 1-10 points is available for shell elements. Previously, 5 were available.
- Shell element formulations can be changed in a full deck restart.
- The tied interface which is based on constraint equations, TIED_SURFACE_TO_SURFACE, can now fail if FAILURE, is appended.
- A general failure criterion for solid elements is independent of the material type, see *MAT_ADD_EROSION
- Load curve control can be based on thinning and a flow limit diagram, see *DEFINE_CURVE_FEEDBACK.
- An option to filter the spotweld resultant forces prior to checking for failure has been added the option, *CONSTRAINED_SPOTWELD, by appending FILTERED_FORCE, to the keyword.
- Bulk viscosity is available for shell types 1, 2, 10, and 16.
- When defining the local coordinate system for the rigid body inertia tensor a local coordinate system ID can be used. This simplifies dummy positioning.

- Prescribing displacements, velocities, and accelerations is now possible for rigid body nodes.
- One way flow is optional for segmented airbag interactions.
- Pressure time history input for airbag type, LINEAR_FLUID, can be used.
- An option is available to independently scale system damping by part ID in each of the global directions.
- An option is available to independently scale global system damping in each of the global directions.
- Added option to constrain global DOF along lines parallel with the global axes. The keyword is *CONSTRAINED_GLOBAL. This option is useful for adaptive remeshing.
- Beam end code releases are available, see *ELEMENT_BEAM.
- An initial force can be directly defined for the cable material, *MAT_CABLE_DISCRETE_BEAM. The specification of slack is not required if this option is used.
- Airbag pop pressure can be activated by accelerometers.
- Termination may now be controlled by contact, via *TERMINATION_CONTACT.
- Modified shell elements types 8, 10 and the warping stiffness option in the Belytschko-Tsay shell to ensure orthogonality with rigid body motions in the event that the shell is badly warped. This is optional in the Belytschko-Tsay shell and the type 10 shell.
- A one point quadrature brick element with an exact hourglass stiffness matrix has been implemented for implicit and explicit calculations.
- Automatic file length determination for D3PLOT binary database is now implemented. This insures that at least a single state is contained in each D3PLOT file and eliminates the problem with the states being split between files.
- The dump files, which can be very large, can be placed in another directory by specifying

  d=**/home/user /test/d3dump**

  on the execution line.
- A print flag controls the output of data into the MATSUM and RBDOUT files by part ID's. The option, PRINT, has been added as an option to the *PART keyword.
- Flag has been added to delete material data from the D3THDT file. See *DATABASE_EXTENT_BINARY and column 25 of the 19th control card in the structured input.
- After dynamic relaxation completes, a file is written giving the displaced state which can be used for stress initialization in later runs.

Capabilities added during 1998-2000 in Version 960:

Most new capabilities work on both the MPP and SMP versions; however, the capabilities that are implemented for the SMP version only, which were not considered critical for this release, are flagged below. These SMP unique capabilities are being extended for MPP calculations and will be available in the near future. The implicit capabilities for MPP require the development of a scalable eigenvalue solver, which is under development for a later release of LS-DYNA.

- Incompressible flow solver is available. Structural coupling is not yet implemented.
- Adaptive mesh coarsening can be done before the implicit springback calculation in metal forming applications.
- Two-dimensional adaptivity can be activated in both implicit and explicit calculations. (SMP version only)
- An internally generated smooth load curve for metal forming tool motion can be activated with the keyword: *DEFINE_CURVE_SMOOTH.
- Torsional forces can be carried through the deformable spot welds by using the contact type: *CONTACT_SPOTWELD_WITH_TORSION (SMP version only with a high priority for the MPP version if this option proves to be stable.)
- Tie break automatic contact is now available via the *CONTACT_AUTOMATIC_…_TIEBREAK options. This option can be used for glued panels. (SMP only)
- *CONTACT_RIGID_SURFACE option is now available for modeling road surfaces (SMP version only).
- Fixed rigid walls PLANAR and PLANAR_FINITE are represented in the binary output file by a single shell element.
- Interference fits can be modeled with the INTERFERENCE option in contact.
- A layered shell theory is implemented for several constitutive models including the composite models to more accurately represent the shear stiffness of laminated shells.
- Damage mechanics is available to smooth the post-failure reduction of the resultant forces in the constitutive model *MAT_SPOTWELD_DAMAGE.
- Finite elastic strain isotropic plasticity model is available for solid elements. *MAT_FINITE_ELASTIC_STRAIN_PLASTICITY.
- A shape memory alloy material is available: *MAT_SHAPE_MEMORY.
- Reference geometry for material, *MAT_MODIFIED_HONEYCOMB, can be set at arbitrary relative volumes or when the time step size reaches a limiting value. This option is now available for all element types including the fully integrated solid element.

- Non orthogonal material axes are available in the airbag fabric model. See *MAT_-FABRIC.
- Other new constitutive models include for the beam elements:
  - *MAT_MODIFIED_FORCE_LIMITED
  - *MAT_SEISMIC_BEAM
  - *MAT_CONCRETE_BEAM
- for shell and solid elements:
  - *MAT_ELASTIC_VISCOPLASTIC_THERMAL
- for the shell elements:
  - *MAT_GURSON
  - *MAT_GEPLASTIC_SRATE2000
  - *MAT_ELASTIC_VISCOPLASTIC_THERMAL
  - *MAT_COMPOSITE_LAYUP
  - *MAT_COMPOSITE_LAYUP
  - *MAT_COMPOSITE_DIRECT
- for the solid elements:
  - *MAT_JOHNSON_HOLMQUIST_CERAMICS
  - *MAT_JOHNSON_HOLMQUIST_CONCRETE
  - *MAT_INV_HYPERBOLIC_SIN
  - *MAT_UNIFIED_CREEP
  - *MAT_SOIL_BRICK
  - *MAT_DRUCKER_PRAGER
  - *MAT_RC_SHEAR_WALL
- and for all element options a very fast and efficient version of the Johnson-Cook plasticity model is available:
- *MAT_SIMPLIFIED_JOHNSON_COOK
- A fully integrated version of the type 16 shell element is available for the resultant constitutive models.
- A nonlocal failure theory is implemented for predicting failure in metallic materials. The keyword *MAT_NONLOCAL activates this option for a subset of elasto-plastic constitutive models.
- A discrete Kirchhoff triangular shell element (DKT) for explicit analysis with three in plane integration points is flagged as a type 17 shell element. This element has much better bending behavior than the C0 triangular element.
- A discrete Kirchhoff linear triangular and quadrilateral shell element is available as a type 18 shell. This shell is for extracting normal modes and static analysis.

- A C0 linear 4-node quadrilateral shell element is implemented as element type 20 with drilling stiffness for normal modes and static analysis.
- An assumed strain linear brick element is available for normal modes and statics.
- The fully integrated thick shell element has been extended for use in implicit calculations.
- A fully integrated thick shell element based on an assumed strain formulation is now available. This element uses a full 3D constitutive model which includes the normal stress component and, therefore, does not use the plane stress assumption.
- The 4-node constant strain tetrahedron element has been extended for use in implicit calculations.
- Relative damping between parts is available, see *DAMPING_RELATIVE (SMP only).
- Preload forces are can be input for the discrete beam elements.
- Objective stress updates are implemented for the fully integrated brick shell element.
- Acceleration time histories can be prescribed for rigid bodies.
- Prescribed motion for nodal rigid bodies is now possible.
- Generalized set definitions, i.e., SET_SHELL_GENERAL etc. provide much flexibility in the set definitions.
- The command “sw4.” will write a state into the dynamic relaxation file, D3DRLF, during the dynamic relaxation phase if the D3DRLF file is requested in the input.
- Added mass by PART ID is written into the MATSUM file when mass scaling is used to maintain the time step size, (SMP version only).
- Upon termination due to a large mass increase during a mass scaled calculation a print summary of 20 nodes with the maximum added mass is printed.
- Eigenvalue analysis of models containing rigid bodies is now available using BCSLIB-EXT solvers from Boeing. (SMP version only).
- Second order stress updates can be activated by part ID instead of globally on the *CONTROL_ACCURACY input.
- Interface frictional energy is optionally computed for heat generation and is output into the interface force file (SMP version only).
- The interface force binary database now includes the distance from the contact surface for the FORMING contact options. This distance is given after the nodes are detected as possible contact candidates. (SMP version only).
- Type 14 acoustic brick element is implemented. This element is a fully integrated version of type 8, the acoustic element (SMP version only).
- A flooded surface option for acoustic applications is available (SMP version only).

- Attachment nodes can be defined for rigid bodies. This option is useful for NVH applications.
- CONSTRAINED_POINTS tie any two points together. These points must lie on a shell element.
- Soft constraint is available for edge to edge contact in type 26 contact.
- CONSTAINED_INTERPOLATION option for beam to solid interfaces and for spreading the mass and loads. (SMP version only).
- A database option has been added that allows the output of added mass for shell elements instead of the time step size.
- A new contact option allows the inclusion of all internal shell edges in contact type *CONTACT_GENERAL, type 26. This option is activated by adding "_INTERIOR" after the GENERAL keyword.
- A new option allows the use deviatoric strain rates rather than total rates in material model 24 for the Cowper-Symonds rate model.
- The CADFEM option for ASCII databases is now the default. Their option includes more significant figures in the output files.
- When using deformable spot welds, the added mass for spot welds is now printed for the case where global mass scaling is activated. This output is in the log file, d3hsp file, and the messag file.
- Initial penetration warnings for edge-to-edge contact are now written into the MESSAG file and the d3hsp file.
- Each compilation of LS-DYNA is given a unique version number.
- Finite length discrete beams with various local axes options are now available for material types 66, 67, 68, 93, and 95. In this implementation the absolute value of SCOOR must be set to 2 or 3 in the *SECTION_BEAM input.
- New discrete element constitutive models are available:
    - *MAT_ELASTIC_SPRING_DISCRETE_BEAM
    - *MAT_INELASTIC_SPRING_DISCRETE_BEAM
    - *MAT_ELASTIC_6DOF_SPRING_DISCRETE_BEAM
    - *MAT_INELASTIC_6DOF_SPRING_DISCRETE_BEAM
- The latter two can be used as finite length beams with local coordinate systems.
- Moving SPC's are optional in that the constraints are applied in a local system that rotates with the 3 defining nodes.
- A moving local coordinate system, CID, can be used to determine orientation of discrete beam elements.
- Modal superposition analysis can be performed after an eigenvalue analysis. Stress recovery is based on type 18 shell and brick (SMP only).

- Rayleigh damping input factor is now input as a fraction of critical damping, i.e. 0.10. The old method required the frequency of interest and could be highly unstable for large input values.
- Airbag option "SIMPLE_PRESSURE_VOLUME" allows for the constant CN to be replaced by a load curve for initialization. Also, another load curve can be defined which allows CN to vary as a function of time during dynamic relaxation. After dynamic relaxation CN can be used as a fixed constant or load curve.
- Hybrid inflator model utilizing CHEMKIN and NIST databases is now available. Up to ten gases can be mixed.
- Option to track initial penetrations has been added in the automatic SMP contact types rather than moving the nodes back to the surface. This option has been available in the MPP contact for some time. This input can be defined on the fourth card of the *CONTROL_CONTACT input and on each contact definition on the third optional card in the *CONTACT definitions.
- If the average acceleration flag is active, the average acceleration for rigid body nodes is now written into the D3THDT and NODOUT files. In previous versions of LS-DYNA, the accelerations on rigid nodes were not averaged.
- A capability to initialize the thickness and plastic strain in the crash model is available through the option *INCLUDE_STAMPED_PART, which takes the results from the LS-DYNA stamping simulation and maps the thickness and strain distribution onto the same part with a different mesh pattern.
- A capability to include finite element data from other models is available through the option, *INCLUDE_TRANSFORM. This option will take the model defined in an INCLUDE file: offset all ID's; translate, rotate, and scale the coordinates; and transform the constitutive constants to another set of units.

Features added during 2001-2002 for the 970 release of LS-DYNA:

Some of the new features, which are also listed below, were also added to later releases of version 960. Most new explicit capabilities work for both the MPP and SMP versions; however, the implicit capabilities for MPP require the development of a scalable eigenvalue solver and a parallel implementation of the constraint equations into the global matrices. This work is underway. A later release of version 970 is planned in 2003 that will be scalable for implicit solutions.

Below is list of new capabilities and features:

- MPP decomposition can be controlled using *CONTROL_MPP_DECOMPOSITION commands in the input deck.
- The MPP arbitrary Lagrangian-Eulerian fluid capability now works for airbag deployment in both SMP and MPP calculations.

- Euler-to-Euler coupling is now available through the keyword *CONSTRAINED_EULER_TO_EULER.
- Up to ten ALE multi-material groups may now be defined. The previous limit was three groups.
- Volume fractions can be automatically assigned during initialization of multi-material cells. See the GEOMETRY option of *INITIAL_VOLUME_FRACTION.
- A new ALE smoothing option is available to accurately predict shock fronts.
- DATABASE_FSI activates output of fluid-structure interaction data to ASCII file DBFSI.
- Point sources for airbag inflators are available. The origin and mass flow vector of these inflators are permitted to vary with time.
- A majority of the material models for solid materials are available for calculations using the SPH (Smooth Particle Hydrodynamics) option.
- The Element Free Galerkin method (EFG or meshfree) is available for two-dimensional and three-dimensional solids. This new capability is not yet implemented for MPP applications.
- A binary option for the ASCII files is now available. This option applies to all ASCII files and results in one binary file that contains all the information normally spread between a large number of separate ASCII files.
- Material models can now be defined by numbers rather than long names in the keyword input. For example the keyword *MAT_PIECEWISE_LINEAR_PLASTICITY can be replaced by the keyword: *MAT_024.
- An embedded NASTRAN reader for direct reading of NASTRAN input files is available. This option allows a typical input file for NASTRAN to be read directly and used without additional input. See the *INCLUDE_NASTRAN keyword.
- Names in the keyword input can represent numbers if the *PARAMETER option is used to relate the names and the corresponding numbers.
- Model documentation for the major ASCII output files is now optional. This option allows descriptors to be included within the ASCII files that document the contents of the file.
- ID's have been added to the following keywords:
    - *BOUNDARY_PRESCRIBED_MOTION
    - *BOUNDARY_PRESCRIBED_SPC
    - *CONSTRAINED_GENERALIZED_WELD
    - *CONSTRAINED_JOINT
    - *CONSTRAINED_NODE_SET
    - *CONSTRAINED_RIVET
    - *CONSTRAINED_SPOTWELD

- *DATABASE_CROSS_SECTION
- *ELEMENT_MASS

- Penetration warnings for the contact option, ignore initial penetration, î are added as an option. Previously, no penetration warnings were written when this contact option was activated.
- Penetration warnings for nodes in-plane with shell mid-surface are printed for the AUTOMATIC contact options. Previously, these nodes were ignored since it was assumed that they belonged to a tied interface where an offset was not used; consequently, they should not be treated in contact.
- For the arbitrary spot weld option, the spot welded nodes and their contact segments are optionally written into the d3hsp file. See *CONTROL_CONTACT.
- For the arbitrary spot weld option, if a segment cannot be found for the spot welded node, an option now exists to error terminate. See *CONTROL_CONTACT.
- Spot weld resultant forces are written into the SWFORC file for solid elements used as spot welds.
- Solid materials have now been added to the failed element report.
- A new option for terminating a calculation is available, *TERMINATION_CURVE.
- A 10-noded tetrahedron solid element is available with either a 4 or 5 point integration rule. This element can also be used for implicit solutions.
- A new 4 node linear shell element is available that is based on Wilson's plate element combined with a Pian-Sumihara membrane element. This is shell type 21.
- A shear panel element has been added for linear applications. This is shell type 22. This element can also be used for implicit solutions.
- A null beam element for visualization is available. The keyword to define this null beam is *ELEMENT_PLOTEL. This element is necessary for compatibility with NASTRAN.
- A scalar node can be defined for spring-mass systems. The keyword to define this node is *NODE_SCALAR. This node can have from 1 to 6 scalar degrees-of-freedom.
- A thermal shell has been added for through-thickness heat conduction. Internally, 8 additional nodes are created, four above and four below the mid-surface of the shell element. A quadratic temperature field is modeled through the shell thickness. Internally, the thermal shell is a 12 node solid element.
- A beam OFFSET option is available for the *ELEMENT_BEAM definition to permit the beam to be offset from its defining nodal points. This has the advantage that all beam formulations can now be used as shell stiffeners.

- A beam ORIENTATION option for orienting the beams by a vector instead of the third node is available in the *ELEMENT_BEAM definition for NASTRAN compatibility.
- Non-structural mass has been added to beam elements for modeling trim mass and for NASTRAN compatibility.
- An optional checking of shell elements to avoid abnormal terminations is available. See *CONTROL_SHELL. If this option is active, every shell is checked each time step to see if the distortion is so large that the element will invert, which will result in an abnormal termination. If a bad shell is detected, either the shell will be deleted or the calculation will terminate. The latter is controlled by the input.
- An offset option is added to the inertia definition. See *ELEMENT_INERTIA_-OFFSET keyword. This allows the inertia tensor to be offset from the nodal point.
- Plastic strain and thickness initialization is added to the draw bead contact option. See *CONTACT_DRAWBEAD_INITIALIZE.
- Tied contact with offsets based on both constraint equations and beam elements for solid elements and shell elements that have 3 and 6 degrees-of-freedom per node, respectively. See BEAM_OFFSET and CONSTRAINED_OFFSET contact options. These options will not cause problems for rigid body motions.
- The segment-based (SOFT = 2) contact is implemented for MPP calculations. This enables airbags to be easily deployed on the MPP version.
- Improvements are made to segment-based contact for edge-to-edge and sliding conditions, and for contact conditions involving warped segments.
- An improved interior contact has been implemented to handle large shear deformations in the solid elements. A special interior contact algorithm is available for tetrahedron elements.
- Coupling with MADYMO 6.0 uses an extended coupling that allows users to link most MADYMO geometric entities with LS-DYNA FEM simulations. In this coupling MADYMO contact algorithms are used to calculate interface forces between the two models.
- Release flags for degrees-of-freedom for nodal points within nodal rigid bodies are available. This makes the nodal rigid body option nearly compatible with the RBE2 option in NASTRAN.
- Fast updates of rigid bodies for metalforming applications can now be accomplished by ignoring the rotational degrees-of-freedom in the rigid bodies that are typically inactive during sheet metal stamping simulations. See the keyword: *CONTROL_RIGID.
- Center of mass constraints can be imposed on nodal rigid bodies with the SPC option in either a local or a global coordinate system.

- Joint failure based on resultant forces and moments can now be used to simulate the failure of joints.
- CONSTRAINED_JOINT_STIFFNESS now has a TRANSLATIONAL option for the translational and cylindrical joints.
- Joint friction has been added using table look-up so that the frictional moment can now be a function of the resultant translational force.
- The nodal constraint options *CONSTRAINED_INTERPOLATION and *CONSTRAINED_LINEAR now have a local option to allow these constraints to be applied in a local coordinate system.
- Mesh coarsening can now be applied to automotive crash models at the beginning of an analysis to reduce computation times. See the new keyword: *CONTROL_COARSEN.
- Force versus time seatbelt pretensioner option has been added.
- Both static and dynamic coefficients of friction are available for seat belt slip rings. Previously, only one friction constant could be defined.
- *MAT_SPOTWELD now includes a new failure model with rate effects as well as additional failure options.
- Constitutive models added for the discrete beam elements:
    - *MAT_1DOF_GENERALIZED_SPRING
    - *MAT_GENERAL_NONLINEAR_6DOF_DISCRETE_BEAM
    - *MAT_GENERAL_NONLINEAR_1DOF_DISCRETE_BEAM
    - *MAT_GENERAL_SPRING_DISCRETE_BEAM
    - *MAT_GENERAL_JOINT_DISCRETE_BEAM
    - *MAT_SEISMIC_ISOLATOR
- for shell and solid elements:
    - *MAT_PLASTICITY_WITH_DAMAGE_ORTHO
    - *MAT_SIMPLIFIED_JOHNSON_COOK_ORTHOTROPIC_DAMAGE
    - *MAT_HILL_3R
    - *MAT_GURSON_RCDC
- for the solid elements:
    - *MAT_SPOTWELD
    - *MAT_HILL_FOAM
    - *MAT_WOOD
    - *MAT_VISCOELASTIC_HILL_FOAM
    - *MAT_LOW_DENSITY_SYNTHETIC_FOAM
    - *MAT_RATE_SENSITIVE_POLYMER
    - *MAT_QUASILINEAR VISCOELASTIC

- *MAT_TRANSVERSELY_ANISOTROPIC_CRUSHABLE_FOAM
- *MAT_VACUUM
- *MAT_MODIFIED_CRUSHABLE_FOAM
- *MAT_PITZER_CRUSHABLE FOAM
- *MAT_JOINTED_ROCK
- *MAT_SIMPLIFIED_RUBBER
- *MAT_FHWA_SOIL
- *MAT_SCHWER_MURRAY_CAP_MODEL

- Failure time added to MAT_EROSION for solid elements.
- Damping in the material models *MAT_LOW_DENSITY_FOAM and *MAT_-LOW_DENSITY_VISCOUS_FOAM can now be a tabulated function of the smallest stretch ratio.
- The material model *MAT_PLASTICITY_WITH_DAMAGE allows the table definitions for strain rate.
- Improvements in the option *INCLUDE_STAMPED_PART now allow all history data to be mapped to the crash part from the stamped part. Also, symmetry planes can be used to allow the use of a single stamping to initialize symmetric parts.
- Extensive improvements in trimming result in much better elements after the trimming is completed. Also, trimming can be defined in either a local or global coordinate system. This is a new option in *DEFINE_CURVE_TRIM.
- An option to move parts close before solving the contact problem is available, see *CONTACT_AUTO_MOVE.
- An option to add or remove discrete beams during a calculation is available with the new keyword: *PART_SENSOR.
- Multiple jetting is now available for the Hybrid and Chemkin airbag inflator models.
- Nearly all constraint types are now handled for implicit solutions.
- Calculation of constraint and attachment modes can be easily done by using the option: *CONTROL_IMPLICIT_MODES.
- Penalty option, see *CONTROL_CONTACT, now applies to all *RIGIDWALL options and is always used when solving implicit problems.
- Solid elements types 3 and 4, the 4 and 8 node elements with 6 degrees-of-freedom per node are available for implicit solutions.
- The warping stiffness option for the Belytschko-Tsay shell is implemented for implicit solutions. The Belytschko-Wong-Chang shell element is now available for implicit applications. The full projection method is implemented due to it accuracy over the drill projection.
- Rigid to deformable switching is implemented for implicit solutions.

- Automatic switching can be used to switch between implicit and explicit calculations. See the keyword: *CONTROL_IMPLICIT_GENERAL.
- Implicit dynamics rigid bodies are now implemented. See the keyword *CONTROL_IMPLICIT_DYNAMIC.
- Eigenvalue solutions can be intermittently calculated during a transient analysis.
- A linear buckling option is implemented. See the new control input: *CONTROL_IMPLICIT_BUCKLE
- Implicit initialization can be used instead of dynamic relaxation. See the keyword *CONTROL_DYNAMIC_RELAXATION where the parameter, IDFLG, is set to 5.
- Superelements, i.e., *ELEMENT_DIRECT_MATRIX_INPUT, are now available for implicit applications.
- There is an extension of the option, *BOUNDARY_CYCLIC, to symmetry planes in the global Cartesian system. Also, automatic sorting of nodes on symmetry planes is now done by LS-DYNA.
- Modeling of wheel-rail contact for railway applications is now available, see *RAIL_TRACK and *RAIL_TRAIN.
- A new, reduced CPU, element formulation is available for vibration studies when elements are aligned with the global coordinate system. See *SECTION_SOLID and *SECTION_SHELL formulation 98.
- An option to provide approximately constant damping over a range of frequencies is implemented, see *DAMPING_FREQUENCY_RANGE.

Features added during 2003-2005 for the 971 release of LS-DYNA:

Initially, the intent was to quickly release version 971 after 970 with the implicit capabilities fully functional for distributed memory processing using MPI. Unfortunately, the effort required for parallel implicit was grossly underestimated, and, as a result, the release has been delayed. Because of the delay, version 971 has turned into a major release. Some of the new features, listed below, were also added to later releases of version 970. The new explicit capabilities are implemented in the MPP version and except for one case, in the SMP version as well.

Below is list of new capabilities and features:

- A simplified method for using the ALE capability with airbags is now available with the keyword *AIRBAG_ALE.
- Case control using the *CASE keyword, which provides a way of running multiple load cases sequentially within a single run
- New option to forming contact: *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE_SMOOTH, which use fitted surface in contact calculation.

- Butt weld definition by using the *CONSTRAINED_BUTT_WELD option which makes the definition of butt welds simple relative to the option: *CONSTRAINED_GENERALIZED_WELD_BUTT.
- H-adaptive fusion is now possible as an option with the control input, *CONTROL_ADAPTIVE.
- Added a parameter on, *CONTROL_ADAPTIVE, to specify the number of elements generated around a 90 degree radius. A new option to better calculate the curvature was also implemented.
- Added a new keyword: *CONTROL_ADAPTIVE_CURVE, to refine the element along trimming curves
- Birth and death times for implicit dynamics on the keyword *CONTROL_IMPLICIT_DYNAMICS.
- Added an option to scale the spot weld failure resultants to account for the location of the weld on the segment surface, see *CONTROL_SPOTWELD_BEAM.
- Added an option which automatically replaces a single beam spot weld by an assembly of solid elements using the same ID as the beam that was replaced, see *CONTROL_SPOTWELD_BEAM.
- Boundary constraint in a local coordinate system using *CONSTRAINED_LOCAL keyword.
- A cubic spline interpolation element is now available, *CONSTRAINED_SPLINE.
- Static implicit analyses in of a structure with rigid body modes is possible using the option, *CONTROL_IMPLICIT_INERTIA_RELIEF.
- Shell element thickness updates can now be limited to part ID's within a specified set ID, see the *CONTROL_SHELL keyword. The thickness update for shells can now be optionally limited to the plastic part of the strain tensor for better stability in crash analysis.
- Solid element stresses in spot welds are optionally output in the local system using the SWLOCL parameter on the *CONTROL_SOLID keyword.
- SPOTHIN option on the *CONTROL_CONTACT keyword cards locally thins the spot welded parts to prevent premature breakage of the weld by the contact treatments.
- New function: *CONTROL_FORMING_PROJECT, which can initial move the penetrating slave nodes to the master surface
- New function *CONTROL_FORMING_TEMPLATE, which allows user to easily set up input deck. Its function includes auto-position, define travel curve, termination time, and most of the forming parameters for most of the typical forming process.

- New function *CONTROL_FORMING_USER, *CONTROL_FORMING_POSITION, and *CONTROL_FORMING_TRAVEL, when used together, can allow the user to define atypical forming process.
- Added new contact type *CONTACT_GUIDED_CABLE.
- Circular cut planes are available for *DATABASE_CROSS_SECTION definitions.
- New binary database FSIFOR for fluid structure coupling.
- Added *DATABASE_BINARY_D3PROP for writing the material and property data to the first D3PLOT file or to a new database D3PROP.
- DATABASE_EXTENT_BINARY has new flags to output peak pressure, surface energy density, nodal mass increase from mass scaling, thermal fluxes, and temperatures at the outer surfaces of the thermal shell.
- Eight-character alphanumeric labels can now be used for the parameters SECID, MID, EOSID, HGID, and TMID on the *PART keyword.
- Two NODOUT files are now written: one for high frequency output and a second for low frequency output.
- Nodal mass scaling information can now be optionally written to the D3PLOT file.
- Added option, MASS_PROPERTIES, to include the mass and inertial properties in the GLSTAT and SSSTAT files.
- Added option in *CONTROL_CPU to output the cpu and elapsed time into the GLSTAT file.
- Added an option, IERODE, on the *CONTROL_OUTPUT keyword to include eroded energies by part ID into the MATSUM file. Lumped mass kinetic energy is also in the MATSUM file as part ID 0.
- Added an option, TET10, on the *CONTROL_OUTPUT keyword to output ten connectivity nodes into D3PLOT database rather than 4.
- New keyword, *ELEMENT_SOLID_T4TOT10 to convert 4 node tetrahedron elements to 10 node tetrahedron elements.
- New keyword, *ELEMENT_MASS_PART defines the total additional non-structural mass to be distributed by an area weighted distribution to all nodes of a given part ID.
- New keyword option, SET, for *INTIAL_STRESS_SHELL_SET allows a set of shells to be initialized with the state of stress.
- New option allows the number of cpu's to be specified on the *KEYWORD input.
- Tubular drawbead box option for defining the elements that are included in the drawbead contact, see *DEFINE_BOX_DRAWBEAD.
- New function: *DEFINE_CURVE_DRAWBEAD, allow user to conveniently define drawbead by using curves (in x, y format or iges format)

- New function: *DEFINE_DRAWBEAD_BEAM, which allows user to conveniently define drawbead by using beam part ID, and specify the drawbead force.
- Analytic function can be used in place of load curves with the option *DEFINE_-CURVE_FUNCTION.
- Friction can now be defined between part pair using the *DEFINE_FRICTION input.
- New keyword: *DEFINE_CURVE_TRIM_3D, to allow trimming happens based on blank element normal, rather than use pre-defined direction
- A new trimming algorithm was added: *DEFINE_CURVE_TRIM_NEW, which allow seed node to be input and is much faster then the original algorithm.
- A new keyword, *DEFINE_HEX_SPOTWELD_ASSEMBLY, is available to define a cluster of solid elements that comprise a single spot weld.
- The definition of a vector, see *DEFINE_VECTOR, can be done by defining coordinates in a local coordinate system.
- The definition of a failure criteria between part pairs is possible with a table defined using the keyword, *DEFINE_SPOTWELD_FAILURE_RESULTANTS.
- A new keyword, *DEFINE_CONNECTION_PROPERTIES is available for defining failure properties of spot welds.
- Added *DEFINE_SET_ADAPTIVE to allow the adaptive level and element size to be specified by part ID or element set ID.
- Static rupture stresses for beam type spot welds can be defined in the keyword input, *DEFINE_SPOTWELD_RUPTURE_STRESS.
- Section properties can be define in the *ELEMENT_BEAM definitions for resultant beam elements using the SECTION option.
- Physical offsets of the shell reference surface can be specified on the shell element cards, see the OFFSET option on *ELEMENT_SHELL.
- File names can be located in remote directories and accessed through the *IN-CLUDE_PART keyword.
- New features to *INCLUDE_STAMPED_PART: two different mirror options, user-defined searching radius.
- *INTIAL_STRESS_SECTION allows for stress initialization across a cross-section, which consists of solid elements.
- An option, IVATN, is available for setting the velocities of slaved nodes and parts for keyword, *INITIAL_VELOCITY_GENERATION.
- Twenty-two built-in cross-section are now available in the definition of beam integration rules, see *INTEGRATION_BEAM.

- The possibility of changing material types is now available for shells using the user defined integration rule, see *INTEGRATION_SHELL.
- The interface springback file created by using the keyword, *INTERFACE_SPRINGBACK is now optionally written as a binary file.
- An optional input line for *KEYWORD allows the definition of a prefix for all file names created during a simulation. This allows multiple jobs to be executed in the same directory.
- Body force loads can now be applied in a local coordinate system for *LOAD_BODY.
- A pressure loading feature allows moving pressures to be applied to a surface to simulate spraying a surface with stream of fluid through a nozzle. See keyword *LOAD_MOVING_PRESSURE.
- Thermal expansion can be added to any material by the keyword, *MAT_ADD_THERMAL_EXPANSION.
- Curves can now be used instead of eight digitized data points in the material model *MAT_ELASTIC_WITH_VISCOSITY_CURVE
- New options for spot weld failure in *MAT_SPOTWELD, which apply to beam and solid elements.
- Failure criteria based on plastic strain to failure is added to material *MAT_ANISOTROPIC_VISCOPLASTIC.
- Strain rate failure criterion is added to material *MAT_MODIFIED_PIECEWISE_LINEAR_PLASTICITY.
- Strain rate scaling of the yield stress can now be done differently in tension and compression in material with separate pressure cut-offs in tension and compression in material model *MAT_PLASTICITY_TENSION_COMPRESSION.
- The RCDC model is now available to predict failure in material *MAT_PLASTICITY_WITH_DAMAGE.
- Two additional yield surfaces have been added to material *MAT_MODIFIED_HONEYCOMB to provide more accurate predictions of the behavior of honeycomb barrier models.
- Unique coordinate systems can be assigned to the two nodal points of material *MAT_1DOF_GENERALIZED_SPRING.
- Poisson's ratio effects are available in foam defined by load curves in the material *MAT_SIMPLIFIED_RUBBER/FOAM
- Failure effects are available in the rubber/foam material defined by load curves in the *MAT_SIMPLIFIED_RUBBER/FOAM_WITH_FAILURE.
- The material option *MAT_ADD_EROSION now allows the maximum pressure at failure and the minimum principal strain at failure to be specified.

- Strains rather than displacements can now be used with the material model for discrete beams, *MAT_GENERAL_NONLINEAR_6DOF_DISCRETE_BEAM.
- New option for *MAT_TRANSVERSELY_ANISOTROPIC_ELASTIC_PLASTIC_(ECHANGE), which allow two ways to change the Young's modulus during forming simulation.
- New Material model: *MAT_HILL_3R: includes the shear term in the yield surface calculation by using Hill's 1948 an-isotropic material model.
- New Material model: *MAT_KINEMATIC_HARDENING_TRANSVERSELY_ANISOTROPIC: which integrates Mat #37 with Yoshida's two-surface kinematic hardening model.
- Improved formulation for the fabric material, *MAT_FABRIC for formulations 2, 3, and 4. The improved formulations are types 12, 13, and 14.
- Constitutive models added for truss elements:
    - *MAT_MUSCLE
- For beam elements
    - *MAT_MOMENT_CURVATURE
- For shell elements
    - *MAT_RESULTANT_ANISOTROPIC
    - *MAT_RATE_SENSITIVE_COMPOSITE_FABRIC.
    - *MAT_SAMP-1
    - *MAT_SHAPE_MEMORY is now implemented for shells.
- for shell and solid elements:
    - *MAT_BARLAT_YLD2000 for anisotropic aluminum alloys.
    - *MAT_SIMPLIFIED_RUBBER_WITH_DAMAGE
    - *MAT_VISCOELASTIC_THERMAL
    - *MAT_THERMO_ELASTO_VISCOPLASTIC_CREEP
- for the solid elements:
    - *MAT_ARUP_ADHESIVE
    - *MAT_BRAIN_LINEAR_VISCOELASTIC.
    - *MAT_CSCM for modeling concrete.
    - *MAT_PLASTICITY_COMPRESSION_TENSION_EOS for modeling ice.
    - *MAT_COHESIVE_ELASTIC
    - *MAT_COHESIVE_TH
    - *MAT_COHESIVE_GENERAL
    - *MAT_EOS_GASKET

    - *MAT_SIMPLIFIED_JOHNSON_COOK is now implemented for solids.
    - *MAT_PLASTICITY_WITH_DAMAGE is now implemented for solids.
    - *MAT_SPOTWELD_DAIMLERCHRYSLER

- User defined equations-of-state are now available.
- There is now an interface with the MOLDFLOW code.
- Damping defined in *DAMPING_PART_STIFFNESS now works for the Belytschko –Schwer beam element.
- The option *NODE_TRANSFORMATION allows a node set to be transformed based on a transformation defined in *DEFINE_TRANSFORMATION.
- Parameters can be defined in FORTRAN like expressions using *PARAMETER_EXPRESSION.
- A part can be moved in a local coordinate system in *PART_MOVE.
- A simplified method for defining composite layups is available with *PART_COMPOSITE
- The rigid body inertia can be changed in restart via *CHANGE_RIGID_BODY_INERTIA.
- A part set can now be defined by combining other part sets in *SET_PART_ADD.
- Termination of the calculation is now possible if a specified number of shell elements are deleted in a give part ID. See *TERMINATION_DELETED_SHELLS.
- Added hourglass control type 7 for solid elements for use when modeling hyperelastic materials.
- Shell formulations 4, 11, 16, and 17 can now model rubber materials.
- Added a new seatbelt pretensioner type 7 in which the pretensioner and retractor forces are calculated independently and added.
- A new composite tetrahedron element made up from 12 tetrahedron is now available as solid element type 17.
- Shell thickness offsets for *SECTION_SHELL now works for most shell elements, not just the Hughes-Liu shell.
- The Hughes-Liu beam has been extended to include warpage for open cross-sections.
- A resultant beam formulation with warpage is available as beam type 12.
- Two nonlinear shell elements are available with 8 degrees-of-freedom per node to include thickness stretch.
- Tetrahedron type 13, which uses nodal pressures, is now implemented for implicit applications.
- Cohesive solid elements are now available for treating failure.

- Seatbelt shell elements are available for use with the all seatbelt capabilities.
- Superelements can now share degrees-of-freedom and are implemented for implicit applications under MPI.
- A user defined element interface is available for solid and shell elements.
- Thermal shells are available for treating heat flow through shell elements.
- EFG shell formulations 41 and 42 are implemented for explicit analysis.
- EFGPACK is implemented in addition to BCSLIB-EXT solver on the keyword *CONTROL_EFG.
- EFG MPP version is available for explicit analysis.
- EFG fast transformation method is implemented in the EFG solid formulation.
- EFG Semi-Lagrangian kernel and Eulerian kernel options are added for the foam materials.
- EFG 3D adaptivity is implemented for the metal materials.
- EFG E.O.S. and *MAT_ELASTIC_FLUID materials are included in the 4-noded background element formulation.
- Airbag simulations by using ALE method can be switched to control volume method by *ALE_CV_SWITCH.
- *MAT_ALE_VISCOUS now supports Non-Newtonian viscosity by power law or load curve.
- *DATABASE_BINARY_FSIFOR outputs fluid-structure interaction data to binary file.
- *DATABASE_FSI_SENSOR outputs ALE element pressure to ASCII file dbsor.
- *MAT_GAS_MIXTURE supports nonlinear heat capacities.
- *INITIAL_VOLUME_FRACTION_GEOMETRY uses an enhanced algorithm to handle both concave and convex geometries and substantially reduce run time.
- A new keyword *DELETE_FSI allows the deletion of coupling definitions.
- Convection heat transfer activates by *LOAD_ALE_CONVECTION in ALE FSI analysis.
- *ALE_FSI_SWITCH_MMG is implemented to switch between ALE multi-material groups to treat immersed FSI problems.
- Type 9 option is added in *ALE_REFERENCE_SYSTEM_GROUP to deal complex ALE mesh motions including translation, rotation, expansion and contraction, etc.

    - New options in *CONSTRAINED_LAGRANGE_IN_SOLID
    - Shell thickness option for coupling type 4.
    - Bulk modulus based coupling stiffness.
    - Shell erosion treatment.

- Enable/disable interface force file.

- New coupling method for fluid flowing through porous media are implemented as type 11 (shell) and type 12 (solid) in *CONSTRAINED_LAGRANGE_IN_SOLID.
- *ALE_MODIFIED_STRAIN allows multiple strain fields in certain ALE elements to solve sticking behavior in FSI. (MPP underdevelopment)
- *ALE_FSI_PROJECTION is added as a new constraint coupling method to solve small pressure variation problem. (MPP underdevelopment)
- *BOUNDARY_PRESCRIBED_ORIENTATION_RIGID is added as a means to prescribe as a function of time the general orientation of a rigid body using a variety of methods. This feature is available in release R3 and higher of Version 971.
- *BOUNDARY_PRESCRIBED_ACCELEROMETER_RIGID is added as a means to prescribe the motion of a rigid body based un experimental data gathered from accelerometers affixed to the rigid body. This feature is available in release R3 and higher of Version 971.

Capabilities added during 2008-2011 for Version 971R6 of LS-DYNA:

During the last four years the implicit capabilities are now scalable to a large number of cores; therefore, LS-DYNA has achieved a major goal over 15 years of embedding a scalable implicit solver. Also, in addition to the progress made for implicit solutions many other new and useful capabilities are now available.

- The keyword *ALE_AMBIENT_HYDROSTATIC initializes the hydrostatic pressure field in the ambient ALE domain due to an acceleration like gravity.
- The keyword *ALE_FAIL_SWITCH_MMG allows switching an ALE multi-material-group ID (AMMGID) if the material failure criteria occurs.
- The keyword *ALE_FRAGMENTATION allow switching from the ALE multi-material-group ID, AMMGID, (FR_MMG) of this failed material to another AMMGID (TO_MMG). This feature may typically be used in simulating fragmentation of materials.
- The keyword *ALE_REFINE refines ALE hexahedral solid elements automatically.
- The keyword *BOUNDARY_ALE_MAPPING maps ALE data histories from a previous run to a region of elements. Data are read from or written to a mapping file with a file name given by the prompt “map=” on the command line starting the execution.
- The keyword *BOUNDARY_PORE_FLUID is used to define parts that contain pore fluid where defaults are given on *CONTROL_PORE_FLUID input.

- With the keyword, *BOUNDARY_PRESCRIBED_FINAL_GEOMETRY, the final displaced geometry for a subset of nodal points is defined. The nodes of this subset are displaced from their initial positions specified in the *NODE input to the final geometry along a straight line trajectory. A load curve defines a scale factor as a function of time that is bounded between zero and unity corresponding to the initial and final geometry, respectively. A unique load curve can be specified for each node, or a default load curve can apply to all nodes.
- The keyword, *BOUNDARY_PWP defines pressure boundary conditions for pore water at the surface of the software.
- The keyword, *CONSTRAINED_JOINT_COOR, defines a joint between two rigid bodies. The connection coordinates are given instead of the nodal point IDs used in *CONSTRAINED_JOINT.
- The keyword, *CONSTRAINED_SPR2, defines a self-piercing rivet with failure. This model for a self-piercing rivet (SPR2) includes a plastic-like damage model that reduces the force and moment resultants to zero as the rivet fails. The domain of influence is specified by a diameter, which should be approximately equal to the rivet's diameter. The location of the rivet is defined by a single node at the center of two riveted sheets.
- Through the keyword, *CONTROL_BULK_VISCOSITY, bulk viscosity is optional for the Hughes-Liu beam and beam type 11 with warpage. This option often provides better stability, especially in elastic response problems.
- The display of nodal rigid bodies is activated by the parameter, PLOTEL, on the *CONTROL_RIGID keyword.
- The mortar contact, invoked by appending the suffix MORTAR to either FORMING_SURFACE_TO_SURFACE, AUTOMATIC_SURFACE_TO_SURFACE or AUTOMATIC_SINGLE_SURFACE, is a segment to segment penalty based contact. For two segments on each side of the contact interface that are overlapping and penetrating, a consistent nodal force assembly taking into account the individual shape functions of the segments is performed. In this respect the results with this contact may be more accurate, especially when considering contact with elements of higher order. By appending the suffix TIED to the CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR keyword or the suffix MORTAR to the CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK keyword, this is treated as a tied contact interface with tiebreak failure in the latter case. Only OPTION = 9 is supported for the mortar tiebreak contact. The mortar contact is intended for implicit analysis in particular but is nevertheless supported for explicit analysis as well.
- In the database, ELOUT, the number of history variables can be specified for output each integration point in the solid, shell, thick shell, and beam elements. The number of variables is given on the *DATABASE_ELOUT keyword definition.

- A new option is available in *DATABASE_EXTENT_BINARY. Until now only one set of integration points were output through the shell thickness. The lamina stresses and history variables were averaged for fully integrated shell elements, which results in less disk space for the D3PLOT family of files, but makes it difficult to verify the accuracy of the stress calculation after averaging. An option is now available to output all integration point stresses in fully integrated shell elements: 4 x # of through thickness integration points in shell types 6, 7, 16, 18-21, and 3 x # of through thickness integration points in triangular shell types 3, and 17.
- The keyword *DATABASE_PROFILE allows plotting the distribution or profile of data along x, y, or z-direction.
- The purpose of the keyword, *DEFINE_ADAPTIVE_SOLID_TO_SPH, is to adaptively transform a Lagrangian solid Part or Part Set to SPH particles when the Lagrange solid elements comprising those parts fail. One or more SPH particles (elements) will be generated for each failed element to. The SPH particles replacing the failed element inherit all of the properties of failed solid element, e.g. mass, kinematic variables, and constitutive properties.
- With the keywords beginning with, *DEFINE_BOX, a LOCAL option is now available. With this option the diagonal corner coordinates are given in a local coordinate system defined by an origin and vector pair.
- The keyword, *DEFINE_CURVE_DUPLICATE, defines a curve by optionally scaling and offsetting the abscissa and ordinates of another curve defined by the *DEFINE_CURVE keyword.
- The keyword, *DEFINE_ELEMENT_DEATH, is available to delete a single element or an element set at a specified time during the calculation.
- The purpose of the keyword, *DEFINE_FRICTION_ORIENTATION, is to allow for the definition of different coefficients of friction (COF) in specific directions, specified using a vector and angles in degrees. In addition, COF can be scaled according to the amount of pressure generated in the contact interface.
- With the new keyword, *DEFINE_FUNCTION, an arithmetic expression involving a combination of independent variables and other functions, i.e.,

  $$f(a,b,c) = a^*2 + b^*c + sqrt(a^*c)$$

  is defined where a, b, and c are the independent variables. This option is implemented for a subset of keywords.

  - *ELEMENT_SEATBELT_SLIPRING
  - *LOAD_BEAM
  - *LOAD_MOTION_NODE
  - *LOAD_MOVING_PRESSURE
  - *LOAD_NODE
  - *LOAD_SEGMENT

- *LOAD_SEGMENT_NONUNIFORM
- *LOAD_SETMENT_SET_NONUNIFORM
- *BOUNDARY_PRESCRIBED_MOTION

- If a curve ID is not found, then the function ID's are checked.
- The keyword, *DEFINE_SPH_TO_SPH_COUPLING, defines a penalty based contact to be used for the node to node contacts between SPH parts.
- The keyword, *DEFINE_TABLE_2D, permits the same curve ID to be referenced by multiple tables, and the curves may be defined anywhere in the input.
- The keyword, *DEFINE_TABLE_3D, provides a way of defining a three-dimensional table. A 2D table ID is specified for each abscissa value defined for the 3D table.
- The keyword, *ELEMENT_BEAM_PULLEY, allows the definition of a pulley for truss beam elements (see *SECTION_BEAM, ELFORM = 3). Currently, the beam pulley is implemented for *MAT_001 and *MAT_156. Pulleys allow continuous sliding of a string of truss beam element through a sharp change of angle.
- The purpose of the keyword, *ELEMENT_MASS_MATRIX, is to define a 6x6 symmetric nodal mass matrix assigned to a nodal point or each node within a node set.
- The keyword, *ELEMENT_DISCRETE_SPHERE, allows the definition of a discrete spherical element for discrete element calculations. Each particle consists of a single node with its mass, mass moment of inertia, and radius. Initial coordinates and velocities are specified via the nodal data.
- The two keywords, *ELEMENT_SHELL_COMPOSITE and *ELEMENT_TSHELL_COMPOSITE, are used to define elements for a general composite shell part where the shells within the part can have an arbitrary number of layers. The material ID, thickness, and material angle are specified for the thickness integration points for each shell in the part
- The keyword, *EOS_USER_DEFINED, allows a user to supply their own equation-of-state subroutine.
- The new keyword *FREQUENCY_DOMAIN provides a way of defining and solving frequency domain vibration and acoustic problems. The related keyword cards given in alphabetical order are:

  - *FREQUENCY_DOMAIN_ACOUSTIC_BEM_{*OPTION*}
  - *FREQUENCY_DOMAIN_ACOUSTIC_FEM
  - *FREQUENCY_DOMAIN_FRF
  - *FREQUENCY_DOMAIN_RANDOM_VIBRATION
  - *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM
  - *FREQUENCY_DOMAIN_SSD

- The keyword, *INITIAL_AIRBAG_PARTICLE, initializes pressure in a closed airbag volume, door cavities for pressure sensing studies, and tires.
- The keyword *INITIAL_ALE_HYDROSTATIC initializes the hydrostatic pressure field in an ALE domain due to an acceleration like gravity.
- The keyword *INITIAL_ALE_MAPPING maps ALE data histories from a previous run. Data are read from a mapping file with a file name given by the prompt "map=" on the command line starting the execution.
- The keyword, *INITIAL_AXIAL_FORCE_BEAM, provides a simplified method to model initial tensile forces in bolts.
- The keyword, *INITIAL_FIELD_SOLID, is a simplified version of the *INITIAL_STRESS_SOLID keyword which can be used with hyperelastic materials. This keyword is used for history variable input. Data is usually in the form of the eigenvalues of diffusion tensor data. These are expressed in the global coordinate system.
- The equation-of-state, *EOS_MIE_GRUNEISEN, type 16, is a Mie-Gruneisen form with a p-α compaction model.
- The keyword, *LOAD_BLAST_ENHANCED, defines an air blast function for the application of pressure loads due the explosion of conventional charge. While similar to *LOAD_BLAST this feature includes enhancements for treating reflected waves, moving warheads and multiple blast sources. The loads are applied to facets defined with the keyword *LOAD_BLAST_SEGMENT. A database containing blast pressure history is also available (see *DATABASE_BINARY_BLSTFOR).
- The keyword, *LOAD_ERODING_PART_SET, creates pressure loads on the exposed surface composed of solid elements that erode, i.e., pressure loads are added to newly exposed surface segments as solid elements erode.
- The keyword, *LOAD_SEGMENT_SET_ANGLE, applies traction loads over a segment set that is dependent on the orientation of a vector. An example application is applying a pressure to a cylinder as a function of the crank angle in an automobile engine
- The keyword, *LOAD_STEADY_STATE_ROLLING, is a generalization of *LOAD_BODY, allowing the user to apply body loads to part sets due to translational and rotational accelerations in a manner that is more general than the *LOAD_BODY capability. The *LOAD_STEADY_STATE_ROLLING keyword may be invoked an arbitrary number of times in the problem as long as no part has the option applied more than once and they can be applied to arbitrary meshes. This option is frequently used to initialize stresses in tire.
- The keywords INTERFACE_SSI, INTERFACE_SSI_AUX, INTERFACE_SSI_AUX_EMBEDDED and INTERFACE_SSI_STATIC are used to define the soil-

structure interface appropriately in various stages of soil-structure interaction analysis under earthquake ground motion.

- The keyword, *LOAD_SEISMIC_SSI, is used to apply earthquake loads due to free-field earthquake ground motion at certain locations — defined by either nodes or coordinates — on a soil-structure interface. This loading is used in earthquake soil-structure interaction analysis. The specified motions are used to compute a set of effective forces in the soil elements adjacent to the soil-structure interface, according to the effective seismic input–domain reduction method.
- The keyword *DEFINE_GROUND_MOTION is used to specify a ground motion to be used in conjunction with *LOAD_SEISMIC_SSI.
- Material types *MAT_005 and *MAT_057 now accept table input to allow the stress quantity versus the strain measure to be defined as a function of temperature.
- The material option *MAT_ADD_EROSION, can now be applied to all nonlinear shell, thick shell, fully integrated solids, and 2D solids. New failure criteria are available.
- The GISSMO damage model, now available as an option in *MAT_ADD_EROSION, is a phenomenological formulation that allows for an incremental description of damage accumulation, including softening and failure. It is intended to provide a maximum in variability for the description of damage for a variety of metallic materials (e.g. *MAT_024, *MAT_036, …). The input of parameters is based on tabulated data, allowing the user to directly convert test data to numerical input.
- The keyword, *MAT_RIGID_DISCRETE or MAT_220, eliminates the need to define a unique rigid body for each particle when modeling a large number of rigid particles. This gives a large reduction in memory and wall clock time over separate rigid bodies. A single rigid material is defined which contains multiple disjoint pieces. Input is simple and unchanged, since all disjoint rigid pieces are identified automatically during initialization.
- The keyword, *NODE_MERGE, causes nodes with identical coordinates to be replaced during the input phase by the node encountered that has the smallest ID.
- The keyword, *PART_ANNEAL, is used to initialize the stress states at integration points within a specified part to zero at a given time during the calculation. This option is valid for parts that use constitutive models where the stress is incrementally updated. This option also applies to the Hughes-Liu beam elements, the integrated shell elements, thick shell elements, and solid elements.
- The keyword, *PART_DUPLICATE, provides a method of duplicating parts or part sets without the need to use the *INCLUDE_TRANSFORM option.
- To automatically generate elements to visualize rigid walls the DISPLAY option is now available for *RIGIDWALL_PLANAR and *RIGIDWALL_GEOMETRIC.

- A one point integrated pentahedron solid element with hourglass control is implemented as element type 115 and can be referenced in *SECTION_SOLID. Also, the 2 point pentahedron solid, type 15, no longer has a singular mode.
- The keyword *SECTION_ALE1D defines section properties for 1D ALE elements.
- The keyword *SECTION_ALE2D defines section properties for 2D ALE elements.
- The keywords *SET_BEAM_INTERSECT, *SET_SHELL_INTERSECT, *SET_SOLID_INTERSECT, *SET_NODE_INTERSECT, and *SET_SEGMENT_INTER-SECT, allows the definition of a set as the intersection, ∩, of a series of sets. The new set, SID, contains all common members.
- The keyword, *SET_SEGMENT_ADD, is now available for defining a new segment set by combining other segment sets.
- The two keywords, *DEFINE_ELEMENT_GENERALIZED_SHELL and *DEFINE_ELEMENT_GENERALIZED_SOLID, are used to define general shell and solid element formulations to allow the rapid prototyping of new element formulations. They are used in combination with the new keywords *ELEMENT_GENERLIZED_SHELL and *ELEMENT_GENERALIZED_SOLID.
- The two keywords, *ELEMENT_INTERPOLATION_SHELL and *ELEMENT_INTERPOLATION_SOLID, are used to interpolate stresses and other solution variables from the generalized shell and solid element formulations for visualization. They are used together with the new keyword *CONSTRAINED_NODE_INTERPOLATION.
- The keyword, *ELEMENT_SHELL_NURBS_PATCH, is used to define 3D shell elements based on NURBS (Non-Uniform Ration B-Spline) basis functions. Currently four different element formulations, with and without rotational degrees of freedom are available.
- The keyword LOAD_SPCFORC is used to apply equivalent SPC loads, read in from the d3dump file during a full-deck restart, in place of the original constraints in order to facilitate the classical non-reflecting boundary on an outside surface.

Capabilities added in 2012 to create Version 971R6.1, of LS-DYNA:

- A new keyword *MAT_THERMAL_DISCRETE_BEAM defines thermal properties for ELFORM 6 beam elements.
- An option *CONTROL_THERMAL_SOLVER, invoked by TSF < 0, gives the thermal speedup factor via a curve. This feature is useful when artificially scaling velocity in metal forming.
- A nonlinear form of Darcy's law in *MAT_ADD_PORE_AIR allows curves to define the relationship between pore air flow velocity and pore air pressure gradient.
- An extension to the PART option in *SET_SEGMENT_GENERAL allows reference to a beam part. This allows for creation of 2D segments for traction application.

- Options “SET_SHELL”, “SET_SOLID”, “SET_BEAM”, “SET_TSHELL”, “SET_-SPRING” are added to *SET_NODE_GENERAL so users can define a node set using existing element sets.
- Options “SET_SHELL”, “SET_SOLID”, “SET_SLDIO”, “SET_TSHELL”, “SET_-TSHIO” are added to *SET_SEGMENT_GENERAL so users can use existing element sets to define a segment set.
- *BOUNDARY_PRESCRIBED_MOTION_SET_BOX prescribes motion to nodes that fall inside a defined box.
- IPNINT > 1 in *CONTROL_OUTPUT causes d3hsp to list the IPNINT smallest element timesteps in ascending order.
- Section and material titles are echoed to d3hsp.
- A new parameter, MOARFL, in *DEFINE_CONNECTION_PROPERTIES permits reduction in modeled area due to shear.
- A new option HALF_SPACE in *FREQUENCY_DOMAIN_ACOUSTIC_BEM enables treatment of a half-space in boundary element method, frequency domain acoustic analysis.
- A shell script “kill_by_pid” is created during MPP startup. When executed, this script will run “kill -9” on every LS-DYNA process started as part of the MPP job. This is for use at the end of submission scripts, as a “fail safe” cleanup in case the job aborts.
- A new parameter IAVIS in *CONTROL_SPH selects the artificial viscosity formulation for the SPH particles. If set to 0, the Monaghan type artificial viscosity formulation is used. If set to 1, the standard artificial viscosity formulation for solid elements is used which may provide a better energy balance but is less stable in specific applications such as high velocity impact.
- Contact friction may be included in *CONTACT_2D_NODE_TO_SOLID for SPH.
- A new keyword *ALE_COUPLING_NODAL_CONSTRAINT provides a coupling mechanism between ALE solids and non-ALE nodes. The nodes can be from virtually any non-ALE element type including DISCRETE_SPHERE, EFG, and SPH, as well as the standard Lagrangian element types. In many cases, this coupling type may be a better alternative to *CONSTRAINED_LAGRANGE_IN_SOLID.
- The keyword *ALE_ESSENTIAL_BOUNDARY assigns essential boundary conditions to nodes of the ALE boundary surface. The command can be repeated multiple times and is recommended over use of EBC in *CONTROL_ALE.
- The keyword *DELETE_ALECPL in a small restart deck deletes coupling defined with *ALE_COUPLING_NODAL_CONSTRAINT. The command can also be used to reinstate the coupling in a later restart.
- *DEFINE_VECTOR_NODES defines a vector with two node points.

- *CONTACT_AUTOMATIC_SINGLE_SURFACE_TIED allows for the calculation of eigenvalues and eigenvectors for models that include *CONTACT_AUTOMATIC_SINGLE_SURFACE.
- A new parameter RBSMS in *CONTROL_RIGID affects rigid body treatment in Selective Mass Scaling (*CONTROL_TIMESTEP). When rigid bodies are in any manner connected to deformable elements, RBSMS = 0 (default) results in spurious inertia due to improper treatment of the nodes at the interface. RBSMS = 1 alleviates this effect but an additional cost is incurred.
- A new parameter T10JTOL in *CONTROL_SOLID sets a tolerance for issuing a warning when J_min/J_max goes below this tolerance value (i.e., quotient between minimum and maximum Jacobian value in the integration points) for tetrahedron type 16. This quotient serves as an indicator of poor tetrahedral element meshes in implicit that might cause convergence problems.
- A new option MISMATCH for *BOUNDARY_ACOUSTIC_COUPLING handles coupling of structural element faces and acoustic volume elements (ELFORMs 8 and 14) in the case where the coupling surfaces do not have coincident nodes.
- A porosity leakage formulation in *MAT_FABRIC (*MAT_034, FLC < 0) is now available for particle gas airbags (*AIRBAG_PARTICLE).
- *BOUNDARY_PRESCRIBED_ACCELEROMETER is disabled during dynamic relaxation.
- A new parameter CVRPER in *BOUNDARY_PAP defines porosity of a cover material encasing a solid part.
- A parameter TIEDID in *CONTACT_TIED_SURFACE_TO_SURFACE offers an optional incremental normal update in SMP to eliminate spurious contact forces that may appear in some applications.
- A new option SPOTSTP = 3 in *CONTROL_CONTACT retains spot welds even when the spot welds are not found by *CONTACT_SPOTWELD.
- The SMP consistency option (ncpu < 0) now pertains to the ORTHO_FRICTION contact option.
- Forces from *CONTACT_GUIDED_CABLE are now written to ncforc (both ASCII and binout).
- Discrete beam materials 70, 71, 74, 94, 121 calculate axial force based on change in length. Output the change in length instead of zero axial relative displacement to ASCII file disbout (*DATABASE_DISBOUT).
- *DATABASE_RCFORC_MOMENT is now supported in implicit.
- After the first implicit step, the output of projected cpu and wall clock times is written and the termination time is echoed.
- *DATABASE_MASSOUT is upgraded to include a summary table and to optionally add mass for nodes belonging to rigid bodies.

- Generate and store resultant forces for the LaGrange Multiplier joint formulation so as to give correct output to jntforc (*DATABASE_JNTFORC).
- Control the number of messages for deleted and failed elements using parameter MSGMAX in *CONTROL_OUTPUT.
- Nodal and resultant force output is written to nodfor for nodes defined in *DATABASE_NODAL_FORCE_GROUP in *FREQUENCY_DOMAIN_SSD analysis (SMP only).
- Ncforc data is now written for guided cables (*CONTACT_GUIDED_CABLE) in MPP.
- Jobid handling is improved in l2a utility so that binout files from multiple jobs, with or without a jobid-prefix, can be converted with the single command "l2a -j *binout*". The output contains the correct prefix according to the jobid.
- ALE_MULTI-MATERIAL_GROUP (AMMG) info is written to matsum (both ASCII and binout).
- Shell formulation 14 is switched to 15 (*SECTION_SHELL) in models that include axisymmetric SPH.
- *ELEMENT_BEAM_PULLEY is permitted with *MAT_CABLE_DISCRETE_BEAM.
- A warning during initialization is written if a user creates DKT triangles, either by ELFORM = 17 on *SECTION_SHELL or ESORT = 2 on *CONTROL_SHELL, that are thicker than the maximum edge length.
- Account is taken of degenerate acoustic elements with ELFORM 8. Tria and quad faces at acoustic-structure boundary are handled appropriately according to shape.
- The compression elimination option for 2D seatbelts, CSE = 2 in *MAT_SEATBELT is improved.
- Detailed material failure (*MAT_ADD_EROSION) messages in messag and d3hsp are suppressed when number of messages > MSGMAX (*CONTROL_OUTPUT).
- Implement SMP consistency (ncpu < 0) in *MAT_COHESIVE_GENERAL (*MAT_186) solids and shells.
- Viscoelastic model in *MAT_077_O now allows up to twelve terms in Prony series instead of standard six.
- Large curve IDs for friction table (*CONTACT_… with FS = 2) are enabled.
- Efficiency of GISSMO damage in *MAT_ADD_EROSION is improved.
- *MAT_ADD_PERMEABILITY_ORTHOTROPIC is now available for pore pressure analysis (*…_PORE_FLUID).
- For *MAT_224 solids and shells, material damage serves as the failure variable in *CONSTRAINED_TIED_NODES_FAILURE.

- The behavior of *MAT_ACOUSTIC is modified when used in combination with dynamic relaxation (DR). Acoustic domain now remains unperturbed in the DR phase but hydrostatic pressure from the acoustic domain is applied to the structure during DR.
- Option for 3D to 2D mapping is added in *INITIAL_ALE_MAPPING.
- *CONTACT_ERODING_NODES_TO_SURFACE contact may be used with SPH particles.
- Total Lagrangian SPH formulation 7 (*CONTROL_SPH) is now available in MPP.
- The output formats for linear equation solver statistics now accommodate very large numbers as seen in large models.
- *CONTROL_OUTPUT keyword parameter NPOPT is now applicable to thermal data. If NPOPT = 1, then printing of the following input data to d3hsp is suppressed:
    - *INITIAL_TEMPERATURE
    - *BOUNDARY_TEMPERATURE
    - *BOUNDARY_FLUX
    - *BOUNDARY_CONVECTION
    - *BOUNDARY_RADIATION
    - *BOUNDARY_ENCLOSURE_RADIATION
- Beam energy balance information is written to TPRINT file.
- MPP performance for LS-DYNA/MADYMO coupling is improved.
- Shell adaptivity (*CONTROL_ADAPTIVE) is improved to reduce the number of elements along curved surfaces in forming simulations.
- One-step unfolding (*CONTROL_FORMING_ONESTEP) is improved to accommodate blanks with small initial holes.
- Efficiency of FORM 3 isogeometric shells is improved.
- The processing of *SET_xxx_GENERAL is faster.
- *KEYWORD_JOBID now works even when using the *CASE command.
- Parts may be repositioned in a small restart by including *DEFINE_TRANSFORMATION and *NODE_TRANSFORM in the small restart deck to move nodes of a specified node set prior to continuing the simulation.

Capabilities added during 2012/2013 to create LS-DYNA R7.0:

- Three solvers, EM, CESE, and ICFD, and a volume mesher to support the latter two solvers, are new in Version 7. Brief descriptions of those solvers are given below. Keyword commands for the new solvers are in Volume III of the LS-DYNA

Keyword User's Manual. These new solvers are only included in double precision executables.

- Keyword family: *EM_, the keywords starting with *EM refer to and control the Electromagnetic solver problem set up:
  - EM Solver Characteristics:
    - Implicit
    - Double precision
    - Dynamic memory handling
    - SMP and MPP
    - 2D axisymmetric solver / 3D solver
    - Automatic coupling with structural and thermal LS-DYNA solvers
    - FEM for conducting pieces only, no air mesh needed (FEM-BEM system)
    - Solid elements for conductors, shells can be insulators
  - EM Solver Main Features:
    - Eddy Current (a.k.a Induction-Diffusion) solver
    - Induced heating solver
    - Resistive heating solver
    - Imposed tension or current circuits
    - Exterior field
    - Magnetic materials (beta version)
    - Electromagnetic contact
    - EM Equation of states (Conductivity as a function of temperature)
  - EM Solver Applications (Non-exhaustive) :
    - Electromagnetic forming
    - Electromagnetic welding
    - Electromagnetic bending
    - Inductive heating
    - Resistive heating
    - Rail-gun
    - Ring expansions
- Keyword family: *CESE_, the keywords starting with *CESE refer to and control the Compressible CFD solver problem set up:
  - CESE Solver Characteristics:
    - Explicit
    - Double precision
    - Dynamic memory handling

        - SMP and MPP
        - 3D solver / special case 2D solver and 2D axisymmetric solver
        - Automatic coupling with structural and thermal LS-DYNA solvers
        - Eulerian fixed mesh or moving mesh (Either type input with *ELEMENT_SOLID cards or using *MESH cards)

    - CESE Solver Main Features:

        - The CESE (Conservation Element / Solution Element) method enforces conservation in space-time
        - Highly accurate shock wave capturing
        - Cavitation model
        - Embedded (immersed) boundary approach or moving (fitting) approach for FSI problems
        - Coupled stochastic fuel spray solver (See *STOCHASTIC keywords)
        - Coupling with chemistry (See *CHEMISTRY keywords) solver

    - CESE Solver Applications (Non-exhaustive):

        - Shock wave capturing
        - Shock/acoustic wave interaction
        - Cavitating flows
        - Conjugate heat transfer problems
        - Many different kinds of stochastic particle flows, e.g, dust, water, fuel.
        - Chemically reacting flows, e.g, detonating flow, supersonic combustion.

- Keyword family: *ICFD_, the keywords starting with *ICFD refer to and control the incompressible CFD solver problem set up:

    - ICFD Solver Characteristics:

        - Implicit
        - Double precision
        - Dynamic memory handling
        - SMP and MPP
        - 2D solver / 3D solver
        - Makes use of an automatic volume mesh generator for fluid domain (See *MESH keywords)
        - Coupling with structural and thermal LS-DYNA solvers

    - ICFD Solver Main Features:

        - Incompressible fluid solver
        - Thermal solver for fluids
        - Free Surface flows

        - Two-phase flows
        - Turbulence models
        - Transient or steady-state problems
        - Non-Newtonian fluids
        - Boussinesq model for convection
        - Loose or strong coupling for FSI (Fluid-structure interaction)
        - Exact boundary condition imposition for FSI problems

    - ICFD Solver Applications (Non-exhaustive) :

        - External aerodynamics for incompressible flows
        - Internal aerodynamics for incompressible flows
        - Sloshing, Slamming and Wave impacts
        - FSI problems
        - Conjugate heat transfer problems

- Keyword family: *MESH_, the keywords starting with *MESH refer to and control the tools for the automatic volume mesh generator for the CESE and ICFD solvers.

    - Mesh Generator Characteristics:

        - Automatic
        - Robust
        - Generic
        - Tetrahedral elements for 3D, Triangles in 2D
        - Closed body fitted mesh (surface mesh) needs to be provided for volume generation

    - Mesh Generator Main Features:

        - Automatic remeshing to keep acceptable mesh quality for FSI problems (ICFD only)
        - Adaptive meshing tools (ICFD only)
        - Anisotropic boundary layer mesh
        - Mesh element size control tools
        - Remeshing tools for surface meshes to ensure mesh quality

    - Mesh Generator Applications :

        - Used by the Incompressible CFD solver (ICFD).
        - Used by the Compressible CFD solver (CESE).

Other additions to Version 7 include:

- Add new parameter VNTOPT to *AIRBAG_HYBRID, that allows user more control on bag venting area calculation.

- Allow heat convection between environment and CPM bag (*AIRBAG_PARTICLE) bag. Apply proper probability density function to part's temperature created by the particle impact.
- *AIRBAG_PARTICLE and *SENSOR_SWITCH_SHELL_TO_VENT allows user to input load curve to control the venting using choking flow equation to get proper probability function for vents. Therefore, this vent will have the same vent rate as real vent hole.
- Add new option NP2P in *CONTROL_CPM to control the repartition frequency of CPM particles among processors (MPP only).
- Enhance *AIRBAG_PARTICLE to support a negative friction factor (FRIC or PFRIC) in particle to fabric contact. Particles are thus able to rebound at a trajectory closer to the fabric surface after contact.
- Use heat convection coefficient HCONV and fabric thermal conductivity KP to get correct effective heat transfer coefficient for heat loss calculation in *AIRBAG_PARTICLE. If KP is not given, H will be used as effective heat transfer coefficient.
- Extend CPM inflator orifice limit from 100 to unlimited (*AIRBAG_PARTICLE).
- Support dm_in_dt and dm_out_dt output to CPM chamber database (*DATABASE_ABSTAT) to allow user to study mass flow rate between multiple chambers.
- Previously, the number of ships (rigid bodies) in *BOUNDARY_MCOL, as specified by NMCOL, was limited to 2. Apparently, this was because the code had not been validated for more than 2 rigid bodies, but it is believed that it should not be a problem to remove this restriction. Consequently, this limit has been raised to 10, with the caveat that the user should verify the results for NMCOL > 2.
- Implemented a structural-acoustic mapping scheme (*BOUNDARY_ACOUSTIC_MAPPING), for mapping transient structural nodal velocity to acoustic volume surface nodes. This is useful if the structure finite element mesh and the acoustic boundary/finite element mesh are mismatched.
- *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURACE_ORTHO_FRICTION can now be defined by part set IDs when supplemented by *DEFINE_FRICTION_ORIENTATION. Segment sets with orientation per *DEFINE_FRICTION_ORIENTATION are generated automatically.
- Contact force of *CONTACT_ENTITY is now available in intfor (*DATABASE_BINARY_INTFOR).
- *CONTACT_FORCE_TRANSDUCER_PENALTY will now accept node sets for both the slave and master sides, which should allow them to work correctly for eroding materials. BOTH sides should use node sets, or neither.
- Added option to create a backup penalty-based contact for a tied constraint-based contact in the input (IPBACK on Card E of *CONTACT).

- New option for *CONTACT_ENTITY. If variable SO is set to 2, then a constraint-like option is used to compute the forces in the normal direction. Friction is treated in the usual way.
- *CONTACT_ENTITY: allow friction coefficient to be given by a "coefficient vs time" load curve (input < 0 -> absolute value is the load curve ID). Also, if the friction coefficient bigger or equal 1.0, the node sticks with no sliding at all.
- Minor tweak to the way both MPP and SMP handle nodes sliding off the ends of beams in *CONTACT_GUIDED_CABLE.
- Frictional energy output in sleout (*DATABASE_SLEOUT) supported for *CONTACT_…_MORTAR.
- Tiebreak damage parameter output as "contact gap" in intfor file for *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK_MORTAR, OPTION = 9.
- Added MPP support for *CONTACT_2D_AUTOMATIC_SINGLE_SURFACE and *CONTACT_2D_AUTOMATIC_SURFACE_TO_SURFACE.
- Added keyword *CONSTRAINED_MULTIPLE_GLOBAL for defining multi-node constraints for imposing periodic boundary conditions.
- Enhancement for *CONSTRAINED_INTERPOLATION_SPOTWELD (SPR3): calculation of bending moment is more accurate now.
- If *CONSTRAINED_NODAL_RIGID_BODY nodes are shared by several processors with mass scaling on, the added mass is not summed up across processors. This results in an instability of the NRB. (MPP only)
- *ALE_REFINE has been replaced and expanded upon by the *CONTROL_REFINE family of commands. These commands invoke local mesh refinement of shells, solids, and ALE elements based on various criteria.
- Shells or solids in a region selected for refinement (parent element) are replaced by 4 shells or 8 solids, respectively. *CONTROL_REFINE_SHELL applies to shells, *CONTROL_REFINE_SOLID applies to solids and *CONTROL_REFINE_ALE and *CONTROL_REFINE_ALE2D applies to ALE elements. Each keyword has up to 3 lines of input. If only the 1st card is defined, the refinement occurs during the initialization. The 2nd card defines a criterion CRITRF to automatically refine the elements during the run. If the 3rd card is defined, the refinement can be reversed based on a criterion CRITM. All commands are implemented for SMP and MPP, but SMP is not parallelized.
- *CONTROL_REFINE_MPP_DISTRIBUTION distributes the elements required by the refinement across the MPP processes.
- Eliminate automatic writing of a d3plot plot state after each 3D tetrahedral remeshing operation (*CONTROL_REMESHING) to reduce volume of output.
- Generate disbout output (*DATABASE_DISBOUT) for MPP and SMP binout files.

- Extend *DATABASE_MASSOUT to include option to output mass information on rigid body nodes.
- Added new keyword *CHANGE_OUTPUT for full deck restart to override default behavior of overwriting existing ASCII files. For small restart, this option has no effect since all ASCII output is appended to the result of previous run already.
- Added new option (NEWLENGD) to 2nd field of 3rd card of *CONTROL_OUTPUT to write more detailed legend in ASCII output files. At present, only rcforc and jntforc are implemented.
- Increased default binary file size scale factor (x=) from 7 to 1024. That means the default binary file size will be 1 Gb for single version and 2 Gb for double version.
- Add echo of new "max frequency of element failure summaries" flag (FRFREQ in *CONTROL_OUTPUT) to d3hsp file.
- Support LSDA/binout output for new pllyout file (*DATABASE_PLLYOUT, *ELEMENT_BEAM_PULLEY) in both SMP and MPP.
- Allow degenerated hexahedrons (pentas) for cohesive solid elements (ELFORM = 19, 20) that evolve from an extrusion of triangular shells. The input of nodes on the element cards for such a pentahedron is given by: N1, N2, N3, N3, N4, N5, N6, N6.
- Add new option to activate drilling constraint force for shells in explicit calculations. This can be defined by parameters DRCPSID (part set) and DRCPRM (scaling factor) on *CONTROL_SHELL.
- Add SMP ASCII database "pllyout" (*DATABASE_PLLYOUT) for *ELEMENT_BEAM_PULLEY.
- *FREQUENCY_DOMAIN_ACOUSTIC_BEM:
    - Added an option to output real part of acoustic pressure in time domain.
    - Enabled BEM acoustic computation following implicit transient analysis.
    - Implemented coupling between steady state dynamics and collocation acoustic BEM.
    - Implemented Acoustic Transfer Vector (ATV) to variational indirect BEM acoustics.
    - Enabled boundary acoustic mapping in BEM acoustics.
- *FREQUENCY_DOMAIN_ACOUSTIC_FEM:
    - Added boundary nodal velocity to binary plot file d3acs.
    - Implemented pentahedron elements in FEM acoustics.
    - Enabled using boundary acoustic mapping in FEM acoustics.
- *FREQUENCY_DOMAIN_FRF:
    - Updated FRF to include output in all directions (VAD2 = 4).

- Added treatment for FRF with base acceleration (node id can be 0).

- *FREQUENCY_DOMAIN_RANDOM_VIBRATION:
  - Updated calculation of PSD and RMS von Mises stress in random vibration environment, based on Sandia National Laboratories report, 1998.

- *FREQUENCY_DOMAIN_RANDOM_VIBRATION_FATIGUE:
  - Implemented an option to incorporate initial damage ratio in random vibration fatigue.

- *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM:
  - Implemented double sum methods (based on Gupta-Cordero coefficient, modified Gupta-Cordero coefficient, and Rosenblueth-Elorduy coefficient).
  - Updated calculating von Mises stress in response spectrum analysis.
  - Implemented treatment for multi simultaneous input spectra.
  - Improved double sum methods by reducing number of loops.

- *FREQUENCY_DOMAIN_SSD:
  - Added the option to output real and imaginary parts of frequency response to d3ssd.
  - Added the option to output relative displacement, velocity and acceleration in SSD computation in the case of base acceleration. Previously only absolute values were provided.

- Implemented keyword *FREQUENCY_DOMAIN_MODE_{OPTION} so that user can select the vibration modes to be used for frequency response analysis.
- Implemented keyword *SET_MODE_{OPTION} so that user can define a set of vibration modes, to be used for frequency response analysis.
- Implemented keyword *FREQUENCY_DOMAIN_PATH to define the path of binary databases containing mode information, used in restarting frequency domain analysis, e.g. frf, ssd, random vibration.
- Compute normal component of impulse for oblique plates in *INITIAL_MINE_IMPULSE. The feature is no longer limited to horizontal plates.
- Disable license security for *INITIAL_IMPULSE_MINE. The feature is no longer restricted.
- Enabled hourglass type 7 to work well with *INITIAL_FOAM_REFERENCE_GEOMETRY so that initial hourglass energy is properly calculated and foam will spring back to the initial geometry.
- Accommodate erosion of thin shells in *LOAD_BLAST_ENHANCED.

- *LOAD_VOLUME_LOSS has been changed such that after the analysis time exceeds the last point on the curve of volume change fraction versus time, the volume change is no longer enforced.
- *LOAD_BODY_POROUS new option AOPT added to assign porosity values in material coordinate system.
- Added *LOAD_SEGMENT_FILE.
- Add new sensor definition, *SENSOR_DEFINE_ANGLE. This card traces the angle formed between two lines.
- *SENSOR_DEFINE_NODE can be used to trace the magnitude of nodal values (coordinate, velocity or accleration) when VID is "0" or undefined.
- Add two new parameters to *SENSOR_DEFINE_ELEMENT, scale factor and power, so that user can adjust the element-based sensor values (strain, stress, force, …).
- Change history variables 10-12 in *MAT_054/*MAT_ENHANCED_COMPOSITE_DAMAGE (thin shells only) to represent strains in material coordinate system rather than in local element coordinate system. This is a lot more helpful for post-processing issues. This change should not lead to different results other than due to different round-off errors.
- New features and enhancements to *MAT_244/*_MAT_UHS_STEEL:
    - Added implicit support for MAT_244.
    - Changed the influence of the austenite grain size in Mat244 according to Li et al.
    - Changed the start temperatures to fully follow WATT et al and Li et al.
    - Hardness calculation is now improved when noncontinuous cooling is applied i.e., tempering.
    - Added temperature dependent Poisson ratio and advanced reaction kinetics.
    - Added new advanced option to describe the thermal expansion coefficients for each phase.
    - Added option to use Curve ID or a Table ID for describing the latent heat generation during phase transormations.
    - Added support for table definition for Youngs modulus. Now you can have one temperature dependent curve for each of the 5 phases
- Added support for implicit to *MAT_188.
- Added material model *MAT_273/*MAT_CDPM/*MAT_CONCRETE_DAMAGE_PLASTIC_MODEL. This model is aimed at simulations where failure of concrete structures subjected to dynamic loadings is sought. The model is based on effective stress plasticity and has a damage model based on both plastic and elastic strain measures. Implemented for solids only but both for explicit and

implicit simulations. Using an implicit solution when damage is activated may trigger a slow convergense. IMFLAG = 4 or 5 can be useful.

- Added an option in *MAT_266 (*MAT_TISSUE_DISPERSED) so that the user can tailor the active contribution with a time dependent load curve instead of using the internal hardcoded option. See ACT10 in the User's Manual.
- *MAT_173/*MAT_MOHR_COULOMB is available in 2D.
- Enable *MAT_103 and *MAT_104 to discretize the material load curves according to the number of points specified by LCINT in *CONTROL_SOLUTION.
- Implement Prony series up to 18 terms for shells using *MAT_076/*MAT_GENERAL_VISCOELASTIC.
- Added *DEFINE_STOCHASTIC_VARIATION and the STOCHASTIC option for *MATs 10, 15, 24, 81, 98 for shells, solids, and type 13 tets. This feature defines a stochastic variation in the yield stress and damage/failure of the aforementioned material models.
- Add Moodification for *DEFINE_CONNECTION_PROPERTIES, PROPRUL = 2: thinner weld partner is first partner, PROPRUL = 3: bottom (nodes 1-2-3-4) weld partner is first partner.
- Add spotweld area to debug output of *DEFINE_CONNECTION_PROPERTIES which is activated by *CONTROL_DEBUG.
- Add support of *MAT_ADD_EROSION option NUMFIP < 0 for standard (non-GISSMO) failure criteria. Only for shells.
- Improve implicit convergence of *MAT_ADD_EROSION damage model GISSMO by adding damage scaling (1-D) to the tangent stiffness matrix.
- Provide plastic strain rates (tension/compression, shear, biaxial) as history variables no. 16, 17, and 18 for *MAT_187.
- Add new variables to user failure routine matusr_24 (activated by FAIL < 0 on *MAT_024 and other materials): integration point numbers and element id.
- Add new energy based, nonlocal failure criterion for *MAT_ADD_EROSION, parameters ENGCRT (critical energy) and RADCRT (critical radius) after EPSTHIN. Total internal energy of elements within a radius RADCRT must exceed ENGCRT for erosion to occur. Intended for windshield impact.
- Add new option to *MAT_054 for thin shells: Load curves for rate dependent strengths and a rate averaging flag can be defined on new optional card 9.
- Add new option for *MAT_MUSCLE: Input parameter SSP < 0 can now refer to a load curve (stress vs. stretch ratio) or a table (stress vs. stretch ratio vs. normalized strain rate).
- Expand list of variables for *MAT_USER_DEFINED_MATERIAL_MODELS by characteristic element size and element ID.

- Enable *MAT_USER_DEFINED_MATERIAL_MODELS to be used with tetrahedron element type 13. New sample routines “umat41_t13” and “umat41v_t13” show corresponding pressure calculation in the elastic case.
- Add a new feature to *MAT_125 allowing C1 and C2 to be used in calculation of back stress. When plastic strain < 0.5%, C1 is used, otherwise C2 is used as described in Yoshida's paper.
- Extend non-linear strain path (_NLP_FAILURE) in *MAT_037 to implicit.
- *MAT_173/*MAT_MOHR_COULOMB now works in ALE. A new option has been added to suppress the tensile limit on hydrostatic stress recommended for ALE multi-material use.
- Upgraded *MAT_172/*MAT_CONCRETE_EC2.
    - Corrections to DEGRAD option.
    - Concrete and reinforcement types 7 and 8 have been added to reflect changes to Eurocode 2.
    - Extra history variables for reinforcement stress and strain are now output as zero for zero-fraction reinforcement directions.
- Added RCDC model for solid *MAT_082.
- Added Feng's failure model to solid *MAT_021.
- Added *MAT_027 for beams.
- Added *DEFINE_HAZ_PROPERTIES and *DEFINE_HAZ_TAILOR_WELDED_BLANK for modifying material behavior near a spot weld.
- Added fourth rate form to viscoplastic Johnson-Cook model (*MAT_015).
- Added option to *MAT_224 to not delete the element if NUMINT = -200.
- New damage initiation option 3 in multi fold damage criteria in *MAT_ADD_EROSION. Very similar to option 2 but insensitive to pressure.
- Added rotational resistance in *MAT_034/*MAT_FABRIC. Optionally the user may specify the stiffness, yield and thickness of and elastic-perfectly-plastic coated layer of a fabric that results in a rotational resistance during the simulation.
- FLDNIPF < 0 in *MAT_190/*MAT_FLD_3-PARAMETER_BARLAT for shell elements means that failure occurs when all integration points within a relative distance of -FLDNIPF from the mid surface has reached the fld criterion.
- A computational welding mechanics *MAT_270/*MAT_CWM material is available that allows for element birth based on a birth temperature as well as annealing based on an annealing temperature. The material is in addition a thermo-elasto-plastic material with kinematic hardening and temperature dependent properties.
- Added *MAT_271/*MAT_POWDER, a material for manufacturing (i.e., compaction and sintering) of cemented carbides. It is divided into an elastic-plastic

compaction model that is supposed to be run in a first phase, and a viscoelastic sintering model that should be run in a second phase. This model is for solid elements.

- For IHYPER = 3 on a *MAT_USER_DEFINED_… shell material, the deformation gradient is calculated from the geometry instead of incremented by the velocity gradient. The deformation gradient is also passed to the user defined subroutines in the global system together with a transformation matrix between the global and material frames. This allows for freedom in how to deal with the deformation gradient and its transformations in orthotropic (layered) materials.
- The Bergstrom-Boyce viscoelastic rubber model is now available in explicit and implicit analysis as *MAT_269/*MAT_BERGSTROM_BOYCE_RUBBER. The Arruda-Boyce elastic stress is augmented with a Bergstrom-Boyce viscoelastic stress corresponding to the response of a single entangled chain in a polymer gel matrix.
- Added a new parameter IEVTS to *MAT_USER_DEFINED_MATERIAL_MODELS (*MAT_041-050). IEVTS is optional and is used only by thick shell formulation 5. It points to the position of E(a) in the material constants array. Following E(a), the next 5 material constants must be E(b), E(c), v(ba), v(ca), and v(cb). This data enables thick shell formulation 5 to calculate an accurate thickness strain, otherwise the thickness strain will be based on the elastic constants pointed to by IBULK and IG.
- Implemented enhancements to fabric material (*MAT_034), FORM = 14. Stress-strain curves may include a portion for fibers in compression. When unload/reload curves with negative curve ID are input (curve stretch options), the code that finds the intersection point now extrapolates the curves at their end rather than simply printing an error message if an intersection point cannot be found before the last point in either curve.
- Map 1D to 3D by beam-volume averaging the 1D data over the 3D elements (*INITIAL_ALE_MAPPING).
- In a 3D to 3D mapping (*INITIAL_ALE_MAPPING), map the relative displacements for the penalty coupling in *CONSTRAINED_LAGRANGE_IN_SOLID.
- The [name].xy files associated with *DATABASE_ALE_MAT are now created when sense switches sw1, sw2, quit, or stop are issued.
- *ALE_ESSENTIAL_BOUNDARY is available in 2D.
- *DATABASE_FSI is available for 2D (MPP).
- *ALE_ESSENTIAL_BOUNDARY implemented to apply slip-only velocity BC along ALE mesh surface.
- *CONTROL_ALE flag INIJWL = 2 option added to balance initial pressure state between ALE Soil and HE.
- Include SPH element (*ELEMENT_SPH) in time step report.

- Time step and internal energy of 2D axisymmetric SPH elements are calculated in a new way more consistent with the viscosity force calculation.
- Only apply viscosity force to x and y components of 2D axisymmetric SPH element, not on hoop component.
- MAXV in *CONTROL_SPH can be defined as a negative number to turn off velocity checking.
- Improve calculation of 2D axisymmetric SPH contact force in *DEFINE_SPH_TO_SPH_COUPLING.
- Added the following material models for SPH particles: *MAT_004/*MAT_ELASTIC_PLASTIC_THERMAL (3D only) and *MAT_106/*MAT_ELASTIC_VISCOPLASTIC_THERMAL
- Added a new parameter DFACT for *DEFINE_SPH_TO_SPH_COUPLING. DFACT invokes a viscous term to damp the coupling between two SPH parts and thereby reduce the relative velocity between the parts.
- Added BOUNDARY_CONVECTION and BOUNDARY_RADIATION for explicit SPH thermal solver.
- *CONTROL_REMESHING_EFG:
    - Add eroding failed surface elements and reconstructing surface in EFG adaptivity.
    - Add a control parameter for monotonic mesh resizing in EFG adaptivity.
    - Add searching and correcting self-penetration for adaptive parts in 3D tetrahedron remeshing.
- Enhance 3D axisymmetric remeshing with 6-node/8-node elements
- *CONTROL_REMESHING:
    - Use RMIN/RMAX along with SEGANG to determine element size.
    - Remove the restriction that the reference point of computational model must be at original point $(0, 0, 0)$.
    - Rewrite the searching algorithm for identifying the feature lines of cross-sections in order to provide more stable remeshing results.
- Improve rigid body motion in EFG shell type 41.
- Support EFG pressure smoothing in EFG solid type 42 for *MAT_ELASTIC_VISCOPLASTIC_THERMAL.
- Add visco effect for implicit EFG solid type 42.
- Add new EFG solid type 43 (called Meshfree-Enriched FEM, MEFEM) for both implicit and explicit. This element formulation is able to relieve the volumetric locking for nearly incompressible material (eg. rubber) and performs strain smoothing across elements with common faces.

- EFG shell adaptivity no longer requires a special license.
- Application of EFG in an implicit analysis no longer requires a special license.
- Add *SENSOR_CONTROL for prescribed motion constraints in implicit.
- Update *INTERFACE_LINKING_NODE in implicit to catch up with explicit, including adding scaling factors.
- Add support for *DATABASE_RCFORC_MOMENT for implicit.
- Enhance Iterative solvers for Implicit Mechanics.
- Add, after the first implicit time step, the output of projected cpu and wall clock times. This was already in place for explicit. Also echo the termination time.
- Add variable MXDMP in *CONTROL_THERMAL_SOLVER to write thermal conductance matrix and right-hand side every MXDMP time steps.
- Add keyword *CONTROL_THERMAL_EIGENVALUE to calculate eigenvalue(s) of each thermal conductance matrix.
- Added thermal material model *MAT_THERMAL_ORTHOTROPIC_TD_LC. This is an orthotropic material with temperature dependent properties defined by load curves.
- Changed structured file format for control card 27 (first thermal control card). Several input variables used i5 format limiting their value to 99,999. A recent large model exceeded this limit. The format was changed to i10. This change is not backward compatible. Old structured input files will no longer run unless control card 27 is changed to the new i10 format. This change does not affect the KEYWORD file.
- Add thermal material *MAT_T07/*MAT_THERMAL_CWM for welding simulations, to be used in conjunction with mechanical counterpart *MAT_270/*MAT_CWM.
- Modify decomposition costs of *MAT_181 and *MAT_183.
- Introduce new timing routines and summary at termination.
- Echo "MPP contact is groupable" flag to d3hsp
- Bodies using *MAT_RIGID_DISCRETE were never expected to share nodes with non-rigid bodies, but this now works in MPP.
- There is no longer any built-in limitation on the number of processors that may be used in MPP.
- Echo contents of the MPP pfile (including keyword additions) to the d3hsp and mes0000 files.
- Add new keyword *CONTROL_MPP_PFILE, which allows for insertion of text following this command to be inserted into the MPP pfile (p = pfile).

- Change in MPP treatment of *CONSTRAINED_TIEBREAK. They now share a single MPI communicator, and a single round of communication. This should improve performance for problems with large numbers of these, without affecting the results.
- Added two input variables for *CONTROL_FORMING_ONESTEP simulation, TSCLMIN is a scale factor limiting the thickness reduction and EPSMAX defines the maximum plastic strain allowed.
- Added output of strain and stress tensors for onestep solver *CONTROL_FORMING_ONESTEP, to allow better evaluation of formability.
- Improved *CONTACT_AUTO_MOVE: before changes the termination time, and it causes problems when several tools need to be moved. Now *CONTACT_AUTO_MOVE does not change the termination time, but changes the current time. In this way, several tools can be moved without the need to worry about the other tool's move. This is especially useful in multi-flanging and hemming simulations.
- Made improvements to previously undocumented keyword *INTERFACE_BLANKSIZE, including adding the options INITIAL_TRIM, and INITIAL_ADAPTIVE. This keyword was developed for blank size development in sheet metal forming. Generally, for a single forming process, only the option DEVELOPMENT is needed and inputs are an initial estimated blank shape, a formed blank shape, and a target blank shape in either mesh or boundary coordinates. Output will be the calculated/corrected initial blank shape. Initial blank mesh and formed blank mesh can be different (e.g. adaptive). For a multi-stamping process involving draw, trimming and flanging, all three options are needed. Related commands for blank size estimation are *CONTROL_FORMING_ONESTEP, and for trim line development, *CONTROL_FORMING_UNFLANGING.
- Made improvements and added features to previously undocumented keyword *CONTROL_FORMING_UNFLANGING, this keyword unfolds flanges of a deformable blank, e.g., flanged or hemmed portions of a sheet metal part, onto a rigid tooling mesh using the implicit static solver. It is typically used in trim line mapping during a draw die development process. The roots of the flanges or hemmed edges are automatically processed based on a user input of a distance tolerance between the flanges/hemmed edges and rigid tool. It includes the ability to handle a vertical flange wall. Other keywords related to blank size development are, *CONTROL_FORMING_ONESTEP, and *INTERFACE_BLANKSIZE_DEVELOPMENT.
- Added keyword *CONTROL_FORMING_OUTPUT which allows control of d3plot output by specifying distances to tooling home. It works with automatic position of stamping tools using *CONTROL_FORMING_AUTOPOSITION_PARAMETER.
- Added the LOCAL_SMOOTH option to *INTERFACE_COMPENSATION_NEW which features smoothing of a tool's local area mesh, which could otherwise become distorted due to, e.g., bad/coarse mesh of the original tool surface, tooling

pairs (for example, flanging post and flanging steel) do not maintain a constant gap and several compensation iterations. This new option also allows for multiple regions to be smoothed. Local areas are defined by *SET_LIST_NODE_SMOOTH.

- Added output to rcforc for *DEFINE_DE_TO_SURFACE_COUPLING.
- Implement traction surface for *DEFINE_DE_TO_SURFACE_COUPLING.
- Add keyword *DATABASE_BINARY_DEMFOR with command line option dem = dem_int_force. This will turn on the DEM interface force file for DEM coupling option. The output frequency is controlled by the new keyword.
- Add new feature *DEFINE_DE_INJECTION to allow DEM particle dropping from user defined plane.
- Add new option_VOLUME to *ELEMENT_DISCRETE_SPHERE. This will allow DEM input based on per unit density and use *MAT card to get consistent material properties.
- Added FORM = -4 for *ELEMENT_SHELL_NURBS_PATCH. Rotational dofs are automatically set at control points at the patch boundaries, whereas in the interior of the patch only translational dofs are present. This helps for joining multiple nurbs patches at their C0-boundaries.
- Disabled FORM = 2 and 3 for *ELEMENT_SHELL_NURBS_PATCH. These formulations are experimental and not fully validated yet.
- Added energy computation for isogeometric shells (*ELEMENT_SHELL_-NURBS_PATCH) to matsum.
- Allow isogeometric shells (*ELEMENT_SHELL_NURBS_PATCH) to behave as rigid body (*MAT_RIGID).
- Added “g” as abbreviation for gigawords in specification of memory on execution line, e.g, memory = 16g is 16 billion words.
- Suppress non-printing characters in *COMMENT output.
- Add command line option “pgpkey” to output the current public PGP key used by LS-DYNA. The output goes to the screen as well as a file named “lstc_pgp-key.asc” suitable for directly importing into GPG.
- When reading the NAMES file, allow a “+” anywhere on a line to indicate there will be a following line, not just at the end. This was never intended, but worked before r73972 and some customers use it that way.
- Check for integer overflow when processing command line arguments and the memory value on the *KEYWORD card.
- Added new capability for *INTERFACE_LINKING_NODE to scale the displacements of the moving interface.
- Support for *KEYWORD_JOBID with internal *CASE driver.

- *DAMPING_FREQUENCY_RANGE now works for implicit dynamic solutions. An error check has been added to ensure that the timestep is small enough for the damping card to work correctly.
- Added new option *DAMPING_FREQUENCY_RANGE_DEFORM to damp only the deformation instead of the global motion.
- Added *DEFINE_VECTOR_NODES. A vector is defined using two node IDs.
- Add sense switch "prof" to output current timing profile to message (SMP) file or mes#### (MPP) files. Also, for MPP only, collect timing information from processor and output to prof.out when sense switch "prof" is detected.

Capabilities added during 2013/2014 to create LS-DYNA R7.1:

- Add MUTABLE option for *PARAMETER so that parameter values can be redefined later in the input deck.
- Change MPP treatment of two-sided *CONTACT_FORCE_TRANSDUCER so that proper mass and moment values can be output to the rcforc file.
- MPP support for non-zero birthtime for *CONTACT_SINGLE_EDGE.
- Add new command line option "ldir=" for setting a *local* working directory. In MPP, this has the same effect as setting the "directory { local }" pfile option (and it overrides that option). For SMP, it indicates a directory where local, working files should be placed.
- Add support for SMOOTH option in MPP groupable contact.
- Add new keyword card *CONTROL_REQUIRE_REVISION to prevent the model from being run in old versions of LS-DYNA.
- Add part set specification for dynamic relaxation with implicit using *CONTROL_DYNAMIC_RELAXATION. This is a new feature specified with idrflg = 6 on *CONTROL_DYNAMIC_RELAXATION. This allows implicit to be used for the dynamic relaxation phase for models involving parts being modeled with SPH and/or ALE while excluding those parts from the dynamic relaxation phase.
- Add new feature for implicit automatic time step control to cooperate with thermal time step control. On *CONTROL_IMPLICIT_AUTO, IAUTO = 2 is the same as IAUTO = 1 with the extension that the implicit mechanical time step is limited by the active thermal time step.
- On *CONTROL_IMPLICIT_SOLUTION, add negative value of MAXREF for implicit mechanics. Nonlinear iteration will terminate after |MAXREF| iterations. With MAXREF < 0 convergence is declared with a warning. Simulation will continue. Positive values of MAXREF still cause failure of convergence to be declared leading to either a time step reduction or an error termination.

- Add *CONTROL_IMPLICIT_MODAL_DYNAMIC keywords and features. This elevates the modal dynamic features of IMASS = 2 on *CONTROL_IMPLICIT_-DYNAMICS. It also adds additional features of damping and mode selection and stress computations.
- New material model *MAT_DRY_FABRIC / MAT_214, which can be used in modeling high strength woven fabrics with transverse orthotropic behavior.
- Add *ALE_COUPLING_NODAL_PENALTY, penalty-based nodal coupling with ALE.
- Add type 8 *ELEMENT_SEATBELT_PRETENSIONER which takes energy-time curve, instead of pull-in or force curve.
- Add type 9 *ELEMENT_SEATBELT_PRETENSIONER for energy-based buckle / anchor pretensioner.
- Add *DATABASE_BINARY_FSILNK. This feature stores coupling pressure from *CONSTRAINED_LAGRANGE_IN_SOLID in a binary time history file for use in a separate model that does not include ALE.
- Add *LOAD_SEGMENT_FSILNK. Use pressure loads stored in aforementioned binary time history file to load model that does not have ALE elements.
- Add new keyword *DEFINE_SPH_DE_COUPLING to allow SPH particles to contact discrete element spheres (DES).
- Add MOISTURE option to *MAT_076 solids. Allows moisture content to be input as a function of time. Material parameters are then scaled according to the moisture and a moisture strain is also introduced.
- Add *RIGIDWALL_FORCE_TRANSDUCER to output forces from rigidwalls acting on node sets.
- Add LOG_INTERPOLATION option to *MAT_024. This offers an alternate means of invoking logarithmic interpolation for strain rate effects. The other way is to input the natural log of strain rate in the table LCSS.
- Add capability in *MAT_ADD_EROSION (NUMFIP < -100) to set stress to zero in each shell integration point as it reaches the failure criterion. When |NUMFIP|-100 integration points have failed, the shell is eroded. In contrast, when NUM-FIP > 0, failed integration points continue to carry full load as though they were unfailed until element erosion occurs.
- Add new keyword, *PARAMETER_TYPE, for use by LS-PrePost when combining keyword input files. The appropriate offset is applied to each ID value defined using *PARAMETER_TYPE, according to how that ID is used.
- Allow use of load curve to specify damping as a function of time in *DAMPING_-RELATIVE.
- Add a segment based (SOFT = 2) contact option to include the overlap area in the contact stiffness calculation. This is good for improving the friction calculation

and possibly for implicit convergence. The option is turned on by setting FNLSCL > 0 and DNLSCL = 0. As DNLSCL = 0, the contact stiffness is not non-linear. This new option is also useful when used with another improvement that was made to the FS = 2 friction coefficient by table lookup option in segment based contact. When the above mentioned FNLSCL > 0, option is used, the FS = 2 option is now very accurate.

- Add a new RCDC damage option, *MAT_PLASTICITY_WITH_DAMAGE_ORTHO_RCDC1980 which is consistent with the WILKINS paper. It uses the principal values of stress deviators and a different expression for the A_d term.
- Add a TIETYP option to *CONTACT_2D_AUTOMATIC. By default the tied contact automatically uses constraint equations when possible for 2D tied contact. If a conflict is detected with other constraints, or to avoid 2-way constraints, penalty type ties are used when constraints are not possible. The TIETYP option, when set to 1, causes all ties to use the penalty method. This is useful if in spite of the code's best efforts to avoid problems, there is still a conflict in the model.
- Add a scale factor for scaling the frictional stiffness for contact. The parameter is FRICSF on optional card E and it's only supported for segment based (SOFT = 2) contact. This was motivated by a rubber vs. road skidding problem where the friction coefficent had static, dynamic and decay parameters defined. The growth of the frictional force was too slow so the static coulomb value could not be achieved. By scaling the frictional stiffness higher, the coulomb value could approach the static value.
- Add keyword *CONTACT_2D_AUTOMATIC_FORCE_TRANSDUCER. Like the 3D force transducers, it does no contact calculation but only measures the contact forces from other contact definitions. When only a slave side is defined, the contact force on those segments is measured. Currently, two surface force transducers are not available.
- Add options to *MAT_058:
    - Load curves for rate dependent strain values (E11C, E11T, …) can be defined on new optional card 9.
    - Load curves for rate dependent strengths (XC, XT, …) and a rate averaging flag can be defined on new optional card 8.
    - Abscissa values in above curves are taken to be natural log of strain rate when the first value is negative.
    - Add optional transverse shear damage to *MAT_058.
- Add MAT_261 and MAT_262 for general use. *MAT_261 is *MAT_LAMINATED_FRACTURE_DAIMLER_PINHO. *MAT_262 is *MAT_LAMINATED_FRACTURE_DAIMLER_CAMANHO.
- Add pentahedra cohesive solid element types (TYPE = 21 & 22). Type = 21 is the pentahedra version of Type = 19 and Type = 22 is the pentahedra version of

Type = 20. Using ESORT > 0 in *CONTROL_SOLID will automatically sort out the pentahedra elements (19 to 21 and 20 to 22).

- Add *DEFINE_DE_BY_PART to define control parameters for DES by part ID, including damping coefficient, friction coefficient, spring constant, etc. If defined, it will overwrite the parameters in *CONTROL_DISCRETE_ELEMENT.
- Add new feature for *MAT_030 (*MAT_SHAPE_MEMORY) as optional 3rd card. Curves or tables (strain rate dependency) can be defined to describe plastic loading and unloading behavior.
- New feature for *ELEMENT_BEAM_PULLEY. Beam elements BID1 and BID2 can now both be defined as "0" (zero). In that case, adjacent beam elements are automatically detected. Therefore, the first two beam elements with nodal distance < 10^{-6} to the pulley node (PNID) will be chosen.
- Add new feature to *MAT_ADD_EROSION's damage model GISSMO. By default, damage is driven by equivalent plastic strain. Now, users can optionally define another history variable as driving quantity by setting DMGTYP.
- Add volumetric plastic strain to *MAT_187 as history variable 6.
- Add internal energy calculation for *ELEMENT_BEAM_PULLEY.
- Add viscoplastic option to *MAT_157: new parameter VP on Card 5, Column 6.
- Add new keyword *MAT_ADD_COHESIVE which is intended to make 3D material models available for cohesive elements.
- Add new parameters to *MAT_CABLE_DISCRETE / *MAT_071. MXEPS (Card 2, Column 4) is equal the maximum strain at failure and MXFRC (Card 2, Column 5) is equal to the maximum force at failure
- Add *MAT_124 as potential weld partner material for PROPRUL = 2/3 of *DEFINE_CONNECTION_PROPERTIES.
- Add new material *MAT_TOUGHENED_ADHESIVE_POLYMER (TAPO) or *MAT_252 for epoxy-based, toughened, ductile adhesives.
- Add new option to *MAT_002_ANIS: parameter IHIS on Card 4, Column 8. IHIS = 0: terms C11, C12, … from Cards 1, 2, and 3 are used. IHIS = 1: terms C11, C12, … initialized by *INITIAL_STRESS_SOLID's extra history variables.
- Add new option to *MAT_102. Instead of constant activation energy Q, one can define a load curve LCQ on Card 2, Column 7:
  - LCQ.GT.0: Q as function of plastic strain
  - LCQ.LT.0: Q as function of temperature
- Add new option to *MAT_071 (MAT_CABLE_DISCRETE_BEAM). New parameter FRACL0 (Card 2, Column 3) is fraction of initial length that should be reached over time period of TRAMP. That means the cable element length gets modified from L0 to FRACL0 × L0 between t = 0 and t = TRAMP.

- Add internal energy calculation for SPR models *CONSTRAINED_INTERPOLATION_SPOTWELD (SPR3) and *CONSTRAINED_SPR2. Their contribution was missing in energy reports like glstat.
- Add new failure model OPT = 11 to *MAT_SPOTWELD/*MAT_100 for beam elements.
- Add three new failure criteria for shell elements to *MAT_ADD_EROSION on optional card 4, columns 6-8:
    - LCEPS12: load curve in-plane shear strain limit vs. element size.
    - LCEPS13: load curve cross-thickness shear strain limit vs. element size.
    - LCEPSMX: load curve in-plane major strain limit vs. element size.
- Add new capability to *MAT_ADD_EROSION damage model GISSMO. Strain rate scaling curve LCSRS can now contain natural logarithm values of strain rates as abscissa values. This is automatically assumed when the first value is negative.
- Add new parameter NHMOD to *MAT_266. The constitutive model for the isotropic part can now be chosen:
    - NHMOD = 0: original implementation (modified Neo-Hooke)
    - NHMOD = 1: standard Neo-Hookeon (as in umat45)
- New keyword *DEFINE_TABLE_MATRIX is an alternative way of defining a table and the curves that the table references from a single unformatted text file, e.g., as saved from an Excel spreadsheet.
- Change long format so that all data fields are 20 columns and each line of input can hold up to 200 columns. In this way, the number of input lines is the same for long format as for standard format.
    - 8 variables per line in long format = 160 columns
    - 10 variables per line in long format = 200 columns
- Add a new option (SOFT = 6) in *CONTACT_FORMING_NODES_TO_SURFACE for blank edge and guide pin contact.
- Add user-defined criteria for mesh refinement (or coarsening) in *CONTROL_REFINE_….
- Add new contact option that currently only works for MPP SINGLE_SURFACE contact with SOFT = 0 or 1. If SRNDE (field 4 of optional card E) is a 1, then free edges of the contact definition will be rounded WITHOUT extending the segments. Rather than having cylindrical caps on the ends of the segments, the “corners” of the squared off thickness are rounded over.
- Add geometric contact entity type -3 “finite cylinder”.

- Add irate = 2 to *CONTROL_IMPLICIT_DYNAMICS to turn off rate effects for both implicit and explicit.
- Add quadratic 8-node and 6-node shells (shell formulations 23 and 24).
- Add LOG_LOG_INTERPOLATION option for table defining strain rate effects in *MAT_083, *MAT_181, and *MAT_183.
- Add automatic generation of null shells for quadratic shell contact (*PART_DUPLICATE_NULL_OVERLAY).
- Add beam contact forces to rcforc output (*DATABASE_RCFORC).
- Add SHL4_TO_SHL8 option to *ELEMENT_SHELL to automatically convert 4-node shells to 8-node quadratic shells.
- Add 3-node beam element with quadratic interpolation that is tailored for the piping industry. It includes 12 degrees of freedom, including 6 ovalization degrees of freedom, per node for a total of 36 DOF. An internal pressure can be given that can stiffen and elongate the pipe.
    - ELFORM = 14 in *SECTION_BEAM.
    - *ELEMENT_BEAM_ELBOW.
    - NEIPB in *DATABASE_EXTENT_BINARY to direct output of elbow loop-stresses to d3plot. Otherwise, output goes to ASCII file elbwls.k.
    - Supported by a subset of material models including mats 3, 4, 6, 153, 195.
- Add discrete element option DE to *DATABASE_TRACER.
    - Includes variable RADIUS. average result of all
        - RADIUS > 0: Reports the average result of all DE particles in a spherical volume having radius equal to RADIUS and centered at the tracer.
        - RADIUS < 0: Reports result of the closest particle to the tracer.
    - If a tracer node NID is given, then the tracer moves with this node. The node must belong to a DES.
- Add new options *PART_COMPOSITE_LONG and *ELEMENT_SHELL_COMPOSITE_LONG. In contrast to "COMPOSITE", one integration point is defined per card. This is done to allow for more information, such as "ply id".
- Add support of *MAT_ADD_EROSION option NUMFIP < 0 for standard (non-GISSMO) failure criteria. Only for shells.
- Add viscoplastic behavior to *MAT_157, i.e., parameter LCSS can now refer to a table with strain rate dependent yield curves.
- Add singular finite element with midside nodes for 2D plane strain fracture analysis (ELFORM = 55 in *SECTION_SHELL). This is an 8-noded element and can

induce a singular displacement field by moving mid-side nodes to quarter locations.

- If HCONV < 0 in *AIRBAG_PARTICLE, |HCONV| is a curve of heat convection coefficient vs. time.
- Add new option DECOMPOSITION for *AIRBAG_PARTICLE -- MPP only.This will automatically invoke the recommended decomposition commands, *CONTROL_MPP_DECOMPOSITION_BAGREF (if applicable) and *CONTROL_-MPP_DECOMPOSITION_ARRANGE_PARTS, for the bag.
- Add new blockage option for vents in *AIRBAG_PARTICLE:
    - blockage considered
        - .eq.0: no
        - .eq.1: yes
        - .eq.2: yes, exclude external vents
        - .eq.3: yes, exclude internal vents
        - .eq.4: yes, exclude all vents
- Add option in *CONTROL_CPM to consider CPM in the time step size calculation.
- When using *AIRBAG_PARTICLE with IAIR = 2, user should keep mole / particle similar between inflator gas and initial air particles to ensure the correct elastic collision. If different by more than 10%, code will issue warning message and provide the suggested initial air particle number.
- Enable *DEFINE_CURVE_FUNCTION for *SECTION_POINT_SOURCE_MIXTURE and *SECTION_POINT_SOURCE.
- Make *BOUNDARY_PRESCRIBED_MOTION_SET compatible with *CONTROL_REFINE
- Change *BOUNDARY_ACOUSTIC_COUPLING_MISMATCH to rank order opposing acoustic faces and structural segments by proximity, thereby accelerating the preprocessing stage, enhancing reliability and allowing some liberalization of the search parameters.
- Implement hemispherical geometry for particle blast (*DEFINE_PBLAST_GEOMETRY).
- Add explosive type for *PARTICLE_BLAST.
- For particle-based blast *PARTICLE_BLAST:
    - Include random distribution of initial air molecules
    - Modify algorithm to account for the non-thermally-equilibrated state of high velocity gas.

- Improve particle contact method for particle-based blast loading *PARTICLE_-BLAST.
- *CONTACT now works for parts refined using *CONTROL_REFINE_SOLID or *CONTROL_REFINE_SHELL.
- Improve calculation of shell element contact segment thicknesses, particularly at material boundaries.
- MPP: Add output to rcforc file for *CONTACT_AUTOMATIC_TIEBREAK to record the # of nodes tied, and the total tied area.
- MPP: Add calculation of "contact gap" for master side of FORMING contact.
- MPP: Add support for table-based friction (FS = 2.0) to groupable contact.
- Implement splitting-pinball contact, Belytschko & Yeh (1992, 1993). This new contact option is invoked by setting SOFT = 2, SBOPT = 3 and DEPTH = 45. A penetration check method based on LS-PrePost version 4.0 is implemented for the new bilinear-patch-based contact, SOFT = 2, DEPTH = 45 & Q2TRI = 0. The new method provides more accurate intersection information when Q2TRI = 0.
- Add support for birth time for *CONTACT_2D_AUTOMATIC_TIED.
- Improve the segment based single surface contact search for thick segment pairs that are too close together. The code was not working well with triangluar segments. This change affects models with shell segments that have thickness greater than about 2/3 of the segment length.
- Enable segment based quad splitting options to work when shell sets or segment sets are used to define the surface that will be split. This is really a bug fix because there was no check to prevent this and the result was writing past the allocated memory for segment connectivites.
- Allow *CONSTRAINED_INTERPOLATION to use node set to define the independent nodes.
- Add a length unit to the tolerance used for the checking of noncoincident nodes in *CONSTRAINED_JOINTs excluding spherical joints. The old tolerance was 1.e-3. The new tolerance is 1.e-4 times the distance between nodes 1 and 3. The error messages were changed to warnings since this change might otherwise cause existing models to stop running.
- Add d3hsp output for *CONSTRAINED_INTERPOLATION_SPOTWELD (SPR3) and *CONSTRAINED_SPR2. Can be deactivated by setting NPOPT = 1 on *CONTROL_OUTPUT.
- Support NFAIL1 and NFAIL4 of *CONTROL_SHELL in coupled thermal-mechanical analysis, i.e. erode distorted elements instead of error termination.
- PTSCL on *CONTROL_CONTACT can be used to scale contact force exerted on shell formulations 25, 26, 27 as well as shell formulations 2, 16 (IDOF = 3).

- Use SEGANG in *CONTROL_REMESHING to define positive critical angle (unit is radian) to preserve feature lines in 3D tetrahedral remeshing (ADPOPT = 2 in *PART).
- For 3D solid adaptive remeshing including ADPOPT = 2 and ADPOPT = 3 (*PART), the old mesh will be used automatically if the remesher fails generating a new mesh.
- Add option INTPERR on *CONTROL_SHELL (Optional Card 3, Column 8). By default, warning messages INI+143/144/145 are written in case of non-matching number of integration points between *INITIAL_STRESS_SHELL and *SECTION_SHELL. Now with INTPERR = 1, LS-DYNA can terminate with an error.
- Add variable D3TRACE on *CONTROL_ADAPTIVE: The user can now force a plot state to d3plot just before and just after an adaptive step. This option is necessary for tracing particles across adaptive steps using LS-PrePost.
- By putting MINFO = 1 on *CONTROL_OUTPUT, penetration info is written to message files for mortar contact., see also *CONTACT_…. Good for debugging implicit models, not available for explicit.
- Change the default scale factor for binary file sizes back to 70. This value can be changed using "x=" on the execution line. In version R7.0, the default value of x is 4096, and that sometimes leads to difficulty in postprocessing owing to the large size of the d3plot file(s).
- Enable *CONTROL_OUTPUT flag, EOCS, which wasn't having any effect on the shells output to elout file.
- *DATABASE_FSI_SENSOR: Create sensors at solid faces in 3D and at shell sides in 2D.
- *DATABASE_PROFILE: Implement the option DIR = 4 to plot data with curvilinear distributions and the flag UPDLOC to update the profile positions.
- In *CONTROL_SHELL, add options for deletion of shells based on:
    - diagonal stretch ratio (STRETCH)
    - w-mode amplitude in degrees (W-MODE)
- New element formulation ELFORM = 45 in *SECTION_SOLID: Tied Meshfree-enriched FEM (MEFEM). This element is based on the 4-noded MEFEM element (ELFORM = 43, *SECTION_SOLID). Combined with *CONSTRAINED_TIED_NODES_FAILURE, *SET_NODE_LIST and cohesive model, this element can be used to model dynamic multiple-crack propagation along the element boundaries.
- New high order tetrahedron CPE3D10 based on Cosserat Point theory can be invoked by specifying element formulation ELFORM = 16 and combining this with hourglass formulation IHQ = 10. See *SECTION_SOLID and *HOURGLASS.

- Add database D3ACS for collocation acoustic BEM (*FREQUENCY_DOMAIN_-ACOUSTIC_BEM) to show the surface pressure and normal velocities.
- Implement biased spacing for output frequencies for random vibration (*FREQUENCY_DOMAIN_RANDOM_VIBRATION).
- Add frequency domain nodal or element velocity output for acoustic BEM (*FREQUENCY_DOMAIN_ACOUSTIC_BEM).
- Implement boundary acoustic mapping to acoustic BEM in MPP (*BOUNDARY_-ACOUSTIC_MAPPING). This is enabled only for segment sets at present.
- Implement panel contribution analysis capability to Rayleigh method (*FREQUENCY_DOMAIN_ACOUSTIC_BEM_PANEL_CONTRIBUTION).
- Implement a scheme to map velocity boundary condition from dense BEM mesh to coarse mesh to speed up the computation (*FREQUENCY_DOMAIN_ACOUSTIC_BEM).
- Add user node ID for acoustic field points in D3ATV (*FREQUENCY_DOMAIN_-ACOUSTIC_BEM). Now D3ATV is given for multiple field points, and multiple frequencies.
- Add database D3ATV for acoustic transfer vector binary plot (*FREQUENCY_-DOMAIN_ACOUSTIC_BEM_ATV, *DATABASE_FREQUENCY_BINARY_-D3ATV).
- Implement acoustic panel contribution analysis to collocation BEM and dual collocation BEM (*FREQUENCY_DOMAIN_ACOUSTIC_BEM).
- Enable *FREQUENCY_DOMAIN_MODE in response spectrum analysis (*FREQUENCY_DOMAIN_RESPONSE_SPECTRUM).
- Implement an option to read in user-specified nodal velocity history data for running BEM acoustics (*FREQUENCY_DOMAIN_ACOUSTIC_BEM).
- Extend Kirchhoff acoustic method to MPP (*FREQUENCY_DOMAIN_ACOUSTIC_BEM).
- Extend response spectrum analysis to multiple load spectra cases (*FREQUENCY_DOMAIN_RESPONSE_SPECTRUM).
- Add BAGVENTPOP for *SENSOR_CONTROL. This allows user more flexibilty controlling the pop-up of the venting hole of *AIRBAG_HYBRID and *AIRBAG_-WANG_NEFSKE
- Add command *SENSOR_DEFINE_FUNCTION. Up to 15 *DEFINE_SENSORs can be referenced in defining a mathematical operation.
- LAYER of *SENSOR_DEFINE_ELEMENT can now be an integer “I” representing the Ith integration point at which the stress/strain of the shell or tshell element will be monitored.
- Add control of *LOAD_MOVING_PRESSURE by using *SENSOR_CONTROL.

- Add thick shells to the ETYPE option list of *SENSOR_DEFINE_ELEMENT.
- Add *CONTROL_MPP_MATERIAL_MODEL_DRIVER in order to enable the Material Model Driver for MPP (1 core).
- Add table input of thermal expansion coefficient for *MAT_270. Supports temperature-dependent curves arranged according to maximum temperature.
- Add table input of heat capacity for *MAT_T07. Supports temperature dependent curves arranged according to maximum temperature.
- Add two more kinematic hardening terms for *MAT_DAMAGE_3/MAT_153, c2 & gamma2.
- Add materials *MAT_CONCRETE_DAMAGE_REL3/*MAT_072R3 and *MAT_CSCM_CONCRETE/*MAT_159 to Interactive Material Model Driver.
- Enable *MAT_JOHNSON_COOK/*MAT_015 for shell elements to work with coupled structural / thermal analysis.
- Allow *MAT_SOIL_AND_FOAM/*MAT_005 to use positive or negative abscissa values forload curve input of volumetric strains.
- Add *MAT_ACOUSTIC elform = 8 support for pyramid element case using 5-pt integration.
- Add support to *MAT_219 (*MAT_CODAM2) for negative AOPT values which point to coordinate system ID's.
- Modify *MAT_224 so it uses the temperatures from the thermal solution for a coupled thermal-mechanical problem.
- Add alternative solution method (Brent) for *MAT_015 and *MAT_157 in case standard iteration fails to converge.
- Add shell element IDs as additional output to messag file for *MAT_036's warning “plasticity algorithm did not converge”.
- For *MAT_USER_DEFINED_MATERIAL_MODELS, the subroutines crvval and tabval can be called with negative curve / table id which will extract values from the user input version of the curve or table instead of the internally converted “100-point” curve / table.
- In the damage initiation and evolution criteria of *MAT_ADD_EROSION (invoked by IDAM < 0), add the option Q1 < 0 for DETYP = 0. Here, |Q1| is the table ID defining the ufp (plastic displacement at failure) as a function of triaxiality and damage value, i.e., ufp = ufp(eta, D), as opposed to being constant which is the default.
- In *MAT_RHT, ONEMPA = -6 generates parameters in g, cm, and μS and ONEMPA = -7 generates parameters in g, mm, and mS

- In *MAT_SIMPLIFIED_RUBBER/FOAM, STOL > 0 invokes a stability analysis and warning messages are issued if an unstable stretch point is found within a logarithmic strain level of 100%.
- Implement *DATABASE_ALE to write time history data (volume fractions, stresses, …) for a set of ALE elements. Not to be confused with *DATABASE_-ALE_MAT.
- Implement *DELETE_PART in small restarts for ALE2D parts.
- Add conversion of frictional contact energy into heat when doing a coupled thermal-mechanical problem for SPH (variable FRCENG in *CONTROL_CONTACT). This option applys to all 3D contact types supported by SPH particles.
- For keyword *DEFINE_ADAPTIVE_SOLID_TO_SPH, add support of explicit SPH thermal solver for the newly generated SPH particles which were converted from solid elements. The temperatures of those newly generated SPH particles are mapped from corresponding solid elements.
- Implement DE to surface tied contact *DEFINE_DE_TO_SURFACE_TIED. The implementation includes bending and torsion.
- Implement keyword *DEFINE_DE_HBOND to define heterogeneous bond for discrete element spheres (DES). DES (*ELEMENT_DISCRETE_SPHERE) with different material models can be bonded.
- Implement keyword *INTERFACE_DE_BOND to define multiple failure models for various bonds within one part or between different parts through the keyword *DEFINE_DE_HBOND.
- Implement *DEFINE_DE_TO_BEAM_COUPLING for coupling of discrete element spheres to beam elements.
- Add variable MAXGAP in *DEFINE_DE_BOND to give user control of distance used in judging whether to bond two DES together or not, based on their initial separation.
- Add IAT = -3 in *CONTROL_REMESHING_EFG, which uses FEM remapping scheme in EFG adaptivity. Compared to IAT = -2, -1, 1, 2, IAT = -3 is faster and more robust but less accurate.
- Add control flag MM in *CONTROL_REMESHING_EFG to turn on/off monotonic mesh resizing for EFG 3D general remeshing (ADPOPT = 2 in *PART).
- *CONTROL_IMPLICIT_BUCKLING - Extend Implicit Buckling Feature to allow for Implicit problems using Inertia Relief. This involves adding the Power Method as a solution technology for buckling eigenvalue problems. Using the power method as an option for buckling problems that are not using inertia relief has been added as well.

- Extend Implicit Buckling to allow for Intermittent extraction by using negative values of NMODE on *CONTROL_IMPLICIT_BUCKLING similar to using negative values of NEIG on *CONTROL_IMPLICIT_EIGENVALUE.
- Extend implicit-explicit switching specified on *CONTROL_DYNAMIC_RELAXATION to allow explicit simulation for the dynamic relaxation phase and implicit for the transient phase.
- New implementation for extracting resultant forces due to joints for implicit mechanics.
- New implementation of extracting resultant forces due to prescribed motion for implicit mechanics.
- Add support for IGAP > 2 in implicit, segment based (SOFT = 2) contact.
- Add constraint-based, thermal nodal coupling for *CONSTRAINED_LAGRANGE_IN_SOLID. HMIN < 0 turns it on.
- Add FRCENG = 2 on CONTROL_CONTACT keyword.
    - if FRCENG = 1, convert contact frictional energy to heat.
    - if FRCENG = 2, do not convert contact frictional energy to heat.
- Add effect of thermal time scaling (TSF in *CONTROL_THERMAL_SOLVER) to 2D contact.
- Add new pfile decomposition region option: partsets. Takes a list of part sets (*SET_PART) from the keyword input and uses them to define a region, e.g., region { partsets 102 215 sy 1000 } This example would take partsets, scale y by 1000, and decompose them and distribute them to all processors.
- Reduce MPP memory usage on clusters.
- Add MPP support for *ELEMENT_SOURCE_SINK.
- Add new pfile options:
    - decomp { d2r_as_rigid }
    - decomp { d2ra_as_rigid }

  which cause materials appearing in "*DEFORMABLE_TO_RIGID" and "*DEFORMABLE_TO_RIGID_AUTOMATIC" to have their computational costs set as if they were rigid materials during the decomposition.
- Add option ISRCOUT to *INCLUDE_STAMPED_PART to dump out the transformed source/stamp mesh.
- *CONTROL_FORMING_OUTPUT: Allow NTIMES to be zero; support birth and death time; support scale factor in curve definition.
- Add a new option (INTFOR) to *CONTROL_FORMING_OUTPUT to control the output frequency of the INTFOR database.

- Add new features (instant and progressive lancing) in *ELEMENT_LANCING for sheet metal lancing simulation.
- Add a new keyword: *CONTROL_FORMING_INITIAL_THICKNESS.
- Add a new option for springback compensation: *INCLUDE_COMPENSATION_ORIGINAL_TOOLS.
- Add a new keyword: *INTERFACE_COMPENSATION_NEW_PART_CHANGE.
- Add a new keyword (*DEFINE_CURVE_BOX_ADAPTIVITY) to provide better control of mesh refinement along two sides of the curve.
- Isogeometric analysis: contact is available in MPP.
- Normalize tangent vectors for local coordinate system for the rotation free isogeometric shells.
- Add support for dumping shell internal energy density for isogeometric shells (*ELEMENT_SHELL_NURBS_PATCH) via interpolation shells.
- Add support for dumping of strain tensor (STRFLG.EQ.1) for isogeometric shells (*ELEMENT_SHELL_NURBS_PATCH) via interpolation shells.
- Add H-field, magnetization and relative permeability to d3plot output.
- *ICFD_INITIAL: Add a reference pressure (pressurization pressure) for when no pressure is imposed on the boundaries.
- Add the initialization of all nodes at once by setting PID = 0.
- Add the non-inertial reference frame implementation defined by the keyword *ICFD_DEFINE_NONINERTIAL.
- Add several new state variables to LSO. Please refer to the LSO manual to see how to print out the list of supported variables.
- Add support for FSI with thick shells.
- 2D shells are now supported for FSI in MPP. In the past only beams could be used in MPP and beams and shells could be used in SMP.
- The keyword ICFD_CONTROL_FSI has a new field to control the sensitivity of the algorithm to find the solid boundaries used in FSI calculations.
- The 2D mesh now generates semi-structured meshes near the boundaries.
- Add heat flux boundary condition using ICFD_BOUNDARY_FLUX_TEMP.
- Add divergence-free and Space Correlated Synthetic Turbulence Inlet Boundary Condition for LES (Smirnov et al.) using *ICFD_BOUNDARY_PRESCRIBED_VEL.
- *ICFD_BOUNDARY_PRESCRIBED_VEL: Add inflow velocities using the wall normal and a velocity magnitude using the 3rd field VAD.
- Add the activation of synthetic turbulence using the 3rd field VAD.

- Add the option to control the re-meshing frequency in both keywords: see *ICFD_-CONTROL_ADAPT_SIZE and *ICFD_CONTROL_ADAPT.
- *ICFD_CONTROL_TURB_SYNTHESIS: control parameters for the synthetic turbulence inflow.
- *ICFD_BOUNDARY_PRESCRIBED_MOVEMESH: Allows the mesh to slide on the boundaries following the cartesian axis.
- Add a PART_SET option for *CESE_BOUNDARY_…_PART cards.
- Bring in more 2D mesh support, both from the PFEM mesher and a user input 2D mesh (via *ELEMENT_SOLID with 0 for the last 4 of 8 nodes).
- Enable the 2D ball-vertex mesh motion solver for the 2D CESE solver.
- Add new input cards:
    - *CESE_BOUNDARY_CYCLIC_SET
    - *CESE_BOUNDARY_CYCLIC_PART
- Add code for 2D CESE sliding boundary conditions.
- Add support in CESE FSI for 2D shells in MPP.
- Add support for CESE FSI with thick shells.
- Add 2D & 2D-axisymmetric cases in the CESE-FSI solver (including both immersed boundary method & moving mesh method) .
- Add the CSP reduced chemistry model with 0D, 2D, and 3D combustion. The 2D and 3D combustion cases couple with the CESE compressible flow solver.
- Add the G-scheme reduced chemistry model only for 0D combustion.
- Add two different reduced chemistry models.
    - The Computational Singular Perturbation (CSP) reduced model is implemented with existing compressible CESE solver. The CSP is now working on 0-dimensional onstant volume and pressure combustion, 2-D, and 3-D combustion problems.
    - The new reduced chemistry model, G-scheme, is implemented, but currently works only 0-dimensional problems such as constant combustors.
- Jobid can now be changed in a restart by including “jobid=“ on the restart execution line. Previously, the jobid stored in d3dump could not be overwritten.
- Part labels (PID) can be up to 8 characters in standard format; 20 characters in long format.
- Labels for sections (SID), materials (MID), equations of state (EOSID), hourglass IDs (HGID), and thermal materials (TMID) can be up to 10 characters in standard format; 20 characters in long format.

- Create bg_switch and kill_by_pid for SMP. Both files will be removed at the termination of the run.
- Increase the overall length of command line to 1000 characters and length of each command line option to 50 characters.
- Increase MPP search distance for tied contacts to include slave and master thicknesses.
- For *CONTACT_AUTOMATIC_…_MORTAR, the mortar contact now supports contact with the lateral surface of beam elements.
- On *CONTACT_..._MORTAR, IGAP.GT.1 stiffens the mortar contact for large penetrations. The mortar contact has a maximum penetration depth DMAX that depends on geometry and input parameters; if penetration is larger than this value the contact is released. To prevent this release, which is unwanted, the user may put IGAP.GT.1 which stiffens the behavior for penetrations larger than 0.5*DMAX without changing the behavior for small penetrations. This should hopefully not be as detrimental to convergence as increasing the overall contact stiffness.
- For initialization by prescribed geometry in dynamic relaxation (IDRFLG = 2, *CONTROL_DYNAMIC_RELAXATION), add an option where displacements are not imposed linearly but rather according to a polar coordinate system. This option was added to accommodate large rotations.
- The flag RBSMS on *CONTROL_RIGID is now active for regular and selective mass scaling to consistently treat interfaces between rigid and deformable bodies
- Remove static linking for l2a as many systems do not have the required static libraries.
- Add IELOUT in *CONTROL_REFINE to handle how child element data is handled in elout (*DATABASE_HISTORY_SOLID and *DATABASE_HISTORY_-SHELL). Child element data are stored if IELOUT = 1 or if refinement is set to occur only during initialization.
- Include eroded hourglass energy in hourglass energy in glstat file to be consistent with KE & IE calculations so that the total energy = kinetic energy + internal energy + hourglass energy + rigidwall energy.
- Remove *DATABASE_BINARY_XTFILE since it is obsolete.
- When using *PART_AVERAGED for truss elements (beam formulation 3), calculate the time step based on the total length of the combined macro-element instead of the individual lengths of each element.
- Enable writing of midside nodes to d3plot or 6- and 8-node quadratic shell elements.
- Write complete history variables to dynain file for 2D solids using *MAT_NULL and equation-of-state.

- Shell formulations 25, 26, and 27 are now fully supported in writing to dynain file (*INTERFACE_SPRINGBACK_LSDYNA).
- Shell formulations 23 (quad) and 24 (triangle) can now be mixed in a single part. When ESORT = 1 in *CONTROL_SHELL, triangular shells assigned by *SECTION_SHELL to be type 23 will automatically be changed to type 24.
- Enable hyperelastic materials (those that use Green's strain) to be used with thick shell form 5. Previously, use of these materials (2, 7, 21, 23, 27, 30, 31, 38, 40, 112, 128, 168, and 189) with thick shell 5 has been an input error.
- Update acoustic BEM to allow using *DEFINE_CURVE to define the output frequencies (*FREQUENCY_DOMAIN_ACOUSTIC_BEM).
- When using *CONTROL_SPOTWELD_BEAM, convert *DATABASE_HISTORY_BEAM to *DATABASE_CROSS_SECTION and *INITIAL_AXIAL_FORCE_BEAM to *INITIAL_STRESS_CROSS_SECTION for the spot weld beams that are converted to hex spot welds.
- Improve output of *INITIAL_STRESS_BEAM data to dynain via *INTERFACE_SPRINGBACK_LSDYNA. Now, large format can be chosen, history variables are written, and local axes vectors are included.
- Update *MAT_214 (*MAT_DRY_FABRIC) to allow fibers to rotate independently.
- Enable regularization curve LCREGD of *MAT_ADD_EROSION to be used with FLD criterion, i.e. load curve LCFLD. Ordinate values (major strain) will be scaled with the regularization factor.
- Modify *MAT_ADD_EROSION parameter EPSTHIN:
    - EPSTHIN > 0: individual thinning for each IP from *z*-strain (as before).
    - EPSTHIN < 0: averaged thinning strain from element thickness (new).
- Enable regularization curve LCREGD of *MAT_ADD_EROSION to be used with standard (non-GISSMO) failure criteria. Users can now define a failure criterion plus IDAM = 0 plus LCREGD = scaling factor vs. element size to get a regularized failure criterion.
- *MAT_ADD_EROSION: equivalent von Mises stress SIGVM can now be a function of strain rate by specifying a negative load curve ID.
- *SECTION_ALE1D and *SECTION_ALE2D now work on multiple processors (SMP and MPP).
- *CONSTRAINED_LAGRANGE_IN_SOLD ctype 4/5 now converts friction energy to heat. Note it only works for ALE elform 12.

Capabilities added September 2013 – January 2015 to create LS-DYNA R8.0:

See release notes (published separately) for further details.

- Add RDT option for *AIRBAG_SHELL_REFERENCE_GEOMETRY.
- LCIDM and LCIDT of *AIRBAG_HYDRID can now be defined through *DEFINE_CURVE_FUNCTION.
- New variable RGBRTH in *MAT_FABRIC to input part-dependent activation time for airbag reference geometry.
- Negative PID of *AIRBAG_INTERACTION considers the blockage of partition area due to contact.
- Enhancements to *AIRBAG_PARTICLE:
    - New blockage (IBLOCK) option for vents.
    - External work done by inflator gas to the structure is reported to glstat.
    - Enhance segment orientation checking of CPM bag and chambers.
    - Allow user to excluded some parts surface for initial air particles.
    - Support compressing seal vent which acts like flap vent.
    - Support Anagonye and Wang porosity equation through *MAT_FABRIC.
    - Add keyword option _MOLEFRACTION.
- Add ID keyword option to *AIRBAG_REFERENCE_GEOMETRY and *AIRBAG_SHELL_REFERENCE which includes optional input of variables for scaling the reference geometry.
- Enable *DEFINE_CURVE_FUNCTION for *AIRBAG_SIMPLE_AIRBAG_MODEL.
- Calculate heat convection (HCONV) between environment and airbag in consistent fashion when TSW is used to switch from a particle airbag to a control volume.
- For *AIRBAG_PARTICLE, add ENH_V = 2 option for vent hole such that two-way flow can occur, i.e., flow with or against the pressure gradient.
- *BOUNDARY_ALE_MAPPING: add the following mappings: 1D to 2D, 2D to 2D, 3D to 3D.
- *SET_POROUS_ALE: new keyword to define the properties of an ALE porous media by an element set. The porous forces are computed by *LOAD_BODY_POROUS.
- *ALE_FSI_SWITCH_MMG: applies also now to 2D.
- *ALE_SWITCH_MMG: new keyword to switch multi-material groups based on criteria defined by the user with *DEFINE_FUNCTION.
- *CONTROL_ALE: Allow PREF (reference pressure) to be defined by materials.
- Implement *ALE_COUPLING_NODAL_DRAG to model the drag force coupling between discrete element spheres or SPH particles and ALE fluids.

- Implement *ALE_COUPLING_RIGID_BODY as an efficient alternative for constraint type coupling between ALE fluids and a Lagrangian rigid body.
- Error terminate if *BOUNDARY_SPC_NODE_BIRTH_DEATH is applied to a node that belongs to a rigid body.
- Modify *BOUNDARY_PRESCRIBED_ORIENTATION_VECTOR to accommodate bodies which undergo no changes in orientation.
- Add a new keyword *BOUNDARY_SPC_SYMMETRY_PLANE.
- Solid part or solid part set is now allowed for *PARTICLE_BLAST.
- Add ambient pressure boundary condition flag BC_P for *PARTICLE_BLAST.
- New command *DEFINE_PBLAST_GEOMETRY allows the high explosive domain for*PARTICLE_BLAST to be defined by various geometric shapes.
- Allow multiple *PARTICLE_BLAST definitions.
- Add *DATABASE_PBSTAT to output particle blast statistics.
- Output the initial volume and initial mass of HE particles and air particles for *PARTICLE_BLAST to d3hsp.
- Add the command *CESE_BOUNDARY_BLAST_LOAD to allow a blast described by the *LOAD_BLAST_ENHANCED command to be used as a boundary condition in CESE.
- Modify the FSI interface reflective boundary condition pressure treatment in some calculations for the moving mesh and immersed boundary solvers.
- Change the CESE derivatives calculation method to use the current values of flow variables.
- Add two new MAT commands for CESE solver, *CESE_MAT_000 and *CESE_MAT_002.
- Add a non-inertial reference frame solver for fluid and FSI problems using the moving-mesh method.
- For the moving mesh CESE solver, replace the all-to-all communication for conjugate heat and FSI quantities with a sparse communication mechanism.
- Add structural element erosion capability to the immersed boundary method CESE FSI solver (serial capability only).
- Add 2D cyclic boundary conditions capability.
- Add a NaN detection capability for the CESE solver.
- Switch all CESE boundary conditions that use a mesh surface part to define the boundary to use the character string "MSURF" instead of "PART" in the option portion of the keyword name.

- Add missing temperature interpolation in time for imposing solid temperatures as a boundary condition in the CESE solver.
- Optimize the IDW-based mesh motion for the CESE moving mesh solver.
- Treat the input mesh as 3D by default for the CESE solver.
- All of the chemistry features mentioned below are coupled only to the CESE compressible flow solver when 2D or 3D calculations are involved.
- Chemical source Jacobians have been added.
- Introduce *CHEMISTRY_CONTROL_PYROTECHNIC and *CHEMISTRY_PROPELLANT_PROPERTIES for airbag applications. In conjunction with these commands, basic airbag inflator models are implemented.
- The pyrotechnic inflator model using NaN3/Fe2O3 propellant is newly implemented. To connect with the existing ALE airbag solver, two load curves, mass flow rate and temperature, are saved in "inflator_outfile" as a function of time. This model computes three sub-regions: combustion chamber, gas plenum, and discharge tank. Each region can be initialized with different *CHEMISTRY_COMPOSITION models, which means that user can compute Propellant+Gas hybrid mode.
- The following 0-dimensional combustion problems have been improved: constant volume, constant pressure, and CSP.
- For iso-combustion. temperature and species mass fractions as a function of time are displayed on screen and saved in "isocom.csv" to plot with LS-PrePost.
- Another chemical ODE integration method has been implemented.
- The output file of the pyrotechnic inflator is updated so that this file can be read from ALE solver for an airbag simulation.
- 2-D and 3-D TNT gaseous blast explosives, categorized as TBX (thermobaric explosives), are implemented for the Euler equation systems (CESE-only). Also, 3-D TNT blast + aluminum combustion for serial problems is now implemented.
- Implement a mix modeling method for use with CESE solvers.
- Modify *CHEMISTRY-related keyword commands to allow multiple chemistry models in the same problem.
- Add command *CHEMISTRY_MODEL which identifies the files that define a Chemkin chemistry model.
- Modify the following commands such that the files related to the chemistry model have been removed. These commands are only used to select the type of chemistry solver:
    - *CHEMISTRY_CONTROL_CSP
    - *CHEMISTRY_CONTROL_FULL
    - *CHEMISTRY_CONTROL_1D

- Modify *CHEMISTRY_DET_INITIATION where the files related to the chemistry model have been removed, and the Model ID used is inferred through a reference to a chemistry composition ID.
- Modify *CHEMISTRY_COMPOSITION and *CESE_CHEMISTRY_D3PLOT to add model ID.
- Add *CONTACT_TIED_SHELL_EDGE_TO_SOLID for transferring moments from shells into solids.
- Add frictional energy calculation for beams in *CONTACT_AUTOMATIC_GENERAL.
- Enhance ERODING contacts for MPP. The new algorithm uses a completely different approach to determining the contact surface. The old algorithm started from scratch when identifying the exterior of the parts in contact. The new algorithm is smarter about knowing what has been exposed based on what is eroded, and is faster.
- Force EROSOP = 1 for all ERODING type contacts, with a warning to the user if they had input it as 0.
- Add error check in case of a contact definition with an empty node set being given for the slave side.
- Modify output of ncforc (*DATABASE_NCFORC) in order to support output in a local coordinate system.
- For ERODING contacts, reduce memory allocated for segments so each interior segment is only allocated once.
- Add keyword *DEFINE_CONTACT_EXCLUSION (MPP only) to allow for nodes tied in some contacts to be ignored in certain other contacts.
- Rewrite meshing of *CONTACT_ENTITY to use dynamic memory, which removes the previous limit of 100 meshed contact entities. There is now no limit.
- Remove undocumented release condition for MPP's *CONTACT_AUTOMATIC_TIEBREAK, options 5 and greater.
- Add new experimental "square edge" option to select SOFT = 0,1 contacts. This new option applies only to AUTOMATIC_SINGLE_SURFACE and the segment-to-segment treatment of AUTOMATIC_GENERAL, and is invoked by setting SRNDE = 2 on *CONTACT's Optional Card E. This new option does not apply to SOFT = 2; SOFT = 2 square edge option is set using SHLEDG in *CONTROL_CONTACT.
- BT and DT in *CONTACT can be set to define more than one pair of birthtime/death-time for the contact by pointing to a curve or table. These pairs can be unique for the dynamic relaxation phase and the normal phase of the simulation.

- Add EDGEONLY option to *CONTACT_AUTOMATIC_GENERAL to exclude node-to-segment contact and consider only edge-to-edge and beam-to-beam contact.
- VDC defines the coefficient of restituion when variable CORTYP is defined. Available for *CONTACT_AUTOMATIC_NODES_TO_SURFACE, *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE, and *CONTACT_AUTOMATIC_SINGLE_SURFACE; SOFT = 0 or 1 only.
- Enhancements for *CONTACT_AUTOMATIC_GENERAL:
    - Add beam to beam contact option CPARM8 in *PART_CONTACT (MPP only).
    - Add option whereby beam generated on exterior shell edge will be shifted into the shell by half the shell thickness. In this way, the shell-edge-to-shell-edge contact starts right at the shell edge and not at an extension of the shell edge (see OPT2 = 10, CPARM8, MPP Card 1).
- Implement *CONTROL_CONTACT PENOPT = 3 option to *CONTACT_AUTOMATIC_NODES_TO_SURFACE and *CONTACT_ERODING_NODES_TO_SURFACE for SMP.
- Update segment based (SOFT = 2) contact to improve accuracy at points away from the origin. The final calculations are now done with nodal and segment locations that have been shifted towards the origin so that coordinate values are small.
- Enable user defined friction (*USER_INTERFACE_FRICTION; subroutine usrfrc) for MPP contact SOFT = 4.
- Unify automatic tiebreak messages for damage start and final failure. SMP and MPP should now give the same output to d3hsp and messag. This affects *CONTACT_AUTOMATIC_...TIEBREAK, OPTIONs 6, 7, 8, 9, 10, and 11.
- *CONTACT_ADD_WEAR: Associates wear calculations to a forming contact interface whose quantities can be posted in the intfor database file. Adaptivity is supported.
- *CONTACT_..._MORTAR:
    - Detailed warning outputs activated for mortar contact, also clarifies echoed data in d3hsp.
    - Contact thickness made consistent with other contacts in terms of priority between ISTUPD on CONTROL_SHELL, SST on CONTACT and OPTT on PART_CONTACT.
    - Efficency improvement of bucket sort in mortar contact allowing for significant speedup in large scale contact simulations.
- *CONTACT_..._MORTAR, *DEFINE_FRICTION, *PART_CONTACT:

  - Mortar contact supports FS = -1.0, meaning that frictional coefficients are taken from *PART_CONTACT parameters.
  - Mortar contact supports FS.EQ.-2 meaning that friction is taken from *DEFINE_FRICTION.

- *CONTACT_AUTOMATIC_SINGLE_SURFACE_MORTAR: Using IGNORE < 0 for single surface mortar contact will ignore penetrations of segments that belong to the same part.
- Friction factors are now a function of temperature for *CONTACT_..._THERMAL_FRICTION.
- *SET_POROUS_LAGRANGIAN: new keyword to define the porosity of Lagrangian elements in an element set. The porous forces are computed by *CONSTRAINED_LAGRANGE_IN_SOLID CTYPE = 11 or 12.
- *CONSTRAINED_LAGRANGE_IN_SOLID: CTYPE = 12 is now also available in 2D.
- Add helix angle option for *CONSTRAINED_JOINT_GEARS.
- Change keyword from *CONSTRAINED_BEARING to *ELEMENT_BEARING.
- Enhance explicit to use the implicit inertia relief constraints. This allows implicit-explicit switching for such problems.
- Add new input options to *CONTROL_IMPLICIT_INERTIA_RELIEF:

  - user specified number of nodes
  - user specified list of modes to constrain out.

- Implement *CONSTRAINED_BEAM_IN_SOLID. This feature is basically an overhauled constraint couping between beams and Lagrangian solids that includes features that make it more attractive in some cases than *CONSTRAINED_LAGRANGE_IN_SOLID, for example, in modeling coupling of rebar in concrete.
- Allow *CONSTRAINED_INTERPOLATION to use node set to define the independent nodes.
- Add new feature MODEL.GE.10 to *CONSTRAINED_INTERPOLATION_SPOTWELD (SPR3). This allows parameters STIFF, ALPHA1, RN, RS, and BETA to be defined as *DEFINE_FUNCTIONs of thicknesses and maximum engineering yield stresses of connected sheets.
- Add failure reports for *CONSTRAINED_SPR2.
- Add more d3hsp output for *CONSTRAINED_INTERPOLATION_SPOTWELD and *CONSTRAINED_SPR2. Can be deactivated by setting NPOPT = 1 on *CONTROL_OUTPUT.

- Add option to *CONSTRAINED_JOINT: Relative penalty stiffness can now be defined as function of time when RPS < 0 refers to a load curve. Works for SPHERICAL, REVOLUTE, CYLINDRICAL in explixit analyses.
- Variable MODEL invokes new SPR4 option in *CONSTRAINED_INTERPOLATION_SPOTWELD.
- *CONSTRAINED_JOINT_GEARS: Gear joint now supports bevel gears and similar types, i.e., the contact point does not necessarily have to be on the axis between the gear centers.
- *CONSTRAINED_MULTIPLE_GLOBAL: Support multiple constraints defined on the extra DOFs of user-defined elements.
- Make the *CONTROL_SHELL PSNFAIL option work with the W-MODE deletion criterion for shells.
- New subcycling scheme activated for *CONTROL_SUBCYCLE and *CONTROL_SUBCYCLE_MASS_SCALED_PART. By default the ratio between the largest and smallest time step is now 16 and the external forces are evaluated every time step. The old scheme had a hard wired ratio of 8. The ratios can be optionally changed by *CONTROL_SUBCYCLE_K_L where K is the maximum ratio between time steps for internal forces and L is likewise the ratio for external forces.
- *DATABASE_PROFILE:
    - output kinetic and internal energy profiles,
    - output volume fraction profiles,
    - add a parameter MMG to specify the ALE group for which element data can be output.
- *DATABASE_ALE_MAT: can now use *DEFINE_BOX to compute the material energies, volumes and masses for elements inside boxes (instead of the whole mesh).
- *DATABASE_TRACER_GENERATE: new keyword to create ALE tracer particles along iso-surfaces.
- *DATABASE_FSI: add option to output moments created by FSI forces about each node in a node set. These moments about nodes are reported in dbfsi.
- Add *DATABASE_BEARING to write brngout data pertaining to *ELEMENT_BEARINGs.
- Include eroded hourglass energy in hourglass energy in glstat file to be consistent with KE & IE calculations so that the total energy = kinetic energy + internal energy + hourglass energy + rigidwall energy.
- Add support for new database pbstat (*DATABASE_PBSTAT) for *PARTICLE_BLAST.
    - internal energy and translational energy of air and detonation products

    - force/pressure of air and detonation products for each part

- *DATABASE_EXTENT_INTFOR: New parameter NWEAR on optional card governs the output of wear depth to the intfor database.
- Using CMPFLG = -1 in *DATABASE_EXTENT_BINARY will work just as CMPFLG = 1, except that for *MAT_FABRIC (form 14 and form -14) and *MAT_FABRIC_MAP the local strains and stresses will be engineering quantities instead of Green-Lagrange strain and 2nd Piola-Kirchhoff stress.
- For some materials and elements, thermal and plastic strain tensors can be output to d3plot database, see STRFLG in *DATABASE_EXTENT_BINARY.
- Add option for output of detailed (or long) warning/error messages to d3msg. See MSGFLG in *CONTROL_OUTPUT. Only a few "long" versions of warnings/errors at this time but that list is expected to grow.
- Add two new options for rigid body data compression in d3plot; see DCOMP in *DATABASE_EXTENT_BINARY.
- Add option to write revised legend to jntforc, secforc, rcforc, deforc and nodout files via input flag NEWLEG in *CONTROL_OUTPUT. This helps to avoid confusion over unassigned IDs and duplicated IDs.
- If any input data is encrypted and dynain is requested, the code issues an error message and stops the job.
- Solid part or solid part set is now allowed for *DEFINE_DE_TO_SURFACE_COUPLING.
- Implement *DELETE_PART for Discrete Element Sphere.
- The unit of contact angle changed from radian to degree for *CONTROL_DISCRETE_ELEMENT.
- Implement Archard's wear law to *DEFINE_DE_TO_SURFACE_COUPLING for discrete element spheres. Wear factor is output to DEM binout database.
- Add damping energy and frictional energy of discrete elements to "damping energy" and "sliding interface energy" terms in glstat.
- Introduce a small perturbation to the initial position of newly generated discrete elements for *DEFINE_DE_INJECTION. This allows a more random spatial distribution of the generated particles.
- *INTERFACE_DE_HBOND replaces *INTERFACE_DE_BOND. Used to define the failure models for bonds linking various discrete element (DE) parts within one heterogeneous bond definition (*DEFINE_DE_HBOND).
- *DEFINE_ADAPTIVE_SOLID_TO_DES: Embed and/or transform failed solid elements to DES (*ELEMENT_DISCRETE_SPHERE) particles. The DES particles inherit the material properties of the solid elements. All DES-based features are available through this transformation, including the bond models and contact

algorithms. This command is essentially to DES what *DEFINE_ADAPTIVE_-SOLID_TO_SPH is to SPH particles.

- Add EM orthotropic materials where the electric conductivity is a 3x3 tensor, see new card, *EM_MAT_003.
- Add new keyword family, *EM_DATABASE_... which triggers the output of EM quantities and variables. All EM related ASCII outputs now start with em_***. Keywords are:
    - EM_DATABASE_CIRCUIT
    - EM_DATABASE_CIRCUIT0D
    - EM_DATABASE_ELOUT
    - EM_DATABASE_GLOBALENERGY
    - EM_DATABASE_NODOUT
    - EM_DATABASE_PARTDATA
    - EM_DATABASE_POINTOUT
    - EM_DATABASE_ROGO
    - EM_DATABASE_TIMESTEP
- Add capability to plot magnetic field lines in and around the conductors at given times, see *EM_DATABASE_FIELDLINE. ASCII output files are generated (lspp_fieldLine_xx) and are readable by LSPP in order to plot the field lines. In the future, LSPP will be capable of directly generating the field lines.
- Add EM quantities in *DEFINE_CURVE_FUNCTION:
    - EM_ELHIST for element history (at element center).
    - EM_NDHIST for node history.
    - EM_PAHIST for part history (integrated over the part).
- Add *EM_EOS_TABULATED2 where a load curve defines the electrical conductivity vs time.
- Introduce capability to use the EM solver on (thin) shells: An underlying solid mesh (hexes and prisms) is built where the EM is solved and the EM fields are then collapsed onto the corresponding shell. The EM mat for shells is defined in *EM_MAT_004. This works for EM solvers 1, 2 and 3 and the EM contact is available for shells.
- Add different contact options in the *EM_CONTACT card.
- Add new methods to calculate electric contact resistance between two conductors for Resistive Spot Welding applications (RSW). See *EM_CONTACT_RESISTANCE.
- Add Joule Heating in the contact resistance (*EM_CONTACT_RESISTANCE). The Joule heating is evenly spread between the elements adjacent to the faces in contact.

- Add new circuit types 21 and 22 (see *EM_CIRCUIT) allowing users to put in their own periodic curve shape when using the inductive heating solver. This is useful in cases where the current is not a perfect sinusoidal.
- Provide default values for NCYCLEBEM and NCYCLEFEM (=5000) and set default value of NUMLS to 100 in *EM_CIRCUIT.
- Add two additional formulations, FORM = 3 and 4, to *PART_MODES.
- Add 20-node solid element, ELFORM = 23 in *SECTION_SOLID.
- Add H8TOH20 option to *ELEMENT_SOLID to convert 8-node to 20-node solids.
- Add option SOLSIG to *CONTROL_OUTPUT which will permit stresses and other history variables for multi-integration point solids to be extrapolated to nodes. These extrapolated nodal values replace the integration point values normally stored in d3plot. NINTSLD must be set to 8 in *DATABASE_EXTENT_BINARY when a nonzero SOLSIG is specified. Supported solid formulations are solid elements are: -1, -2, 2, 3, 4, 18, 16, 17, 23.
- Activate contact thickness input from *PART_CONTACT for solids.
- Made many enhancements for *PART_MODES for robustness and MPP implementation.
- Add new cohesive shell element (elform = 29) for edge-to-edge connectivity between shells. This element type takes bending into account and supports MPP and implicit solvers.
- Error terminate with message, STR+1296, if same node is defined multiple times in *ELEMENT_MASS_MATRIX.
- Add support for negative MAXINT option in *DATABASE_EXTENT_BINARY for thick shell elements.
- *ELEMENT_TSHELL: Add "BETA" as option for *ELEMENT_TSHELL to provide an orthotropic material angle for the element.
- Add Rayleigh damping (*DAMPING_PART_STIFFNESS) for triangular shell element types 3 and 17.
- Add new keyword *ELEMENT_BEAM_SOURCE. Purpose: Define a nodal source for beam elements. This feature is implemented for truss beam elements (ELFORM = 3) with material *MAT_001 and for discrete beam elements (ELFORM = 6) with material *MAT_071.
- Add new option to *DEFINE_ELEMENT_DEATH. New variable IDGRP defines a group id for simultaneous deletion of elements.
- Convert cohesive solid type 20 and 22 to incremental formulation to properly handle large rotations. Also use consistent mass.
- Add Smoothed Particle Galerkin (SPG) method for solid analysis (ELFORM = 47) and corresponding keyword option *SECTION_SOLID_SPG. SPG is a true

particle method in Galerkin formulation that is suitable for severe deformation problems and damage analysis.

- Enhance *ELEMENT_LANCING by supporting *PARAMETER, *PARAMETER_EXPRESSION.
- Add a new feature, *CONTROL_FORMING_TRIMMING, for 2D and 3D trimming of a 3-layer, sandwich laminate blank via *DEFINE_CURVE_TRIM.
- Add 3D normal trimming of solid elements via *DEFINE_CURVE_TRIM_3D.
- Add new features for solid elements 2D trimming *DEFINE_CURVE_TRIM_NEW:
    - Allow support of arbitrary trimming vector (previously only global z direction was allowed).
    - Improve trimming algorithm for speed up.
    - Allow trimming curves to project to either the top or bottom surface.
- Add a new AUTO_CONSTRAINT option to *CONTROL_FORMING_ONESTEP which is convenient for blank nesting.
- Add new features to *CONTROL_FORMING_SCRAP_FALL. Previously the user was required to define the trimmed blank properly. Now the blank is trimmed by the cutting edge of the trim steel, which is defined by a node set and a moving vector.
- Enhance *CONTROL_FORMING_SCRAP_FALL: Allow the node set (NDSET) on the trim steel edge to be defined in any order.
- Improve *CONTROL_FORMING_ONESTEP:
    - Reposition the initial part before unfolding, using the center element normal.
    - Add a message showing that the initial unfolding is in process.
- Add 2D trimming for solid elements *DEFINE_CURVE_TRIM_NEW, support *DEFINE_TRIM_SEED_POINT_COORDINATES.
- Add *CONTROL_FORMING_AUTOCHECK to detect and fix flaws in the mesh for the rigid body that models the tooling.
- Add new features to *CONTROL_FORMING_UNFLANGING:
    - The incoming flange mesh will be automatically checked for mesh quality and bad elements fixed.
    - Allow thickness offset of deformable flange to use the blank thickness from user's input.
    - Allow definition any node ID in the outer boundary of the flange, to speed up the search when holes are present in the part.
    - Add a new parameter CHARLEN to limit the search region.

- Allow holes to exist in the flange regions.
- Output a suggested flange part after unflanging simulation, with the failed elements deleted from the unflanged part.
- Automatically define a node set and constraints for the flange boundary nodes through the user definition of three nodes.
- Add output of forming thickness, effective strain and trim curves after unflanging simulation.

- Add a new keyword *CONTROL_FORMING_TRIM to replace *ELEMENT_TRIM.
- Add a new keyword: *CONTROL_FORMING_UNFLANGING_OUTPUT: Failed elements are removed to come up with the trim curves.
- Add new features to *INTERFACE_BLANKSIZE_DEVELOPMENT including allowing for trimming between initial and final blank.
- Enhance *CONTROL_FORMING_OUTPUT for controlling the number of states.
- Add *CONTROL_FORMING_TRIM_MERGE to close a user specified (gap) value in the trim curves, so each trim curve will form a closed loop, which is required for a successful trimming.
- Add *CONTROL_FORMING_MAXID to set a maximum node ID and element ID for the incoming dynain file (typically the blank) in the current simulation.
- Enhance *FREQUENCY_DOMAIN_ACOUSTIC_BEM:

  - Update the boundary condition definition for BEM acoustics so that impedance and other user defined boundary conditions can be combined with time domain velocity boundary condition.
  - Implement Burton-Miller BEM to MPP.
  - Implement impedance boundary condition to Burton-Miller BEM.
  - Implement half space option (*FREQUENCY_DOMAIN_ACOUSTIC_BEM_HALF_SPACE) to variational indirect BEM.
  - Implement half space option to acoustic scattering problems.
  - Extend acoustic ATV computation to elements, in addition to nodes.
  - Support element based ATV output in d3atv.
  - Add an option (_MATV) to run modal acoustic transfer vector. Implement MATV to MPP.
  - Implement running BEM Acoustics based on modal ATV (SSD excitation only).

- *FREQUENCY_DOMAIN_ACOUSTIC_FEM: Enable running FEM acoustics based on restarting SSD (*FREQUENCY_DOMAIN_SSD).
- Add *FREQUENCY_DOMAIN_ACOUSTIC_INCIDENT_WAVE to define the incident waves for acoustic scattering problems. To be used with *FREQUENCY_DOMAIN_ACOUSTIC_BEM.

- Add *FREQUENCY_DOMAIN_ACOUSTIC_SOUND_SPEED to define frequency dependent complex sound speed, which can be used in BEM acoustics. By using complex sound speed, the damping in the acoustic system can be considered. To be used with *FREQUENCY_DOMAIN_ACOUSTIC_BEM.
- *FREQUENCY_DOMAIN_FRF: Add mode dependent rayleigh damping to frf and ssd (DMPMAS and DMPSTF).
- *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM:
  - Add output of nodout_spcm and elout_spcm, to get nodal results and element results at user specified nodes and elements.
  - Add von Mises stress computation.
- *FREQUENCY_DOMAIN_RANDOM_VIBRATION: Add semi-log, and linear-linear interpolation on PSD curves (parameter LDFLAG).
- *FREQUENCY_DOMAIN_SSD:
  - Add strain computation.
  - Add parameter LC3 to define the duration of excitation for each frequency.
  - Implement fatigue analysis option (_FATIGUE) based on ssd (sine sweep).
  - Add option to use *DAMPING_PART_MASS and *DAMPING_PART_-STIFFNESS in SSD (DMPFLG = 1).
- Add *MAT_ADD_FATIGUE to define material's SN fatigue curve for application in vibration fatigue and SSD fatigue analysis.
- Add *FREQUENCY_DOMAIN_ACCELERATION_UNIT to facilitate the acceleration unit conversion.
- The icfd_mstats.dat file now outputs the ten worst quality element locations (ICFD solver).
- Add option in *ICFD_CONTROL_OUTPUT allowing terminal output to be written to messag file.
- Add keyword *ICFD_CONTROL_OUTPUT_SUBDOM to output only part of the domain. Available for vtk, dx and gmv formats.
- Add new keyword family, *ICFD_DATABASE_... which triggers the output of ICFD variables. All ICFD related output files now start with icfd_***.
- Add new keyword family *ICFD_SOLVER_TOL_... which allows the user to control tolerances and iteration number for the fractional step solve, the mesh movement solve, and the heat equation solve.
- Curves in *ICFD_BOUNDARY_PRESCRIBED_VEL each provide a scaling factor vs. x, y, or z coordinate, respectively. These scaling factors are applied to the velocity boundary condition.
- Enable free-slip condition for FSI walls (ICFD solver).

- Add new variable IDC to *ICFD_CONTROL_FSI that allows the modification of the scaling parameter that multiplies the mesh size to detect contact.
- Add automatic squeezing to the ICFD elements of the boundary layer when there are two very close surfaces with poor (coarse) mesh resolution.
- Add the initialization for all nodes using *ICFD_INITIAL with PID = 0.
- Add a curve (LCIDSF in *ICFD_CONTROL_TIME) that scales the CFL number as a function of time.
- Add a Heaviside function that allows the solution of simple multiphase problems (ICFD).
- Add the computation of the heat convection coefficient (ICFD).
- Add MPP support for y+ and shear for output (ICFD).
- Add uniformity index (ICFD).
- Add *ICFD_CONTROL_TAVERAGE to control the restarting time for computing the time average values.
- Implement the XMl format for vtk. See *ICFD_CONTROL_OUTPUT.
- Improve temperature stabilization for thermal problems (ICFD).
- Add the Generalized Flow Through Porous Media model monolithically coupled to the incompressible Navier-Stokes model. See keyword *ICFD_MAT for the new options.
- Add the Anisotropic version of the Generalized Flow in Porous Media. See *ICFD_MAT for details.
- Add the capability to define the porous properties using the Pressure-Velocity (P-V) experimental curves. See *ICFD_MAT.
- Compute drag forces around anisotropic/isotropic porous domains (ICFD).
- Extend implicit debug checking when LPRINT = 3 on *CONTROL_IMPLICIT_-SOLVER.
- Add option for implicit dynamic relaxation so that only a subset of parts is active during the dynamic relaxation phase.
- Extend implicit time step control via IAUTO < 0 in *CONTROL_IMPLICIT_AU-TO to linear analysis.
- Add self-piercing rivet capability to implicit (*CONSTRAINED_SPR2, *CON-STRAINED_INTERPOLATION_SPOTWELD).
- Add MTXDMP in *CONTROL_IMPLICIT_SOLVER to dump the damping matrix from implicit mechanics.
- Improve stress and strain computation induced by mode shapes. See MSTRES in *CONTROL_IMPLICIT_EIGENVALUE.

- Add variable MSTRSCL to *CONTROL_IMPLICIT_EIGENVALUE for user control of geometry scaling for the stress computation.
- Make SMP and MPP treatment of autospc constraints consistent. See AUTOSPC on *CONTROL_IMPLICIT_SOLVER.
- Enhance output for *ELEMENT_DIRECT_MATRIX_INPUT (superelements) to describe how they are attached to the LS-DYNA model.
- Enhance superelement computation (*CONTROL_IMPLICIT_MODES or *CONTROL_IMPLICIT_STATIC_CONDENSATION):
    - The computation of the inertia matrix in the presense of rigid bodies is correct.
    - Adjust superelement computation to accept initial velocities.
    - Add null beams for the visualization of superelements.
- Enhance implicit to allow the use of *CONSTRAINED_RIVET in conjunction with axisymmetric shell element problems.
- Add output of performance statistics for the MPP implicit eigensolver to mes0000.
- Add stress computation to modal dynamics (*CONTROL_IMPLICIT_MODAL_DYNAMIC).
- Allow nonsymmetric terms to the assembled stiffness matrix from some implicit features.
- Enhance implicit-explicit switching (IMFLAG < 0 in *CONTROL_IMPLICIT_GENERAL) so that curve |IMFLAG| can be defined using *DEFINE_CURVE_FUNCTION.
- Upgrade the implicit implementation of rack and pinion and screw joints so the joint is driven by relative motion of the assembly instead of absolute motion.
- Add *CONTACT_1D to implicit mechanics.
- *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS is added to study Rotordynamics using the implicit time integrator.
- *MAT_SEATBELT is supported for implicit by introducing bending stiffness.
- *INITIAL_LAG_MAPPING added to initialize a 3D Lagrangian mesh from the last cycle of a 2D Lagrangian simulation.
- *ELEMENT_SHELL_NURBS_PATCH:
    - Add support for dumping of strain tensor and shell internal energy density for isogeometric shells via interpolation shells.
    - Add conventional mass-scaling for isogeometric shells.
- *LOAD_BODY_POROUS: applies also now to 1D and 2D problems.

- Add *LOAD_SEGMENT_CONTACT_MASK, which currently works in MPP only. This feature masks the pressure from a *LOAD_SEGMENT_SET when the pressure segments are in contact with another material.
- Curve LCID of *LOAD_NODE can be defined by *DEFINE_CURVE_FUNCTION.
- *USER_LOADING: pass more data to user-defined loading subroutine loadud including nodal moment, nodal rotational displacement and velocity, and nodal translational mass and rotational inertia.
- Add load curves for dynamic relaxation for *LOAD_THERMAL_VARIABLE.
- *LOAD_SEGMENT_NONUNIFORM, *LOAD_SEGMENT_SET_NONUNIFORM: By specifying a negative load curve ID the applied load becomes a follower force, i.e., the direction of the load is constant with respect to a local coordinate system that rotates with the segment.
- Make several enhancements to *MAT_172.
- *MAT_HYPERELASTIC_RUBBER (*MAT_077_H) has new thermal option for material properties.
- Add *MAT_ORTHOTROPIC_PHASE_CHANGE, *MAT_ELASTIC_PHASE_CHANGE, and *MAT_MOONEY-RIVLIN_PHASE_CHANGE whereby elements change phase as they cross a plane in space.
- Add P1DOFF to 2D seatbelt material, *MAT_SEATBELT_2D, to specify a part ID offset for the internally created 1D seatbelt elements.
- All load curves for *MAT_067 can be defined via *DEFINE_FUNCTION.
- Enhance *MAT_CWM:
    - Add support for shell elements.
    - Add support for hardening curves. Yield stress can be supplied as table depending on plastic strain and temperature.
- Check diagonal elements of C-matrix of *MAT_002/MAT_*OPTION*-TROPIC_ELASTIC and error terminate with message, STR+1306, if any are negative.
- Add a keyword option called MIDFAIL for *MAT_024, (MAT_PIECEWISE_LINEAR_PLASTICITY). When MIDFAIL appears in the keyword, failure by plastic strain will only be checked at the mid-plane. If the mid-plane fails, then the element fails. If there are an even number of integration points through the thickness, then the two points closest to the middle will check for failure and the element fails when both layers fail.
- Enable solid and solid assembly spot welds (*MAT_SPOTWELD) to use the NF parameter for force filtering.
- Add the shear angle in degrees as the first history variable for shell material *MAT_214 (DRY_FABRIC).

- Expand from 2 to 5 the number of additional cards that can be used for the user defined weld failure, OPT = 12 or OPT = 22 on *MAT_SPOTWELD. Now a total of 46 user variables are possible.
- Add a solid spot weld material option in *MAT_SPOTWELD to treat the stress state as uniaxial. This option is available for solid assemblies also.
- Add *MAT_FABRIC form 24 which is a modified version of form 14. The main improvement is that the Poisson's effects work correctly with the nonlinear curves for fiber stress. Also, the output of stress and strain to d3plot are engineering stress and strain instead of 2nd PK stress and Green's strain. Added an option to input curves in engineering stress and strain rather than 2nd PK stress vs. Green's strain. To use this, set DATYP = -2 on *DEFINE_CURVE.
- Increase maximum number of plies from 8 to 24 in a sublaminate with *MAT_CODAM2.
- Add *MAT_THERMAL_CHEMICAL_REACTION to model a material undergoing a chemical reaction such as an epoxy used in manufacturing composite materials.
- *MAT_058:
    - Add option to use nonlinear (elastic) stress-strain curves instead of constant stiffnesses (EA, EB, GAB).
    - Add option to use strain-rate dependent nonlinear (elastic) stress-strain curves instead of constant stiffnesses (EA, EB, GAB).
    - Add option to define proper poisson ratios PRCA and PRCB (also added in *MAT_158).
- Add option to use yield curve or table in *MAT_100 (*MAT_SPOTWELD) for solid elements.
- Add *MAT_157 for solid elements. This includes an optional variable IHIS that invokes *INITIAL_STRESS_SOLID to initialize material properties on an element-by-element basis. This was developed to allow a user to map/initialize anisotropic material properties from an injection molding simulation.
- *MAT_157 (shells):
    - Add anisotropic scale factor for plastic strain rate (VP = 1 only).
    - Improve local stress projection for VP = 1.
    - Add optional variable IHIS, similar to that described for solids above.
- Add strain rate dependence to *MAT_103 for solids via a table (isotropic hardening only).
- *MAT_136 (*MAT_CORUS_VEGTER): Implemented an alternative, implicit plasticity algorithm (define N.lt.0) for enhanced stability.
- *MAT_244 (*MAT_UHS_STEEL):

- In plasticity with non-linear hardening, temperature effects and strain rate effects are now dealt with the same way they are implemented in *MAT_106. In particular, strain rate now refers to the plastic strain rate.
- Allow for the definition of start temperatures for each phase change, for cooling and heating.
- Account for elastic transformation strains, given as a curve wrt temperature.
- Add feature to *MAT_244 for welding simulations. Similar to *MAT_270, material can be initialized in a quiet (ghost) state and activated at a birth temperature.

- Furthermore, annealing is accounted for.
- Modify formula for Pearlite phase kinetics based on Kirkaldy and Venugoplan (1983).
- *MAT_249 (*MAT_REINFORCED_THERMOPLASTIC): Implement new material formulation for shells, which is based on additive split of stress tensor.
  - For the thermoplastic matrix, a thermo-elasto-plastic material is implemented,where the temperature dependence is defined by load curves/tables in the input file.
  - Includes hyperelastic fiber contribution.
  - For any integration point, up to three different fiber directions can be defined. Their (non-linear) response to elongation and shear deformations can also be defined with load curves.
  - Includes input parameters for anisotropic transverse shear stiffness.
- *MAT_T07 (*MAT_THERMAL_CWM): Add HBIRTH and TBIRTH which are specific heat and thermal conductivity, resp., used for time t < TISTART.
- One additional parameter (exponent GAMMA) for B-K law of *MAT_138.
- MAT_187: Speed-up of load curve lookup for curves with many points.
- Add new option "MAGNESIUM" to *MAT_233. Differences between tension and compression are included.
- Add enhanced damage model with crack closure effects to *MAT_104.
- Some improvements for *MAT_075 (BILKHU/DUBOIS_FOAM): Volumetric strain rate can now be averaged over NCYCLE cycles, original input curve LCRATE is instead of a rediscretized curve, and averaged strain rate is stored as history variable #3.
- Add new history variables to *MAT_123: A mixed failure indicator as history variable #10 and triaxiality as #11.
- Decrease memory requirements for *MAT_ADD_EROSION by 50%.
- Add *MAT_098 for tetrahedral solid type 13.

- Add new history variable #8 to *MAT_157 for shell elements: "Anisotropic equivalent plastic strain".
- Add tangent stiffness to *MAT_224 for implicit analyses with solid and shell elements.
- Put internal enery on "plastic strain" location for *MAT_027 solids.
- Add new option *MAT_224: BETA < 0: strain rate dependent amount given by load curve ID = -BETA
- Add new flag to switch off all MAT_ADD_EROSION definitions globally.
- This will be the 1st parameter "MAEOFF" on new keyword *CONTROL_MAT.
- Add option to define a load curve for isotropic hardening in *MAT_135.
- *MAT_CDPM is reimplemented by its original developers (Peter Grassl and Dimitros Xenos at University of Glasgow) for enhanced robustness. A new parameter EFC is introduced governing damage in compression and the bilinear law is exchanged for an exponential one.
- *MAT_3-PARAMETER_BARLAT: HR = 7 is complemented with biaxial/shear hardening curves.
- *MAT_FABRIC_MAP:
    - A stress map material for detailed stress response in fabrics, stress can be prescribed through tables PXX and PYY corresponding to functions of biaxial strain states.
    - A compaction effect due to packing of yarns in compression is obtained by specifying BULKC (bulk modulus) and JACC (critical jacobian for the onset of compaction effect). This results ib increasing pressure that resists membrane elements from collapsing and/or inverting.
    - Strain rate effects can be obtained by specifying FXX and FYY which in effect scales the stress based on engineering strain rate. A smoothing effect is applied by using a time window DT.
    - A hysteresis option TH is implemented for stability, given in fraction dissipated energy during a cycle. Can also depend on the strain state through a table.
- *MAT_GENERAL_HYPERELASTIC_RUBBER, *MAT_OGDEN_RUBBER: By specifying TBHYS.LT.0 a more intuitive interpolation of the damage vs. deviatoric strain energy is obtained. It requires however that the damage and strain energy axes are swapped.
- *MAT_SIMPLIFIED_RUBBER: For AVGOPT.LT.0 the absolute value represents a time window over which the strain rates are averaged. This is for suppressing extensive noise used for evaluating stress from tables.

- *MAT_FABRIC: The bending stiffness contribution in material 34, ECOAT/SCOAT/TCOAT, is now supported in implicit calculations.
- Add *MAT_122_3D which is an extension of *MAT_122 to solid elements. This material model combines orthotropic elastic behavior with Hill's 1948 anisotropic plasticity theory and its applicability is primarily to composite materials.
- MPP groupable tied contact: Output messages about initial node movement due to projection like non-groupable routines do.
- MPP tied contact initialization:
    - Change a tolerance in groupable tied contact bucketsort to match the non-groupable code and fix the slave node thickness used for beam nodes during initial search in non-groupable contact to match groupable contact.
    - Update the slave node from beam thickness calculation for type 9,11, and 12 beams.
- For MPP, set a "last known location" flag to give some indication of where the processors were if an error termination happens. Each writes a message to their own message file. Look for a line that says "When error termination was triggered, this processor was".
- MPP BEAMS_TO_SURFACE contact: Remove "beam" node mass from the penalty stiffness calculation when soft = 1 is used, which matches SMP behavior.
- Make sure the pfile.log file gets created in case of termination due to *CONTROL_-STRUCTURED_TERM.
- Add two new decomposition region-related pfile options "nproc" and "%proc" so that any given decomposition region can be assigned to some subset of all the processors. nproc takes a single argument, which is a specific number of processors. %proc takes a single argument, which is a percentage of processors to use. The old options "lump" and "distribute" are still available and are mapped to the new options thusly:
    - lump => "nproc 1"
    - distribute => "%proc 100.0"
- Tweak MPP beam-to-beam contact routine for better handling of parallel beams.
- MPP: Add support for new solid and shell cost routines, invoked with the pfile option "decomp { newcost }". Will be expanded to include beams, thick shells, etc. in the future.
- MPP contact: add support for IGAP > 2 added to the SINGLE_SURFACE, AUTOMATIC_GENERAL, and *_TO_SURFACE contacts.
- Improve the way MPP computes slave node areas for AUTOMATIC_TIEBREAK contacts (and other that use areas). This should result in less mesh dependency in the failure condition of AUTOMATIC_TIEBREAK contacts.

- MPP: synchronize rigid body flags for shared nodes during rigid-to-deformable switching so that these nodes are handled consistently across processors.
- Add new pfile decomposition region option “partsets”. Takes a list of part sets (SET_PART) from the keyword input and uses them to define a region.
- Apply decomposition transformation (if defined) to:
    - *CONTROL_MPP_DECOMPOSITION_PARTS_DISTRIBUTE
    - *CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE
    - *CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS.
- Honor TIEDPRJ flag on *CONTROL_CONTACT for MPP groupable tied interfaces.
- Increase initial search distance in MPP tied contact to include slave and master thicknesses.
- Tweak MPP_INTERFERENCE contact to better handle deep initial penetrations.
- MPP: Reorganize how *RIGIDWALL_PLANAR_FORCES is handled, which greatly improves scaling.
- Add new MPP pfile option: directory { local_dirs { path1 path2 path3 } which will assign different local working directories to different processors, to balance the I/O load.
- Miscellaneous MPP enhancements:
    - Restructure and reduce memory usage of 3D ALE searching of neighboring algorithm. Now, the code can handle hundreds of millions ALE elements during decomposition.
    - Support *PARTICLE_BLAST.
    - Support SPH 2D contact.
    - Greatly speed up reconstruction of eroding contact surface, (soft = 0,1) when using large number of cores.
- Add the following options for small restarts:
    - *CHANGE_VELOCITY_GENERATION,
    - *CHANGE_RIGIDWALL_option,
    - PSNFAIL option to *CONTROL_SHELL
- MPP full deck restart: Restore behavior consistent with SMP which is that only the nodes of materials being initialized (not all nodes) are initialized from d3full.
- MPP: add full deck restart support for AUTOMATIC_TIEBREAK contact types.
- Implement *DELETE_PART for seatbelt parts. The associated slipring, retractors and pretensioners will be deactivated as well.
- Add support for MPP restarts with USA coupling.

- Add NREP option to *SENSOR_CONTROL to repeat NREP cycles of switches given on Card 2.
- Implement *SENSOR_CONTROL TYPEs BELTPRET, BELTRETRA and BELTSLIP control the pretensioners, retractors and sliprings of a 2D seatbelt.
- Add function SENSORD to *DEFINE_CURVE_FUNCTION to return the value of a sensor.
- Replace *SENSOR_DEFINE_ANGLE with more general *SENSOR_DEFINE_MISC. MTYPEs include ANGLE, RETRACTOR, RIGIDBODY, and TIME.
- Add rcforc output for *CONTACT_2D_NODE_TO_SOLID (supported for ASCII output only; not binout).
- Add temperature output (when applicable) to sphout file (*DATABASE_SPHOUT).
- Add support of *MAT_ALE_VISCOUS for SPH particles. This allows modeling of non-viscous fluids with constant or variable viscosity, i.e, non-newtonian type fluid using SPH.
- Add support of *EOS for *MAT_272 with SPH particles.
- Add support of *MAT_255, *MAT_126, and *MAT_26 (with AOPT = 2 only) for SPH particles.
- Add new keyword command *SECTION_SPH_INTERACTION: Combined with CONT = 1 in *CONTROL_SPH card, this keyword is used to define the partial interaction between SPH parts through normal interpolation method and partial interaction through the contact option. All the SPH parts defined through this keyword will interact with each other through normal interpolation method automatically.
- Add support for *DATABASE_TRACER for axisymmetric SPH (IDIM = -2 in *CONTROL_SPH).
- ICONT in *CONTROL_SPH now affects *DEFINE_SPH_TO_SPH_COUPLING in the sense of enabling or disabling the coupling for deactivated particles.
- The commands *STOCHASTIC_TBX_PARTICLES and *CHEMISTRY_CONTROL_TBX are now available for use (along with the CESE solver) in TBX-based explosives simulations.
- Multi-nozzle injection mode is implemented for spray injection.
- Add logic to skip thermal computations during dynamic relaxation for a coupled thermal-structual problem (i.e. when SOLN = 2 on the *CONTROL_SOLUTION keyword). This does not affect the use of *LOAD_THERMAL keywords during dynamic relaxation.
- Implement *DEFINE_CURVE_FUNCTION for convection, flux, radiation boundary

- conditions in thermal-only analyses, both 2D and 3D.
- *BOUNDARY_CONVECTION, *BOUNDARY_FLUX, and thermal dynamics are implemented for 20 node brick element.
- Include the reading of thermal data to *INCLUDE_BINARY.
- Allow *DEFINE_FUNCTION_TABULATED to be used in any place that requires a function of 1 variable. Specifically, as a displacement scale factor with *INTERFACE_LINKING_NODE.
- Add new MUTABLE option for *PARAMETER and *PARAMETER_EXPRESSION to indicate that it is OK to redefine a specific parameter even if *PARAMETER_DUPLICATION says redefinition is not allowed. Also, only honor the first *PARAMETER_DUPLICATION card.
- Add functions DELAY and PIDCTL to *DEFINE_CURVE_FUNCTION for simulating PID (proportional-integral-derivative) controllers.
- *DEFINE_TABLE: Add check of table's curves for mismatching origin or end points.
- Update ANSYS library to version 16.0.
- Enhance report of "Elapsed time" in d3hsp.
- Add keyword *INCLUDE_UNITCELL to create a keyword file containing user-defined unit cell information with periodic boundary conditions.
- Add *INCLUDE_AUTO_OFFSET: the node and element IDs of the include file will be checked against IDs of the previously read data to see if there is any duplication. If duplicates are found, they will be replaced with another unique ID.

Capabilities added to create LS-DYNA R9.0:

See release notes (published separately) for further details.

- ***AIRBAG**
  - Disable CPM airbag feature during DR and reactivate in the transient phase.
  - *AIRBAG_WANG_NEFSKE_POP_ID pop venting based on RBIDP is now supported correctly (MPP only).
  - *AIRBAG_INTERACTION:
    - Fixed MPP airbag data sync error to allow final pressure among interacted airbags to reach equilibrium.
  - *AIRBAG_PARTICLE:
    - When IAR = -1 and Pbag or Pchamber is lower than Patm, ambient air will inflate the bag through external vents and also fabric porosity.

- Treat heat convection when chamber is defined.
- Output pres+ and pres- to CPM interface forces file for internal parts.
- Allow IAIR = 4 to gradually switch to IAIR = 2 to avoid instability.
- Allow using shell to define inflator orifice. The shell center and normal will be used as orifice node and flow vector direction.
- Bug fix for porous leakage for internal fabric parts using CPM.
- New feature to collect all ring vents into a single vent in order to correctly treat enhanced venting option. All the vent data will only be output to the first part defined in the part set.
- Evaluate airbag volume based on relative position to avoid truncation. The bag volume becomes independent of coordinate transformation.
- Support explicit/implicit switch and dynamic relaxation for *AIRBAG_PARTICLE.
- Support vent/fabric blockage for CPM and ALE coupled analysis.
- New option in *CONTROL_CPM to allow user defined smoothing of impact forces.
- Fixed bug affecting *AIRBAG_PARTICLE_ID with PGP encryption.

- ***ALE**
  - *ALE_REFERENCE_SYSTEM_GROUP: For prtype = 4, allow the ALE mesh to follow the center of mass of a set of nodes.
  - *CONTROL_ALE:
    - Add a variable DTMUFAC to control the time step related to the viscosity from
    - *MAT_NULL (if zero, the viscosity does not control the time step).
    - Implement a 2D version of BFAC and CFAC smoothing algorithm.
  - *ALE_SMOOTHING: Automatically generate the list of 3 nodes for the smoothing constraints and implement for MPP.
  - *SECTION_ALE2D, *SECTION_SOLID_ALE: Allow a local smoothing controlled by AFAC,...,DFAC.
  - *ALE_SWITCH_MMG: Allow the variables to be modified at the time of the switch.
  - *CONTROL_REFINE_ALE: Add a variable to delay the refinement after removal (DELAYRGN), one to delay the removal after the refinement (DELAYRMV), and one to prevent any removal in a certain radius around latest refinements (RADIUSRMV).
  - *ALE_STRUCTURED_MESH: Implemented structured ALE mesh solver to facilitate rectilinear mesh generation and to run faster.

- ***BOUNDARY**
  - *BOUNDARY_AMBIENT_EOS: Implement *DEFINE_CURVE_FUNCTION for the internal energy and relative volume curves.

- *BOUNDARY_AMBIENT: Apply ambient conditions to element sets.
- Fix for adaptivity dropping SPCs in some cases (MPP only).
- Added conflict error checking between rigid body rotational constraints and joints between rigid bodies (*CONSTRAINED_JOINT) with *BOUNDARY_PRESCRIBED_ORIENTATION.
- The first rigid body of the prescribed orientation cannot have any rotational constraints. Only spherical joints or translational motors can be used between the two rigid bodies of the prescribed orientation. For now explicit will be allowed to continue with these as warnings.Implicit will terminate at end of input checking.
- Instead of error terminating with warning message, STR+1371, when *BOUNDARY_PRESCRIBED_MOTION and *BOUNDARY_SPC are applied to same node and dof, issue warning message, KEY+1106, and release the conflicting SPC.
- Fix erroneous results if *SET_BOX option is used for *BOUNDARY_PRESCRIBED_MOTION.
- Fix *BOUNDARY_PRESCRIBED_ACCELEROMETER_RIGID for MPP. It may error terminate or give wrong results if more than one of this keyword are used.
- Fix segmentation fault when using *BOUNDARY_PRESCRIBED_ORIENTATION with vad = 2, i.e. cubic spline interpolation.
- Fix incorrect behavior if multiple *BOUNDARY_SPC_SYMMETRY_PLANE, i.e. > 1, are used.
- Fix incorrect motion if *BOUNDARY_PRESCRIBED_MOTION_RIGID_LOCAL is on a rigid part which is merged with a deformable part that has been switched to rigid using *DEFORMABLE_TO_RIGID.
- Fix incorrect external work when using *BOUNDARY_PRESCRIBED_MOTION with or without_RIGID option. The dof specified in *BPM was not considered when computing the external work. Also, when multiple *BPM applied to the same node/rigid body with different dof may also cause incorrect computation of external work.
- Fix incorrect velocities when using *BOUNDARY_PRESCRIBED_MOTION_RIGID_LOCAL and *INITIAL_VELOCITY_RIGID_BODY for rigid bodies.
- Implement check for cases where *MAT_ACOUSTIC nodes are merged with structural nodes on both sides of a plate element and direct the user to the proper approach to this situation - *BOUNDARY_ACOUSTIC_COUPLING.
- *BOUNDARY_ACOUSTIC_COUPLING with unmerged, coincident node coupling now implemented in MPP.
- MPP logic corrected so *MAT_ACOUSTIC and *BOUNDARY_ACOUSTIC_COUPLING features may be used with 1 MPP processor.
- Fixed bug for *BOUNDARY_PRESCRIBED_MOTION if part label option is used.

- **BLAST**

  - Improve *LOAD_BLAST_ENHANCED used with ALEPID option in *LOAD_BLAST_SEGMENT:
  - Rearrange the ambient element type 5 and its adjacent element into same processor to avoid communications.
  - Eliminate several n-by-n searches for segment set and ambient type 5 with its neighboring elements to speed up the initialization.
  - Change the name of keyword *DEFINE_PBLAST_GEOMETRY to *DEFINE_PBLAST_HEGEO. Both names will be recognized.

- ***CESE (Compressible Flow Solver)**

  - Modified the CESE moving mesh CHT interface condition calculation to deal with some occasional MPP failures that could occur with mesh corner elements.
  - Improved the CESE spatial derivatives approximation in order to bring better stability to the CESE solvers.
  - The 3D SMP and MPP CESE immersed boundary solvers now work with structural element erosion.
  - A new energy conservative conjugate heat transfer method has been added to the following 2D and 3D CESE Navier-Stokes equation solvers:

    - Fixed mesh (requires use of *CESE_BOUNDARY_CONJ_HEAT input cards)
    - Moving mesh FSI
    - Immersed boundary FSI

  - Prevent the fluid thermal calculation from using too short a distance between the fluid and structure points in the new IBM CHT solvers.
  - In the under resolved situation, prevent the CHT interface temperature from dipping below the local structural node temperature.
  - Add detection of blast wave arrival at CESE boundary condition face first sensing the leading edge of the pulse (used with *LOAD_BLAST_ENHANCED).
  - Set CESE state variable derivatives to more stable values for the blast wave boundary condition.
  - Corrected time step handling for the CESE Eulerian conjugate-heat transfer solver. This affected only the reported output time.
  - Added CESE cyclic BC capability to the moving mesh CESE solver.
  - Fixed some issues with 2D CESE solvers where the mesh is created via *MESH cards.
  - For the CESE solver coupled with the structural solver (FSI), corrected the time step handling.

- For the CESE mesh motion solvers, and the ICFD implicit ball-vertex mesh motion solver, added a mechanism to check if all of the imposed boundary displacements are so small that it is not necessary to actually invoke the mesh motion solver. This is determined by comparing the magnitude of the imposed displacement at a node with the minimum distance to a virtual ball vertex (that would appear in the ball-vertex method). The relative scale for this check can be input by the user via field 4 of the *CESE_CONTROL_-MESH_MOV card.
- Changed the NaN check capability for the CESE solvers to be activated only upon user request. This is input via a non-zero entry in field 7 of the *CESE_-CONTROL_SOLVER card.
- Much like the ICFD solver, added a mechanism to adjust the distance used by the contact detection algorithm for the *CESE_BOUNDARY_FSI cards, as well as the new moving mesh conjugate heat transfer solvers. This is available through field 6 of the *CESE_CONTROL_SOLVER card.
- Added a correction to the moving mesh CESE solver geometry calculation.
- Corrected the initial time step calculation for both the 2D and 3D moving mesh CESE solvers.
- For the moving mesh CESE solver, replaced the all-to-all communication for fsi quantities with a sparse communication mechanism.

- ***CHEMISTRY**

  - The immersed boundary FSI method coupled with the chemistry solver is released.

    - Only Euler solvers, both in 2D and 3D, are completed with full chemistry.
    - Using this technique, CESE FSI Immerged Boundary Method coupled to the chemistry solver can be applied to high speed combustion problems such as explosion, detonation shock interacting with structures, and so on.
    - Some examples are available on our ftp site.

- ***CONTACT**

  - Fix MPP groupable contact problem that could in some cases have oriented the contact surfaces inconsistently.
  - Fix bug in *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIED_-WELD.
  - Fix seg fault when using *CONTACT_AUTOMATIC_SINGLE_SURFACE_-TIED with consistency mode, .i.e. ncpu < 0, for SMP.
  - Fix false warnings, SOL+1253, for untied nodes using *CONTACT_AUTO-MATIC_SURFACE_TO_SURFACE_TIEBREAK and *CONTACT_AUTO-MATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK.

- Fix *CONTACT_TIED_SHELL_EDGE_TO_SURFACE when rigid nodes are not tied even when ipback = 1. This applies to SMP only.
- Issue warning if SOFT = 4 is used with an unsupported contact type, and reset it to 1.
- Change "Interface Pressure" report in intfor file from abs(force/area) to -force/area, which gives the proper sign in case of a tied interface in tension.
- Increase MPP contact release condition for shell nodes that contact solid elements in SINGLE_SURFACE contact.
- Fix for MPP IPBACK option for creating a backup penalty-based tied contact.
- Fix for MPP orthotropic friction in contact.
- Fix for MPP *CONTACT_SLIDING_ONLY that was falsely detecting contact in some cases.
- Skip constraint based contacts when computing the stable contact time step size.
- Add error trap if node set is input for slave side of single surface contact.
- MPP: some fixes for constrained tied contact when used with adaptivity. The behavior of the slave nodes in adaptive constraints was not correct if they were also master nodes of a tied interface. This has been fixed, and support for the rotations required for CONTACT_SPOTWELD have also been added.
- MPP: update to AUTOMATIC_TIEBREAK option 5 to release the slave nodes (and report them as having failed) when the damage curve reaches 0.
- Fix made to routine that determines the contact interface segments, which was not handling pentahedral thick shell elements correctly.
- MPP: fix for strange deadlock that could happen if a user defines a *CONTACT_FORCE_TRANSDUCER that has no elements in it and so gets deleted.
- MPP contact: add support for *DEFINE_REGION to define an active contact region. Contact occurring outside this region is ignored. This is only for MPP contact types:

  - AUTOMATIC_SINGLE_SURFACE
  - AUTOMATIC_NODES_TO_SURFACE
  - AUTOMATIC_SURFACE_TO_SURFACE
  - AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE

- MPP fix for table based friction in non-groupable contact.
- MPP: add frictional work calculation for beams in *CONTACT_AUTOMATIC_GENERAL.
- Added new option "FTORQ" for contact. Currently implemented only for beams in *CONTACT_AUTOMATIC_GENERAL in MPP. Apply torque to the nodes to compensate for the torque introduced by friction. Issue error message when users try to use SOFT = 2/DEPTH = 45 contact for solid elements.

- R-adaptivity, ADPTYP = 7 in *CONTROL_ADAPTIVE, is now available for SMP version of *CONTACT_SURFACE_TO_SURFACE, _NODES_TO_SURFACE, _AUTOMATIC_SURFACE_TO_SURFACE, and _AUTOMATIC_NODES_TO_SURFACE (SOFT = 0 or 1 only).
- The options AUTOMATIC_SURFACE_TO_SURFACE_COMPOSITE has been added to model composite processing. The same option may be used to model certain types of lubrication, and AUTOMATIC_SURFACE_TO_SURFACE_LUBRICATION may be used instead of the COMPOSITE option for clarity. (The two keyword commands are equivalent.)
- Added AUTOMATIC_SURFACE_TO_SURFACE_TIED_WELD to model the simulation of welding. As regions of the surfaces are heated to the welding temperature and come into contact, the nodes are tied.
- Added *CONTACT_TIED_SHELL_EDGE_TO_SOLID. This contact transmits the shell moments into the solid elements by using forces unlike the SHELL_EDGE_TO_SURFACE contact with solid elements. This capability is easier for users than *CONSTRAINED_SHELL_TO_SOLID. The input is identical to *CONTACT_TIED_SHELL_EDGE_TO_SURFACE (except for the keyword).
- Fix incorrect motion of displayed rigidwall between 0.0 < time < birth_time when birth time > 0.0 for *RIGIDWALL_GEOMETRIC_FLAT_MOTION_DISPLAY. The analysis was still correct. Only the displayed motion of the rigidwall is incorrect.
- Fix corrupted intfor when using parts/part sets in *CONTACT_AUTOMATIC_.... This affects SMP only.
- Fix incorrect stonewall energy when using *RIGIDWALL_PLANAR_ORTHO.
- Fix unconstrained nodes when using *CONTACT_TIED_SURFACE_TO_SURFACE_CONSTRAINED_OFFSET resulting in warning message, SOL+540. This affects SMP only.
- Fix spurious repositioning of nodes when using *CONTACT_SURFACE_TO_SURFACE for SMP.
- Enable MAXPAR from optional card A to be used in *CONTACT_TIED_SURFACE_TO_SURFACE. It was originally hard-coded to 1.07.
- The shells used for visualisation of *RIGIDWALL_PLANAR_MOVING_DISPLAY and *RIGIDWALL_PLANAR_MOVING_DISPLAY in d3plot were not moving with the rigidwall. This is now fixed.
- Fix incorrect frictional forces if ORTHO_FRICTION is used in *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE.
- Fix seg fault when using *CONTACT_ENTITY and output to intfor file with MPP, i.e. s = intfor in command line.
- Fix ineffective birth time for *CONTACT_TIED_NODES_TO_SURFACE.
- Fix untied contacts when using *CONTACT_TIED... with *MAT_ANISOTROPIC_ELASTIC_PLASTIC/*MAT_157.
- Fix MPP hang up when using *CONTACT_ENTITY.

- Allow *CONTACT_AUTOMATIC_GENERAL to use MAXPAR from contact optional card A instead of using the hard coded value of 1.02. This will better detect end to end contact of beams. This applies to SMP only.
- Fix *CONTACT_TIED_SHELL_EDGE_TO_SURFACE for SMP which ignores MAXPAR in contact optional card A.
- Fix seg fault when using *CONTACT_GUIDED_CABLE.
- Fix segmentation fault when using *CONTACT_AUTOMATIC_SINGLE_-SURFACE_TIED in consistency mode, i.e. ncpu < 0 in command line, for SMP.
- Fix incorrect contacts when using *CONTACT_AUTOMATIC_GENERAL_-INTERIOR for beams with large differences in thickness and when the thinner beams are closer to each other than to the thicker beams. Affects SMP only.
- Fixed force transducers with MPP segment-based contact when segments are involved with multiple 2 surface force transducers. The symptom was that some forces were missed for contact between segments on different partitions.
- Fixed an MPP problem in segment-based contact that cased a divide by zero during the bucket sort. During an iteration of the bucket sort, all active segments were somehow in one plane which was far from the origin such that a dimension rounded to zero. The fix for this should affect only this rare case and have no effect on most models.
- Fixed thermal MPP segment-based contact. The message passing of thermal energy due to friction was being skipped unless peak force data was written to the intfor file.
- Fixed MPP segment based implicit contact. A flaw in data handling caused possible memory errors during a line search.
- Fixed implicit dynamic friction for segment-based contact. For sliding friction, the implicit stiffness was reduced to an infinitesimal value. Also, the viscous damping coefficient is now supported for implicit dynamic solutions.
- Fixed segment-based contact when the data has all deformable parts that are switched to rigid at the start of the calculation and then switched back to deformable prior to contact occurring. A flaw was causing contact to be too soft. This is now corrected.
- Fixed a flaw in segment-based contact with DEPTH = 25 that could allow penetration to occur.
- Improved edge-to-edge contact checking (DEPTH = 5, 25, 35) and the sliding option (SBOPT = 4, 5) in areas where bricks have eroded when using segment based eroding contact.
- Improved the initial penetration check (IGNORE = 2 on *CONTROL_CONTACT) of segment-based contact to eliminate false positives for shell segments. Previously, the search was done using mid-plane nodes and the gap or penetration adjusted to account for segment thicknesses after. The new way projects the nodes to the surface first and uses the projected surface to

measure penetration. For brick segments with zero thickness there should be no difference. For shell segments, the improved accuracy will me more noticeable for thicker segments.

- Improved segment-based contact when SHAREC = 1 to run faster when there are rigid bodies in the contact interface.
- Fixed a possible problem during initialization of segment-based contact. Options that use neighbor segment data such as the sliding option and edge-to-edge checking could access bad data if the same nodes were part of both the slave and master surfaces. This would not be a normal occurrence but could happen.
- Updated segment-based contact to improve accuracy at points away from the origin. The final calculations are now done with nodal and segment locations that have been shifted towards the origin so that coordinate values are small.
- The reporting of initial penetrations and periodic intersection reports by segment-based contact was corrected for MPP solutions which were reporting incorrect element numbers.
- Fixed memory errors in 2D automatic contact initialization when friction is used.
- Fixed 2D force transducers in the MPP version which could fail to report master surface forces. Also fixed 2 surface 2D force transducers when the smp parallel consistency option is active.
- Fixed *CONTACT_2D_AUTOMAITC_SINGLE_SURFACE and SURFACE_TO_SURFACE which could exhibit unpredictable behavior such as a force spike or penetration.
- Fixed a serious MPP error in the sliding option of *CONTACT_2D_AUTOMATIC that could lead to error termination.
- Fixed a problem with birth time for *CONTACT_2D_AUTOMATIC_TIED when used with sensor switching. Also, fixed a problem in the contact energy calculation that could lead to abnormal terminations. Finally, I made the process of searching for nodes to tie more robust as some problem was found with nodes being missed.
- Fixed a 2D automatic contact bug that occurred if a segment had zero length. An infinite thickness value was calculated by A/L causing the bucket sort to fail.
- Added support for *CONTACT_ADD_WEAR for smp and mpp segment based (SOFT = 2) contact. This option enables wear and sliding distance to be measured and output to the intfor file.
- Added support to segment-based contact for the SRNDE parameter on optional card E of *CONTACT.
- Added support to segment based eroding contact for SBOXID and MBOXID on card 1 of *CONTACT.
- Added support for *ELEMENT_SOURCE_SINK used with segment-based contact. With this update, inactive elements are no longer checked for contact.

- Added a segment-based contact option to allow the PSTIFF option on *CONTROL_CONTACT to be specified for individual contact definitions. The new parameter is PSTIFF on *CONTACT on optional card F, field 1. Prior to this change, setting PSTIFF on *CONTROL_CONTACT set all contact to use the alternate penalty stiffness method. With this update, PSTIFF on *CONTROL_CONTACT now sets a default value, and PSTIFF on card F can be used to override the default value for an individual contact interface.
- Added support for REGION option on optional card E of *CONTACT when using segment based, SOFT = 2 contact. This works for all supported keywords, SMP and MPP.
- Added master side output in the MPP version for 2-surface force transducers when used with segment based (soft = 2) contact.
- Added contact friction energy to the sleout database file for
  - 2D_AUTOMATIC_SURFACE_TO_SURFACE and
  - 2D_AUTOMATIC_SINGLE_SURFACE contact.
- Enabled segment-based contact (SMP and MPP) to work with type 24 (27-node) solid elements.
- Enabled the ICOR parameter on *CONTACT, optional card E to be used with segment based (SOFT = 2) contact.
- Fixed output to d3hsp for *CONTACT_DRAWBEAD using negative curve ID for LCIDRF
- Add slave node thickness and master segment thickness as input arguments to the *USER_INTERFACE_FRICTION subroutine usrfrc (SMP).
- Forming mortar contact can now run with deformable solid tools and honors ADPENE to account for curvatures and penetrations in adaptive step. This applies to h- as well as r-adaptivity.
- Single surface and surface-to-surface mortar contact accounts for rotational degrees of freedom when contact with beam elements. This allows for beams to "roll" on surfaces and prevents spurious friction energy to be generated when in contact with rotating parts.
- Maximum allowable penetration in forming and automatic mortar contacts is hereforth .5*(tslav+tmast)*factor where tmast = thickness of slave segment and tmast = thickness of master segment. The factor is hardwired to 0.95, but is subject to change. Prior to this it was .5*tslav, which seems inadequate (too small) in coping with initial penetrations in automotive applications using standard modeling approaches.
- Up to now, mortar contact has only acted between flat surfaces, now account is taken for sharp edges in solid elements (the angle must initially be larger than 60 degrees), may have to increase the corresponding stiffness in the future.
- When solid elements are involved in mortar contact the default stiffness is increased by a factor of 10. This is based on feedback from customers indicating that the contact behavior in those cases has in general been too soft.

This may change the convergence characteristics in implicit but the results should be an improvement from earlier versions.

- The OPTT parameter on *PART_CONTACT for the contact thickness of beams is now supported in mortar contact.
- *CONTACT_ADD_WEAR: A wear law, Archard's or a user defined, can be associated with a contact interface to assess wear in contact. By specifying WTYPE < 0 a user defined wear subroutine must be written to customize the wear law. For the Archard's wear law, parameters can depend on contact pressure, relative sliding velocity and temperature. Contacts supported are *CONTACT_FORMING_SURFACE_TO_SURFACE, *CONTACT_-FORMING_ONE_WAY_TO_SURFACE and *CONTACT_AUTOMATIC_-SURFACE_TO_SURFACE. To output wear data set NWEAR = 1 or NWEAR = 2 on *DATABASE_EXTENT_INTFOR. If NWEAR is set to 2 then the sliding distance is output to the intfor file, in addition to the wear depth. Otherwise only wear depth is output. Also, the parameter NWUSR specifies the number of user wear history variables to be output in case a user defined wear routine is used. By specifying CID (contact interface id) to a negative number, the wear depth will couple to the contact in the simulation in the sense that the penetration is reduced with wear. The effect is that contact pressure will be redistributed accordingly but is only valid for relatively small wear depths. A formulation for larger wear depths lie in the future which will require modification of the actual geometry.
- Fixed bug affecting *CONTACT_RIGID_NODE_SURFACE (broken at rev. 86847). The bug was in reading *NODE_RIGID_SURFACE.
- A bug fix in *CONTACT_DRAWBEAD_INITILIZE. - The bug was caused by a sudden increase in effective strain after the element passed the drawbead. When the increase in strain is too big, the search algorithm was not working reasonably in the material routine. At the drawbead intersection point, an element could be initialized twice by two bead curves, and cause abnormal thickness distribution.
- Fix a bug in *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE_SMOOTH which removes the limitation that the contact must be defined by segment set.
- SMOOTH option does not apply to FORMING_SURFACE_TO_SURFACE contact. When the SMOOTH option is used, we now write a warning message and disregard the SMOOTH option.

- ***CONSTRAINED**

  - *CONSTRAINED_LAGRANGE_IN_SOLID: Implement *CONSTRAINED_-LAGRANGE_IN_SOLID_EDGE in 2D.
  - Fixed bug in *DAMPING_RELATIVE. If the rigid part PIDRB is the slave part in *CONSTRAINED_RIGID_BODIES, the damping card did not work correctly. There is a work-around for previous LS-DYNA versions: set

PIDRB to the master part in *CONSTRAIEND_RIGID_BODIES, not the slave part.

- *CONSTRAINED_RIGID_BODY_INSERT: This keyword is for modeling die inserts. One rigid body, called slave rigid body, is constrained to move with another rigid body, called the master rigid body, in all directions except for one.
- A variety of enhancements for *CONSTRAINED_INTERPOLATION.
  - Enhanced the error message when nodes involved in the constraint have been deleted.
  - Removed printing of 0 node ID in MPP.
  - Added a warning if there are too many (now set at 1000) nonzeroes in a constraint row for *CONSTRAINED_INTERPOLATION or *CONSTRAINED_LINEAR to protect implicit's constraint processing. These constraints will be processed differently in future releases. We modified the constraint processing software to robustly handle constraint rows with thousands of nonzero entries. We added error checking for co-linear independent nodes as these constraints allow singularities in the model.
- Improved implicit's treatment of the constraints for *CONSTRAINED_BEAM_IN_SOLID.
- Added error checking on the values of the gear ratios in *CONSTRAINED_JOINTS.
- *CONSTRAINED_BEAM_IN_SOLID:
  - Thick shell elements supported.
  - Wedge elements supported.
  - Debonding law by user-defined subroutine (set variable AXFOR > 1000).
  - Debonding law by *DEFINE_FUNCTION (set variable AXFOR < 0).
- Error terminate with message, SOL+700, if CIDA and CIDB is not defined for *CONSTRAINED_JOINT_STIFFNESS_GENERALIZED.
- Fix incorrect constraints on rotary dof for adaptivity.
- Fix incorrect motion if NRBF = 2 in *DEFORMABLE_TO_RIGID_AUTOMATIC and if any of the *CONSTRAINED_NODAL_RIGID_BODY nodes belongs to a solid element.
- Fix input error when using large load curve ID for FMPH, FMT, FMPS in card 3 of *CONSTRAINED_JOINT_STIFFNESS with GENERALIZED or TRANSLATIONAL options.
- Fix seg fault if using tables for FMPH of *CONSTRAINED_JOINT_STIFFNESS and if the angle of rotation is less than the abscissa of the table or load curves.

- Fixed a problem with *CONSTRAINED_BEAM_IN_SOLID when used in a model that also uses segment based eroding contact in the MPP version. This combination now works.
- Improved the precision of spot weld constraints (*CONSTRAINED_SPOTWELD) to prevent possible divide by zeroes when the inertia tensor is inverted. This affects the single precision version only.
- Fix for damage function in *CONSTRAINED_INTERPOLATION_SPOTWELD, MODEL = 2.
- Add some user-friendly output (rigid body ID) to d3hsp for *CONSTRAINED_NODAL_RIGID_BODY_INERTIA.
- Add new option to *CONSTRAINED_SPR2 to connect up to 6 shell element parts (metal sheets) with only one rivet location node. This is invoked by defining extra part IDs for such a multi-sheet connection.
- Add more flexibility to *CONSTRAINED_SPR2: Load curve function exponent values originally hardwired as "8" can now be defined with new input parameters EXPN and EXPT.
- Fixed bug wherein the joint ID in *CONSTRAINED_JOINT_COOR was read incorrectly.
- Fixed duplicate ID for *CONSTRAINED_SPOTWELD, ..._NODE_SET, _POINTS and _SPR2.
- Fix keyword reader for SPR4 option in *CONSTRAINED_INTERPOLATION_SPOTWELD, where BETA2 was replaced by BETA3.
- Significantly reduce the memory demand in the initialization stage of *CONSTRAINED_MULTIPLE_GLOBAL for implicit analysis.
- The unit cell mesh and constraint generated by *INCLUDE_UNITCELL now supports job ID.

- ***CONTROL**

  - Terminate and print error KEY+1117 for cases that use *INCLUDE_TRANSFORM in 3d r-adaptvity. More work is needed to make this combination work.
  - Changed SOL+41 message ("reached minimum step") from an error to a warning and terminate normally. This message is triggered when the DTMIN criterion set in *CONTROL_TERMINATION is reached.
  - Fixed bug in which h-adaptivity missed some ADPFREQ-based adaptations when IREFLG < 0 (*CONTROL_ADAPTIVE).
  - Fixed bug: MS1ST in *CONTROL_TIMESTEP causes non-physical large mass and inertia on Nodal Rigid Bodies if Dynamic Relaxation is active. The error occurs at the start of the transient solution. The mass can become very large, so the model may appear to be over-restrained.
  - Add new input check for curves. After rediscretizing curves, check to see how well the original values can be reproduced. If the match is poor, write out See variable CDETOL in *CONTROL_OUTPUT.

- Added the ability to specify unique values LCINT for each curve, which override the value set in *CONTROL_SOLUTION. Note: the largest value of LCINT that appears will be used when allocating memory for each load curve, so a single large value can cause significant increases in the memory required for solution.
- The DELFR flag in *CONTROL_SHELL has new options for controlling the deletion of shell elements. This feature is aimed at eliminating single, detached elements and/or elements hanging on by one shared node.
- Fix spurious deletion of elements when using TSMIN.ne.0.0 in *CONTROL_TERMINATION, ERODE = 1 in *CONTROL_TIMESTEP and initialized implicitly in dynamic relaxation.
- Fix spurious error, STR+755, if using *DAMPING_FREQUENCY_RANGE with *CONTROL_ADAPTIVE.
- Add new feature to *CONTROL_SOLUTION, LCACC, to truncate load curve to 6 significant figures for single precision & 13 significant figures for double precision. The truncation is done after applying the offset and scale factors.
- Fix "*** termination due to mass increase ***' error when using mass scaling with *ELEMENT_MASS_PART.
- Fix input error 'node set for nodal rigid body # not found' when using *PART_INERTIA with *CONTROL_SUBCYCLE.
- Fixed the negative DT2MS option on *CONTROL_TIMESTEP for thick shell types 5, 6, and 7.
- Fixed bug in *CONTROL_CHECK_SHELL if PSID.lt.0 (part set ID) is used
- Add new option NORBIC to *CONTROL_RIGID to bypass the check of rigid body inertia tensors being too small.
- Add new option ICRQ to *CONTROL_SHELL for continuous treatment of thickness and plastic strain across element edges for shell element types 2, 4, and 16 with max. 9 integration points through the thickness.
- Add new option ICOHED to *CONTROL_SOLID. If this value is set to 1, solid cohesive elements (ELFORM 19-22) will be eroded when neighboring (nodewise connected) shell or solid elements fail.
- Beam release conditions are now properly supported in selective mass scaling, see IMSCL on *CONTROL_TIMESTEP.
- Modified MSGMAX in *CONTROL_OUPUT: MSGMAX is the maximum number of each error/warning message

  - > 0 number of message to screen output, all messages written to messag/d3hsp
  - < 0 number of messages to screen output and messag/d3hsp
  - = 0 the default is 50

- Fix bugs in 3D solid adaptivity (*CONTROL_ADAPTIVE, ADPTYP = 7) so that the solid adaptivity will still work when there are any of the following in the model:

- thick shells (*SECTION_TSHELL),
- massless nodes,
- *LOAD_SEGMENT_*{OPTION}*.

◦ Added PARA = 2 to *CONTROL_PARALLEL which activates consistent force assembly in parallel for SMP. An efficient parallel algorithm is implemented for better performance when the consistency flag is turned on. It shows better scaling with more cpus. This option is overridden by parameter "para=" on the execution line.

- **DEM (Discrete Element Method)**

◦ Added output of following DES history variables to d3plot:

- nodal stress and force
- pressure
- density
- force chain
- damage calculation when *DEFINE_DE_BOND is defined

◦ Added output of following DES history variables to demtrh (*DATABASE_-TRACER_DE):

- coordination number
- porosity and void ratio
- stress
- pressure
- density

◦ Output ASCII format for demrcf if BINARY.eq.3.
◦ Implement gauss distribution of DE sphere radius for *DEFINE_DE_INJEC-TION. The mean radius is 0.5 × (rmin + rmax) and standard deviation is 0.5 × (rmax - rmin).
◦ For DE sphere, implement the stress calculation for REV (Representative Elementary Volume) using *DATABASE_TRACER_DE and specific RADIUS.
◦ Add *BOUNDARY_DE_NON_REFLECTING for defining non-reflecting boundary conditions for DE spheres.
◦ For *CONTROL_DISCRETE_ELEMENT, add the option to create the liquid bridge if the initial distance between two DE spheres is smaller than predefined gap.
◦ Added *DATABASE_DEMASSFLOW, see *DEFINE_DE_MASSFLOW_-PLANE, for measuring the mass flow of DE spheres through a surface. The surface is defined by part or part set. Output file is 'demflow'.
◦ Add *DEFINE_DE_INJECTION_ELLIPSE, to define a circular or elliptical injection plane.

- Add *DEFINE_PBLAST_AIRGEO for *PARTICLE_BLAST which defines initial geometry for air particles.
- Add DEM stress calculation when coupling with segment (*DEFINE_DE_TO_SURFACE_COUPLING).
- Fix error in demtrh file output (Windows platform only).

- **EFG (Element Free Galerkin)**

  - Fix bug for ELFORM = 41 implicit when there are 6-noded/4-noded elements.

- ***ELEMENT**

  - Fix a 2d seatbelt bug triggered by having both 1d and 2d seatbelts, and a 1d pretensioner of type 2, 3 or 9.
  - Fix MPP bug initializing multiscale spot weld in the unexpected case where the spot weld beam is merged with the shells rather than tied via contact.
  - Fix bug for *INCLUDE_UNITCELL.
  - *CONTROL_REFINE_...: Implement the parent-children transition in *CONTACT_2D_SINGLE_SURFACE when a shell refinement occurs.
  - Fix error traps for *ELEMENT_SEATBELT_..., for example, error termination due to convergence failure in retractors. These error traps worked but could lead to a less graceful termination than other LS-DYNA error traps.
  - Correct calculation of wrap angle in seatbelt retractor.
  - Add MPP support for *ELEMENT_LANCING.
  - *ELEMENT_SEATBELT:

    - Fix an MPP belt bug that can happen when buckle pretensioner is modeled as a type-9 pretensioner.
    - 2D belt and 1D belt now can share the same *MAT_SEATBELT.
    - The section force for 2d belt is recoded to provide more robust and accurate results.
    - The loading curve LLCID of *MAT_SEATBELT can be a table defining strain-rate dependent stiffness curve.
    - IGRAV of *ELEMENT_SEATBELT_ACCELEROMETER can be a curve defining gravitation flag as a function of time.

  - Add *NODE_THICKNESS to override shell nodal thickness otherwise determined via *SECTION_SHELL, *PART_COMPOSITE, or *ELEMENT_SHELL_THICKNESS.
  - Fix input error when using *DEFINE_ELEMENT_DEATH with BOXID > 0 for MPP.
  - Implement subcycling for thick shells.
  - Fix ineffective *DEFINE_HAZ_PROPERTIES when solid spotwelds and hex spotweld assemblies are both present.

- Fix incorrect beta written out for *ELEMENT_SHELL_BETA in dynain file when *PART_COMPOSITE keyword is present in the original input.
- Fix NaN output to elout_det and spurious element deletion if NOD-OUT = STRAIN or STRAIN_GL or ALL or ALL_GL.
- Fix incorrect reading of TIME in card 3 of *ELEMENT_SEATBELT_SENSOR SBSTYP = 3 when long = s in command line.
- *PART_COMPOSITE: Increased the explicit solution time step for thin shell composite elements. The existing method was overly conservative. The new method is based on average layer stiffness and density.
- In conjunction with the above change in composite time step calculation, increase nodal inertia in the rare cases of *PART_COMPOSITE in which the bending stability is not satisfied by the membrane stability criterion. The inertia is only increased in the cases where it is necessary; for most models this change has no effect, but this can occur in the case of sandwich sections with stiffer skins around a less stiff core.
- Corrected rotational inertia of thin shells when layers have mixed density and the outer layers are more dense than inner layers. The fix will mostly affect elements that are very thick relative to edge length.
- Fixed default hourglass control when the *HOURGLASS control card is used but no HG type is specified. We were setting to type 1 instead of 2. Also, fixed the default HG types to match the User's Manual for implicit and explicit.
- Fixed the part mass that was reported to d3hsp when *ELEMENT_SHELL_-SOURCE_SINK is used. The inactive elements were being included causing too high mass.
- Prevent inactive shell elements (from *ELEMENT_SHELL_SOURCE_SINK) from controlling the solution time step.
- Fixed the reported strain tensor in elements created by *ELEMENT_-SHELL_SOURCE_SINK when strain output is requested. The history was being retained from the previous elements with the same ID.
- Fixed torsion in linear beam form 13. A failure to add the torsional moment at node 2 caused an inability to reach equilibrium in the torsional mode.
- Fixed solid element 4 so that rigid body translation will not cause strain and stress due to round-off error.
- Mixed parallel consistency when used with solid element type 20. A buffer was not being allocated leading to a memory error.
- Changed the MPP behavior of discrete beams (ELFORM = 6) when attached to elements that fail. They were behaving like null beams, in the sense that it was possible for beam nodes to become dead due to attached elements failing, and discrete beams would be no longer visualized even if the beams themselves had not failed. With this change, the MPP discrete beams now behave like other beams in that the beams have to fail before they are re-moved. MPP and SMP behavior is now consistent.
- Improved the precision of the type 2 Belytschko Schwer resultant beam to prevent energy growth in single precision.

- Fixed the NLOC option on *SECTION_SHELL for the BCIZ triangle elements (ELFORM = 3) and the DKT triangle elements (ELFORM = 17). The offset was scaled by the solution time step so typically the offset was much smaller than expected.
- Fixed elout stress output for shell element forms 23 and 24. The in-plane averaging was incorrect causing wrong output.
- Changed *ELEMENT_TSHELL so that both the COMPOSITE and BETA options can be read at the same time. Prior to the fix, only the first one would be read.
- Fixed all thick shells to work with anisotropic thermal strains which can be defined by *MAT_ADD_THERMAL. Also, this now works by layer for layered composites.
- Fixed implicit solutions with thick shells with *MAT_057 when there are also solid elements in the model that use *MAT_057. Thick shells support only the incremental update of the F tensor but a flag was set incorrectly in the material model.
- Fixed *MAT_219 when used with thick shell types 3, 5, and 7. A failure to initialize terms for the time step caused a possible wrong time step.
- Fixed orthotropic user defined materials when used with thick shell elements. The storing of the transformation matrix was in the wrong location leading to wrong stress and strain.
- For thick shell composites that use element forms 5 and 7, the user can now use laminated shell theory along with the TSHEAR = 1 on *SECTION_TSHELL to get a constant shear stress through the thickness with a composite.
- Fixed the initialization of *MAT_CODAM2/*MAT_219 when used with thick shell forms 3, 5, or 7. The 3D thick shell routine uses only 2 terms for the transformation and therefore needs unique initialization of the transformation data.
- Fixed thick shell types 3 and 5 when used in implicit solutions with *MATs 2, 21, 261, and 263. The material constitutive matrix for *MATs 2 and 21 was not rotated correctly causing wrong element stiffness. The constitutive matrix for *MATs 261 and 263 was not orthotropic. Also, for *MAT_021, type 5 thick shell needed some material terms defined to correct the assumed strain.
- Fixed thick shell forms 3 and 5 when used in implicit solutions with non-isotropic materials. The stiffness matrix was wrong due to incorrect transformations.
- Also, fixed the implicit stiffness of thin and thick shells when used with laminated shell theory by assumed strain (LAMSHT = 3,4,5 on *CONTROL_ACCURACY). Elements were either failing to converge or converging more slowly due to the failure to adjust the stiffness matrix to be consistent with the assumed strain.
- Added support for *ELEMENT_SHELL_SOURCE_SINK to form 2 elements with BWC = 1 on *CONTROL_SHELL.

- Fixed the s-axis and t-axis orientation of beam spot welds in the MPP version when those beam weld elements are defined with a 3rd node. The 3rd node was being discarded prior to initializing the beam orientation so the s and t-axes were being randomly assigned as if the 3rd node had not been assigned. The effect on solutions is likely fairly minimal since beam material is isotropic and failure typically is too but may not be.
- Added Rayleigh damping (*DAMPING_PART_STIFFNESS) for thick shell formulations 1, 2, and 6. Previously, it was available for only the thick shells that call 3D stress updates, (forms 3 and 5), but now it is available for all thick shell formulations.
- Added new SCOOR options for discrete beam section 6 (*SECTION_-BEAM). A flaw was found in how the discrete beam accounts for rigid body rotation when SCOOR = -3, -2, +2, and +3. A correction for this is made and introduced as new options, SCOOR = -13, -12, +12, and +13. A decision was made to leave the existing options SCOOR = -2, +2, -3 and +3 unchanged so that legacy data could run without changes.
- Enabled the ELFORM 18 linear DKT shell element to work with *PART_-COMPOSITE and with an arbitrary number of through thickness integration points. It was limited to a single material and 10 Gauss points.
- Added the possibility to write *ELEMENT_SOLID_ORTHO into dynain file if requested. To activate this, add OPTCARD to *INTERFACE_SPRING-BACK and set SLDO = 1.
- Refine characteristic length calculation for 27-node solid (ELFORM 24). This change may increase the time step substantially for badly distorted elements.
- Implement selective reduced integration for 27-node solid (ELFORM 24).
- Allow part sets to be used in *DEFORMABLE_TO_RIGID_AUTOMATIC. Either PID is defined negative or "PSET" is set in column 3 (D2R) or 2 (R2D).
- Add new option STRESS = 2 to *INCLUDE_STAMPED_PART: no stresses and no history variables are mapped with that setting.
- New keyword *PART_STACKED_ELEMENTS provides a method to define and to discretize layered shell-like structures by an arbitrary sequence of shell and/or solid elements over the thickness.
- The geometric stiffness matrix for the Belytschko beam element type 2 has been extended to include nonsymmetric terms arising from nonzero moments. Provides "almost" quadratic convergence, still some terms missing to be added in the future. Also support a strongly objective version activated by IACC on *CONTROL_ACCURACY.
- The geometric stiffness for the Hughes-Liu element type 1 is fixed.
- Fix parsing error in *SECTION_BEAM_AISC.

- **EM (Electromagnetic Solver)**

  - Add the new EM 2d axi solver in SMP and MPP for EM solver 1 (eddy current). It is coupled with the mechanics and thermal solvers.

- The new EM 2d can be used with RLC circuits on helix/spiral geometries using *EM_CIRCUIT_CONNECT.
- Add EM contact into new EM 2d axi, in SMP and MPP.
- Add *EM_BOUNDARY support in new EM 2d axi solver.
- Introduce scalar potential in new EM 2d axi. The 2d axi can also be coupled with imposed voltage.
- Add new keyword *EM_CIRCUIT_CONNECT to impose linear constraints between circuits with imposed currents in 3d solvers. This allows for example to impose that the current in circuit 1 is equal to the current in circuit 2 even if the 2 corresponding parts are not physically connected.
- Add *EM_VOLTAGE_DROP keyword to define a voltage drop between 2 segment sets. This voltage drop constraint is coupled to the contact constraint so that the contact (voltage drop = 0) has priority over the *EM_VOLTAGE_DROP constraint.
- Add *EM_CONTROL_SWITCH_CONTACT keyword to turn the EM contact detection on and off.
- NCYCLBEM/NCYCLFEM in *EM_SOLVER_... can now be different than 1 when EM_CONTACT detected.
- Add RLC circuit for type 3 solver (resistive heating).
- Add computation of mutuals/inductances in 2d axi for output to em_circuit.dat
- Add criteria on autotimestep calculation when RLC circuit used to take into account RLC period.
- Fix keyword counter in d3hsp.
- Better and clearer output to terminal screen.
- Support jobid for EM ascii file outputs.

- **Forming**

  - Improvements to trimming:

    - *DEFINE_CURVE_TRIM_NEW: if trim seed node is not defined, we will search a seed node based on nodes from the sheet blank and the inside/outside flag definition for the trimming curves.
    - Map strain tensors to triangular elements after trimming.

  - Add a new function to the trim of solid elements in normal (3-D) trimming case, related to *DEFINE_CURVE_TRIM_3D. If the trimming curve is close to the bottom side, set TDIR = -1. If the trimming curve is close to the upper side, set TDIR = 1.
  - Add to *ELEMENT_LANCING. Allow parametric expression for variables END and NTIMES.
  - A bug fix for *CONTROL_FORMING_AUTOPOSITION_PARAMETER_SET: Fix distance calculation error when the target mesh is too coarse.
  - Improvements to springback compensations:

- Output the new trimming curve with *DEFINE_CURVE_TRIM_3D (previously *DEFINE_CURVE_TRIM), so that it can be easily converted to IGES curve by LS-PrePost. or used in another trimming calculation.
- Output each curve to IGES format in the following name format: newcurve_scp001.igs, newcurve_scp002.igs, newcurve_scp003.igs, etc.
- Output change in file "geocur.trm". This update will allow change from *DEFINE_CURVE_TRIM(_3D, _NEW), whatever is used for input.

◦ Add a new keyword: *DEFINE_FORMING_CONTACT to facilitate the forming contact definitions.
◦ Add a new keyword *DEFINE_FORMING_CLAMP, to facilitate clamping simulation.
◦ A new feature in mesh fusion, which allows a moving box to control the fusion, only if the center of the elements is inside the box can the elements be coarsened. Can be used in conjunction with *DEFINE_BOX_ADAPTIVE.
◦ Add a new feature to *DEFINE_BOX_ADAPTIVE: Moving box in adaptivity, useful in roller hemming and incremental forming.
◦ In mesh coarsening, if the node is defined in a node set, the connected elements will be kept from being coarsened. Previously, only *SET_NODE_LIST was supported. Now option *SET_NODE_GENERAL is allowed.
◦ Add a new function: mesh refinement for sandwich part. The top and bottom layers are shell elements and the middle layer is solid elements. Set IFSAND to 1 in *CONTROL_ADAPTIVE.

- Applies to both 8-noded and 6-noded solid elements.
- Map stress and history variables to the new elements.

◦ New features related to blank size development *INTERFACE_BLANKSIZE_DEVELOPMENT:

- Add *INTERFACE_BLANKSIZE_SYMMETRIC_PLANE to define symmetric plane in blank size development
- Add *INTERFACE_BLANKSIZE_SCALE_FACTOR. For each trimming, different scale factors can be used to compensate the blanksize. This is especially useful when the inner holes are small. Includes an option of offset the target curve which is useful if multiple target curves (e.g., holes) and formed curves are far from each other.
- Allow target curve to be outside of the surface of the blank.
- Add sorting to the mesh so the initial mesh and the formed mesh do not need to have the same sequence for the nodes.
- Add a new variable ORIENT, set to "1" to activate the new algorithm to potentially reduce the number of iterations with the use of *INTERFACE_BLANKSIZE_SCALE_FACTOR (scale = 0.75 to 0.9).

- Fix smooth problem along calculated outer boundary.
- Automatically determine the curve running directions (IOPTION = 2 and -2 now both give the same results).
- Accept parameteric expression.

◦ A bug fix for springback compensation: *INCLUDE_COMPENSATION_-SYMMETRIC_LINES Fix reading problem of free format in the original coding.
◦ Add a new keyword *CONTROL_FORMING_BESTFIT. Purpose: This keyword rigidly moves two parts so that they maximally coincide. This feature can be used in sheet metal forming to translate and rotate a spring back part (source) to a scanned part (target) to assess spring back prediction accuracy. This keyword applies to shell elements only.
◦ Improvements to *CONTROL_FORMING_AUTOCHECK:

- When IOFFSET = 1, rigid body thickness is automatically offset, based on the MST value defined in *CONTACT_FORMING_ONE_WAY_-SURFACE.
- Add new variable IOUTPUT that when set to 1 will output the offset rigid tool mesh, and the new output tool file is: rigid_offset.inc. After output the simulation stops. See R9.0 Manual for further details.
- When both normal check and offset are used, small radius might cause problem for offsetting. The new modification will check the normal again after offsetting the tool
- When outputting the rigid body mesh, output the bead nodes also.
- Changes to *CONTROL_FORMING_AUTOCHECK when used together with SMOOTH option: check and fix rigid body bad elements before converting the master part ID to segment set id to be used by SMOOTH option.
- Set IOUTPUT.eq. 3 to output rigid body mesh before and after offset.
- Fix problems offseting a small radius to a even smaller radius.
- Remove T-intersection.

◦ For *CONTROL_IMPLICIT_FORMING, fix output messages in d3hsp that incorrectly identified steps as implicit dynamic when they were actually implicit static.
◦ Improve *CONTROL_FORMING_UNFLANGING:

- Automatically calculate CHARLEN, so user does not need to input it anymore.
- Allow nonsmooth flange edge.
- Instead of using preset value of 0.4 (which works fine for thin sheet metal), blank thickness is now used to offset the slave node (flanges) from the rigid body (die).

- ***FREQUENCY_DOMAIN**
  - *FREQUENCY_DOMAIN_RANDOM_VIBRATION: Fixed a bug in dumping d3psd binary database, when both stress and strain are included.
  - *FREQUENCY_DOMAIN_SSD_ERP: Implemented the Equivalent adiated Power (ERP) computation to MPP.
  - *FREQUENCY_DOMAIN_ACOUSTIC_BEM:
    - Enabled running dual collocation BEM based on Burton-Miller formulation (METHOD = 4) with vibration boundary conditions provided by Steady State Dynamic analysis (*FREQUENCY_DOMAIN_SSD).
    - Added exponential window function for FFT (FFTWIN = 5).
    - Implemented a new forward and backward mixed radix FFT.
    - Implemented acoustic computation restart from frequency domain boundary conditions, in addition to time domain boundary conditions (RESTRT = 1).
    - Enabled out-of-core velocity data storage, to solve large scale problems.
    - Implemented option HALF_SPACE to Rayleigh method (METHOD = 0) to consider acoustic wave reflection.
    - Added velocity interpolation to take care of mismatching between acoustic mesh and structural mesh (*BOUNDARY_ACOUSTIC_MAPPING), for the case that the boundary conditions are provided by Steady State Dynamic analysis.
    - Added weighted SPL output to acoustic computation (DBA = 1,2,3,4).
    - Implemented radiated sound power, and radiation efficiency computation to collocation BEMs (METHOD = 3,4). Added new ASCII xyplot databases Press_Power and Press_radef to save the sound power and radiation efficiency results.
    - Enabled using both impedance and vibration (velocity) boundary conditions in acoustic simulation.
  - *FREQUENCY_DOMAIN_ACOUSTIC_FEM:
    - Added weighted SPL output to FEM acoustics (DBA = 1,2,3,4).
    - Implemented option EIGENVALUE to perform acoustic eigenvalue analysis; added ASCII database eigout_ac to save acoustic eigenvalue results; added binary plot database d3eigv_ac to save acoustic eigenvectors.
    - Enabled consideration of nodal constraints in acoustic eigenvalue analysis.
    - Enabled FEM acoustic analysis with frequency dependent complex sound speed.
    - Implemented pressure and impedance boundary conditions.

- *FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT:
  - Added this keyword to 1) generate acoustic field points as a sphere or plate mesh (options SPHERE and PLATE), or 2) define acoustic field points mesh based on existing structure components (options PART, PART_SET and NODE_SET) so that user can get fringe plot of acoustic pressure and SPL. The results are saved in binary plot database d3acs (activated by keyword *DATABASE_FREQUENCY_BINARY_-D3ACS).
- *FREQUENCY_DOMAIN_RANDOM_VIBRATION:
  - Changed displacement rms output in d3rms to be the displacement itself, without adding the original nodal coordinates.
  - Implemented von mises stress PSD computation in beam elements.
  - Implemented fatigue analysis with beam elements.
  - Added strain output to binary plot databases d3psd and d3rms, and binout database elout_psd.
  - Added initial damage ratio from multiple loading cases (INFTG > 1).
- *FREQUENCY_DOMAIN_SSD:
  - Implemented option ERP to compute Equivalent Radiated Power. It is a fast and simplified way to characterize acoustic behavior of vibrating structures. The results are saved in binary plot database d3erp (activated by keyword *DATABASE_FREQUENCY_BINARY_D3ERP), and ASCII xyplot files ERP_abs and ERP_dB.
  - Implemented fatigue analysis based on maximum principal stress and maximum shear stress.

- **ICFD (Incompressible Flow Solver)**
  - *ICFD_BOUNDARY_FSWAVE: Added a boundary condition for wave generation of 1st order stokes waves with free surfaces.
  - *ICFD_DATABASE_DRAG_VOL: For computing pressure forces on volumes ID (useful for forces in porous domains), output in icfdragivol.dat and icfdragivol.#VID.dat.
  - *ICFD_CONTROL_DEM_COUPLING: Coupling the ICFD solver with DEM particles is now possible.
  - *ICFD_CONTROL_MONOLITHIC: Added a monolithic solver (=1) which can be selected instead of the traditional fractional step solver (=0).
  - *ICFD_CONTROL_POROUS: This keyword allows the user to choose between the Anisotropic Generalized Navier-Stokes model (=0) or the Anisotropic Darcy-Forchheimer model (=1) (for Low Reynolds number flows). The Monolithic solver is used by default for those creeping flows.
  - *ICFD_CONTROL_TURBULENCE:

- Modified existing standard k-epsilon.
- Added Realizable k-epsilon turbulence model.
- Added Standard 98 and 06 Wilcox and Menter SST 03 turbulence models.
- Added Several laws of the wall.
- Added Rugosity law when RANS turbulence model selected.

◦ *ICFD_MODEL_POROUS:

- Added Porous model 5 for anistropic materials defined by P-V experimental curves.
- Added porous model 6 for moving domain capabilities for Porous Media volumes using load curves for permeabilities directions.
- Added porous model 7 for moving domain capabilities for Porous Media volumes using ICFD_DEFINE_POINT for permeabilities directions.
- Added porous model 9 for a new Anisotropic Porous Media flow model (PM model ID = 9): It uses a variable permeability tensor field which is the result of solid dynamic problems. The model reads the solid mesh and the field state and maps elemental permeability tensor and solid displacements to the fluid mesh.

◦ *ICFD_MODEL_NONNEWT:

- Added a few models for non newtonian materials and temperature dependant viscosity :
  - model 1 : power law non newtonian (now also temperature dependant)
  - model 2 : carreau fluid
  - model 3 : cross fluid
  - model 4 : herschel-bulkley
  - model 5 : cross fluid II
  - model 6 : temperature dependant visc (sutherland)
  - model 7 : temperature dependant visc (power law)
  - model 8 : load curve dependant visc, model 8 is especially interesting since a DEFINE_FUNCTION can be used (for solidification applications).

◦ *ICFD_SOLVER_TOL_MONOLITHIC: Used to define atol, rtol, dtol and maxits linear solver convergence controls of the monolithic NS time integration

◦ *MESH_BL: Added support for boundary layer mesh creation by specifying the thickness, number of layers, first node near the surface and the strategy to use to divide and separate the elements inside the BL adding.

- *ICFD_BOUNDARY_PRESCRIBED_VEL: Added the support of DEFINE_-FUNCTION making the second line of the keyword obsolete.
- *ICFD_CONTROL_TIME: Min and Max timestep values can be set.
- *ICFD_DATABASE_DRAG:
  - Added frequency output.
  - Added option to output drag repartition percentage in the d3plots as a surface variable.
- *ICFD_CONTROL_IMPOSED_MOVE: This keyword now uses *ICFD_-PART and *ICFD_PART_VOL instead of *MESH_VOL for ID. It is now possible to impose a rotation on a part using Euler angles.
- *ICFD_CONTROL_OUTPUT:
  - Field 4 now to output mesh in LSPP format and in format to be run by the icfd solver (icfd_fluidmesh.key and icfd_mesh.key)
  - icfd_mesh.key now divides the mesh in ten parts, from best quality element decile to worst.
  - A new mesh is now output at every remeshing.
  - Added support for parallel I/O for Paraview using the PVTU format.
- *ICFD_DEFINE_POINT: Points can now be made to rotate or translate.
- *ICFD_MAT:
  - Nonnewtonian models and Porous media models are now selected in the third line by using the new ICFD_MODEL keyword family.
  - HC and TC can now be made temperature dependent.
- *ICFD_CONTROL_DIVCLEAN: Added option 2 to use a potential flow solver to initialize the Navier Stokes solver.
- *ICFD_CONTROL_FSI: Field 5 provides a relaxation that starts after the birthtime.
- *ICFD_CONTROL_MESH: Field 3 added a new strategy to interpolate a mesh size during the node insertion. In some cases it speeds up the meshing process and produces less elements. Field 4 changes the meshing strategy in 2d.
- *ICFD_CONTROL_SURFMESH: Added support for dynamic re-meshing/adaptation of surface meshing.
- *ICFD_BOUNDARY_PRESCRIBED_VEL:VAD = 3 now works with DOF = 4.
- SF can be lower than 0.
- PID can be over 9999 in *ICFD_DATABASE_FLUX.
- Fixed d3hsp keyword counter.
- Clarified terminal output.
- Y+ and Shear now always output on walls rather than when a turbulence model was selected.

- Added coordinate of distorted element before remeshing occurs. Output on terminal and messag file
- Fixed bug in conjugate heat transfer cases. When an autotimestep was selected in *ICFD_CONTROL_TIME, it would always only take the thermal timestep.
- An estimation of the CFL number is now output in the d3plot files. This is not the value used for the autotimestep calculation.
- Turbulence intensity is now output in the d3plots.
- Jobid now supported for ICFD ASCII File outputs.
- Fixed communication of turbulent constants in MPP.
- Fixed the Near Velocity field output.
- Increasing the limit of number of parts for the model.
- Temperature added as a surface variable in output.
- Fixed non-linear conjugate heat solver.

- **Implicit**

  - Fixed Implicit for the case of Multi-step Linear (*CONTROL_IMPLICIT_GENERAL with NSOLVR = 1) with Intermittent Eigenvalue Computation (*CONTROL_IMPLICIT_EIGENVALUE with NEIG < 0).
  - Recent fix for resultant forces for Multi-step Linear cause segmentation fault when Intermittent Eigenvalue Computation was also active.
  - Fix possible issue related to constrained contacts in MPP implicit not initializing properly.
  - Fixed label at beginning of implicit step to be correct for the case of controlling implicit dynamics via a load curve (*CONTROL_IMPLICIT_DYNAMICS).
  - Corrected the computation of modal stresses with local coordinate terms and for some shell elements (see MSTRES on *CONTROL_IMPLICIT_EIGENVALUE).
  - Corrected *CONTROL_IMPLICIT_INERTIA_RELIEF logic in MPP. In some cases the rigid body modes were lost.
  - Enhanced implicit's treatment of failing spotwelds (*CONSTRAINED_SPOTWELD).
  - Added additional error checking of input data for *CONTROL_IMPLICIT_MODAL_DYNAMICS_DAMPING.
  - Per user request we added the coupling of prescribed motion constraints for Modal Dynamics by using constraint modes. See *CONTROL_IMPLICIT_MODAL_DYNAMIC.
  - Added reuse of the matrix reordering for MPP implicit execution. This will reduce the symbolic processing time which is noticeable when using large numbers of MPP processes. Also added prediction of non-tied contact connections for standard contact and mortar contact. This allows reuse of the ordering when contact interfaces are changing very slightly but can increase the cost of the numerical factorization. Useful only for MPP using large

numbers of processes for large finite element models. This reuse checking happens automatically for MPP and is not required for SMP.

- Apply improvements to Metis memory requirements used in Implicit MPP.
- Enhanced Metis ordering software (ORDER = 2, the default, on *CONTROL_IMPLICIT_SOLVER).
- Added new keyword *CONTROL_IMPLICIT_ORDERING to control of features of the ordering methods for the linear algebra solver in MPP Implicit. Only should be used by expert users.
- The following 4 enhancements are applicable when IMFLAG > 1 on *CONTROL_IMPLICIT_GENERAL.

    - Implicit was modified to reset the time step used in contact when switching from implicit to explicit.
    - Adjusted implicit mechanical time step for the case of switching from explicit to implicit so as not to go past the end time.
    - Explicit with intermittent eigenvalue analysis was getting incorrect results after the eigenvalue analysis because an incorrect time step was used for the implicit computations. For this scenario implicit now uses the explicit time step.
    - The implicit time step is now reset for the dump file in addition to explicit's time.

- Implicit's treatment of prescribed motion constraints defined by a box had to be enhanced to properly handle potential switching to explicit.
- The following 6 enhancements are for matrix dumping (MTXDMP > 0 on *CONTROL_IMPLICIT_SOLVER) or for frequency response (*FREQUENCY_DOMAIN) computations.
- Corrected the collection of *DAMPING_PART_STIFFNESS terms for elements like triangles and 5, 6, and 7 node solid elements.
- Corrected Implicit's access of *DAMPING_PART_STIFFNES parameter when triangle and tet sorting is activated.
- Fixed Implicit's collecting of damping terms for beams that have reference nodes.
- There is an internal switch that turns off damping for beams if the run is implicit static. This switch needed to be turned off for explicit with intermittent eigenvalue analysis.
- Fixed collecting of stiffness damping terms for implicit. Corrected the loading of mass damping terms when collecting damping terms for post processing.
- Extend matrix dumping to include dumping the solution vector in addition to the matrix and right-hand-side.
- Adjusted Implicit's handling of sw1. and sw3. sense switches to properly handle dumping. If sw1. sense switch is issued when not at equilibrium, then reset time and geometry to that at the end of last implicit time step. If

sw3. sense switch is issued, then wait until equilibrium is reached before dumping and continuing.

- Enable the use of intermittent eigenvalue computation for models using inertia relief and/or rotational dynamics. See NEIG < 0 on *CONTROL_IMPLICIT_EIGENVALUE and *CONTROL_INERTIA_RELIEF and *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS. Due to round-off, an implicit intermittent eigenvalue computation was occasionally skipped. A fudge factor of 1/1000 of the implicit time step was added to compensate for round-off error in the summation of the implicit time. See NEIG < 0 on *CONTROL_IMPLICIT_EIGENVALUE.
- Added support for *CONSTRAINED_LINEAR for 2D implicit problems. It was already supported for standard 3D problems.
- Added warning for implicit when the product of ILIMIT and MAXREF (two parameters on *CONTROL_IMPLICIT_SOLUTION) is too small. For the special case when the user changes the default of ILIMIT to 1 to choose Full Newton and does not change MAXREF then MAXREF is reset to 165 and a warning is generated. Reinstate the option of MAXREF < 0.
- Fixed the display of superelements in LS-PrePost. Enhanced reading of Nastran dmig files to allow for LS-DYNA-like comment lines starting with '$'. Fixed a problem with implicit initialization in MPP with 2 or more superelements. See *ELEMENT_DIRECT_MATRIX_INPUT.
- Turned off annoying warning messages associated with zero contact elemental stiffness matrices coming from mortar contact. See *CONTACT_..._MORTAR
- Fixed construction of d3mode file in MPP. Involves proper computation of the reduced stiffness matrix. See *CONTROL_IMPLICIT_MODES
- Fixed up *PART_MODES to correctly handle constraint modes.
    - removed rigid body modes
    - correct construction of reduced stiffness matrix
- Enhanced the error handling for input for *PART_MODES.
- Modified open statements for binary files used by implicit to allow for use of *CASE.
- Removed internal use files such as spooles.res when not required for debugging.
- Fixed implicit static condensation and implicit mode computation to properly deal with the *CASE environment. See *CONTROL_IMPLICIT_STATIC_CONDENSATION and *CONTROL_IMPLICIT_MODES. Sort node/dof sets for implicit_mode to get correct results. Properly handle cases with only solid elements.
- Add implicit implementation of the new "last location" feature for MPP error tracking.
- Fixed problem with implicit processing of rigid body data with deformable to rigid switching (*DEFORMABLE_TO_RIGID).

- Extended Implicit model debugging for LPRINT = 3 (*CONTROL_IMPLICIT_SOLVER) to isogeometric and other large elemental stiff matrices.
- Added beam rotary mass scaling to the modal effective mass computation. Enhanced implicit computation of modal effective mass that is output to file eigout with *CONTROL_IMPLICIT_EIGENVALUE. We had to account for boundary SPC constraints as well as beam reference nodes to get the accumulated percentage to add up to 100%.
- Fixed a problem reporting redundant constraints for MPP Implicit.
- Enhanced *CONTACT_AUTO_MOVE for implicit.
- Fixed Implicit handling of *CONSTRAINED_TIE-BREAK in MPP.
- Added support for implicit dynamics to *MAT_157 and *MAT_120.
- Skip frequency damping during implicit static dynamic relaxation.
- Added feature to simulate brake squeal. Transient and mode analysis can be combined to do the brake squeal study by intermittent eigenvalue analysis. Besides *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS, *CONTROL_IMPLICIT_SOLVER should also be used, setting LCPACK = 3 to enable nonsymmetric stiffness matrix. In the nonsymmetric stiffness matrix analysis such as brake squeal analysis, the damping ratio, defined as -2.0*RE(eigenvalue)/ABS(IMG(eigenvalue)), can be output to the eigout file and plotted in LS-PrePost. A negative damping ratio indicates an unstable mode.
- Add a warning message if the defined rotational speed is not the same as NOMEG in *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS.
- *CONTROL_IMPLICIT: Fixed a bug to initialize velocity correctly when using a displacement file in dynamic relaxation for implicit MPP.
- Nonlinear implicit solver 12 is made default implicit solver, which is aimed for enhanced robustness in particular relation to BFGS and line search.
- Parameter IACC available on *CONTROL_ACCURACY to invoke enhanced accuracy in selected elements, materials and tied contacts. Included is strong objectivity in the most common elements, strong objecitity and physical respons in most commont tied contacts and full iteration plasticity in *MATs 24 and 123. For more detailed information refer to the manual.
- Bathe composite time integration scheme implemented for increased stability and conservation of energy/momentum, see *CONTROL_IMPLICIT_DYNAMICS. Time integration parameter ALPHA on CONTROL_IMPLICIT_DYNAMICS is used for activation.
- For NLNORM.LT.0 all scalar products in implicit are with respect to all degrees of freedom, sum of translational and rotational (similar to NLNORM.EQ.4), just that the rotational dofs are scaled using ABS(NLNORM) as a characteristic length to appropriately deal with consistency of units.
- The message 'convergence prevented due to unfulfilled bc...' has annoyed users. Here this is loosened up a little and also accompanied with a check that the bc that prevents convergence is actually nonzero. Earlier this prevention has activated even for SPCs modelled as prescribed zero motion, which does not make sense.

- Implicit now writes out the last converged state to the d3plot database on error termination if not already written.
- Fixed bug for *CONTROL_IMPLICIT_MODAL_DYNAMIC if jobid is used.

- ***INITIAL**

  - Fix incorrect NPLANE and NTHICK for *INITIAL_STRESS_SHELL when output to dynain file for shell type 9.
  - Fix *INITIAL_STRAIN_SHELL output to dynain for shell types 12 to 15 in 2D analysis.
  - Write out strain at only 1 intg point if INTSTRN = 0 in *INTERFACE_SPRINGBACK_LSDYNA and all strains at all 4 intg points if INTSTRN = 1 and nip = 4 in *SECTION_SHELL.
  - *INITIAL_EOS_ALE: Allow initialization of internal energy density, relative volume, or pressure in ALE elements by part, part set, or element set.
  - *INITIAL_VOLUME_FRACTION_GEOMETRY: Add option (FAMMG < 0) to form pairs of groups in *SET_MULTI-MATERIAL_GROUP_LIST to replace the first group of the pair by the second one.
  - *INITIAL_STRESS_DEPTH can now work with parts that have an Equation of State (EOS types 1, 4, 6 only). Note however that *INITIAL_STRESS_DEPTH does not work with ALE.
  - Fix several instances of overwriting the initial velocities of any interface nodes read in from a linking file (SMP only).
  - *INITIAL_VOLUME_FRACTION_GEOMETRY: Add local coordinate system option for box.
  - The initial strain and energy is calculated for *INITIAL_FOAM_REFERENCE_GEOMETRY.
  - Add the option of defining the direction cosine using two nodes for *INITIAL_VELOCITY_GENERATION.
  - Fix incorrect transformation of *DEFINE_BOX which results in incorrect initial velocities if the box is used in *INITIAL_VELOCITY.
  - Fix incorrect initial velocity when using *INITIAL_VELOCITY with NX = -999.
  - Fix seg fault when using *INITIAL_INTERNAL_DOF_SOLID_TYPE4 in dynain file.
  - Do not transform the translational velocities in *INITIAL_VELOCITY or *INITIAL_VELOCITY_GENERATION if the local coordinate system ICID is defined.
  - Fix uninitialized velocities when using *INITIAL_VELOCITY_GENERATION with STYP = 2, i.e. part id, for *ELEMENT_SHELL_COMPOSITE/*ELEMENT_TSHELL_COMPOSITE.
  - Fix incorrect initialization of velocities if using *INITIAL_VELOCITY_GENERATION with STYP = 1, i.e. part set for shells with formulation 23 & 24.
  - Fix incorrect initial velocity and also mass output to d3hsp for shell types 23 & 24.

- Fix incorrect initial velocities when using *INITIAL_VELOCITY_GENERATION with irigid = 1 and *PART_INERTIA with xc = yc = zc = 0 and nodeid > 0 with *DEFINE_TRANSFORMATION.
- Fix incorrect stress initialization of *MAT_057/MAT_LOW_DENSITY_FOAM using dynain file with *INITIAL_STRESS_SOLID when NHISV is equal to the number of history variables for this mat 57.
- Fix seg fault when reading dynain.bin
- Fixed stress initialization (*INITIAL_STRESS_SECTION) for type 13 tetrahedral elements. The pressure smoothing was causing incorrect pressure values in the elements adjacent to the prescribed elements.
- Assign initial velocities (*INITIAL_VELOCITY) to beam nodes that are generated when release conditions are defined (RT1, RT2, RR1, RR2 on *ELEMENT_BEAM.)
- Added an option to retain bending stiffness in spot weld beams that have prescribed axial force. To use is, set KBEND = 1 on *INITIAL_AXIAL_FORCE_BEAM.
- Fix for *INITIAL_STRESS_BEAM when used with spotweld beam type 9. It was possible that error/warning message INI+140 popped up even if number of integration points matched exactly.
- Fix for the combination of type 13 tet elements and *INITIAL_STRESS_SOLID. The necessary nodal values for averaging (element volume, Jacobian) were not correctly initialized. Now the initial volume (IVEFLG) is used to compute the correct initial nodal volume.

- **Isogeometric Elements**

  - Enable spc boundary condition to be applied to extra nodes of nurbs shell, see *CONSTRAINED_NODES_TO_NURBS_SHELL
  - Fix a bug for isogeometric element contact, IGACTC = 1, that happens when more than one NURBS patches are used to model a part so that a interpolated elements have nodes belonging to different NURB patches.
  - *ELEMENT_SOLID_NURBS_PATCH:

    - Enable isogeometric analysis for solid elements, it is now able to do explicit and implicit analysis, such as contact and eigenvalue analysis, etc.
    - Add mode stress analysis for isogeometric solid and shell elements so that the isogeometric element is also able to do frequency domain analysis.

  - Add reduced, patch-wise integration rule for C1-continuous quadratic NURBS. This can be used by setting INT = 2 in *ELEMENT_SHELL_NURBS_PATCH.

- Add trimmed NURBS capability. Define NL trimming loops to specify a trimmed NURBS patch. Use *DEFINE_CURVE (DATTYP = 6) to specify define trimming edges in the parametric space.
- Fix bug in added mass report for *ELEMENT_SHELL_NURBS_PATCH in MPP.

- ***LOAD**

  - *LOAD_GRAVITY_PART and staged construction (*DEFINE_STAGED_CONSTRUCTION_PART) were ignoring non-structural mass MAREA (shells) and NSM (beams). Now fixed.
  - Fix for *INTERFACE_LINKING in MPP when used with adaptivity.
  - Updates for *INTERFACE_LINKING so that it can be used with adaptivity, provided the linked parts are adapting.
  - Fix for *INTERFACE_LINKING when used with LSDA based files generated by older versions of the code.
  - *DEFINE_CURVE_FUNCTION:

    - Functions "DELAY", PIDCTL" and "IF" of are revised.
    - Add sampling rate and saturation limit to PIDCTL of *DEFINE_CURVE_FUNCTION.
    - "DELAY" of *DEFINE_CURVE_FUNCTION can delay the value of a time-dependent curve by "-TDLY" time steps when TDLY < 0.

  - Add edge loading option to *LOAD_SEGMENT_SET_NONUNIFORM.
  - Fix insufficient memory error,SOL+659, when using *LOAD_ERODING_PART_SET with mpp.
  - Fix incorrect loading when using *LOAD_ERODING_PART_SET with BOXID defined.
  - Fix incorrect pressure applied if the directional cosines, V1/V2/V3, for *LOAD_SEGMENT_SET_NONUNIFORM do not correspond to a unit vector.
  - Add *DEFINE_FUNCTION capability to *LOAD_SEGMENT_SET for 2D analysis.
  - Fix incorrect behavior when using arrival time, AT, or box, BOXID, in *LOAD_ERODING_PART_SET.
  - Fix error when runing analysis with *LOAD_THERMAL_CONSTANT_ELEMENT_(OPTION) in MPP with ncpu > 1.
  - Fixed *LOAD_STEADY_STATE_ROLLING when used with shell form 2 when used with Belytschko-Wong-Chang warping stiffness (BWC = 1 *CONTROL_SHELL).
  - Add "TIMESTEP" as a code defined value available for *DEFINE_FUNCTION and *DEFINE_CURVE_FUNCTION. It holds the current simulation timestep.
  - Fixed issues involving *LOAD_THERMAL_D3PLOT.

- Allow extraction of node numbers in loadsetud for all values of LTYPE in *USER_LOADING_SET. Comments included appropriately in the code. Argument list of loadsetud is changed accordingly.
- Implemented SPF simulation (*LOAD_SUPERPLASTIC_FORMING) for 2d problems.
- Added effective stress as target variable for SPF simulation.
- Added box option for SPF simulation to limit target search regions.

- ***MAT**

  - Fix output to d3hsp for *MAT_HYPERELASTIC_RUBBER. Broken in r93028.
  - Error terminate with message, KEY+1115, if_STOCHASTIC option is invoked for *MATs 10,15,24,81,98, 123 but no *DEFINE_STOCHASTIC_VARIATION or *DEFINE_HAZ_PROPERTIES keyword is present in the input file.
  - Fix spurious error termination when using *DEFINE_HAZ_PROPERTIES with adaptivity.
  - Fixed *MATs 161 and 162 when run with MPP. The array that is used to share delamination data across processors had errors.
  - *MAT_261/*MAT_262: Fixed problem using *DAMPING_PART_STIFFNESS together with RYLEN = 2 in *CONTROL_ENERGY.
  - Added safety check for martensite phase kinetics in *MAT_244.
  - Fix for combination of *MAT_024_STOCHASTIC and shell elementstype 13, 14, and 15 (with 3d stress state).
  - Fix bug in *MATs 21 and 23 when used with *MAT_ADD_THERMAL_EXPANSION.
  - *MAT_ALE_VISCOUS: Implement a user defined routine in dyn21.F to compute the dynamic viscosity.
  - Add histlist.txt to usermat package. This file lists the history variables by material.
  - Bug in *MAT_089 fixed: The load curve LCSS specifies the relationship between "maximum equivalent strain" and the von Mises stress. The "maximum equivalent strain" includes both elastic and plastic components. The material model was not calculating this variable as intended, so was not following LCSS accurately. The error was likely to be more noticeable when elastic strains are a significant proportion of the total strain e.g. for small strains or low initial Youngs modulus.
  - Fixed bug affecting *MAT_119: unpredictable unloading behaviour in local T-direction if there are curves only for the T-direction and not for the S-direction.
  - Fixed bug in *MAT_172: Occured when ELFORM = 1 (Hughes-Liu shell formulation) was combined with Invariant Numbering (INN > 0 on *CONTROL_ACCURACY). In this case, the strain-softening in tension did not work: after cracking, the tensile strength remained constant.

- New option for *MAT_079: Load curve LCD defining hysteresis damping versus maximum strain to date. This overrides the default Masing behaviour.
- *MAT_172:
  - Added error termination if user inputs an illegal value for TYPEC. Previously, this condition could lead to abnormal terminations that were difficult to diagnose.
  - Fixed bug affecting ELFORM = 16 shells made of *MAT_172 – spurious strains could develop transverse to the crack opening direction.
- Fixed bug in *MAT_ARUP_ADHESIVE (*MAT_169). The displacement to failure in tension was not as implied by the inputs TENMAX and GCTEN. For typical structural adhesives with elastic stiffness of the order of 1000-10000 MPa, the error was very small. The error became large for lower stiffness materials.
- *MAT_SPR_JLR:
  - Modify output variables from *MAT_SPR_JLR (see Manual).
  - Fix bug that caused spurious results or unexpected element deletion if TELAS = 1.
- Fixed bug in *MAT_174 - the code could crash when input parameters EUR = 0 and FRACR = 0..
- Fix MPP problem when writing out aea_crack file for *MAT_WINFRITH.
- Include *MAT_196 as one that triggers spot weld thinning.
- *MAT_ADD_FATIGUE: Implemented multi slope SN curves to be used in random vibration fatigue (*FREQUENCY_DOMAIN_RANDOM_VIBRATION_FATIGUE) and SSD fatigue (FREQUENCY_DOMAIN_SSD_FATIGUE).
- Guard against possible numerical round off that in some cases might result in unexpected airflow in *MAT_ADD_PORE_AIR.
- Added new material *MAT_115_O/*MAT_UNIFIED_CREEP_ORTHO.
- *MAT_274: Added support for 2D-solids. New flag (parameter 8 on card 2) is used to switch normal with in-plane axis.
- *MAT_255: Fixed bug in plasticity algorithm and changed from total strain rate to plastic strain rate for stability. Added VP option (parameter 5 on card 2) for backwards compatibility: VP = 0 invokes total strain rate used as before.
- Added new cohesive material *MAT_279/*MAT_COHESIVE_PAPER to be used in conjunction with *MAT_274/*MAT_PAPER.
- User materials: Added support for EOS with user materials for tshell formulations 3 and 5.
- Fixed bug in dyna.str when using EOS together with shells and orthotropic materials.

- *MAT_122: A new version of *MAT_HILL_3R_3D is available. It supports temperature dependent curves for the Young's/shear moduli, Possion ratios, and Hill's anisotropy parameters. It also supports 2D-tables of yield curves for different temperatures. Implicit dynamics is supported. The old version is run if parameter 5 on card 3 is set to 1.0.
- Added the phase change option to *MAT_216, *MAT_217, *MAT_218 to allow material properties to change as a function of location. This capability is designed to model materials that change their properties due to material processing that is otherwise not modeled. For example, increasing the mass and thickness due to the deposition of material by spraying. It is not used for modeling phase changes caused by pressure, thermal loading, or other mechanical processes modeled within LS-DYNA.
- Fix internal energy computation of *MAT_ELASTIC_VISCOPLASTIC_-THERMAL/MAT_106.
- Fix incorrect results or seg fault for *MAT_FU_CHANG_FOAM/MAT_083 if KCON > 0.0 and TBID.ne.0.
- If SIGY = 0 and S = 0 in *MAT_DAMAGE_2/MAT_105, set S = EPS1/200, where EPS1 is the first point of yield stress input or the first ordinate point of the LCSS curve.
- Set xt = 1.0E+16 as default if user inputs 0.0 for *MAT_ENHANCED_COMPOSITE_DAMAGE/MAT_054. Otherwise, random failure of elements may occur. Implemented for thick shells and solids.
- Allow *MAT_ENHANCED_COMPOSITE_DAMAGE/MAT_054 failure mechanism to work together with *MAT_ADD_EROSION for shells.
- Fix incorrect erosion behavior if *MAT_ADD_EROSION is used with failure criteria defined for *MAT_123/MAT_MODIFIED_PIECEWISE_LINEAR_PLASTICITY.
- Fix non-failure of triangular elements type 4 using *MAT_ADD_EROSION with NUMFIP = -100.
- Implement scaling of failure strain for *MAT_MODIFIED_PIECEWISE_-LINEAR_PLASTICITY_STOCHASTIC/MAT_123_STOCHASTIC for shells.
- Fix incorrect behavior for *MAT_LINEAR_ELASTIC_DISCRETE_-BEAM/MAT_066 when using damping with implicit(statics) to explicit switching.
- Fix error due to convergence when using *MAT_CONCRETE_-EC2/MAT_172 in implicit and when FRACRX = 1.0 or FRACRY = 1.0
- Fix incorrect fitting results for *MAT_OGDEN_RUBBER/MAT_077_O if the number of data points specified in LCID is > 100.
- Fix incorrect fitting results for *MAT_MOONEY-RIVLIN-RUBBER/MAT_027 if the number of data points specified in LCID is > 100.
- Fix incorrect forces/moments when preloads are used for *MAT_-067/NONLINEAR_ELASTIC_DISCRETE_BEAM and the strains changes sign.

- Implement *MAT_188/MAT_THERMO_ELASTO_VISCO-PLASTIC_CREEP for 2D implicit analysis.
- Support implicit for *MAT_121/MAT_GENERAL_NONLIN-EAR_1DOF_DISCRETE_BEAM.
- Fix seg fault when using *DEFINE_HAZ_TAILOR_WELDED_BLANK with *DEFINE_HAZ_PROPERTIES.
- Fix ineffective *MAT_ADD_EROSION if the MID is defined using a alpha-numeric label.
- Fix seg fault when using *MAT_PIECEWISE_LINEAR_PLASTIC_THER-MAL/MAT_255 for solids.
- Zero the pressure for *MAT_JOHNSON_HOLMQUIST_JH1/MAT_241 af-ter it completely fractures, i.e. D>=1.0, under tensile load.
- Fix incorrect element failure when using EPSTHIN and VP = 0 for *MAT_-123/MODIFIED_PIECEWISE_LINEAR_PLASTICITY.
- Fix error termination when using adaptive remeshing for 2D analysis with *MAT_015/JOHNSON_COOK and NIP = 4 in *SECTION_SHELL and ELFORM = 15.
- Fix erosion due to damage, max shear & critical temperature in elastic state for *MAT_MODIFIED_JOHNSON_COOK/MAT_107 for solids.
- Check diagonal elements of C-matrix of *MAT_002/MAT_*OPTION* TROP-IC_ELASTIC and error terminate with message, STR+1306, if any of them are negative.
- Fix plastic strain tensor update for *MAT_082/*MAT_PLASTICITY_-WITH_DAMAGE.
- Fix error when using *MAT_144/MAT_PITZER_CRUSHABLE_FOAM with solid tetahedron type 10.
- Fix out-of-range forces after dynamic relaxation when using VP = 1 for *MAT_PIECEWISE_LINEAR_PLASTICITY and non-zero strain rate parameters, C & P, and the part goes into plastic deformation during dynamic relaxation.
- Fixed unit transformation for GAMAB1 and GAMAB2 on *MAT_DRY_-FABRIC. We were incorrectly transforming them as stress.
- Fixed implicit solutions with shell elements that use *MAT_040 and laminated shell theory.
- Fixed the stress calculation in the thermal version of *MAT_077.
- Corrected the AOPT = 0 option of ortho/anisotropic materials when use with skewed solid elements. Previously, the material direction was initialized to be equivalent to the local coordinate system direction. This is not consistent with the manual for skewed elements which states that the material a-axis is in the 1-2 directions for AOPT = 0. This is now fixed and the manual is correct.
- Fixed the AOPT = 0 option of ortho/anisotropic materials for tetrahedral element forms 10, 13, and 44.
- Fixed *MAT_082 for solid elements. An error in the history data was causing possible energy growth or loss of partially damaged elements.

- Modified *MAT_FABRIC/*MAT_034 FORM = 24 so that Poisson's effects occur in tension only.
- Modified *MAT_221/*MAT_ORTHOTROPIC_SIMPLIFIED_DAMAGE to correct the damage behavior. Prior to this fix, damage was applied to new increments of stress, but not the stress history, so material softening was not possible.
- Fixed *MAT_106 when used with curves to define the Young's modulus and Poisson's ratio and when used with thick shell form 5 or 6. The assumed strain field was unreasonable which caused implicit convergence to fail.
- Added 2 new erosion criteria for *MAT_221/*MAT_ORTHOTROPC_SIMPLIFIED_DAMAGE. The new options are NERODE = 10: a or b directions failure (tensile or compressive) plus out of plane failure bc or ca. NERODE = 11: a or b directions failure (tensile only) plus out of plane failure bc or ca.
- Added a new option for shell *MAT_022/*MAT_COMPOSITE_DAMAGE. When ATRACK = 1, the material directions will follow not only element rotation, but also deformation. This option is useful for modeling layered composites, that have material a-directions that vary by layer, by allowing each layer to rotate independently of the others. Within each layer, the b-direction is always orthogonal to the a-direction.
- Fixed the TRUE_T option on *MAT_100 and *MAT_100_DA. If the weld connects shells with different thickness and therefore different bending stiffness, the scheme used by TRUE_T to reduce the calculated moment could behave somewhat unpredictably. With the fix, TRUE_T behaves much better, both for single brick welds and brick assemblies.
- Added a warning message and automatically switch DMGOPT > 0 to DMGOPT = 0 on *MAT_FABRIC when RS < EFAIL or RS = EFAIL. This prevents a problem where weld assemblies did not fail at all when RS = 0.
- *MATs 9, 10, 11, 15, 88, and 224 are now available for thick shells, however only *MATs 15, 88, and 224 are available for the 2D tshell forms 1,2, and 6.
- Added thick shell support for the STOCHASTIC option of *MATs 10, 15, 24, 81, and 98.
- Added support for *MAT_096 for several solid element types including ELFORMs 3, 4, 15, 18, and 23.
- Added a MIDFAIL keyword option for *MAT_024, (MAT_PIECEWISE_LINEAR_PLASTICITY). With this option, element failure does not occur until the failure strain is reached in the mid plane layer. If an even number of layers is used, then the failure occurs when the 2 closest points reach the failure strain.
- Enabled *MATs 26 and 126 (HONEYCOMB) to be used with thick shell forms 3, 5, and 7. These was initialized incorrectly causing a zero stress.
- Enabled *MAD_ADD_EROSION to be used with beams that have user defined integration. Memory allocation was fixed to prevent memory errors.
- Enabled OPT = -1 on *MAT_SPOTWELD for solid elements.

- Enabled thick shells to use *MATs 103 and 104 in an implicit solution. These materials were lacking some data initialization so they would not converge.
- Enabled solid elements with user-defined orthotropic materials to work with the INTOUT and NODOUT options on *DATABASE_EXTENT_BINARY. The transformation matrix was stored in the wrong place causing strain and stress transformations to fail.
- Enabled *MAT_017 to run with thick shell forms 3 and 5. Neither element was initialized correctly to run materials with equations of state.
- Add degradation factors and strain rate dependent strength possibility for *MAT_054/*MAT_ENHANCED_COMPOSITE_DAMAGE solids.
- Fixed bug in *MAT_058/*MAT_LAMINATED_COMPOSITE_FABRIC when used with strain-rate dependent tables for stiffnesses EA, EB and GAB and LAMSHT = 3.
- Add strain rate dependency of ERODS in *MAT_058.
- Add possibility to use *DEFINE_FUNCTION for *MAT_SPOTWELD_DAMAGE_FAILURE (*MAT_100), OPT = -1/0. If FVAL = FunctionID, then a *DEFINE_FUNCTION expression is used to determine the weld failure criterion using the following arguments: func (N_rr, N_rs, N_rt, M_rr, M_ss, M_tt).
- Store tangential and normal separation (delta_II & delta_I) as history variables 1&2 of *MAT_138/*MAT_COHESIVE_MIXED_MODE.
- Add second normalized traction-separation load curve (TSLC2) for Mode II in *MAT_186/*MAT_COHESIVE_GENERAL.
- Fixed bug in using *MAT_157/*MAT_ANISOTROPIC_ELASTIC_PLASTIC with IHIS.gt.0 for shells. Thickness strain update d3 was not correct and plasticity algorithm failed due to typo.
- Fixed bug in *MAT_157 for solids: This affected the correct stress transformation for post-processing using CMPFLG = 1 in *DATABASE_EXTENT_BINARY.
- Fixed bug in *MAT_225 (*MAT_VISCOPLASTIC_MIXED_HARDENING) when using Table-Definition together with kinematic hardening.
- Add load curves for rate dependent strengths (XC, XT, YC, YT, SC) in *MAT_261/*MAT_LAMINATED_FRACTURE_DAIMLER_PINHO (shells only).
- Add table definition for LCSS for rate dependency in *MAT_261 (shells only).
- Add load curves for rate dependent strengths (XC, XCO, XT, XTO, YC, YT, SC) in *MAT_262/*MAT_LAMINATED_FRACTURE_DAIMLER_CAMANHO (shells only).
- Fixed bug when using *MAT_261 or *MAT_262 solids (ELFORM = 2).
- Add load curves for SIGY and ETAN for rate dependency of *MAT_262 (shells only)
- *MAT_021_OPTION

- Fixed a bug for defining different orientation angles through the thickness of TSHELL elements (formulations 2 and 3)
- Added new option CURING:
- Two additional cards are read to define parameters for curing kinetics. Formulation is based on Kamal's model and considers one ODE for the state of cure.
- State of cure does not affect the mechanical parameters of the material.
- CTE's for othotropic thermal expansione can be defined in a table with respect to state of cure and temperature.
- An orthotropic chemical shrinkage is accounted for.

◦ *MAT_REINFORCED_THERMOPLASTICS_OPTION (*MAT_249_OPTION):

- Fiber shear locking can be defined wrt to the fiber angle or shear angle.
- Output of fiber angle to history variables.
- Simplified input: Instead of always reading 8 lines, now the user only has to specify data for NFIB fibers.
- Added fiber elongation to history variables in *MAT_249 for posprocessing.
- New Option UDFIBER (based on a user defined material by BMW):
  - Transversely isotropic hyperelastic formulation for each fiber family (see Bonet&Burton,1998).
  - Anisotropic bending behavior based on modified transverse shear stiffnesses.
  - Best suited for dry NCF's.

◦ *MAT_GENERALIZED_PHASE_CHANGE (*MAT_254):

- New material that is a generalized version of *MAT_244 with application to a wider range of metals.
- Up to 24 different phases can be included.
- Between each of the phases, the phase transformation can be defined based on a list of generic transformation laws. For heating JMAK and Oddy are implemented. For cooling Koistinen-Marburger, JMAK and Kirkaldy can be chosen.
- Constant parameters for the transformations are given as 2d tables, parameters depending on temperature (rate) or phase concentration employ 3d tables.
- Plasticity model (temperature and strain rate dependent) similar to MAT_244.
- Transformation induced strains.
- TRIP algorithm included.
- Temperature dependent mixture rules.

- Parameter 'dTmax' that defines the maximum temperature increment within a cycle. If the temperature difference at a certain integration point is too high, local subcycling is performed.
- Implemented for explicit/implicit analysis and for 2d/3d solid elements.

◦ *MAT_ADHESIVE_CURING_VISCOELASTIC (*MAT_277):

- New material implementation including a temperature dependent curing process of epoxy resin based on the Kamal-Sourour-model.
- Material formulation is based on *MAT_GENERAL_VISCOELASTIC.
- Viscoelastic properties defined by the Prony series, coefficients as functions of state of cure.
- Chemical and thermal shrinkage considered (differential or secant formulations).
- Available for shell and solid elements.
- Can be used in combination with *MAT_ADD_COHESIVE.
- Implemented for explicit and implicit analysis.
- An incremental and a total stress calculation procedure available.

◦ Enable *MAT_ADD_EROSION to be safely used with material models that have more than 69 history variables, for now the new limit is 119.
◦ Use correct element ID for output of failed solid elements when GISSMO (*MAT_ADD_EROSION) is used with *CONTROL_DEBUG.
◦ Improve performance of GISSMO (*MAT_ADD_EROSION with IDAM = 1), especially when used with *MAT_024, no other failure criteria, shell elements, and DMGEXP = 1 or 2. Allows speed-up of 10 to 20 percent.
◦ Add new keyword *MAT_ADD_GENERALIZED_DAMAGE. It provides a very flexible approach to add non-isotropic (tensorial) damage to standard materials in a modular fashion. Solely works with shell elements at the moment.
◦ Correct the computation of effective strain for options ERODS < 0 in *MAT_058 (*MAT_LAMINATED_COMPOSITE_FABRIC) and EFS < 0 in *MAT_261 and *MAT_262 (*MAT_LAMINATED_FRACTURE_DAIMLER_...). The shear strain term was twice the size as it should have been.
◦ Adjust stiffness for time step calculation in *MAT_076 and subsequent models (*MAT_176, *MAT_276, ...) to prevent rarely observed instabilities.
◦ Add output of original and fitted curves to messag and separate file (curveplot_<MID>) for *MAT_103.
◦ In *MAT_104 (*MAT_DAMAGE_1), stress-strain curve LCSS can now be used directly with all FLAG options (-1,0,1,10,11), no fitting.
◦ Correct strain calculation for anisotropic damage in *MAT_104 (*MAT_DAMAGE_1) with FLAG = -1.
◦ Initialize stress triaxiality of *MAT_107 (*MAT_MODIFIED_JOHNSON_COOK) to zero instead of 1/3.

- Avoid negative damage in *MAT_107 (*MAT_MODIFIED_JOHNSON_-COOK) with FLAG2 = 0 for solid elements.
- Rectify the characteristic element length in *MAT_138 (*MAT_COHESIVE_-MIXED_MODE) for solids type 21 and 22 (cohesive pentas) and shell type 29 (cohesive shell) for "curve" options T < 0 and S < 0.
- Correct/improve material tangent for *MAT_181 with PR > 0 (foam option).
- Add possibility to define logarithmically defined strain rate table LCID-T in material *MAT_187 (*MAT_SAMP-1).
- Fix missing offset when using *DEFINE_TRANSFORMATION with load curve LCID-P in *MAT_187 (*MAT_SAMP-1).
- Add reasonable limit for biaxial strength in *MAT_187 with RBCFAC > 0.5 to avoid concave yield surface.
- Improve performance of *MAT_187 to reach speed-up of 10 to 40 percent, depending on which options are used.
- Add new option for *MAT_224 (*MAT_TABULATED_JOHNSON_COOK). With BETA < 0 not only a load curve but now also a table can be referred to. The table contains strain rate dependent curves, each for a different temperature.
- Fix for implicit version of *MAT_224 (*MAT_TABULATED_JOHNSON_-COOK). Computations with shell elements should converge faster now.
- *MAT_224 (*MAT_TABULATED_JOHNSON_COOK) can now be used in implicit even with temperature dependent Young's modulus (parameter E < 0).
- Always store the Lode parameter as history variable #10 in *MAT_224 (*MAT_TABULATED_JOHNSON_COOK), not just for LCF being a table.
- Variable LCI of *MAT_224 / *MAT_224_GYS can now refer to a *DEFINE_-TABLE_3D. That means the plastic failure strain can now be a function of Lode parameter (TABLE_3D), triaxiality (TABLE), and element size (CURVE).
- For thick shells type 1 and 2, the element size in *MAT_224 is now correct.
- Add new option for definition of parameters FG1 and FG2 in *MAT_240 (*MAT_COHESIVE_MIXED_MODE_ELASTOPLASTIC_RATE).
- Add new option to *MAT_240: new load curves LCGIC and LCGIIC define fracture energies GIC and GIIC as functions of cohesive element thickness. GIC_0, GIC_INF, GIIC_0, and GIIC_INF are ignored in that case.
- Add new feature to *MAT_248 (*MAT_PHS_BMW). Estimated Hocket-Sherby parameters are written to history variables based on input functions and phase fractions.
- Add new option ISLC = 2 to *MAT_248 (*MAT_PHS_BMW) which allows to define load curves (cooling rate dependent values) for QR2, QR3, QR4, and all parameters on Cards 10 and 11.
- Add new option LCSS to *MAT_252 (*MAT_TOUGHENED_ADHESIVE_-POLYMER): A load curve, table or 3d table can now be used to define rate and temperature dependent stress-strain behavior (yield curve).

- Fix for *MAT_255, evaluation of 2d tables LCIDC and LCDIT. Negative temperatures were interpreted as logarithmic rates.
- Add new material model *MAT_280 (*MAT_GLASS) for shell elements. It is a smeared fixed crack model with a selection of different brittle, stress-state dependent failure criteria and crack closure effects.
- *DEFINE_FABRIC_ASSEMBLIES: Assemblies of *MAT_FABRIC part sets can be specified to properly treat bending of t-intersecting fabrics that are stitched or sewn together. See ECOAT, TCOAT and SCOAT on *MAT_FABRIC_... Bending can only occur within an assembly, aka a part set.
- *MAT_USER_DEFINED_MATERIAL_MODELS: In user defined material models, a logical parameter 'reject' can be set to .true. to indicate to the implicit solver that equilibrium iterations should be aborted. The criterion is the choise of the implementor, but it could be if plastic strain increases by more than say 5% in one step or damage increases too much, whatever that might render an inaccurate prediction and bad results. Setting this parameter for explicit won't do anything.
- IHYPER = 3 for user shell materials now supports thickness train update, see *MAT_USER_DEFINED_MATERIAL_MODELS.
- *MAT_SIMPLIFIED_RUBBER/FOAM: AVGOPT < 0 is now supported for the FOAM option, which activates a time averaged strain rate scheme to avoid noisy response.
- MAT_181 is now supported for 2D implicit simulations.
- *MAT_ADD_EROSION:

  - A number of extensions and improvements to the DIEM damage model were made, IDAM < 0.
  - General efficiency, it was slow, now it's GOT to be faster.
  - NCS can be used as a plastic strain increment to only evaluate criteria in quantifications of plastic strain.
  - NUMFIP < 0 is employing the GISSMO approach, number of layers for erosion.
  - A new ductile damage criterion based on principal stress added (DMITYP = 4).
  - MSFLD and FLD can be evaluated in mid or outer layers to separate membrane and bending instability (P2).
  - MSFLD and FLD can use an incremental or direct update of instability parameter (P3).
  - Output of integration point failure information made optional (Q2).
  - Specifying DCTYP = -1 on the damage evolution card will not couple damage to stress but the damage variable is only calculated and stored.

- *MAT_SMOOTH_VISCOELASTIC_VISCOPLASTIC, *MAT_275: An elastic-plastic model with smooth transition between elastic and plastic mode is available. It incorporates viscoelasticity and viscoplasticity and is based on hyper-elastoplasticity so it is valid for arbitrarily large deformations and

rotations. A sophisticated parameter estimation is required to match test data, it is available for implicit and explicit analyisis but perhaps mostly suited for implicit.

- *MAT_FABRIC_MAP: Stress map material 34 is equipped with bending properties identical to that of the form 14 and form -14 version of the fabric. Coating properties are set in terms of stiffness, thickness and yield. The material is supported in implicit, including optional accounting for the non-symmetric tangent. Should be used with bending stiffness on, and convergence is improved dramatically if geometric stiffness is turned on.
- *MAT_084 with predefined units (CONM < 0) is now transformed correctly with INCLUDE_TRANSFORM.
- If LCIDTE = 0 in *MAT_121, then LS-DYNA was crashing on some platforms, including Windows. This is fixed.
- Fix initialization issues so that PML models can be run with *CASE commands.
- *MAT_027 is revised to avoid accuracy issues for single precision executables.
- The nearly imcompressible condition is enhanced for *MAT_027 shell elements.
- Add a new material model as a option for *MAT_165. *MAT_PLASTIC_NONLINEAR_KINEMATIC_B is a mixed hardening material model, and can be used for fatigue analysis.
- Output local z-stress in *MAT_037, when *LOAD_STRESS_SURFACE is used. This was previously calculated and saved as another history variable.
- Add a new material model *MAT_260 (2 forms).

    - Uses non-associated flow rule and Hill's yield surface; including strain rate effect and temperate effect. MIT failure criteria is also implemented.
    - Implemented for solids and shells.
    - Strain rate sensitivity for solids.
    - Option to directly input the Pij and Gij values.
    - Separate the material model *MAT_260 into *MAT_260A and *MAT_260B:
        - MAT260A=*MAT_STOUGHTON_NON_ASSOCIATED_FLOW
        - MAT260B=*MAT_MOHR_NON_ASSOCIATED_FLOW
    - Incorporates FLD into the fracture strain, so as to consider the mesh size effect.
    - Calculates the characteristic length of the element for *MAT_260B, so that an size-dependent failure criterial can be used.
    - When failure happens for half of the integration points through the thickness, the element is deleted.

- Add Formablitiy Index to *MAT_036, *MAT_037, *MAT_226.

- Add new history variables for Formability Index, affecting *MAT_036, *MAT_037, *MAT_125, *MAT_226. Those new history variables are FI, beta, effective strain. These comes after the 4 regular history variables.
- *MAT_036, *MAT_125: New option_NLP is added to evaluate formability under non-linear strain paths. User inputs a forming limit diagram (FLD), and Formablitiy Index (F.I.) will be automatically converted to effective stain vs. beta based space.

- **MPP**

  - Fix problem of MPP pre-decomposition that can occur if the local directory specified in the pfile has very different lengths in the initial run vs the actual run The difference resulted in a line count difference in the size of the structured files created, throwing off the reading of the file in the actual run.
  - Straighten out some silist/sidist issues in MPP decomp:

    - silist and sidist outside of a "region" in the pfile are no longer supported, and an error message is issued which suggests the use of "region { silist" instead.
    - They have been undocumented for several years (since "region" was introduced), and had other issues.

  - Fix the keywords, CONTROL_MPP_DECOMPOSITION_CONTACT_DISTRIBUTE and CONTROL_MPP_DECOMPOSITION_CONTACT_ISOLATE, which were not treating each contact interface individually (as the manual states), but collectively.
  - Fix for MPP decomp of part sets.
  - Fixed *CONTROL_MPP_PFILE (when used inside an include file) so that it honors ID offsets from *INCLUDE_TRANSFORM for parts, part sets, and contact ids referenced in "decomp { region {" specifications. Furthermore, such a region can contain a "local" designation, in which case the decomposition of that region will be done in the coordinate system local to the include file, not the global system. For example:
    *CONTROL_MPP_PFILE
    decomp { region {partset 12 local c2r 30 0 -30 0 1 0 1 0 0}}
    would apply the c2r transformation in the coordinate system of the include file, which wasn't previously possible. The local option can be useful even if there are no such transformations, as the "cubes" the decomposition uses will be oriented in the coordinate system of the include file, not the global system. Furthermore, the following decomposition related keywords now have a_LOCAL option, which has the same effect:

    - *CONTROL_MPP_DECOMPOSITION_PARTS_DISTRIBUTE_LOCAL

- *CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE_LOCAL
- *CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS_LOCAL
- *CONTROL_MPP_DECOMPOSITION_CONTACT_DISTRIBUTE_LOCAL
  (**Note:** LOCAL option is only valid when *INCLUDE_TRANSFORM with *DEFINE_TRANSFORMATION is used)

◦ Revert revision 86884, which was:

- "MPP: change to the decomposition behavior of *CONTROL_MPP_DECOMPOSITION_PARTS_DISTRIBUTE
  *CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE
  *CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS
  in the case where a decomposition transformation is also used. Previously, any such regions were distributed without the transformation being applied. This has been fixed so that any given transformation applies to these regions also. So now the transformations will NOT apply to these keywords. Really, the "region" syntax should be used together with *CONTROL_MPP_PFILE as it is more specific.

◦ Modify behavior of DECOMPOSITION_AUTOMATIC so that if the initial velocity used is subject to *INCLUDE_TRANSFORM, the transformed velocities are used.
◦ Fix MPP decomposition issue with "decomp { automatic }" which was not honored when in the pfile.
◦ Save hex weld creation orientation to the pre-decomposition file so that the subsequent run generates the welds in the same way.
◦ Fix for MPP not handling element deletion properly in some cases at decomposition boundaries.
◦ Add new pfile option "contact { keep_acnodes }" which does NOT exclude slave nodes of adaptive constraints from contact, which is the default behavior. (MPP only.)
◦ MPP Performance-Related Improvements:

- Allow user input of *LOAD_SEGMENT_FILE through familied files.
- Bug fix for *LOAD_SEGMENT_FILE to get correct time history data for pressure interpolation.
- Output two csv files for user to check MPP performance:
  - load_profile.csv: general load balance
  - cont_profile.csv: contact load balance
- Allow user to control decomp/distribution of multiple airbags using *CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS
- memory2 = option on *KEYWORD line

        - Disable unreferenced curves after decomposition using *CONTROL_MPP_DECOMPOSITION_DISABLE_UNREF_CURVES. This applies to the curves used in the following options to speed up the execution several times.
            - *BOUNDARY_PRESCRIBED_MOTION_NODE
            - *LOAD_NODE
            - *LOAD_SHELL_ELEMENT
            - *LOAD_THERMAL_VARIABLE_NODE

    - Bug fix for *CONTROL_MPP_DECOMPOSITION_SHOW with *AIRBAG_PARTICLE.
    - Fix cpu dependent results when using function RCFORC() in *DEFINE_CURVE_FUNCTION. This affects MPP only.
    - Fix hang up when using *DEFINE_CURVE_FUNCTION with element function BEAM(id,jflag,comp,rm) and running MPP with np > 1.
    - *CONTROL_MPP_DECOMPOSITION: The cpu cost for solid elements -1 and -2 are accounted for in the mpp domain decomposition.
    - Fix bug in *CONTROL_MPP_IO (Windows platform only) related to insufficient administrative privileges for writing tmp file on root drive.
    - Revise l2a utility on Windows platform to create identical node output format as Linux.

- **Output**

    - Fix for MPP external work when bndout is output and there are *BOUNDARY_PRESCRIBED_MOTION_RIGID commands in the input.
    - Fixed the output of forces and associated energy due to *LOAD_RIGID_BODY for both explicit and implicit (*DATABASE_BNDOUT).
    - Fixed stress and strain output of thick shells when the composite material flag is set on *DATABASE_EXTENT_BINARY. The transformation was backwards.
    - If the size of a single plot state was larger than the d3plot size defined by x=<factor> on the execution line, the d3plot database may not be readable by LS-PrePost. This issue is now fixed.
    - *DATABASE_PROFILE: Output data profiles for beams (TYPE = 5) and add density as DATA = 20.
    - New option HYDRO = 4 on *DATABASE_EXTENT_BINARY. Outputs 7 additional variables: the same 5 as HYDRO = 2 plus volumetric strain (defined as Relative Volume - 1.0) and hourglass energy per unit initial volume.
    - Fix for binout output of swforc file which can get the data vs. ids out of sync when some solid spotwelds fail.
    - Fix for d3plot output of very large data sets in single precision.
    - Fix for output of bndout data for joints in MPP, which was writing out incorrect data in some cases.

- Added new option *INTERFACE_SPRINGBACK_EXCLUDE to exclude selected portions from the generated dynain file.
- Add a new option to *INTERFACE_COMPONENT_FILE to output only 3 degrees of freedom to the file, even if the current model has 6.
- Minor change to how pressure is computed for triangles in the INTFOR output.
- Fix MPP output issue with intfor file.
- Fixes for writing and reading of dynain data in LSDA format.
- Corrected the summation of rigid body moments for output to bndout for some special cases in MPP.
- Corrected the output to d3iter when 10 node tets are present (D3ITCTL on *CONTROL_IMPLICIT_SOLUTION).
- Enhanced implicit collection of moments for the rcforc file.
- For implicit, convert spc constraint resultant forces to local coordinate system for output. Also corrected Implicit's gathering of resultant forces due to certain SPC constraints.
- Fixed the gathering of resultant forces in implicit for prescribed motion on nodes of a constrained rigid body for output to bndout.
- Added output of modal dynamics modal variables to a new file moddynout. Output is controlled by *CONTROL_IMPLICIT_MODAL_DYNAMICS.
- Corrected the output of resultant forces for Implicit Linear analysis. Corrected the output of resultant forces for MPP executions. These enhancements affect a number of ASCII files including bndout.
- The following 4 enhancements are to the eigensolvers, including that used for *CONTROL_IMPLICIT_EIGENVALUE.

    - Standardized and enhance the warning/error messages for Implicit eigensolution for the case where zero eigenmodes are computed and returned in eigout and d3eigv.
    - Added nonsymmetric terms to the stiffness matrix for the implicit rotational dynamics eigenanalysis. This allows brake squeal analysis with the contact nonsymmetric terms from mortar contact now included in the analysis.
    - Updated implicit eigensolution for problems with nonsymmetric stiffness matrices. Fixed Rotational Dynamics eigensolution to work correctly when first order matrix (W) is null. (See *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS).
    - Added the eigensolution for problems with stiffness (symmetric or nonsymmetric), mass, and damping.

- Improve Implicit's treatment of constrained joints to account for rounding errors. Applicable to *CONSTRAINED_JOINT with *CONTROL_IMPLICIT_GENERAL.
- For implicit springback, zero out the forces being reported to rcforc for those contact interfaces disabled at the time of springback. Also enhance the

removal of contact interfaces for springback computations. For *INTERFACE_SPRINGBACK.
- *DATABASE_RECOVER_NODE is available to recover nodal stress.
- Fix a bug for detailed stress output, eloutdet, for SOLID type 18.
- Support new format of interface force files for ALE, DEM, and CPM. LS-PrePost can display the correct label for each output component.
- Added *DATABASE_NCFORC_FILTER option to allow the NCFORC data to be filtered using either single pass or double pass Butterworth filtering to smooth the output. Added the same filtering capability to *DATABASE_BINARY_D3PLOT. This capability is specified on the additional card for the D3PLOT option and does not require "_FILTER" in the keyword input.
- Fix incorrect mass properties for solids in SSSTAT file when using *DATABASE_SSSTAT_MASS_PROPERTIES.
- Fix seg fault during writing of dynain file if INSTRN = 1 in *INTERFACE_SPRINGBACK and STRFLG ≠ 0 in *DATABASE_EXTENT_BINARY and the *DATABASE_EXTENT_BINARY comes after *INTERFACE_SPRINGBACK. Also output warning message, KEY+1104.
- Fix zero strain values output to curvout for *DEFINE_CURVE_FUNCTION using function, ELHIST, for solid elements.
- Fix missing parts in d3part when MSSCL = 1 or 2 in *DATABASE_EXTENT_BINARY.
- Fix incorrect damping energy computation for glstat.
- Fix incorrect part mass in d3plot for shells, beams & thick shells.
- Fix incorrect curvout values when using BEAM(id,jflag,comp,rm) for *DEFINE_CURVE_FUNCTION and if the beam formulation is type 3, i.e. truss.
- Fix incorrect output to curvout file if using ELHIST in *DEFINE_CURVE_FUNCTION for shells.
- Output stresses for all 4 intg points to eloutdet for cohesive element types 19 & 20.
- Fix incorrect rotational displacement to nodout when REF = 2 in *DATABASE_HISTORY_NODE_LOCAL. Affects MPP only.
- Fix incorrect strains output to elout for shell type 5 and when NIP > 1.
- Fix incorrect acceleration output to nodout file when IACCOP = 1 in *CONTROL_OUTPUT and IGRAV = 1 in *ELEMENT_SEATBELT_ACCELEROMETER.
- Fix corrupted d3plot when RESPLT = 1 in *DATABASE_EXTENT_BINARY and idrflg.ge.5 in *CONTROL_DYNAMIC_RELAXATION.
- Fix missing element connectivities in nastin file when using *INTERFACE_SPRINGBACK_NASTRAN_NOTHICKNESS.
- Fix seg fault when using *DATABASE_BINARY_D3PART with *CONTACT_TIED_SHELL_EDGE_TO_SURFACE. This affects SMP only.
- Fix incorrect output to bndout when using multiple *LOAD_NODE_POINT for the same node and running MPP with ncpu > 1.
- Fix incorrect dyna.inc file when using *MAT_FU_CHANG_FOAM/MAT_83, *DEFINE_COORDINATE_NODES, and *CON-

STRAINED_JOINT_STIFFNESS_GENERALIZED with *INCLUDE_-TRANSFORM.

- Fix IEVERP in *DATABASE_EXTENT_D3PART which was not honored in writing out d3part files.
- Fix incorrect stresses written out to dynain for thick shells with formulations 1,2 and 4.
- Fix incorrect output to disbout data for discrete beams.
- Fix incorrect output to binary format of disbout. Affects SMP only.
- Fix error when writing initial stresses for thick shells to dynain. Affects MPP only.
- Fix thick shells strain output to dynain.
- Fix incorrect writing of material data to dyna.str for *MAT_SEATBELT when using long = s.
- Fix coordinate/disp output to d3plot of *CONSTRAINED_NODAL_-RIGID_BODY's pnode.
- Fixed the initial d3plot state in SMP runs when tied contact is used with theCNTCO parameter on *CONTROL_SHELL. The geometry was wrong in that state.
- Add cross section forces output (*DATABASE_SECFORC) for cohesive elements ELFORM type 19, 20, 21, and 22.
- Slight increase of precision for values in nodout file.
- Add new option FSPLIT to *INTERFACE_SPRINGBACK_LSDYNA to split the dynain file into two files (geometry and initial values).
- *DEFINE_MATERIAL_HISTORIES: New keyword for organizing material history outputs, currently only for solids, shells and beams and the d3plot output but to be extended to tshells and ascii/binout. The purpose is to customize the history variables that otherwise are output via NEIPS/NEIPH/NEIPB on *DATABASE_EXTENT_BINARY, to avoid variable conflict and large d3plots and thus facilitate post-processing of these variables. Currently available in small scale but to be continuously extended.
- Fixed bug affecting IBINARY = 1 (32 bit ieee format) in *DATABASE_FORMAT. This option was not working.
- Fixed incorrect printout of node ID for *ELEMENT_INERTIA.
- Increased the header length to 80 for the following files in binout: matsum, nodout, spcforc, ncforc
- Fixed bug in which d3msg was not written for SMP.
- The d3plot output for rigid surface contact was incorrect for MPP.
- Fixed bugs when using curve LCDT to control d3plot output.
- Fixed abnormal increase in d3plot size caused by outputting velocity and acceleration when data compression is on.
- Added new variable GEOM in *CONTROL_OUTPUT for choosing geometry or displacement in d3plot, d3part, and d3drlf.

- Added command line option "msg=" to output warning/error descriptions. See MSGFLG in *CONTROL_OUTPUT for alternate method of requesting such output. Accepted values for "msg=" are message# or all.

  - message#, e.g., KEY+101 or 10101. This option will print the error/warning message to the screen.
  - all. this option will print all error/warning messages to d3msg file.

- Fixed bug for *DATABASE_BINARY_D3PROP file if adaptivity used. The error caused blank d3prop output.
- *DATABASE_HISTORY_SHELL_SET combined with *CONTROL_ADAPTIVITY caused error 20211. The error involves the BOX option being used for shell history output.
- Added *INTEGRATION... data to d3prop.

- **Restarts**

  - Fix bug when deleted uniform pressure (UP) airbag during simple restart.
  - Fix for index error that could cause problems for accelerometers during full deck restart in MPP.
  - Fix for MPP output of LSDA interface linking file when restarting from a dump file.
  - Fix incorrect strains in d3plot after restart when STRLG > 1.
  - Fix incorrect velocity initialization for SMP full deck restart when using
  - *INITIAL_VELOCITY_GENERATION and *INITIAL_VELOCITY_GENERATION_START_TIME.
  - Fix incorrect behavior of *CONTACT_ENTITY in full deck restart.
  - Fix incorrect full deck restart analysis if initial run was implicit and the full deck restart run is explicit.
  - Fix ineffective boundary condition for *MAT_RIGID when using *CHANGE_RIGID_BODY_CONSTRAINT with *RIGID_DEFORMABLE_R2D for small deck restart.
  - Fix initialization of velocities of *MAT_RIGID_DISCRETE nodes after restart using *CHANGE_VELOCITY_GENERATION.
  - Fix internal energy oscillation after full deck restart when using *CONTACT_TIED_SURFACE_TO_SURFACE_OFFSET with TIEDID = 1 in optional card D. This affects SMP only.
  - Corrected bug affecting full restart that included any change to node/element IDs. This bug has existed since version R6.
  - Fixed bug affecting d3plot times following fulldeck restart with curve in SMP.
  - Fixed bug in simple restart: *INTERFACE_COMPONENT_FILE forgets the filename and writes to infmak instead.

- ***SENSOR**
  - Enable full restart for *SENSOR.
  - Add optional filter ID to SENSORD of *DEFINE_CURVE_FUNCTION.
  - Enable LOCAL option of *CONSTRAINED_JOINT to be used with *SENSOR_DEFINE_FORCE.
  - Fix a MPP bug that happens when *SENSOR_DEFINE_NODE has a defined N2.
  - *SENSOR_CONTROL:
    - Fix a bug for TYPE = JOINTSTIF
    - Fix an MPP bug for TYPE = PRESC-MOT when the node subject to prescribed motion is part of a rigid body
    - Add TYPE = BELTSLIP to control the lockup of *ELEMENT_SEATBELT_SLIPRING.
    - Add TYPE = DISC-ELES to delete a set of discrete elements.
  - Add FTYPE = CONTACT2D to *SENSOR_DEFINE_FORCE to track the force from *CONTACT_2D.
  - Add the variable SETOPT for *SENSOR_DEFINE_NODE_SET and *SENSOR_DEFINE_ELEMENT_SET to sense and process data from a node set or element set, resp., resulting in a single reported value.
  - *SENSOR can be used to control *CONTACT_GUIDED_CABLE.
  - Fix a bug related to *SENSOR_DEFINE_FUNCTION triggered by more than 10 sensor definitions.
- **SPG (Smooth Particle Galerkin)**
  - *SECTION_SOLID_SPG (KERNEL = 1): The dilation parameters (DX, DY, DZ) of SPG Eulerian kernel are automatically adjusted according to the local material deformation to prevent tensile instability.
- **SPH (Smooth Particle Hydrodynamics)**
  - Retain user IDs of SPH particles in order to ensure consistent results when changing the order of include files.
  - Add feature to inject SPH particles, *DEFINE_SPH_INJECTION.
  - Added support of various material models for 2D and 3D SPH particles:
    - *MAT_098 (*MAT_SIMPLIFIED_JOHNSON_COOK)
    - *MAT_181 (*MAT_SIMPLIFIED_RUBBER)
    - *MAT_275 (*MAT_SMOOTH_VISCOELASTIC_VISCOPLASTIC)
  - Added support of *DEFINE_ADAPTIVE_SOLID_TO_SPH for 2D shell elements and 2D axisymmetric shell elements.

- When using *DEFINE_ADAPTIVE_SOLID_TO_SPH, eliminated duplicate kinetic energy calculation for SPH hybrid elements (both SPH particles and solid elements contributed kinetic energy into global kinetic energy).
- Added support of second order stress update (OSU = 1 in *CONTROL_ACCURACY keyword) for 2D and 3D SPH particles. This is necessary for simulation of spinning parts.
- Added ISYMP option in *CONTROL_SPH to define as a percentage of original SPH particles the amount of memory allocated for generation of SPH ghost nodes used in *BOUNDARY_SPH_SYMMETRY_PLANE.
- Fixed unsupported part and part set option in *BOUNDARY_SPH_FLOW.
- Fixed unsupported ICONT option from *CONTROL_SPH when combined with *BOUNDARY_SPH_FLOW.
- *DEFINE_SPH_TO_SPH_COUPLING: Output contact forces between two SPH parts (x, y, z and resultant forces) into sphout. The forces can be plotted by LS-PrePost.
- *CONTACT_2D_NODE_TO_SOLID: Added bucket sort searching algorithm to speed up the process of finding contact pairs between SPH particles and solid segments.

- **Thermal**

  - Corrected a long standing bug in MPP thermal associated with spotwelds (*CONSTRAINED_SPOTWELD) using thermal linear solver option 11 or greater. The spotweld loads were not being loaded correctly due to an indexing issue in MPP.
  - Fix for thermal with *CASE.
  - Fix MPP support for thermal friction in SOFT = 4 contact.
  - Fixed bug where thermal solver gives a non-zero residual even though no loads are present.
  - Added SOLVER = 17 (GMRES solver) to *CONTROL_THERMAL_SOLVER for the conjugate heat transfer problem. The GMRES solver has been developed as an alternative to the direct solvers in cases where the structural thermal problem is coupled with the fluid thermal problem in a monolithic approach using the ICFD solver. A significant savings of calculation time can be observed when the problem reaches 1M elements. This solver is implemented for both SMP and MPP.
  - *CONTACT_(option)_THERMAL (3D contact only): Add variable FTOSLV to specify fraction of frictional energy applied to slave surface. It follows that 1.-FTOSLV is applied to master surface. Default is 0.5 which gives a 50% - 50% split between the slave and master surfaces which was hardwired in prior releases.
  - First release of AUTOMATIC_SURFACE_TO_SURFACE_TIED_WELD_THERMAL. This will only work when used with BOUNDARY_THERMAL_WELD. This combination of keywords will activate a condition where sliding contact will become tied contact on cooldown when the temperature

of the segments in contact go above an input specified temperature limit during welding.

- *LOAD_THERMAL_D3PLOT: The d3plot data base was changed such that the 1st family member contains control words, geometry, and other control entities. Time state data begins in the 2nd family member. This change allows the new d3plot data structure to be read in by LS-DYNA when using the *LOAD_THERMAL_D3PLOT keyword. This change is not backward compatible. The old d3plot data structure will no longer be read correctly by LS-DYNA.
- Synchronize data in TPRINT for SMP and MPP:
  - Fixed output to tprint/binout for thermal contact.
  - Fixed part IDs for part energies.
  - Fixed format of TPRINT file generated by l2a.
- Fixed handling of start time defined with *CONTROL_START for thermal solver.
- Change the maximum number of *LOAD_HEAT_CONTROLLER definitions from 10 to 20.
- Added a third parameter to the TIED_WELD contact option. The parameter specifies heat transfer coefficient h_contweld for the welded contact. Before welding, the parameter from the standard card of the thermal contact is used.
- Parameter FRCENG supported for mortar contact to yield heat in coupled thermomechanical problems.

- **XFEM (eXtended Finite Element Method)**
  - Added ductile failure to XFEM using critical effective plastic strain as failure criterion.

- **Miscellaneous**
  - Support *SET_NODE_GENERAL PART with SPH and DES.
  - *DEFINE_POROUS_...: Compute the coefficients A and B with a user defined routine in dyn21.F.
  - Fixed bugs in Staged Construction (*DEFINE_STAGED_CONSTRUCTION_PART):
    - Staged construction not working on SMP parallel. Symptoms could include wrong elements being deleted.
    - Staged construction with beam elements of ELFORM = 2: when these beams are dormant, they could still control the time step.
    - Staged construction with *PART_COMPOSITE. The bug occurred when different material types were used for different layers within the same part, and that part becomes active during the analysis. The

symptom of the bug was that stresses and/or history variables were not set to zero when the part becomes active.

- Bugs fixed in *DAMPING_FREQUENCY_RANGE_DEFORM:
  - Incorrect results when large rigid body rotations occur.
  - If RYLEN on *CONTROL_ENERGY = 2, the energy associated with this damping should be included in the Internal Energy for the relevant part(s). This energy was being calculated only if there was also *DAMPING_PART_STIFFNESS in the model. Now fixed - the damping energy will be included in the internal energy whenever RYLEN = 2.
- Fixed NID option of *DEFINE_COORDINATE_VECTOR (bug occurred in MPP only).
- Fix lsda open mode to require only minimal permissions to avoid unnecessary errors, for example if using an interface linking file that is read only.
- Fix for DPART processing (*SET_..._GENERAL) for solid and thick shell elements.
- Fix for JOBID > 63 characters.
- Fix input processing problem (hang) that could happen in some unusual cases if encrypted *INCLUDE files are used.
- Fix interaction of *CASE with jobid = on command line, so the jobid on the command line is combined with the generated case ids instead of being ignored.
- *INCLUDE_NASTRAN:
  - Integration defaults to Lobatto for Nastran translator.
  - The default number of integration points is set to 5 for Nastran translator.
- Issue error message and terminate when illegal *DEFINE_TRANSFORMATION is specified.
- Add OPTION = POS6N to *DEFINE_TRANSFORMATION to define transformation with 3 reference nodes and 3 target nodes.
- Add OPTION = MIRROR to *DEFINE_TRANSFORMATION.
- Fix a bug that could occur when adapted elements are defined in a file included by *INCLUDE_TRANSFORM.
- Fix a bug that could occur when *BOUNDARY_SPC_SYMMETRIC_PLANE is used together with *INCLUDE_TRANSFORM.
- Fix a bug that occurs when *DEFINE_BOX is included by *INCLUDE_TRANSFORM.
- Make *SET_NODE_COLLECT work together with *NODE_SET_MERGE.
- Fix incorrect shell set generated when using *SET_SHELL_GENERAL with OPTION = PART.

- Add error trap for *SET_PART_LIST_GENERATE_COLLECT to catch missing part IDs.
- Fixed bug in *INCLUDE_TRANSFORM for adaptive case if JOBID is used.
- Fixed bug in memory allocation for *DEFINE_CURVE if total number of points in curve is more than 100.
- Fixed bug with *INCLUDE_TRANSFORM and *CONTROL_ADAPTIVITY due to an *INCLUDE inside *INCLUDE_TRANSFORM file. Added new files: adapt.inc# for *INCLUDE_TRANSFORM file. The *NODE, *ELEMENT_SHELL and *ELEMENT_SOLID are removed from include file.
- Fixed bug for DPART option in *SET_SEGMENT_GENERAL. DPART option was treated as PART option before.
- Fixed failure of *PARAMETER definition in long format.
- Fixed error in reading solid id for *SET_SOLID_GENERAL.
- Ignore any nonexistant part set IDs in *SET_PART_ADD.
- Fix bug in which sense switches sw2 and sw4 don't work when the output interval for glstat is small.
- Fixed bug if *DEFINE_CURVE is used to define adaptivity level.
- Three new keywords are implemented in support of user defined subroutines: *MODULE_PATH[_RELATIVE], MODULE_LOAD, MODULE_USE.

    - The MODULE feature allows users to compile user subroutines into dynamic libraries without linking to the LS-DYNA main executable.
    - The dynamic libraries are independent from the main executable and do not need to be recompiled or linked if the main executable is updated.
    - This feature loads multiple dynamic libraries on demand as specified in the keywords.
    - Without the MODULE feature, only one version of each umat (such as umat41) can be implemented. With the MODULE feature, most umat subroutines can be have multiple versions in multiple dynamic libraries, and used simultaneously.
    - The MODULE feature supports all user subroutines.
    - The LS-DYNA main executable may also run without any dynamic libraries if no user subroutines are required.

Capabilities added to create LS-DYNA R10:

See release notes (published separately) for further details.

- ***AIRBAG**

    - Enhance the robustness of *AIRBAG_INTERACTION to help avoid instability in MPP when the interaction involves more than two bags.
    - *AIRBAG_PARTICLE:

- Adjust dm_out calculation of vent hole to avoid truncation error.
- Fix bug in chamber output when there are multiple airbags and multiple chambers not in sequential order.
- Bug fix for closed volume of airbag/chamber with intersecting tubes.
- Add new feature to allow user to define local coordinates of jetting of particles through internal vents.
- Support *SENSOR_CONTROL for CPM airbag.
- CPM is not supported for dynamic relaxation. Disable CPM airbag feature during DR and reactivate airbag following DR.
- Allow solid parts in definition of internal part set. The solid volume will be excluded from the airbag volume.
- Allow additional internal part set for shells. The shell part should form a closed volume and its volume will be excluded from the airbag volume.

- ***ALE**
  - *LOAD_BLAST_SEGMENT: Automatically generate the ALE ambient elements attached to a segment or segment set.
  - *BOUNDARY_AMBIENT_EOS: implement *DEFINE_CURVE_FUNCTION for the internal energy and relative volume curves.
  - *CONTROL_ALE, *CONSTRAINED_LAGRANGE_IN_SOLID and *ALE_REFERENCE_SYSTEM: If NBKT < 0 in *CONTROL_ALE, call *DEFINE_CURVE to load a curve defining the number of cycles between bucket sorting in function of time. If NBKT > 0, the bucket sorting is activated if the mesh rotations and deformations are large.
  - *ALE_FSI_TO_LOAD_NODE: Implement a mapping of the FSI accelerations (penalty forces/masses) computed by *CONSTRAINED_LAGRANGE_IN_SOLID (ctype = 4) between different meshes.
  - DATABASE_FSI, *DATABASE_BINARY_FSIFOR and *DATABASE_BINARY_FSILNK: Add a parameter CID to output fsi forces in a local coordinate system.
  - Structured ALE (S-ALE) solver:
    - ALE models using rectilinear mesh can be directly converted to S-ALE models and run using S-ALE solver by assigning CPIDX = -1 in *ALE_STRUCTURED_MESH.
    - S-ALE progressive mesh generation via RATIO in *ALE_STRUCTURED_MESH_CONTROL_POINTS.
  - Recode ALE Donor Cell/Van Leer advection routines and restructure *CONSTRAINED_LAGRANGE_IN_SOLID communication algorithm. These give 30% improvement in run time.

- ***BOUNDARY**

- *BOUNDARY_PWP can now accept a *DEFINE_FUNCTION instead of a load curve. The input arguments are the same as for *LOAD_SEGMENT: (time, x, y, z, x0, y0, z0).
- Add option of "toffset" for *BOUNDARY_PRESCRIBED_ORIENTATION_-RIGID to offset the curves by the birth time.
- MPP now supports MCOL coupling, *BOUNDARY_MCOL.
- Fix bug of there being fully constrained motion of a rigid part when prescribing more than one translational dof with *BOUNDARY_PRESCRIBED_MOTION_RIGID while con2 = 7 in *MAT_RIGID, meaning all rotational dof are constrained.
- Instead of error terminating with warning message, STR+1371, when *BOUNDARY_PRESCRIBED_MOTION and *BOUNDARY_SPC is applied to same node and dof, issue warning message, KEY+1106, and release the conflicting SPC.
- Fix erroneous results if SET_BOX option is used for *BOUNDARY_PRESCRIBED_MOTION.
- Fix *BOUNDARY_PRESCRIBED_ACCELEROMETER_RIGID for MPP. It may error terminate or give wrong results if more than one of this keyword is used.
- Fix segmentation fault when using *BOUNDARY_PRESCRIBED_ORIENTATION with vad = 2, i.e. cubic spline interpolation.
- Added instruction *BOUNDARY_ACOUSTIC_IMPEDANCE for explicit calculations that applies an impedance boundary condition to the boundary of *MAT_ACOUSTIC element faces. This is a generalization of the non-reflecting boundary condition. Both *LOAD and *BOUNDARY_ACOUSTIC_IMPEDANCE may be used on the same faces, in which case the boundary acts like both and entrant and exit boundary.
- Fixed a problem with non-reflecting boundaries redefining the bulk modulus which caused contact to change behavior.
- Added support for acoustic materials with non-reflective boundaries.
- Fix the single precision version so that *INCLUDE_UNITCELL now has no problem to identify pairs of nodes in periodic boundaries.
- When using *INCLUDE_UNITCELL to generate Periodic Boundary Constraints (PBC) for an existing mesh, a new include file with PBCs is generated instead of changing the original mesh input file. For example, if users include a file named "mesh.k" through *INCLUDE_UNITCELL (INPT = 0), a new include file named "uc_mesh.k" is generated where all PBCs are defined automatically following the original model information in mesh.k.
- *INCLUDE_UNITCELL now supports long input format in defining the element IDs.
- Include SPC boundary conditions as part of H8TOH20 solid element conversion.
- Add a new option SET_LINE to *BOUNDARY_PRESCRIBED_MOTION: This option allows a node set to be generated including existing nodes and new nodes created from h-adaptive mesh refinement along the straight line

connecting two specified nodes to be included in prescribed boundary conditions.

- **BLAST**
  - *PARTICLE_BLAST and DES:
    - Consider eroding of shell and solid in particle_blast.
    - Support interface force file output for gas particle-structure coupling.
    - Bug fix for wet DES coupled with beam.
    - Support *SET_NODE_GENERAL PART with SPH or DES.
    - MPP now uses async communication for DES coupling to improve general performance.
    - Support for solid element when modeling irregular shaped charge with HECTYPE = 0/1 in *PARTICLE_BLAST.
    - Output adaptive generated DES and NODE to a keyword file.
  - Fix inadvertent detonation of HE part when there are more than one HE part and even though the HE part is not defined with *INITIAL_DETONATION.
  - Fixed explicit *BOUNDARY_USA_COUPLING to support *INITIAL_-STRESS and *INITIAL_STRAIN_ usage, typically from a dynain file.
  - Fixed explicit *BOUNDARY_USA_COUPLING to support *CONTROL_-DYNAMIC_RELAXATION IDRFLF = 5, so a static implicit calculation can be used to initialize/preload a model before conducting an explicit transient calculation. If inertia relief is used during the static phase, then it must be disabled with *CONTROL_IM-PLICIT_INERTIA_RELIEF for the explicit phase.
  - Support imperial unit system for *PARTICLE_BLAST. mass = lbf-s^2/in, length = inch, time = second, force = lbf, pressure = psi.
  - Add option to define detonation point using a node for *PARTICLE_BLAST.
  - Add interface force file output for *PARTICLE_BLAST with keyword *DA-TABASE_BINARY_PBMFOR and command line option "pbm=". This output of forces for gas-particle-structure coupling.
  - For *PARTICLE_BLAST, add built-in smoothing function for particle structure interaction.
  - For *PARTICLE_BLAST, when coupling with DEM, the DEM nodes that are inside HE domain are automatically deactivated.
  - Add support for solid elements when modeling irregular shaped charge with HECTYPE = 0/1 for *PARTICLE_BLAST. The original approach only supports shell elements and the initial coordinates of HE particle are at shell surface. The model had to relax several hundred time step to let particle fill in the interior space, which was not convenient. Using new approach, the initial positions of HE particles are randomly distributed inside the container by using solid element geometry. Both hex and Tet solids are supported.

- For particle blast method (PBM), consider reflecting plane as infinite.
- Change the name of keyword *DEFINE_PBLAST_GEOMETRY to *DEFINE_PBLAST_HEGEO.

- ***CESE (Compressible Fluid Solver)**

  - CESE time steps:

    - Modified the blast wave boundary condition treatment to make it more stable in blast wave calculations (with *LOAD_BLAST_ENHANCED).
    - The flow field calculation will be skipped if the structural time-step is much smaller than the fluid time step, until both time-steps reach the same order. This will save CPU time in some fluid/structure interaction (FSI) problem calculations.
    - In addition to depending upon the local CFL number, the fluid time step 'dt' calculation has been modified to also adjust dynamically to extreme flow conditions. This makes stiff flow problems more stable especially in 3D fluid problem calculations when the mesh quality is poor.

  - Moving mesh solvers:

    - Corrected several aspects of the implicit ball-vertex (BV) mesh motion solver for the following keywords:
      *ICFD_CONTROL_MESH_MOV
      *CESE_CONTROL_MESH_MOV.
    - The absolute tolerance argument is no longer used by the BV solver. As an example, the following is all that is needed for CESE moving mesh problems:

```
*CESE_CONTROL_MESH_MOV
 $    ialg   numiter    reltol
         1        500   1.0e-4
```

    - Also corrected the CESE moving mesh solvers for a special case involving a wedge element. Also, fixed the d3plot output of wedge element connectivities for the CESE moving mesh solvers.

  - CESE d3plot output:

    - Added real 2D CESE output, and this is confirmed to work with LSP-P4.3 and later versions. This also works for d3plot output with the 2D CESE axisymmetric solver.
    - For all immersed-boundary CESE solvers, corrected the plotting of the Schlieren number and the chemical species mass fractions.
    - The following new CESE input cards are related to surface d3plot output:
      *CESE_SURFACE_MECHSSID_D3PLOT

*CESE_SURFACE_MECHVARS_D3PLOT
In conjunction with the above, new FSI and conjugate heat transfer output on solid (volume) mesh outside boundaries is now supported.

- CESE immersed-boundary method (IBM) FSI solvers:
  - *CESE_FSI_EXCLUDE is a new keyword for use with the CESE immersed boundary method FSI solvers. With it, unnecessary structural parts that are not actively participating in the FSI in the CESE IBM-FSI solver can now be excluded from the CESE FSI calculation. This is also supported for the case when some of the mechanics parts involve element erosion.
- CESE chemistry solvers:
  - In R10, we also updated several things in the FSI solver with chemistry called FSIC. In chemical reacting flow, a delta time between iterations is extremely important for code stabilization and thus, to get reasonable results. To this end, we optimized such an iterative delta time, which is based on the CFL number. This optimization is based on the gradient of the local pressure, which we think will dominate control of the CFL number.
  - Next, the total number of species are increased up to 60 species in chemical reacting flow, so that the reduced Ethylene (24~53 species) and Methane (20~60 species) combustion are possible with this version.
  - We will update more practical examples about FSIC problems including precise experimental validations.
  - Note that we can provide some related examples upon user request.
  - Other corrections of note include the following:
    Brought in enthalpy-related corrections to the CESE chemistry solvers.
    Fixed the conjugate heat transfer boundary condition for the 2D and 3D CESE fixed mesh chemistry solvers.
    Corrected the initialization of fluid pressure for CESE IBM chemistry solvers.
    Enabled output of the timing information for the CESE chemistry solvers.
    Added restart capability to the CESE chemistry solvers.

- ***CHEMISTRY**
  - New inflator models of Pyrotechnic and Hybrid type are updated. It is important to note that these are basically 0-dimensional models via the following two main keywords,
    *CHEMISTRY CONTROL_INFLATOR
    *CHEMISTRY_INFLATOR_PROPERTIES

- By using the *CHEMISTRY CONTROL_INFLATOR keyword, the user can select the type of the solver, output mode, running time, delta t, and time interval for output of time history data.
  For example, if we have a keyword set up as,
  *CHEMISTRY CONTROL_INFLATOR,
  $ isolver ioutput runtime delt p_time
  1 0 0.1 1.0e-6 5.0e-4

  with "isolver set to 1", the user can simulate a conventional Pyrotechnic inflator mode, while with "isolver" set to 2 or 3, Hybrid inflator simulation is possible.
- In addition, to continue an airbag simulation via an ALE or CPM method, the user can save the corresponding input data file by using "ioutput" option. For more details about airbag simulations using a saved data file, refer to the keyword manual.
- Also, note that the updated version has two options for the Hybrid models:

  - isolver = 2 => Hybrid model for the cold flow
  - isolver = 3 => Hybrid model for the heated flow.

- In the *CHEMISTRY_INFLATOR_PROPERTIES keyword, there are several cards to set up the required properties of an inflator model. The first two cards are for the propellant properties involved in inflator combustion.
  For example,
  $card1: propellants
  $ comp_id p_dia p_height p_mass p_tmass
  10 0.003 0.0013 2.0e-5 5.425e-3
  $card2: control parameters
  $ t_flame pindex A0 trise rconst
  2473. 0.4 4.45e-5 0.0 0.037
  In the first card, the user can specify the total amount of propellant particles and their shape.
  Using the second card, the user can also specify the thermodynamics of the propellant and its burning rate.
  To support the options in card2, especially the second option, pindex, and the third, A0, we provide a standalone program upon request for the propellant equilibrium simulation.
  The remaining cards are for the combustion chamber, gas chamber, and airbag, respectively.

- ***CONTACT**

  - *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR_TIED_-WELD for modeling welding has been added. Surfaces are tied based on

meeting temperature and proximity criteria. Non-MORTAR version of this contact was introduced at R9.0.1.

- Fix issue setting contact thickness for rigid shells in ERODING contact.
- Add MPP support for *CONTACT_AUTOMATIC_GENERAL with adaptivity.
- Change "Interface Pressure" report in intfor file from abs (force/area) to -force/area, which gives the proper sign in case of a tied interface in tension.
- Rework input processing so that more than one *CONTACT_INTERIOR may be used, and there can be multiple part sets in each one.
- Minor change to how pressure is computed for triangles in the intfor database.
- Fix 2 bugs for contact involving high order shell elements:
  - When high order shell elements are generated by SHL4_TO_SHL8.
  - When using a large part ID like 100000001.
- Implement a split-pinball based contact option for neighbor elements in segment-based contact. Invoke this option by setting |SFNBR|>=1000. The new algorithm is more compatible with DEPTH = 45 so that there is no longer a need to split quads.
- The effect of shell reference system offsets on contact surface location is now properly considered when running MPP. The shell offset may be specified using NLOC in *SECTION_SHELL or in *PART_COMPOSITE, or by using the OFFSET option of *ELEMENT_SHELL. This effect on contact is only considered when CNTCO is set to 1 or 2 in *CONTROL_SHELL.
- Fix bug of zero forces in rcforc at time = 0.0 for *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE after dynamic relaxation when consistency is on in SMP.
- Fix input error when using many *RIGIDWALL_GEOMETRIC_... with _DISPLAY option.
- Fix input error when *CONTACT_ENTITY is attached to a beam part, PID.
- Fix error termination due to negative volume, SOL+509, even when *CONTACT_ERODING... is set. This affects MPP only.
- Check whether a slave/master node belongs to a shell before updating the nodal thickness when ISTUPD > 0.0 in *CONTROL_SHELL and SST/MST.ne.0.0 and in SSFT/SMFT = 0.0 card 3 of *CONTACT_..... For SMP only.
- Fix penetrating nodes when using *CONTACT_ERODING_-NODES_TO_-SURFACE with SOFT = 1 in *MAT_142/*MAT_
- Fix seg fault when using *CONTACT_AUTOMATIC_-SINGLE_SURFACE_TIED with consistency mode, .i.e. ncpu < 0, for SMP.
- Fix corrupted intfor when using parts/part sets in *CONTACT_AUTOMATIC_....This affects SMP only.
- Implement incremental update of normal option, invoked by TIEDID = 1, for *CONTACT_TIED_NODES_TO_SURFACE_CONSTRAINED_OFFSET for SMP.

- Fix unconstrained nodes when using *CONTACT_TIED_-SURFACE_TO_-SURFACE_CONSTRAINED_OFFSET resulting in warning message, SOL+540. This affects SMP only.
- Fix spurious repositioning of nodes when using *CONTACT_-SURFACE_-TO_SURFACE for SMP.
- Added support to segment-based contact for the SRNDE parameter on optional card E. This option allows round edge extensions that do not extend beyond shell edges and also square edges. The latter overlaps with the SHLEDG parameter on card D.
- Fixed a potential memory error that could occur during segment-based contact input.
- Fixed an error that could cause an MPP job to hang in phase 3. The error could occur when SOFT = 2 contact is used with the periodic intersection check and process 0 does not participate in the contact.
- Modified SOFT = 2 contact friction when used with *PART_CONTACT to define friction coefficients, and the two parts in contact have different coefficient values. With this change, the mu values used for contact will be the average of the values that are calculated for each part. Prior to this change, mu was calculated for only the part that is judged to be the master. This change makes the behavior more predictable and also makes it behave like the other contacts with SOFT = 0 and SOFT = 1.
- Added a warning message (STR+1392) for when trying to use the ORTHO_-FRICTION contact option with SOFT = 2 contact, because that option is not available. The contact type is switched to SOFT = 1.
- Fixed serious error in MPP *CONTACT_2D_AUTOMATIC_-SURFACE_-TO_SURFACE when used with node sets to define the contact surfaces. The master side was likely to trigger a spurious error about missing nodes that terminated the job.
- Switched segment based (SOFT = 2) non-eroding contact to prevent it from adding any new segments when brick element faces are exposed when other elements are deleted. There were two problems. The first is that the interface force file could not support NFAIL = 1 on *DATA-BASE_EXTENT_-INTFOR because the intfor file does not expect new segments to replace the old, so it just undeletes the old segments instead of adding the new. The second problem is that when non-eroding contact is used, we only have enough memory in fixed length arrays for the segments that exist at t = 0. When segments are deleted, I was using the space that they vacated to create new segments, but it was very likely that some segments could not be created when the number of open spaces was less than the number of new segments that are needed. In this case, some segments would not be created and there would be surfaces that could be penetrated with no resistance. This behavior is impossible to predict, so it seems better to prevent any new segments from being created unless eroding contact is used.
- Fixed rcforc output for MPP 2D automatic contact. The forces across processors were missed.

- Fixed a segment-based contact error in checking airbag segments. This affects only airbags that are defined by control volumes, that is defined by *AIRBAG. The symptom was a segmentation fault.
- Fixed SMP eroding segment based (SOFT = 2) contact which was not activating the negative volume checking of brick elements. The MPP contact and the other SMP contacts were doing this but not SMP SOFT = 2.
- Fixed support for CNTCO on *CONTROL_SHELL by segment based (SOFT = 2) contact. It was adjusting the contact surface only half of what it should have done.
- Fixed eroding segment-based contact when used with the CNTCO > 0 on *CONTROL_CONTACT. A segmentation fault was occurring.
- Modified MPP segment based (soft = 2) contact to use R8 buffers to pass nodal coordinates. This should reduce MPP scatter when decomposition changes.
- Added support for using a box to limit the contact segments to those initially in the box when using eroding segment-based contact. The box option has not been available for any eroding contact up until now. (SOFT = 2 and SBOXID, MBOXID on *CONTACT_ERODING_...).
- Fixed force transducers with MPP segment-based contact when segments are involved with multiple, 2-surface force transducers. The symptom was that some forces were missed for contact between segments on different partitions.
- Added support for *ELEMENT_SOURCE_SINK used with segment-based contact. With this update, inactive elements are no longer checked for contact.
- Fixed an MPP problem in segment-based contact that cased a divide by zero during the bucket sort. During an iteration of the bucket sort, all active segments were somehow in one plane which was far from the origin such that a dimension rounded to zero. The fix for this should affect only this rare case and have no effect on most models.
- Modified segment based (SOFT = 2) contact to make SMP and hybrid faster, particularly for larger numbers of processors.
- Fixed thermal MPP segment-based contact. The message passing of thermal energy due to friction was being skipped unless peak force data was written to the intfor file.
- Fixed likely memory errors in MPP problems with 2D automatic contact when friction is used.
- Support the VC parameter (coefficient for viscous friction) in the case of segment-based contact, which has previously been unsupported. This option will work best with FNLSCL > 0, DNLSCL = 0 on optional card D. The card D option causes the contact force to be proportional to the overlap area which causes even pressure distribution.
- Enabled segment-based contact (SMP and MPP) to work with type 24 (27-node) brick elements.

- Fixed MPP segment-based contact for implicit solutions. During a line search, some data was not restored correctly when the solver goes back to the last converged state. This caused possible memory errors.
- Fixed friction for MPP segment-based contact in the implicit solver. The sliding velocity was calculated incorrectly using the explicit time step rather than the implicit step.
- Fixed a bug in MPP *CONTACT_2D_AUTOMATIC..., where a flaw in code used during MPP initialization could cause segments to fail to detect penetration.
- Fixed the thick beam checking of *CONTACT_2D_AUTO-MATIC_SINGLE_SURFACE in the MPP version. There was a memory error that could occur if thick beams were in the model.
- New values for user friction element history (*USER_INTERFACE_FRICTION): material directions, relative velocity components and yield stress.
- Add new user-defined interface for tiebreak contact invoked by *CONTACT_-AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK_USER.
- MORTAR CONTACT
  - PENMAX and SLDTHK has taken over the meanings of SST and TKSLS in R9 and earlier, although in a different way. Now PENMAX corresponds to the maximum penetration depth for solid elements (if nonzero, otherwise it is a characteristic length). SLDTHK is used to offset the contact surface from the physical surface of the solid element, instead of playing with SST and TKSLS, which was rather awkward. This update also saves the pain of having to treat shells and solids in separate interfaces if these features are wanted. This changes the behavior in some inputs that did have SST turned on for solids, but a necessary measure to make the contact decent for future versions.
  - The characteristic length for solid elements has been revised to not result in too small sizes that would lead to high contact stiffnesses and less margin for maximum penetration.
  - SFS on CONTACT_..._MORTAR can be input as negative, then contact pressure is the -SFS load curve value vs penetration.
  - Smooth roundoffs of sharp edges in MORTAR contact has been extended to high order segments, meaning that edge contact is valid even in this case.
  - The MORTAR contact now honors the NLOC parameter for shells, see *SECTION_SHELL, adjusting the contact geometry accordingly. Note that CNTCO on *CONTROL_SHELL applies as if always active, meaning that if NLOC is on, then CNTCO will also be "on" for MORTAR contacts.
  - Output of contact gaps to the intfor file is now supported for MORTAR contact, see *DATABASE_EXTENT_INTFOR.

- Transducer contacts, *CONTACT_..._FORCE_TRANSDUCER, are supported for MORTAR contact in SMP and MPP. A disclaimer is that the slave and master sets in the transducer have to be defined through parts or part sets. Warnings are issued if this is violated.
- Option 2 is now supported for tiebreak MORTAR contact, *CONTACT_..._MORTAR_TIEBREAK, but only for small sliding. Options 4 and 7 are supported in the MORTAR tiebreak contact for any type of sliding.
- For explicit analysis, the bucket sort frequency for MORTAR contact is 100, but can be changed through parameter BSORT on the CONTACT_..._MORTAR card or NSBCS on CONTROL_CONTACT. Note that the MPP bucket sort parameter does not apply. This assumes to improve the efficiency of MORTAR explicit contact significantly compared to R9 and earlier versions.
- Dynamic friction is supported in MORTAR contact for explicit and implicit dynamic analysis. See FD and DC on *CONTACT_... card.
- Wear calculations are supported for the MORTAR contact. See CONTACT_ADD_WEAR.
- Triangular shell form 24 is supported with MORTAR forming contact and accounts for high order shape functions.
- Automatic MORTAR contact now supports contact with end faces of beam elements and not just the lateral surfaces.
- Mortar contact is available in 2D plane strain and axisymmetric simulations, but only for SMP implicit. See CONTACT_2D_...MORTAR.

◦ Wear computed from *CONTACT_ADD_WEAR can optionally be output to dynain on optional card of *INTERFACE_SPRINGBACK_LSDYNA. This will generate *INITIAL_CONTACT_WEAR cards for subsequent wear simulations, and LS-DYNA will apply this wear and modify geometry accordingly. Restrictions as described in the manual apply.

◦ Improve SOFT = 6 under *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE to allow users to define part ID and a node set is automatically generated.

- ***CONSTRAINED**

◦ Add frictional energy calculation for constraint-based rigid walls.

◦ *CONSTRAINED_BEAM_IN_SOLID:

- Works with r-adaptivity now.
- Can now constrain beams in tshells as well as solids.

◦ Fix a bug for *CONSTRAINED_LOCAL that might mistakenly constrain z-translation when RC = 0.

- The following options do not support MEMORY = auto properly. The MEMORY = auto option will be turned off in this section and report an error if additional memory allocation is needed.
  *CONSTRAINED_LINEAR_OPTION
  *CONSTRAINED_MULTIPLE_GLOBAL
- Switched translational joints with stiffness to use double precision storage for the displacement value so that the calculated forces are more accurate. This prevents round-off error that can become significant.
- Fixed *CONSTRAINED TIED_NODES_FAILURE when used with MPP single surface segment based contact. Non-physical contact between segments that share tied constraints was being penalized leading to failure of the constraints.
- The SPR models (*CONSTRAINED_SPR2, *CONSTRAINED_INTER-POLATION_SPOTWELD) now support the SPOTDEL option of *CONTROL_-CONTACT. That means if shell elements involved in the SPR domain fail, the SPR gets deactivated.

- ***CONTROL**

  - Fix possible error termination with single precision MPP when PSFAIL.ne.0 in *CONTROL_SOLID and using solid formulation 10/13/44.
  - Fix spurious deletion of elements when using TSMIN.ne.0.0 in *CONTROL_TERMINATION, erode = 1 in *CONTROL_TIMESTEP and initialized implicitly in dynamic relaxation.
  - Added keyword *CONTROL_ACOUSTIC to calculate the nodal motions of *MAT_ACOUSTIC nodes for use in d3plot and time history files. Without this option the *MAT_ACOUSTIC mesh propagates pressure but does not deform because it uses a linear Eulerian solution method. The structural response is unaffected by this calculation; it is only for visualization and will roughly double the time spent computing acoustic element response.
  - When IACC = 1 on *CONTROL_ACCURACY and for shell type 16/-16 in nonlinear implicit, shell thickness change due to membrane strain when ISTUPD > 0 in *CONTROL_SHELL is now included in the solution process and will render continuity in forces between implicit time steps. The output contact forces will reflect the equilibrated state rather than the state prior or after the thickness update.
  - Fix bug when RBSMS in *CONTROL_RIGID, affecting mass scaled solutions, is used in conjunction with *ELEMENT_INERTIA and/or *PART_INERTIA, specifically with choices of IFLAG on *CONSTRAINED_RIGID_-BODIES and *CONSTRAINED_EXTRA_-NODES.
  - Tshells added to the subcycling scheme (*CONTROL_SUBCYCLE).
  - Tshells and spotweld beams are supported in selective mass scaling. See IMSCL in *CONTROL_TIMESTEP.
  - Add a new keyword: *CONTROL_FORMING_SHELL_TO_TSHELL to convert shell elements to tshell elements.

- If a parent node has SPCs, the same SPC constraints will be applied to the corresponding tshell nodes.
- If adaptivity is invoked, *BOUNDARY_SPC_SET is automatically updated to include newly generated nodes.
- Allows the normal of the segment set to be changed.
- Can offset the generated tshells from the mid-surface of the parent shells.
- Automatically generate segment sets for the top and bottom surfaces, which can be used for contact.

- **DISCRETE ELEMENT METHOD**

  - Implement generalized law of erosion for *DEFINE_DE_TO_SURFACE_COUPLING based on the following article in the journal "Wear": Magnee, A., Generalized law of erosion: application to various alloys and intermetallics, Wear, Vol. 181, 500, 1995.
  - Modify tangential force calculation to get better rigid body rotation behavior for *DEFINE_DE_BOND
  - Support restart feature for DEM interface force file and DATABASE output.
  - Instead of using bulk modulus, use mass and time step to estimate contact stiffness for SPH-DEM coupling. This should be better if DEM material is quite different from SPH material.
  - Fix *DEFINE_DE_MASSFLOW_PLANE bug if DE injection is defined.
  - Add CID_RCF to *DEFINE_DE_TO_SURFACE_COUPLING for force output in local coordinates to 'demrcf' file.
  - Update the *DEFINE_DE_BY_PART card so that it matches the capabilities of the *CONTROL_DISCRETE_ELEMENT card.
  - Add penalty stiffness scale factor, thickness scale factor, birth time and death time to *DEFINE_DE_TO_SURFACE_COUPLING.
  - Add dynamic coefficient of friction to *CONTROL_DISCRETE_ELEMENT.
  - Implement Finnie's wear law and user defined wear model to *DEFINE_DE_TO_SURFACE_COUPLING.
  - Implement user-defined curve for DEM frictional coefficient as function of time.
  - Implement user-defined curve for contact force calculation for *CONTROL_DISCRETE_ELEMENT.
  - Fix inconsistent results between *DEFINE_DE_BY_PART and *CONTROL_DISCRETE_ELEMENT.

- ***ELEMENT**

  - Fixed bug affecting output from beam elements ELFORM = 2 when certain uncommon inputs are present. Forces and moments in the output files could be wrongly rotated about the beam axis. This affected the output files only, not the solution inside LS-DYNA. The error could occur under two

circumstances: (a) if IST on *SECTION_BEAM is non-zero, the output forces and moments are supposed to be rotated into the beam's principal axis system, but this rotation could be applied to the wrong beam elements; and (b) when no ELFORM = 2 elements have IST, but the model also contains beams with ELFORM = 6 and RRCON = 1 on the SECTION_BEAM card, some of the ELFORM = 2 elements can have their output forces and moments rotated by 1 radian.

- Fix a bug affecting 2d seatbelt with time-dependent slipring friction.
- Fix erroneous 1d seatbelt slipring message.
- Fix seatbelt consistency issue in SMP (ncpu < 0).
- Add error message when 2d seatbelt part doesn't have shell formulation of 5 and *MAT_SEATBELT.
- Fix a bug for 2d seatbelt that could occur when a model has both 1d and 2d belts, and a 1d pretensioner of type 2, 3 or 9.
- Fix an MPP seatbelt bug that could occur when using a type 9 pretensioner.
- Allows shell formulation 9 to be used for 2d seatbelt. It was reset to formulation 5 by LS-DYNA, no matter what formulation was input. Now, only formulation 5 and 9 are accepted as input. Other formulations will incur error message.
- MPP now supports *ELEMENT_MASS_MATRIX_NODE_(SET).
- Added cohesive shell formulation -29. This formulation uses a cohesive midlayer where local direction q1 coincides with the average of the surrounding shell normals. This formulation is better suited for simulating normal shear.
- Cohesive shell formulation +/-29: Fixed absence of part mass in d3hsp.
- Make *TERMINATION_DELETED_SOLIDS work with hex spot weld failures.
- Fix incorrect load curve used if large value is used for FC < 0 and/or FCS < 0 in *ELEMENT_SEATBELT_SLIPRING.
- Fix incorrect velocity on accelerometer if

  - velocity is prescribed on the rigid body that the accelerometer is attached to, and
  - INTOPT = 1 in *ELEMENT_SEATBELT_ACCELEROMETER, and
  - *INITIAL_VELOCITY_GENERATION_START_TIME is used.

- Fix incorrect discrete spring behavior when used with adaptivity.
- Fix input error when using *DEFINE_ELEMENT_DEATH with BOXID > 0 for MPP.
- Modify tolerances on error messages SOL+865 and SOL+866 to prevent unnecessary error terminations when translational or rotational mass of a discrete beam was close to zero.
- Made the solid element negative volume warning SOL+630 for penta formulatgion 15 consistent with the volume calculation in the element. With this change, elements are deleted rather than the job terminating with error SOL+509.

- Fixed the default hourglass control for shell form 16. It was defaulting to type 5 hourglass control rather than 8.
- Fixed default hourglass control when the *HOURGLASS control card is used but no HG type is specified. We were setting to type 1 instead of 2. Also, fixed the default HG types to match the user's manual for implicit and explicit.
- Fixed the fully integrated membrane element (shell ELFORM = 9) when used with NFAIL4 = 1 on *CONTROL_SHELL and there are triangular elements in the mesh. Triangular elements were being deleted by the distorted element check.
- Fixed a divide by zero error that occurred with *SECTION_BEAM, ELFORM = 6, SCOOR = 12 or -12, and node 3 was omitted on *ELEMENT_BEAM, and nodes 1 and 2 are along the global y-direction or z-direction.
- Fixed laminated shell theory for type 6 and 7 shell elements when made active by LAMSHT = 3 or 5 on *CONTROL_SHELL.
- Added an int.pt. variable for *PART_COMPOSITE_LONG and *PART_COMPOSITE_TSHELL_LONG called SHRFAC which is a scale factor for the out-of-plane shear stress that allows the user to choose the stress distribution through thickness. This was motivated by test data that shows that for large differences is layer shear stiffness, the parabolic assumption is poor.
- Fixed implicit hourglass stiffness in viscoelastic materials when used with tshell forms 5 or 6. The stiffness was much too small.
- Modified tshell type 5 to use the tangent stiffness for calculating the Poisson's affects and hourglass control for *MAT_024. This makes the behavior softer during buckling which is much more realistic.
- Fixed a significant bug in segment based contact when SHLEDG = 1 and SBOPT = 3 or 5 and DEPTH < 45, and shell segments in contact have different thicknesses. A penetration check was using incorrect thicknesses causing contact to be detected too late, particularly for edge to surface contact.
- Improved the time step calculation for triangular tshell elements. The time step was too conservative for elements with significant thickness. This fix does not affect tshell type 7.
- Fixed all tshells to work with anisotropic thermal strains which can be defined by *MAT_ADD_THERMAL. Also, this now works by layer for layered composites.
- Enabled tshell form 5 to recalculate shear stiffness scale factors when plasticity material models 3, 18, 24, 123, or 165 are included in a composite section. Prior to this change the scale factors were based on elastic properties so after yielding, the stress distribution was not what was expected. This new capability supports the constant stress option, the parabolic option, and the SHRFAC option on *PART_COMPOSITE_TSHELL_LONG.
- Improved tshell 5 when used with mixed materials in the layers. A failure to use the correct Poisson's ratio was causing a less accurate stress tensor.

- Modified the time step calculation for tshell forms 3 and 5. A dependence on volumetric strain rate was removed in order to prevent oscillations in the time step which caused stability problems, particularly for tshell 5.
- Fixed tshell constant shear stress option (TSHEAR = 1 on *SECTION_TSELL or *PART_COMPOSITE). It was producing a not very constant stress distribution.
- Fixed stress and strain output of tshells when the composite material flag CMPFLG is set on *DATABASE_EXTENT_BINARY. The transformation was backwards.
- Fixed mass of parts reported to d3hsp when *ELEMENT_SHELL_SOURCE_SINK is used. The mass of inactive elements was being included.
- Enabled *MAT_026 and *MAT_126 (HONEYCOMB) to be used with tshell forms 3, 5, and 7. It was initialized incorrectly causing a zero stress.
- Added a missing internal energy calculation for tshell form 6.
- Enabled tshell forms 1, 2, and 6 to work with material types 54, 55, and 56.
- Modified the z-strain distribution in tshell forms 5 and 6 when used in composites with mixed materials that are isotropic. The existing assumed strain scheme was doing a poor job of creating a constant z-stress through the thickness.
- Increased the explicit solution time step for thin shell composite elements. The existing method calculated a sound speed using the stiffness from the stiffest layer and dividing it by the average density of all layers. This could be overly conservative for composites with soft layers of low density. The new method uses the average stiffness divided by average density. This is still conservative, but less so.
- Corrected rotational inertia of thin shells when layers have mixed density and the outer layers are denser than inner layers. The fix will mostly affect elements that are very thick relative to edge length.
- Added support for *ELEMENT_SHELL_SOURCE_SINK to type 2 shells with BWC = 1 on *CONTROL_SHELL.
- Prevent inactive shell elements (from *ELEMENT_SHELL_SOURCE_SINK) from controlling the solution time step.
- Fixed *LOAD_STEADY_STATE_ROLLING when used with shell form 2 and Belytschko- Wong-Chang warping stiffness (BWC = 1 *CONTROL_SHELL). The load was not being applied.
- Improved the brick element volume calculation that is used by the option erode elements (ERODE = 1 on *CONTROL_TIMESTEP or PSFAIL.ne.0 on *CONTROL_SOLID). It was not consistent with the element calculation which caused an error termination.
- Fixed all tshell forms to work with anisotropic thermal strains which can be defined by *MAT_ADD_THERMAL. Also, this now works by layer for layered composites.
- Reworked shell output so that we can correctly output stress in triangular shells when triangle sorting is active, that is when ESORT = 1 or 2 on *CONTROL_SHELL.

- *ELEMENT_T/SHELL_COMPOSITE(_LONG) and *PART_COMPOSITE_-T/SHELL_(LONG): Permit the definition of zero thickness layers in the stacking sequence. This allows the number of integration points to remain constant even as the number of physical plies varies and eases post-processing since a particular integration point corresponds to a physical ply. Such a capability is important when plies are not continuous across a composite structure.
  To represent a missing ply, set THK to 0.0 for the corresponding integration point and additionally, either set MID = -1 or set PLYID to any nonzero value. Obviously, the PLYID option applies only to the keywords containing LONG.
- Implemented sum factorization for 27-node quadratic solid that may increase speed by a factor of 2 or 3.
- Support second order solid elements (formulations 23,24,25,26) for *SET_-NODE_GENERAL.
- Invoke consistent mass matrix of 27-node hex element for implicit dynamics and eigenvalues.
- Reorder node numbering when assembling global stiffness matrix for 27-node hex. This fixes a bug in which it was reported than the implicit 27-node element didn't work
- Automatically transfer nodal boundary conditions for newly generated nodes if H8TOH27 option is used in *ELEMENT_SOLID.
- Modify initialization of material directions for solid elements. If there are only zeros for all the 6 values in *INITIAL_STRESS_SOLID, then the values from the other input (e.g. *ELEMENT_SOLID_ORTHO) are kept.
- Enable *PART_STACKED_ELEMENTS to pile up shell element layers. Before, it was necessary that solid element layers were placed between shell element layers. Now, shell element layers can follow each other directly. Contact definitions have to be done separately.
- Allow *PART_STACKED_ELEMENTS to be used in adaptive refinement simulations.
- Add alternative mass calculation for critical time step estimate of cohesive elements. This hopefully resolves rarely occurring instability issues. Option ICOH on *CONTROL_SOLID is used for that.
- Correct the strain calculation for tet formulation 13. This did not affect the stress response, only output of strains. Nodal averaging was not accounted for.
- User defined elements (ELFORM = 101 to 105 on *SECTION_-SHELL/SOLID) can now be used together with *MAT_ADD_EROSION.
- Add option to define a pull-out force vs. time curve in *ELEMENT_BEAM_-SOURCE by defining a negative variable FPULL. |FPULL| can refer to *DEFINE_CURVE or *DEFINE_CURVE_FUNCTION.
- Solid tet form 13 supported for all materials in implicit, including a presumable consistency improvement for the future.

- The Hughes-Liu beam is supported in *INTEGRATION_BEAM such each integration point may refer to a different part ID and thus have a different coef. Of thermal expansion. See *MAT_ADD_THERMAL_EXPANSION.
- Shell types 2 and 16 that combines thermal expansion and thick thermal shells, see *MAT_ADD_THERMAL_EXPANSION and TSHELL on *CONTROL_SHELL, now correctly treat temperature gradient through the thickness to create bending moments. All shell types are to be supported in due time.
- *SECTION_BEAM_AISC now provides predefined length conversion factors for specific unit systems.
- 3D tet r-adaptivity now supports *DEFINE_BOX_ADAPTIVE.
  - For every adaptive part, users can define multiple boxes where different BRMIN & BRMAX (corresponding to RMIN & RMAX in *CONTROL_REMESHING) can be specified for 3D tet remesher to adjust the mesh size.
  - Current implementation does not support LOCAL option.
- Fix bug in 3D adaptivity so that users can now have both non-adaptive tshell parts and 3D adaptive parts in one analysis.
- Fix the bug in 3D adaptivity so that users can now have both dummy nodes and 3D adaptive parts in one analysis.

- ***EM (Electromagnetic Solver)**
  - Randles Circuits for Battery Modeling
    - A Randles circuit is an equivalent electrical circuit that consists of an active electrolyte resistance r0 in series with the parallel combination of the capacitance c10 and an impedance r10. The idea of the distributed Randles model is to use a certain number of Randles circuits between corresponding nodes on the two current collectors of a battery unit cell. These Randles circuits model the electrochemistry that happens in the electrodes and separator between the current collectors. The EM solver can then solve for the EM fields in the current collectors, and the connections between them.
    - Added analysis of distributed Randles circuits to MPP.
    - Added d3plot output for distributed Randles circuits:
      D3PL_RAND_r0_EM,
      D3PL_RAND_r10_EM,
      D3PL_RAND_c10_EM,
      D3PL_RAND_soc_EM,
      D3PL_RAND_i_EM,
      D3PL_RAND_u_EM,
      D3PL_RAND_v_EM,

D3PL_RAND_vc_EM,
D3PL_RAND_temperature_EM,
D3PL_RAND_P_JHR_EM,
D3PL_RAND_P_dudt_EM,
D3PL_RAND_i_vector_EM

This output can be visualized in LS-PrePost versions 4.3 and 4.5 on the separator part of the battery cell using Post/FriComp/Extend/EM node.

- Added tshells for EM analysis for use in battery modeling.
- Added new capability for modeling Randles short, based on *DEFINE_FUNCTION so that the user has a lot of freedom to define where and when the short happens as well as the short resistance.
- Added a new capability for battery exothermal reactions also based on *DEFINE_FUNCTION. The new keyword *RANDLE_EXOTHERMAL_REACTION makes it possible to complement the heating of a short circuit created by a short by exothermal reactions if, for example, the temperature becomes higher than a threshold value.

- **FORMING ANALYSIS**

  - Extend *INCLUDE_AUTO_OFFSET to solid and beam elements (draw beads).
  - Add a new keyword for springback compensation: *INTER-FACE_COMPENSATION_NEW_REFINE_RIGID to refine and break rigid tool mesh along the user supplied trim curves so compensated tool mesh follows exactly the blank mesh (file "disp.tmp"). This needs to be done only once in the beginning of the springback compensation (ITER0).
  - *CONTROL_FORMING_ONESTEP:

    - Change the default element formulation option for onestep method to QUAD2.
    - Add a new option QUAD to allow quadrilateral elements to be considered.
    - Limit the maximum thickening by using a new variable TSCLMAX for the sheet blank.
    - Set the value of OPTION to a negative value to output the file 'onestepresult' in large format (E20.0).
    - Calculate and add the damage factor and output to the 6th history variable in the output file "onestepresult". Add the variable for a curve ID to define the fracture strain vs. triaxility. Add another variable DMGEXP (damage parameter), as used in GISSMO model.
    - Keep the original coordinates for the onestep output "onestepresults".

  - Add a new option VECTOR to *CONTROL_FORMING_BESTFIT to output deviation vector (in the format of: NODEID, xdelta, ydelta, zdelta) for each

node to its closest target element. The deviation vectors are output under the keyword *NODE_TO_TARGET_VECTOR.

- *CONTROL_FORMING_OUTPUT:
  - Output will skip any negative abscissa (Y1) value.
  - When CIDT < 0, the positive value defines the time dependent load curve.
- Add a warning in springback compensation *INTERFACE_SPRING-BACK_-COMPENSATION to identify which input file (typically the blank with adaptive mesh not output directly by LS-DYNA) has the wrong adaptive constraints.
- *INTERFACE_COMPENSATION_3D: turn off the output of nikin file.
- *ELEMENT_LANCING:
  - Allow some unused lancing curves to be included in the input.
  - When the gap between the two ends of a lancing curve is not zero, but small enough, then this curve is automatically closed.
  - Allow several parts to be cut during lancing; the parts can be grouped in *SET_PART_LIST, and defined using a negative value IDPT.
  - Specify the distance to bottom dead center as AT and ENDT when the new variable CIVD is defined.
  - Set IREFINE = 1 (default) in lancing, to refine blank mesh automatically along the lancing curves.
  - Re-set the adaptive level to be 1 to prevent those elements along the lancing route to be further refined.
  - When IREFINE = 1, elements along the lancing curve will be refined to make sure that no adapted nodes exist in the neighborhood. This helps get improved lancing boundary.
  - Change of tolerance for lancing to merge the small elements into bigger ones.
- Add a new keyword to perform trimming after lancing (shell elements only): *DEFINE_LANCE_SEED_POINT_COORDINATES. Maximum of two seed nodes can be defined.
- Extend *CONTROL_FORMING_TOLERANC to *MAT_036, *MAT_037, *MAT_125, and *MAT_226. When beta is less than -0.5, there is no necking and no calculation of FI. When beta is greater than 1.0, beta = 1.0/beta. This keyword adds a smoothing method to calculate the strain ratios for a better formability index.
- Sandwiched parts (*CONTROL_ADAPTIVE, *DEFINE_CURVE_TRIM):
  - Disable *CONTROL_ADAPTIVE_CURVEs for sandwich parts, since refinement along the curve is automatically done during trimming.

        - Refine the elements along the trimming curve to make sure no slave nodes are be cut by trimming curves.
        - Allow mesh adaptivity.
        - Allow multi-layers of solids.
        - Add a check to the variable IFSAND in *CONTROL_ADAPTIVE for sandwich part to be refined to exclude solid elements.

    - Solid element trimming (*DEFINE_CURVE_TRIM):

        - Refine those elements along the trimming curve.
        - Improve solid trimmig to allow the trimming of one panel into two panels with two seed nodes.

    - Add a new keyword *CONTROL_FORMING_REMOVE_ADAPTIVE_-CONSTRAINTS to remove adaptive constraints on a formed, adapted blank, and replaced them with triangular elements.
    - *DEFINE_CURVE_TRIM_NEW: Allow trimming of tshells.
    - Add a new keyword: *INTERFACE_WELDLINE_DEVELOPMENT to obtain initial weld line from the final part and the final weld line position.

        - When Ioption = -1, convert weld line from its initial position to the final part.
        - Output the element nodes that intersect the weld line in the final part, and the output file is: affectednd_f.ibo
        - Output the element nodes that intersect the weld line in the initial part, and the output file is: affectednd_i.ibo

    - Add a new variable DT0 to *CONTROL_IMPLICIT_FORMING so there is no need to use *CONTROL_IMPLICIT_GENERAL to specify DT0.
    - *INTERFACE_BLANKSIZE:

        - Add a new feature DEVELOPMENT option. When ORIENT = 2, then a reference mesh file for the formed part should be included. The calculated and compensated boundary will be based on the reference mesh.
        - Add a new option SCALE_FACTOR that allows the target curve to be moved. This is useful when multiple target curves (e.g. holes) and formed curves are far away from each other.

- ***FREQUENCY_DOMAIN**

    - Added new keyword *CONTROL_FREQUENCY_DOMAIN to define global control parameters for frequency domain analysis. Currently two parameters are defined:

- REFGEO: flag for reference geometry in acoustic eigenvalue analysis (either the original geometry at t = 0, or the deformed geometry at the end of transient analysis).
- MPN: large mass added per node, to be used in large mass method for enforced motion.

◦ *FREQUENCY_DOMAIN_ACOUSTIC_BEM:

- Enabled using incident wave (*FREQUENCY_DOMAIN_ACOUSTIC_INCIDENT_WAVE) in Rayleigh method (METHOD = 0).
- Enabled acoustic pressure fringe plot (*FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT) in Rayleigh method (METHOD = 0).
- Fixed bug in running acoustic analysis with multiple boundary conditions in MPP.
- Fixed running MATV (Modal Acoustic Transfer Vector) approach in MPP (*FREQUENCY_DOMAIN_ACOUSTIC_BEM_MATV).
- Added treatment for triangular elements used in Rayleigh method (METHOD = 0).
- Added output of acoustic intensity to binary database D3ACS (defined by *DATABASE_FREQUENCY_BINARY_D3ACS).
- Fixed bug in acoustic pressure fringe plot for collocation BEM (METHOD = 3) and dual BEM based on Burton-Miller formulation (METHOD = 4).

◦ *FREQUENCY_DOMAIN_ACOUSTIC_FEM:

- Fixed bug in acoustic analysis by FEM, when dimensions of mass and k (stiffness) matrices are mismatched.

◦ *FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT:

- Implemented acoustic fringe plot for MPP for the options PART, PART_SET, and NODE_SET.

◦ *FREQUENCY_DOMAIN_FRF:

- Added new loading types:
  VAD1 = 5: enforced velocity by large mass method
  = 6: enforced acceleration by large mass method
  = 7: enforced displacement by large mass method
  = 8: torque
  = 9: base angular velocity
  = 10: base angular acceleration
  = 11: base angular displacement
- Added rotational dof output for FRF.

- *FREQUENCY_DOMAIN_MODE:
  - Added option _EXCLUDE to exclude some eigenmodes in modal superposition in frequency domain analysis.
- *FREQUENCY_DOMAIN_RANDOM_VIBRATION:
  - Fixed bug in running random vibration with random pressure wave load (VAFLAG = 2) in MPP.
  - Improved random vibration analysis by allowing using complex variable cross PSD functions. Previously cross PSD was defined as real variables thus the phase difference was ignored.
  - Added PSD and RMS computation for Von Mises stress in beam elements.
- *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM:
  - Added Von Mises stress output for beam elements in database D3SPCM.
  - Corrected computation of response spectrum at an intermediate damping value by interpolating spectra at two adjacent damping values. Now the algorithm is based on ASCE 4-98 standard.
- *FREQUENCY_DOMAIN_SSD:
  - Added new loading types:
    VAD = 5: enforced velocity by large mass method
    = 6: enforced acceleration by large mass method
    = 7: enforced displacement by large mass method
    = 8: torque
  - Fix for running SSD fatigue in MPP (affected keyword: *FREQUENCY_DOMAIN_SSD_FATIGUE).
  - Updated ssd computation with local damping, and enabled the restart feature by reading damping matrix.
  - Implemented ERP (Equivalent Radiated Power, keyword *FREQUENCY_DOMAIN_SSD_ERP) for MPP.
- *DATABASE_FREQUENCY_ASCII:
  - Added keyword *DATABASE_FREQUENCY_ASCII_{OPTION} to define the frequency range for writing frequency domain ASCII databases NODOUT_SSD, ELOUT_SSD, NODOUT_PSD and ELOUT_PSD.

- ***ICFD (Incompressible Fluid Solver)**
  - New ICFD features and major modifications

- Simple restart is now supported for ICFD.
- Added wave damping capabilities. See *ICFD_DEFINE_WAVE_-DAMPING.
- Added steady state solver. See *ICFD_CONTROL_GENERAL and *ICFD_CONTROL_STEADY.
- Added steady state potential flow solver. See *ICFD_CONTROL_-GENERAL.
- Weak thermal coupling for conjugate heat transfer is now possible in addition to the classic monolithic approach. See *ICFD_CONTROL_-CONJ.
- Windkessel boundary conditions are now available for blood flow. See *ICFD_BOUNDARY_WINDKESSEL.
- It is now possible to output the heat transfer coefficient as a surface variable in LSPP or in ASCII format on segment sets for a subsequent solid-thermal only analysis. See *ICFD_DATABASE_HTC.
- Two way coupling is now possible with DEM particles. See *ICFD_-CONTROL_DEM_COUPLING.
- Modifications introduced in the SUPG stabilization term used in thermal and conjugate heat transfer problems for improved accuracy and speed.

◦ Additions and modifications to existing ICFD keywords

- *ICFD_BOUNDARY_FSWAVE:
  Added a boundary condition for wave generation of 2nd order stokes waves with free surfaces
- *ICFD_CONTROL_FSI:
  Added a flag which, when turned on will project the nodes of the CFD domain that are at the FSI interface onto the structural mesh. This is recommended for cases with rotation.
- *ICFD_CONTROL_MESH:
  Added a flag to allow the user control over whether there will be re-mesh or not. If there is no re-mesh then we can free space used to backup the mesh and lower memory consumption.
- *ICFD_CONTROL_MESH_MOVE:
  Added option to force the solver to turn off any mesh displacements. This can be useful in cases where the mesh is static to save a little bit of calculation time.
- *ICFD_CONTROL_OUTPUT:
  Added option to support output in Fieldview format, binary and ASCII.
  When output of the fluid volume mesh is requested, the mesh will be divided into ten distinct parts, grouping elements in ten deciles based on the mesh quality (Part 1 has the best quality elements, part 10 the worst).

- *ICFD_CONTROL_POROUS:
  Improvements for RTM problems.
- *ICFD_CONTROL_TIME:
  Added an option to define an initial timestep.
  Added an option to shut off the calculation of Navier Stokes after a certain time leaving only the heat equation. This can be useful to save calculation times in conjugate heat transfer cases where the fluid often reaches steady state before the thermal problem.
- *ICFD_DATABASE_DRAG:
  It is now possible to output the force on segment sets in a FSI run directly in LS-DYNA compatible format. This can be useful for a subsequent linear FSI analysis running only the solid mechanics part.
  Added flag to output drag as a surface variable in LSPP.
- *ICFD_DATABASE_FLUX:
  Added option to change output frequency
- *ICFD_DATABASE_NODOUT:
  The user node IDs are now required rather than the internal node IDs
- *ICFD_CONTROL_IMPOSED_MOVE:
  Added the option to choose between imposing the displacements or the velocity.
- *ICFD_CONTROL_TRANSIENT:
  Choose implicit time integration scheme for NS.
- *ICFD_CONTROL_DEM_COUPLING:
  Added a scale factor for the sphere radius in the computation of the DEM force.
- *ICFD_MODEL_POROUS:
  Added a scale factor option on the permeability for model 1 and 2. A *DEFINE_FUNCTION can also be used.
- *MESH_BL:
  Added option to generate boundary layer mesh using a growth factor.

- ICFD bug fixes and minor improvements

  - Fixed bug when multiple *DEFINE_FUNCTIONs were used in an ICFD problem. Only the last one was taken into account.
  - LES turbulence model: fixed van Driest damping issue in the boundary layer. LES models can use wall functions.
  - RANS turbulence models: Standard k-epsilon, realizable k-epsilon, Wilcox k-omega uses HRN laws of the wall by default while SST and Spalart Allmaras use LRN. Improvements on the convergence of all those models.
  - The DEM particle volume is now taken into account in free surface problems.
  - Average shear is now output as a surface variable in the d3plots.

- *ICFD_CONTROL_MONOLITHIC is obsolete (replaced by *ICFD_-CONTROL_GENERAL).
- Added more output for the mesh generation indicating the stage of the meshing process and the amount of elements that are being generated as a multiple of 10000. Added progress % for the extrusion of the mesh during the BL mesh generation.
- Improvements on the element assemble speed in MPP.
- Fixed synchronization problem for the last timestep in an FSI problem.
- More options have been added to the timer output.
- Correction of the calculation of the flux in *ICFD_DATABASE_FLUX in free surface cases.
- Boundary layer mesh can go through free-surfaces or mesh size interfaces.
- The Center of Gravity of the fluid is output in the icfd_lsvol.dat ASCII file in free surface problems

- **Implicit (Mechanical) Solver**

  - Enhanced termination of MPP eigensolver when non eigenmodes are found.
  - Implicit was enforcing birth and death times on *BOUNDARY_SPC during dynamic relaxation contrary to the User's Manual. These times are now ignored by implicit during dynamic relaxation.
  - Corrected output of eigenvalues and frequencies to file eigout for the asymmetric eigenvalue problem.
  - Enhanced logic that determines when to write out the last state to d3plot for implicit.
  - Improved error message for reading d3eigv file for *PART_MODES for the case when the user inputs a d3eigv file from a different model than intended.
  - Corrected the reporting of kinetic and internal energy in file glstat for implicit.
  - Applied corrections to tied contact in implicit (MPP). This affects slave nodes coming from other processes.
  - Corrected output to file d3iter (implicit nonlinear search vectors) for restart.
  - Enhanced termination process when the implicit solver determined an early termination.
  - When implicit springback was following an explicit transient step, the implicit keywords with the _SPR were not properly handled. This is now corrected.
  - Added a warning about the combined use of *CONSTRAINED_RIGID_-BODY_STOPPERS and the Lagrange multiplier formulation for joints (*CONTROL_RIGID) for explicit. The warning recommends switching to the penalty joint formulation.
  - Applied numerous bug fixes to the implicit solver associated with *CONSTRAINED_INTERPOLATION where there are lots of independent degrees-of-freedom.

- Corrected initialization of MPP tied contact with implicit mechanics when the implicit phase follows explicit dynamic relaxation.
- Fixed an implicit problem where a linear implicit analysis follows inertia relief computation.
- Added gathering of damping terms from discrete elements from implicit especially for FRF computations and matrix dumping.
- Fixed Implicit for the case of multi-step Linear (NSOLVR = 1) with Intermittent Eigenvalue Computation.
- Corrected the output to d3iter when 10-noded tets are present.
- Keypoints specified in *CONTROL_IMPLICIT_AUTO are now enforced at the initial time step and on restart from explicit.
- Skip frequency damping during implicit static dynamic relaxation, i.e. IDRFLAG > 5.
- *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS:
  - The VID of the rotating axis can now be defined by both *DEFINE_VECTOR and *DEFINE_VECTOR_NODES. It enables the movement of the rotating axis. Previously, only *DEFINE_VECTOR could be used to define the VID.
  - The rotational dynamics now work in MPP.
- Shell forms 23 and 24 (high order shells), 1D seatbelts, Hughes-Liu and spotweld beams (types 1 and 9) are now supported with the implicit accuracy option (IACC = 1 in *CONTROL_ACCURACY) to render strong objectivity for large rigid body rotations. Also, shell type 16 is supported with implicit accuracy option, resulting in forms 16 and -16 giving the same solution.
- Translational and generalized stiffness joints are now strongly objective for implicit analysis. See CONSTRAINED_JOINT_STIFFNESS....
- In implicit it may happen that the initial loads are zero, for instance in forming problems. In addition, the goal is to move a tool in contact with a workpiece, and the way line search and convergence works, it is hard to get things going. We now attempt to handle this situation by automatically associating an augmented load to the prescribed motion simply to get off the ground.
- New tolerances on maximum norms are introduced for convergence in implicit: ratio of max displacement/energy/residual, and absolute values of nodal and rigid body translation/rotational residual can be specified. See DNORM.LT.0 on *CONTROL_IMPLICIT_SOLUTION for defining an additional card for these parameters DMTOL, EMTOL and RMTOL. Furthermore, maximum absolute tolerances on individual nodal or rigid body parameters can be set on NTTOL, NRTOL, RTTOL and RRTOL on the same card.
- If ALPHA < 0 on first *CONTROL_IMPLICIT_DYNAMICS card, the HHT implicit time integration scheme is activated.

- ***INITIAL**

- Fix *INITIAL_VELOCITY_GENERATION when used with *INCLUDE_-TRANSFORM, which was broken due to misplaced conditionals in r100504.
- Fix 3 bugs for *INITIAL_VELOCITY_GENERATION involving omega > 0 and icid > 0:

  - When nx = -999. Now the directional cosine defined by node NY to node NZ will be the final direction to rotate about. In other words, the direction from node NY to node NZ will not be projected along icid any more.
  - When nx != -999, (xc,yc,zc) should not be rotated along icid, since (xc,yc,zc) are global coordinates.
  - When *INITIAL_VELOCITY_GENERATION is included by *IN-CLUDE_TRANSFORM, (xc,yc,zc) is transformed.

- Add the option of ramping time steps, ndtrrg, for *INITIAL_FOAM_REF-ERENCE_GEOMETRY. The solid elements with reference geometry and ndtrrg > 0 will restore its reference geometry in ndtrrg time steps.
- Fix incorrect initial velocity when ICID.ne.0 in *INITIAL_VELOCITY_GEN-ERATION, and rotational velocity, omega, is not zero and *PART_INERTIA is also present.
- Add variable IZSHEAR in *INITIAL_STRESS_SECTION to initialize shear stress.
- Fix incorrect initial velocity for *INITIAL_VELOCITY if IRIGID = -2 and ICID > 0.
- Fix incorrect NPLANE and NTHICK for *INITIAL_STRESS_SHELL when writing dynain for shell type 9.
- Fix *INITIAL_STRAIN_SHELL output to dynain for shell types 12 to 15 in 2D analysis. Write out strain at only 1 intg point if INTSTRN = 0 in *INTER-FACE_SPRINGBACK_LSDYNA and all strains at all 4 intg points if INTSTRN = 1 and nip = 4 in *SECTION_SHELL.
- Skip transformation of the initial velocities if ICID > 0 and *INCLUDE_-TRANSFORM is used to transform the keyword input file with the *INI-TIAL_VELOCITY.... keyword. Also echo warning message, KEY+1109, that the transformation will be skipped since icid is specified.
- Fix incorrect transformation of *DEFINE_BOX which results in incorrect in-itial velocities if the box is used in *INITIAL_VELOCITY.
- Fixed *INITIAL_STRESS_DEPTH when used with 2D plane strain and ax-isymmetric elements. The prestress was being zeroed.
- Improved the precision of the initial deformation calculation for *INITIAL_-FOAM_REFERENCE_GEOMETRY in the single precision version.
- Fixed stress initialization (*INITIAL_STRESS_SECTION) for type 13 tet ele-ments. The pressure smoothing was causing incorrect pressure values in the elements adjacent to the prescribed elements.
- Add _SET option to *INITIAL_STRESS_SOLID for element sets.

- Fix bug in 3D adaptivity so that users can now define *INITIAL_TEMPERATURE for adaptive parts.

- **Isogeometric Elements**

  - The stability of the trimmed NURBS shell patches has been improved.
  - Add *LOAD_NURBS_SHELL to apply traction type loading directly on the surface of NURBS shell.
  - Users can use the PART option of *SET_SEGMENT_GENERAL to define segment set of a NURBS patch. The segment set will contain all segments of interpolated null shell elements.
  - *ELEMENT_SOLID_NURBS_PATCH:

    - Isogeometric solid analysis implemented for MPP.
    - Isogeometric solid analysis implemented for SMP with multiple CPUs, including consistency (ncpu < 0).
    - Activate user-defined materials for isogeometric solid.

  - *ELEMENT_SHELL_NURBS_PATCH:

    - Isogeometric shell analysis now implemented for SMP with multiple CPUs, including consistency (ncpu < 0).
    - Add a power iteration method to get the maximum eigen-frequency for each isogeometric element. This will be used to set a reasonable time step for trimmed elements.

  - *ELEMENT_SHELL_NURBS_PATCH:

    - Changed the way of projecting the results from isogeometric (NURBS) elements to the interpolation elements. Now a background mesh, spanned over the locations of the integration points of the isogeometric (NURBS) elements serves as basis to interpolate results from the integration points to the centroid of the interpolation elements. This change may lead to slightly different post-processing results in the interpolation elements.

  - Add support for trimmed NURBS to work in single precision. Anyway, it is still recommended to use double precision versions for trimmed NURBS patches.
  - Add post-processing of strains and thickness for interpolation shells.

- ***LOAD**

  - Fixed bugs affecting discrete beam elements (ELFORM = 6) when used with staged construction. Here, "dormant" refers to elements that have not yet

become active as defined on *DEFINE_STAGED_-CONSTRUCTION_-PART.

- Dormant discrete beams could still control the timestep and attract mass-scaling, when they should not do so.
- Dormant discrete beams reaching a failure criterion defined on the *MAT card were deleted, when they should not be.
- The displacements output (see *DATABASE_DISBOUT) included displacements occurring while the elements were dormant. Now, the output displacements are reset to zero at the moment the element becomes active.

- Fixed bug in Staged Construction: if FACT on *CONTROL_-STAGED_-CONSTRUCTION had been left blank, and Dynamic Relaxation was active, an error termination occurred.
- Fixed bug: *LOAD_GRAVITY_PART (and also gravity loading applied by *DEFINE_STAGED_CONSTRUCTION_PART) was failing to account for non-structural mass when calculating gravity load: NSM on *SECTION_-BEAM and MAREA on *SECTION_SHELL.
- Fixed bug in *LOAD_VOLUME_LOSS: inconsistent results when run in SMP parallel.
- Fix bugs affecting *LOAD_SEGMENT_FILE:

  - Remove LOAD_SEGMENT_FILE file size limit (It used to be 200M).
  - Apply correct pressure on the shared boundary between processors.

- Fix GRAV = 1 in *PART which was not working correctly with *LOAD_-DENSITY_DEPTH. Make *LOAD_DENSITY_DEPTH work for Lagrangian 2D elements.
- Fix insufficient memory error, SOL+659, when using *LOAD_-ERODING_-PART_SET with MPP.
- Fix incorrect loading when using *LOAD_ERODING_PART_SET with BOXID defined.
- Added *LOAD_SUPERPLASTIC_FORMING for implicit analysis.
- *LOAD_SUPERPLASTIC_FORMING box option now works in MPP.

- ***MAT and *EOS**

  - *MAT_197 (*MAT_SEISMIC_ISOLATOR) could become unstable when the parameter DAMP was left at its default value. A workaround was to input DAMP as a small value such as 0.05. The timestep for *MAT_197 is now smaller than previously, irrespective of the DAMP setting, and the behavior is now stable even if DAMP is left at the default.
  - Fixed bug: Timestep calculation was wrong for *MAT_089 solid elements. Response could be unstable especially for higher values of Poisson's ratio, e.g. 0.4.

- Fixed bug: An error trap was wrongly preventing ELFORM = 15 for *MAT_-169 (*MAT_ARUP_ADHESIVE). Wedge elements with ELFORM = 15 are now permitted.
- *MAT_172 (*MAT_CONCRETE_EC2):
  Note that items (1) and (2) below can lead to different results compared to previous versions of LS-DYNA.

  - (1) The number of potential cracks in MAT_172 shell elements has been increased from 2 to 4. MAT_172 uses a fixed crack model: once the first crack forms, it remains at the same fixed angle relative to the element axes. Further cracks can then form only at pre-defined angles to the first crack. Previously, only one further crack could form, at 90 degrees to the first crack. Thus, if the loading direction subsequently changed so that the principal tension is at 45 degrees to the first crack, that stress could exceed the user-defined tensile strength by a considerable margin. Now, further cracks may form at 90, +45 and -45 degrees to the first crack. Although the maximum principal stress can still exceed the user-defined tensile strength, the "error" is much reduced. There is an option to revert to the 2-crack model as in R9 (to do this, add 100 to TYPEC).
  - (2) Add element erosion to MAT_172. This change may lead to different results compared to previous versions, because erosion strain limits are now added by default. Elements are now deleted when crack-opening strain becomes very large, or the material is crushed beyond the spalling limit. Plastic strain in the rebar is considered too. Previously, these elements that have passed the point of being able to generate any stress to resist further deformation would remain in the calculation, and sometimes showed very large non-physical deformations and could even cause error terminations. Such elements would now be deleted automatically. Default values are present for the erosion strains but these can be overridden in the input data, see new input fields ERODET, ERODEC, ERODER.
  - (3) New history variables 10,11,12 (maximum value so far of through-thickness shear stress). This is useful for checking results because MAT_172 cracks only in response to in-plane stress; before cracking occurs, the through-thickness shear capacity is unlimited. The data components are:
    Ex History Variable 10 - maximum out of 11 and 12
    Ex History Variable 11 - maximum absolute value of YZ shear stress
    Ex History Variable 12 - maximum absolute value of ZX shear stress
    These are in the element local axis system. Note that these variables are written only if TYPESC is zero or omitted. TYPESC is a pre-existing capability that requests a different type of shear check.

- (4) Fixed bug. Elastic stiffness for MAT_172 beams was not as described in the manual, and the axial response could sometimes become unstable. The bug did not affect shell elements, only beams.
- (5) *MAT_172 can now handle models with temperatures defined in Kelvin (necessary if the model also has heat transfer by radiation). *MAT_172 has thermally-sensitive material properties hard-wired to assume temperatures in Centigrade. A new input TMPOFF in *MAT_-172 offsets the model temperatures before calculating the material properties.
- (6) When the input parameter AGGSZ is defined, the maximum shear stress that can be transferred across closed cracks is calculated from a formula that has tensile strength and compressive stress as inputs. In MAT_172, the tensile strength of concrete is reduced when compressive damage has occurred (see description of UNLFAC). Up to now, compressive damage was therefore influencing the maximum shear across cracks. However, the Norwegian standard from which the shear formula is taken treats the tensile strength as a constant. Therefore, for the purpose of calculating the maximum shear stress across closed cracks only, the compressive damage effect is now ignored.
- (7) Added capability for water pressure in cracks, for offshore applications. The water pressure is calculated from the depth of the element below the water surface (calculated from the z-coordinate). The water pressure is applied as a compressive stress perpendicular to the plane of any crack in the element. See new input fields WRO_G and ZSURF.

◦ *MAT_119 (*MAT__GENERAL_NONLINEAR_6DOF_DISCRETE_BEAM): Fixed bug in UNLOAD option 2. The bug occurs if an unloading curve has been left zero (e.g. LCIDTUR) while the corresponding loading curve was non-zero (e.g. LCIDTR), and UNLOAD = 2. Depending on the computer system, the symptoms could be harmless or the code could crash. Now, if the unloading curve is left blank, it is assumed to be the same as the loading curve i.e. load and unload up and down the same curve. That behavior was already implemented for UNLOAD = 1.

◦ Added Equation Of State 19 (*EOS_MURNAGHAN). Used extensively for fluid modeling in SPH through Weakly-Compressible formulation, in conjunction with SPH formulations 15 (fluid form) and 16 (normalized fluid form).
◦ *MAT_ADD_FATIGUE: Added a new form of Basquin equation to define material's SN curve: LCID = -3: S = a*N^b, where a and b are material constants.
◦ Add the option of A0REF for *MAT_FABRIC. That allows the option of using reference geometry to calculate A0 for the purpose of porosity leakage calculation.

- Add optional parameter DVMIN for *MAT_ADD_PORE_AIR to define the min volume ratio change to trigger pore air flow analysis.
- *DEFINE_HAZ_PROPERTIES:
- Distance of shell from the weld center is treated consistently under MPP and the shell material's yield stress is scaled properly.
- *MAT_168 and *MAT_279: Fixed support for element erosion.
- *MAT_092: Improved of implicit convergence for shells.
- *MAT_224: Fixed bug where wrong shear modulus was used in EOS.
- *MAT_270: Increased stability for thickness strain iterations for shells.
- *MAT_240: Added support for cohesive shell formulation +/-29.
- Scale load curve, LCSRS, of *MAT_ADD_EROSION when used with *INCLUDE_TRANSFORM.
- Fix incorrect results when using *MAT_TABULATED_JOHN-SON_-COOK/*MAT_224 with table LCKT defined and the first abscissa value, temperature, is negative.
- Fix spurious element deletion when using table for LCF in *MAT_TABULATED_JOHNSON_COOK/*MAT_224 and *MAT_TABULA-TED_JOHNSON_COOK_GYS/*MAT_224GYS.
- Error terminate with message, KEY+1142, if *MAT_ADD_EROSION is applied to resultant materials 28,116,117,118,130,139,166,170 and 98(with 1 intg point).
- Increase robustness of *MAT_033/*MAT_BARLAT_ANISOTROPIC_-PLASTICITY for solids.
- Fix input error when using *MAT_ELASTIC_WITH_VISCOSITY_-CURVE/*MAT_060c when LCID = 0.
- Fix seg fault when using shell type 15, axisymmetric volume weighted, with *MAT_ADD_EROSION and also materials with equation-of-states.
- Store computed yield strength as history variable #6 for *MAT_255.
- Fix inconsistency for *MAT_MODIFIED_PIECEWISE_LINEAR_-PLASTICITY/*MAT_123 when ncpu < 0.
- Include original volume output to dynain file for 2D analysis when materials with an equation-of-state are used. This is needed to compute the deformation gradient when initializing a run using the dynain file.
- Fix improper stress initialization using *INITIAL_STRESS_SHELL via dynain for *MAT_018/*MAT_POWER_LAW_PLASTICITY with VP = 1.0.
- Make AOPT < 0 work for *MAT_170/*MAT_RESUL-TANT_ANISOTROPIC, i.e. with material coordinate system using *DEFINE_COORDINATE_(OPTION).
- Fix incorrect operation of TDEL for *MAT_MODIFIED_-PIECEWISE_LINEAR_PLASTICITY/*MAT_124 and *MAT_PLASTI-CITY_WITH_DAMAGE/*MAT_081/*MAT_082.
- Fix incorrect damping when using *DAMPING_PART_STIFFNESS for *MAT_16/*MAT_PSEUDO_TENSOR and *EOS_TABULATED_-COMPACTION.

- Fix incorrect computation of bulk modulus which caused complex sound speed error when using *EOS_TABULATED/EOS_09 with tabulated input.
- Fix moving part with *MAT_220 during dynamic relaxation when velocities are initialized.
- Fix convergence issue for *MAT_065/*MAT_MODIFIED_ZERILLI_-ARM-STRONG for shells when VP = 1.
- Error terminate with message, KEY+1115, if _STOCHASTIC option is invoked for materials 10,15,24,81,98, or 123 but no *DEFINE_STOCH-ASTIC_-VARIATION or *DEFINE_HAZ_PROPERTIES keyword is present in the input file.
- Fix spurious error termination when using *DEFINE_HAZ_PROPERTIES with adaptivity.
- Fix incorrect results or seg fault for *MAT_FU_-CHANG_FOAM/*MAT_-083 if KCON > 0.0 and TBID.ne.0.
- If SIGY = 0 and S = 0 in *MAT_DAMAGE_2/*MAT_105, set S = EPS1/200, where EPS1 is the first point of yield stress input or the first ordinate point of the LCSS curve.
- Allow *MAT_ENHANCED_COMPOSITE_DAMAGE/*MAT_054 failure mechanism to work together with *MAT_ADD_EROSION for shells.
- Fix incorrect erosion behavior if *MAT_ADD_EROSION is used with failure criteria defined for *MAT_123/*MAT_MODIFIED_PIECEWISE_-LIN-EAR_PLASTICITY.
- Implement *MAT_FHWA_SOIL/*MAT_147 for 2D analysis, shell types 13, 14 and 15.
- Implement scaling of failure strain for *MAT_MODIFIED_-PIECEWISE_-LINEAR_PLASTICITY_STOCHASTIC/*MAT_123_STOCHASTIC for shells.
- Fix incorrect behavior for *MAT_LINEAR_ELASTIC_DISCRETE_-BEAM/*MAT_066 when using damping with implicit (static) to explicit switching.
- Fixed *MAT_FABRIC/*MAT_034 with the negative unloading curve option. When searching for the intersection point of the load and unload curves, and extrapolation of one of the curves was needed to find the intersection point, the extrapolated stress was calculated incorrectly causing unpredictable behavior.
- Fixed fabric material forms 0 and 1 when used with a reference geometry. There were two problems, both occurring when there are mixed quad and triangular elements in the same block. A flaw in the strain calculation was leading to possible NaN forces in the elements. When a reference geometry was not used, the forces from triangular elements in mixed element blocks were 2 times too high.
- Added a new option for *MAT_SPOTWELD called FMODE. The FMODE option is available for DMGOPT = 10, 11, and 12. When the failure function is reached, and when FMODE > 0.0 and < 1.0, the value of FMODE will determine if a weld will fail immediately or will have damage initiated. The

failure function may include axial, shear, bending and torsion terms. If the sum of the squares of the shear and torsion terms divided by the sum of the square of all terms is greater than FMODE, then the weld will fail immediately. Otherwise, damage will be initiated.

- Enabled OPT = -1 on *MAT_SPOTWELD for brick elements which had not worked previously. Also, fixed TRUE_T when used with brick element forms 0, 1, and -1.
- Fixed spot welds with DMGOPT = 12 by removing warning STR+1327 which made it impossible to set a small value of RS without triggering this warning, or without setting EFAIL smaller. Setting EFAIL small however could lead to damage initiation by plastic strain when the user wanted only initiation by the failure function.
- If DMGOPT = 10, 11, or 12 and EFAIL = 0, on *MAT_SPOTWELD, damage will now initiate only by the failure function. If EFAIL > 0, then damage will initiate be either then failure function or when plastic strain exceeds EFAIL. Prior to this version, damage could initiate when plastic strain exceeds zero if the user set EFAIL = 0. This behavior is still true for DMGOPT = 0, 1, or 2, but no longer for DMGOPT = 10, 11, or 12.
- Allow solid spot welds and solid spot weld assemblies to have up to 300 points in the running average that is used to smooth the failure function. In other words, up to NF = 300 is possible.
- Fixed a problem with brick spot weld assemblies when OPT = 0 failure is used without defining any weld resultant values. Welds were being immediately deleted.
- Added new PID option for *DEFINE_SPOTWELD_FAILURE (applies to *MAT_SPOTWELD, OPT = 10). Changes the Card 3 input for static strength values to use part set ID's rather than material ID's.
- Modified shell *MAT_214/*MAT_DRY_FABRIC to calculate fiber strains based on the current distance between the points where the fibers intersect with the element edges. Previously, they were calculated from the rate-of-deformation, but this was not as accurate as the new total strain measure.
- Fixed unit scaling for GAMAB1 and GAMAB2 on *MAT_DRY_FABRIC. We were incorrectly transforming them as stress.
- Reworked the plastic stress update in *MAT_225/*MAT_VISCOPLASITC_-MIXED_HARDENING to prevent a divide by zero.
- Enabled *MAT_ADD_EROSION to be used with beams that have user defined integration. Memory allocation was fixed to prevent memory errors.
- Fixed *MAT_106 when used with tshell form 5 or 6. The elastic constants used in the assumed strain field were not reasonable.
- Fix issue that could have led to problems using *MAT_054 (or *MAT_058 or *MAT_158) in combination with TFAIL/TSIZE.gt.0.0 and damping.
- *MAT_054 - *MAT_ENHANCED_COMPOSITE_DAMAGE:

    - Add possibility to use failure criterion in *MAT_054 for solids in a transversal isotropic manner. It is assumed that the material 1-

direction is the main axis and that the behavior in the 2-3 plane is isotropic. This feature is invoked by setting TI = 1 in *MAT_054.

- *MAT_058 - *MAT_LAMINATED_COMPOSITE_FABRIC:
  - Bugfix for shear stiffness behavior in *MAT_058 when using a table definition for GAB and only providing stress-strain-curves for positive shear.
  - Bugfix for strain-rate dependent stiffness behavior in *MAT_058 when using a table definition for EA, EB or GAB under compressive loading.
  - Add default values for strengths (XT,XC,YT,YC,SC) 1.e+16 for *MAT_-058. If no values for the strengths were defined, unpredictable things could have happened.
- *MAT_138 - *MAT_COHESIVE_MIXED_MODE:
  - Store total mixed-mode and normal separation (delta_II & delta_I) on history variables 1&2 for *MAT_COHESIVE_MIXED_MODE (*MAT_-138). This is only for post-processing and should not lead to any changes in the results.
- *MAT_157 - *MAT_ANISOTROPIC_ELASTIC_PLASTIC:
  - Add Tsai-Hill failure criterion (EXTRA = 2).
  - Allow strain-rate dependent strength values (XT,XC,YT,YC,ZT,ZC,SXY,SYZ,SZX) using *DEFINE_CURVE. This is available for Tsai-Wu (EXTRA = 1) and Tsai-Hill.
  - Fixed bug in using *MAT_157 with IHIS.gt.0 for shells. Thickness strain update d3 was not correct and plasticity algorithm may have failed.
  - Add additional option to IHIS in *MAT_157 for SHELLs.
  - Now also the strength values (XT,XC,YT,YC,SXY) may be initialized via *INITIAL_STRESS_SHELL. See variable IHIS and remarks in the User's Manual for details of initializing various blocks of material parameters.
- *MAT_215 - *MAT_4A_MICROMEC:
  - Add new material *MAT_215 that is a micromechanical material model that distinguishes between a fiber/inclusion and a matrix material. The material is intended for anisotropic composite materials, especially for short (SFRT) and long fiber thermoplastics (LFRT). This model is available for shells, tshells and solids.
- *MAT_225 - *MAT_VISCOPLASTIC_MIXED_HARDENING:

- Fixed bug in *MAT_225 (*MAT_VISCOPLASTIC_MIXED_HARDENING) when using a table for LCSS together with kinematic hardening.

- *MAT_261 - *MAT_LAMINATED_FRACTURE_DAIMLER_PINHO:
  *MAT_262 - *MAT_LAMINATED_FRACTURE_DAIMLER_CAMANHO:

  - Allow table input for fracture toughness values for mats 261/262.Table represents fracture toughness vs. element length vs. strain rate (shells, tshells, solids)
  - Fixed bug in mats 261/262 when using *DAMPING_PART_STIFFNESS together with RYLEN = 2 in *CONTROL_ENERGY.
  - Correct shear failure behavior in *MAT_262. This will most probably have no effect to any real application, but could be seen in very special 1-element tests.

- Changed storage of history variables for *MAT_249 (*MAT_REINFORCED_THERMOPLASTIC). A new variable POSTV controls which variables are written and at what history variable location in d3plot.
- *MAT_254 (*MAT_GENERALIZED_PHASE_CHANGE) can now be used with shell elements and thermal thick shells.
- Added flag 'EZDEF' to *MAT_249_UDFIBER. In this case the last row of the deformation gradient is replaced by 0-0-1.
- Add opt. damage limitation curve/table LCDLIM for *MAT_ADD_GENERALIZED_DAMAGE.
- Add pre-defined damage tensors option PDDT to *MAT_ADD_GENERALIZED_DAMAGE.
- *MAT_ADD_GENERALIZED_DAMAGE now works for solid elements (only shells in R9).
- Add optional failure criterion FFCAP to *MAT_100 with OPT = -1 or 0.
- Enable *MAT_ADD_COHESIVE to be used in implicit analysis.
- Add alternative version of *MAT_280 invoked by new flag on 1st card. It is a physically based damage model with 4 new parameters.
- Enable *DEFINE_CONNECTION_PROPERTIES' option PROPRUL>=2 to be used with spotweld clusters, i.e. not only 1 hex element but several (via *DEFINE_HEX_SPOTWELD_ASSEMBLY or RPBHX > 1 on *CONTROL_SPOTWELD_BEAM).
- Enable *MAT_ADD_EROSION to be safely used with material models that have more than 119 history variables, for now the new limit is 169 (e.g. necessary for *MAT_157 with IHIS = 7).
- Add Tsai-Wu failure criterion to *MAT_157 for solid and shell elements invoked by EXTRA = 1 on card 6 and corresponding parameters on cards 8 and 9.
- Add viscoelastic option to *MAT_187 (SAMP-1). Rate dependent Young's modulus and associated settings can be defined on new optional card 5.

- Add new option IRNG for *DEFINE_STOCHASTIC_VARIATION to govern random number generation (deterministic or true random).
- Add option to define element size dependent parameters EN and SN for *MAT_120 and *MAT_120_JC by setting them to negative values (curves).
- Minor improvements for *MAT_252: Optional output of damage initiation information and more post-processing history variables.
- If the first abscissa value of *MAT_224's failure strain curve LCG is negative, it is assumed that all abscissa values are natural logarithms of a strain rate.
- Put *MAT_100_DA's "failure function" value to history variable 18.
- Add optional in-plane failure strain to *MAT_169 (ARUP_ADHESIVE): new input parameter FSIP.
- *MAT_USER_DEFINED_MATERIAL_MODELS now provides a few more variables for cohesive elements, i.e. additional arguments in subroutines umatXXc: temperature, element size, implicit rejection flag, integration point identifier, and total number of integration points.
- A modified version of the 3-parameter Barlat model (*MAT_036) is introduced as *MAT_EXTENDED_3-PARAMETER_BARLAT. In this model, hardening in 00, 45, 90, biaxial and shear can be specified as load curves. Furthermore, r-values in 00, 45, 90, biaxial and shear can be specified in terms of load curves vs plastic strain or constants. This is an extension of hardening law 7 of the original 3-parameter Barlat model.
- Improve implicit version of *MAT_098/*MAT_SIMPLIFIED_JOHNSON_-COOK.
- *MAT_181/*MAT_SIMPLIFIED_RUBBER/FOAM is now supported for 2D implicit simulations.
- Fixed issue in which *MAT_WINFRITH_CONCRETE wrote d3crack data too frequently.
- *EOS_JWL now has an AFTERBURN option. This adds afterburn energy to the EOS, where the energy can be added at a constant or linear rate, or can be added according to Miller's extension.
-
- *MAT_084 (*MAT_WINFRITH_CONCRETE) with predefined units (CONM < 0) is now transformed correctly with *INCLUDE_TRANSFORM.
- User-defined materials for Hughes-Liu beams can now be used with implicit analysis by defining the appropriate tangent modulus in the supplied routine urtanb.
- User-defined cohesive materials can now be used with implicit analysis by defining the appropriate tangent stiffness.
- *MODULE for user-defined materials and other user-defined capabilities:

    - A new command line option "module = filename" is added to load one module file without changing the input deck. It provides back compatibility to input deck without the MODULE keywords.
    - The system paths defined in LD_LIBRARY_PATH are also included for searching module files for those filenames start with "+".

- Add shell implementation to *MAT_277 (*MAT_ADHESIVE_CURING_-VISCOELASTIC).
- Add *MAT_278 for carbon fiber prepreg compression forming simulation. This material model is available for both solid and shell formulations.
- Add *MAT_293 non-orthogonal material model for carbon fiber prepreg forming simulation. This material model is only available for shell formulations.
- *MAT_260A:
  - Extend *MAT_260A to include solid elements.
  - Add a new option XUE for Xue's fracture criteria/theory for *MAT_-M260A (solid elements only).
- *MAT_260B:
  - Set default values for P's and G's in *MAT_260B.
  - Add a length scale to the fracture limit. The fracture limit strongly depends on the length scale in the measurement.
  - Add a new fracture criterion to *MAT_260B (Xue and Wierzbicki, Int. J. solids and Structures 46 (2009) 1423-1435). When the option XUE is activated, an additional card is needed, for example:

```
$     ef0     plim        q     gama        m
    0.70    925.7    0.970    0.296     2.04
```

- *MAT_037:
  - Improve *MAT_037 with negative R value in implicit calculation. The modification will allow the implicit method stress calculation to be more accurate.
  - Add a new option NLP2 to calculate formability index in *MAT_037. The previous method (option NLP_FAILURE) was based on the effective strain method, which assumes that necking happens at one instant. In fact, it might happen over a longer process. The new method calculates the damage accumulation.
- Add *MAT_165B (*MAT_PLASTIC_NONLINEAR_KINEMATIC_B) for shells and solids.

- **MPP**
  - Fix the report of decomp balance (shown as "Normalized element costs assigned during decomposition" in the d3hsp file), which was broken in r109760
  - MPP decomposition has not been properly balanced since r112652 due to a bug in that revision

- Fix MPP SYNC error due to inconsistent summation in *CONTACT_SLIDING_ONLY_PENALTY.
- Allow real values as the scale multipliers for "memory=" on the command line. For example, "memory = 2.5G memory2 = 1.1G" and the like.
- MPP: fix support for nlq setting in *CONTROL_SOLUTION which was not being honored on processors other than 0.
- Significant improvements in MPP groupable routines for FORMING contact.
- MPP: increase contact release distance for SINGLE_SURFACE contacts in the case of a node coming into contact with a solid element. The previous interpretation was releasing when the contact penetration was 0.5*solid thickness, but now when the node passes below the solid surface by 0.5*solid thickness (which is different by the half thickness of the slave material, in the case of a shell slave node).
- MPP: fix for viscous damping in automatic tiebreak contact.
- Implement new bucket sort based extent testing for MPP single surface contact.
- Added MPP support for *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_LUBRICATION.
- Fixed *CONTROL_MPP_PFILE so that it honors ID offsets from *INCLUDE_TRANSFORM for parts, part sets, and contact IDs referenced in "decomp { region {" specifications.
- Furthermore, such a region can contain a "local" designation, in which case the decomposition of that region will be done in the coordinate system local to the include file, not the global system. For example:
- *CONTROL_MPP_PFILE decomp { region { partset 12 local c2r 30 0 -30 0 1 0 1 0 0 } } would apply the c2r transformation in the coordinate system of the include file, which wasn't previously possible. The local option can be useful even if there are no such transformations, as the "cubes" that the decomposition uses will be oriented in the coordinate system of the include file, not the global system.
- Furthermore, the following decomposition related keywords now have a _LOCAL option, which has the same effect:

  *CONTROL_MPP_DECOMPOSITION_PARTS_DISTRIBUTE_LOCAL
  *CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE_LOCAL
  *CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS_LOCAL
  *CONTROL_MPP_DECOMPOSITION_CONTACT_DISTRIBUTE_LOCAL

- MPP job performance profiles are output to both .csv and .xy files.

- **OUTPUT**

- Fix for writing d3plot file when individual output states exceed 8GB in single precision
- Added new option *INTERFACE_SPRINGBACK_EXCLUDE to exclude selected portions from the generated dynain file.
- Add a new option to *INTERFACE_COMPONENT_FILE to output only 3 degrees of freedom to the file even if the current model has 6.
- Fix missing plastic strain tensors in d3plot when STRFLG in *DATA-BASE_-EXTENT_BINARY is set and INTSTRN = 1 in *INTERFACE_-SPRING-BACK.
- Fix no output to bndout when run with q = remap even though the keyword *DATABASE_BNDOUT was present in the remap run but was not present in the initial run.
- Fix d3plot output frequency which was different from the dt specified in *DATABASE_BINARY_D3PLOT when *CONTACT_AUTO_MOVE is used.
- Fix stress output to elout for solid elements which was in the global coordinates instead of local coordinates when CMPFLG = 1 in *DATABASE_EXTENT_BINARY and OPTION1 > 0 in *DATABASE_-ELOUT.
- Fix incorrect mass properties for solids in ssstat file when using *DATABASE_SSSTAT_MASS_PROPERTY.
- Fix seg fault during writing of dynain file if INSTRN = 1 in *INTERFACE_-SPRINGBACK and STRFLG.ne.0 in *DATABASE_-EXTENT_BINARY and the *DATABASE_EXTENT_BINARY comes after *INTERFACE_SPRING-BACK.
- If HYDRO is nonzero in *DATABASE_EXTENT_BINARY, LS-PrePost will now combine the solid and shell internal energy densities when fringing 'Internal Energy Density' in the Misc menu.
- By putting SIGFLG/EPSFLG = 3 in *DATABASE_EXTENT_BINARY, the stresses and plastic trains are excluded not only for shell elements but also for solids. This applies to d3plot and d3eigv.
- Added new file option *DATABASE_BINARY_INTFOR_FILE to define interface file name.
- Fixed legend in bndout in the case of multiple *BOUNDARY_PRESCRIBED_MOTION_SET_ID.
- Fix corrupt d3part data caused by DECOMP = 4 in *DATABASE_-EXTENT_BINARY.
- Fixed the legend of ssstat in binout.
- Added *DATABASE_EXTENT_SSSTAT_ID. The subsystem id will be included in the ASCII ssstat file.
- Fixed bug in stbout (seatbelt output) if NEWLEG = 0 in *CONTROL_OUTPUT.
- Fixed bug in which DECOMP = 2 corrupted d3part.
- Fixed d3plot bug if dynamic relaxation was activated in the input deck.
- Added another digit for coordinates in *NODE in dynain, e.g., what was written as 0.999266236E+00 is now written as 9.992662368E+00.

- Added *DATABASE_EXTENT_BINARY_COMP for alternative (simpler) control of output to d3plot and d3eigv.

  - Output control flags: 0-no 1-yes
  - IGLB : Global data
  - IXYZ : Current coordinate
  - IVEL : Velocity
  - IACC : Acceleration
  - ISTRS: 6 stress data + plastic strain
  - ISTRA: 6 strain data
  - ISED : Strain energy density

  This command can be used in combination with regular *DATABASE_EXTENT_BINARY but will disable most of the options in the latter, including output of extra history variables.
- Bugfix: *DATABASE_TRACER without the optional NID parameter was read incorrectly when used with *INCLUDE_TRANSFORM, but is now fixed
- Fixed incomplete output from Windows version of LS-DYNA. This affected demtrh (*DATABASE_TRACER_DE) and curvout (*DATABASE_-CURVOUT).

- **Restarts**

  - Enable definition of sensors in full restarts.
  - For a small restart in MPP, the value of "memory=" (M1) needed for each processor is stored in the dump files. This is the minimum requirement to read back the model info. If the value of "memory2=" (M2) is specified on the command line, the code will take the maximum of M1 and M2.
  - Fix input error during structured input when using *INITIAL_VELOCITY_-GENERATION and *CHANGE_VELOCITY_-GENERATION together in a full deck restart.
  - Fix incorrect full deck restart analysis if initial run was implicit and the full deck restart run is explicit. This affects MPP only.
  - Fix insufficient tying of nodes when doing full deck restart and the contact is newly added to the restart involving newly added parts. This applies to SMP contact only.
  - Fix incorrect velocity initialization for SMP full deck restart when using *INITIAL_VELOCITY_GENERATION and *INITIAL_VELOCITY_-GENERATION_START_TIME.
  - Fix incorrect initialization of velocities for SMP full deck restart when using *CHANGE_VELOCITY_OPTION & *INITIAL_VELOCITY_OPTION. Velocities of existing parts defined by *STRESS_INITIALIZATION should not be zeroed.
  - Fix *CHANGE_CURVE_DEFINITION for curve specifying d3plot output.

- Fixed bug in full deck restart if the new mesh has different part numbers.

- ***SENSOR**

  - Fix a bug regarding *SENSOR_JOINT_FORCE for *CONSTRAINED_-JOINT_STIFFNESS, that was triggered when the force refers to a local coordinate system.
  - Add the option of "ELESET" to *SENSOR_CONTROL to erode elements.
  - Add the option of NFAILE to *SENSOR_DEFINE_MISC to track number of eroded elements.
  - Fix a bug that was triggered when using a sensor to control spotwelds. The bug was triggered when the spotweld-connected nodal pairs happen to belong to more than 1 core (MPP only).
  - Add FAIL option to *SENSOR_DEFINE_ELEMENT to track the failure of element(s).
  - Fix a bug related to *SENSOR_DEFINE_FUNCTION when there are more than 10 sensor definitions.
  - Effect of TIMEOFF in *SENSOR_CONTROL is implemented for TYPE = PRESC-ORI.
  - *SENSOR_CONTROL can be used to control *BOUNDARY_PRESCRIBED_-ORIENTATION_RIGID.
  - Add optional filter id to SENSORD of *DEFINE_CURVE_FUNCTION.
  - Enable *CONSTRAINED_JOINT_..._LOCAL to be monitored by *SENSOR_-DEFINE_FORCE.
  - Allow moments in SPCFORC and BNDOUT to be tracked by *SENSOR_-DEFINE_FORCE.
  - Fix *SENSOR_CONTROL using TYPE="PRESC-MOT" which was not switching at all.

- **SPG (Smooth Particle Galerkin)**

  - MPP is ready in 3D SPG fluid particle stabilization (ITB = 1 & 2 in *SECTION_SOLID_SPG).
  - Added one SPG control parameter (itb = 2) for semi-brittle fracture analysis. In comparison to itb = 0 or itb = 1, itb = 2 is more efficient in modeling the fragmentation and debris in semi-brittle fracture analysis such as impact and penetration in concrete materials.
  - Fixed a bug related to E.O.S. in SPG.
  - Removed some temporary memory allocations to improve efficiency.
  - Changed the sequence of SPG initialization so that all state variables are properly initialized.
  - Subroutines were developed for SPG failure analysis with thermal effects. Both explicit and implicit (diagonal scaled conjugate gradient iterative only) SPG thermal solvers are available in SMP version only. However, thermal effect is applied only on material properties, which means thermal induced

deformation (i.e., thermal strain or thermal expansion) is not currently included.
- Modified *MAT_072R3 for SPG method in concrete applications.
- Fixed a bug for SPG method in using continuum damage mechanics. (IDAM = 0).
- Added the "fluid particle algorithm" (itb = 1) to SPG method. This algorithm is implemented in R10.0 as an alternative to the (itb = 0) option in previous version to enhance the numerical stability for SPG method. Users are recommended to use this new option for their ductile failure analysis.

- **SPH (Smooth Particle Hydrodynamics)**

  - Add ITHK flag in *CONTROL_SPH, card 3. If flag is set to 1, the volume of the SPH particles is used to estimate a node thickness to be employed by contacts.

    - Affects *AUTOMATIC_NODES_TO_SURFACE and *CONTACT_-2D_-NODE_TO_SOLID.
    - The thickness calculated by ITHK = 1 is used only if SST or OFFD are set to zero in the contact cards definitions.

  - Add SOFT = 1 option to *CONTACT_2D_NODE_TO_SOLID. This should help obtain reasonable contact forces in axisymmetric simulations. Default penalty PEN is 0.1 when SOFT = 1.
  - Implemented non-reflecting boundary conditions for SPH using a new keyword *BOUNDARY_SPH_NON_REFLECTING.
  - Bug fix for renormalized SPH formulations with symmetry planes. The renormalization was slightly incorrect in the vicinity of symmetry planes.
  - Density smoothing in SPH formulations 15 and 16 is now material sensitive. The smoothing only occurs over neighbors of the same material.
  - Resolved an MPP bug in SPH total Lagrangian formulations (FORM = 7/8) which was causing strain concentrations at the interfaces between CPU zones.
  - SPH total Lagrangian (FORM = 7/8) in SMP was pretty much serial, hence much slower than forms 0 or 1. SPH with FORM 7 and 8 now scales properly.
  - Added support for FORMs 0/1 in axisymmetric. Until now, renormalization was always active (equivalent to FORM = 1) which can be problematic for very large deformations or material fragmentation.
  - Improved tracer particles output for SPH: Use normalized kernel function for interpolation between particles.
  - Implemented enhanced fluid flow formulations (FORMs 15/16) with pressure smoothing.
  - Recode SPH neighborhood search algorithm to reduce the memory requirement and produce consistent results from MPP and HYBRID code.

- *DEFINE_ADAPTIVE_SOLID_TO_SPH now reports both active and inactive adaptive SPH particles in the fragment file sldsph_frag. This file gives a report of nodal mass, coordinates, and velocities.
- MPP now supports:
  - SPH type 3 inflow
  - Multiple *BOUNDARY_SPH_FLOW
  - Bulk viscosity option for SPH
- Sort SPH by part and then node ID to ensure consistent results while changing order of input files.
- *DEFINE_SPH_TO_SPH_COUPLING:
  - Corrected the SPH sphere radius (half of the particles distance) for node to node contact detecting algorithm.
  - Updated masses for SPH node to node coupling with damping contact force option.
  - Added a new option (Soft = 1) for SPH to SPH coupling: contact stiffness comes from particles masses and time step for softer contact.
- *DEFINE_ADAPTIVE_SOLID_TO_SPH:
  - Updated temperature transfer (from solid elements to SPH particles) when converting solid elements into SPH particles with ICPL = 1, IOPT = 0.
  - Bug fixed when part ID for newly generated SPH particles is smaller than the original SPH part ID.
  - Introduced a new pure thermal coupling between SPH part and solid parts with ICPL = 3 and IOPT = 0 option (no structural coupling provided).
  - Added a thermal coupling conductivity parameter CPCD. Applies to ICPL = 3 option.
  - Normalized the nodal temperatures for the corner SPH particles with ICPL = 3 and IOPT = 0 option (MPP only).
  - Extended ICPL = 3 and IOPT = 0 option to Lagrangian formulation (form = 7, 8).
- *BOUNDARY_SPH_SYMMETRY_PLANE:
  - Added in an error message if TAIL and HEAD points are at the same location.
- *CONTACT_2D_NODE_TO_SOLID:
  - Added a variable OFFD to specify contact offset.

- Added a new option IEROD = 2 in *CONTROL_SPH in which SPH particles that satisfy a failure criterion are totally eactivated and removed from domain interpolation. This is in contrast to IEROD = 1 option in which particles are partially deactivated and only stress states are set to zero.
- Added *MAT_SPH_VISCOUS (*MAT_SPH_01) for fluid-like material behavior with constant or variable viscosity. Includes a Cross viscosity model.
- Output strain rates for SPH particles to d3plot, d3thdt, and sphout file.
- Added support of *MAT_ADD_EROSION, including GISSMO and DIEM damage, for SPH particles.
- Echo failed SPH particles into d3hsp and messag file.
- *DEFINE_SPH_INJECTION:

  - Changed the method of generating SPH particles. SPH particles will be generated based on the injection volume (injection area*injection velocity*dt)*density from the material model, resulting in more consistent particle masses and particle distribution.
  - Offset injecting distance inside each cycle so that outlet distance will be consistent for different outlet SPH layers.
  - Corrected mass output in d3hsp.

- **Thermal Solver**

  - Modify the thermal solver routines so they return instead of terminating, so that *CASE works properly.
  - *MAT_THERMAL_USER_DEFINED: Fixed bug in element numbering for IHVE = 1.
  - Accept load curve input for dtmin, dtmax and dtemp in *CONTROL_THERMAL_TIMESTEP. As usual if a negative integer number is given its absolute value refers to the load curve id.
  - The temperature results for the virtual nodes of thermal thick shells are now accounted for in *LOAD_THERMAL_D3PLOT. For the mechanics-only simulation thermal thick shells have to be activated.
  - New contact type for thermal solver that models heat transfer from and to a shell edge onto a surface (*CONTACT_..._THERMAL with ALGO > 1):

    - Shells have to be thermal thick shells.
    - Shells are on the slave side.
    - So far only implemented for SMP.
    - Includes support for quads and triangles.

  - New keyword *BOUNDARY_THERMAL_WELD_TRAJECTORY for welding of solid or shell structures.

    - Keyword defines the movement of a heat source on a nodal path (*SET_NODE).
    - Orientation given either by vector or with a second node set.

        - Works for coupled and thermal only analyses.
        - Allows for thermal dumping.
        - Different equivalent heat source descriptions available.
        - Can also be applied to tshells and composite shells.
        - Weld torch motion can be defined relative to the weld trajectory.

    - Solid element formulation 18 now supports thermal analysis.
    - Thermal solver now supports the H8TOH20 option of *ELEMENT_SOLID. This includes support of *INITIAL_TEMPERATURE condition for the extra 12 nodes generated by H8TOH20.
    - Thermal solver now supports the H8TOH27 option of *ELEMENT_SOLID.
    - Explicit Thermal Solver

        - *CONTROL_EXPLICIT_THERMAL_SOLVER: Implement an explicit thermal solver and adapt it to support multi-material ALE cases.
        - *CONTROL_EXPLICIT_THERMAL_PROPERTIES: Enter thermal properties for the explicit thermal solver.
        - *CONTROL_EXPLICIT_THERMAL_CONTACT: Implement a thermal contact for the explicit thermal solver.
        - *CONTROL_EXPLICIT_THERMAL_ALE_COUPLING: Implement a thermal coupling between ALE and Lagrangian structures for use by the explicit thermal solver.
        - *CONSTRAINED_LAGRANGE_IN_SOLID_EDGE: For the explicit thermal ALE coupling, allow the heat transfer through the shell edges if _EDGE is added to *CONSTRAINED_LAGRANGE_IN_SOLID.
        - *CONSTRAINED_LAGRANGE_IN_SOLID: For the explicit thermal solver, add work due to friction to the enthalpies of ALE and structure elements coupled with *CONSTRAINED_LAGRANGE_IN-_SOLID (CTYPE = 4).
        - *CONTROL_EXPLICIT_THERMAL_INITIAL: Initialize the temperatures for the explicit thermal solver.
        - *CONTROL_EXPLICIT_THERMAL_BOUNDARY: Control boundary temperatures for the explicit thermal solver.
        - *CONTROL_EXPLICIT_THERMAL_OUTPUT: Output the temperatures at element centers for the explicit thermal solver.
        - *DATABASE_PROFILE: For the explicit thermal solver, output temperature profiles.

- **Miscellaneous**

    - *INITIAL_LAG_MAPPING: Implement a 3D to 3D lagrangian mapping and map the nodal temperatures.
    - *CONTROL_REFINE_SHELL and *CONTROL_REFINE_SOLID: Add a parameter MASTERSET to call a set of nodes to flag element edges along which new child nodes are constrained.

- *BOUNDARY_PRESCRIBED_MOTION_SET_SEGMENT: Add DOF = 12 to apply velocities in local coordinate systems attached to segments.
- Fixed bug occurring when a part has non-zero *DAMPING_-PART_STIFF-NESS, AND is defined using *PART_COMP-OSITE, AND the MIDs referenced by the different integration points have different material types. Symptoms could include many types of unexpected behavior or error termination, but in other cases it could be harmless.
- *DAMPING_FREQUENCY_RANGE (including _DEFORM option): Improved internal calculation of damping constants such that the level of damping more accurately matches the user-input value across the whole of the frequency range FLOW to FHIGH. As an example, for CDAMP = 0.01, FLOW = 1 Hz and FHIGH = 30 Hz, the actual damping achieved by the previous algorithm varied between 0.008 and 0.012 (different values at different frequencies between FLOW and FHIGH), i.e. there were errors of up to 20% of the target CDAMP. With the new algorithm, the errors are reduced to 1% of the target CDAMP. This change will lead to some small differences in results compared to previous versions of LS-DYNA. Users wishing to retain the old method for compatibility with previous work can do this by setting IFLG (7th field on Card 1) to 1.
- Fixed bug that could cause unpredictable symptoms if Nodal Rigid Bodies were included in the Part Set referenced by *DAMPING_FREQUENCY_-RANGE or *DAMPING_FREQUENCY_RANGE_-DEFORM. Now, the _DEFORM option silently ignores NRBs in the Part Set while *DAMPING_-FREQUENCY_RANGE (non _DEFORM option) damps them.
- Fixed bug in *PART_COMPOSITE: if a layer had a very small thickness defined, such as 1E-9 times the total thickness, that layer would be assigned a weighting factor of 1 (it should be close to zero).
- Fix errors in implementation of *DEFINE_FILTER type CHAIN.
- Fix for *INTERFACE_LINKING_LOCAL when LCID is used. During keyword processing, the LCID value was not properly converted to internal numbering.
- Switch coordinates in keyword reader to double precision.
- Change "Warning" to "Error" for multiply defined materials, boxes, coordinate systems, vectors, and orientation vectors. The check for duplicate section IDs now includes the element type and remains a warning for now, because SPH is still detected as a SOLID. Once that is straightened out, this should be made an error.
- Add "TIMESTEP" as a variable for *DEFINE_CURVE_FUNCTION. This variable holds the current simulation time step.
- Fix a bug for the case of CODE = 5 in *DEFORM-ABLE_TO_RIGID_AUTO-MATIC. (Fields 3 to 8 are now ignored.)
- Issue error message and terminate the simulation when illegal ACTION is used for *DEFINE_TRANSFORM.
- Add option of POS6N for *DEFINE_TRANSFORM to define transformation with 3 reference nodes and 3 target nodes.

- Fix a bug that can occur when adaptive elements are defined in a file included by *INCLUDE_TRANSFORM.
- Merge *DEFORMABLE_TO_RIGID_AUTOMATIC cards if they use the same switch time. This dependency of results on the order of the cards and also gives better performance.
- If *SET_PART_OPTION is used, a "group_file" will be created which can be read into LS-Prepost (Model > Groups > Load) for easy visualization of part sets.
- Forces on *RIGIDWALL_GEOMETRIC_CYLINDER can now be subdivided into sections for output to rwforc. This gives a better idea of the force distribution along the length of the cylinder. See the variable NSEGS.
- Added the keywords *DEFINE_PRESSURE_TUBE and *DATABASE_PRTUBE for simulating pressure tubes in pedestrian crash.
- Fix non-effective OPTIONs DBOX, DVOL, DSOLID, DSHELL, DTSHELL, DSEG for *SET_SEGMENT_GENERAL to delete segments.
- Fix incorrect transformation of valdmp in *DAMPING_GLOBAL with *INCLUDE_TRANSFORM.
- Make *SET_NODE_COLLECT work together with *NODE_SET_MERGE.
- Fixed bug in adaptivity for *INCLUDE_TRANSFORM if jobid is used.
- Bugfix: *INTERFACE_SSI with blank optional card is now read in correctly.

Capabilities added to create LS-DYNA R11:

See release notes (published separately) for further details.

- ***AIRBAG**

  - Fix an airbag bug that can cause MPP to hang when reference geometry is used in a huge model.
  - Limit the EXCP option (excluding application of bag pressure to partition parts) in *AIRBAG_INTERACTION to *AIRBAG_WANG_NEFSKE and *AIRBAG_HYBRID only.
  - Allow no-pressure venting parts for *AIRBAG_WANG_NEFSKE.
  - Output material leakage information, including leakage rate, in abstat for *AIRBAG_WANG_NEFSKE.
  - Allow airbag venting holes of *AIRBAG_HYBRID to be represented by a part set.
  - Enhance the robustness of *AIRBAG_INTERACTION to curtail instability, especially in MPP, due to excessive mass exchange owing to numerical noise.
  - Support UP (uniform pressure) airbag in MPP full deck restart. (We use the equivalent terms UP airbag or CV (control volume) airbag for airbags that are NOT based on ALE or particle (CPM) methods.)

- Treat PPOP for *AIRBAG_WANG_NEFSKE similar to other types of UP airbag - once it pops, it stays open.
- *AIRBAG_CPM_INTERACTION:
  - Support slave bag with chamber definition.
  - Support master/slave bags having multiple gas components.
- New CPM (*AIRBAG_PARTICLE) particle-to-fabric and particle-to-particle contact algorithms. These are about 3x faster than the old scheme and it is the default method without any input modifications.
- Support *SENSOR_SWITCH_SHELL_TO_VENT for SMP.
- New variable TSPLIT in *AIRBAG_PARTICLE to activate particle splitting. Particles that exit by porosity leakage or a vent are removed from the system. If TSPLIT is set, the code keeps track of the number of removed particles (A) and active particles (B) every 200 cycles after time TSPLIT. Once A is greater than B, each active particle will be split into A/B + 1 particles for a better particle density in the volume.
- Enable OpenMP. This allows MPP hybrid to scale better.
- Support the exterior air drag force capability while switching from particle to UP formulation.
- Enable *DEFINE_FUNCTION for user to control the airbag particle deflection angle. Three airbag history variables are passed to the user defined function to control the surface roughness: bag pressure, bag volume, current time.
- Support *MAT_ADD_AIRBAG_POROSITY_LEAKAGE
  - Support FAC in the option can be defined as a factor/define_curve/define_function
  - If defined_function, it only works with vopt 7/8. the porosity leakage velocity is a function of current part pressure and time.
- Support molar-fraction-based inflator gas flow rate curve LCMASS (MOLEFRACTION option) even after particle airbag switches to CV airbag via the TSW switch.
- Enhance dm_out calculation to treat trunction error.
- Support specification of inflator orifice area as function of time to control the distribution of mass flowrate.
- Fix bug affecting particle-to-UP switch for multi-chambered airbag. The bug was introduced in r82352 and showed up if gas contains multi-species.
- *AIRBAG_LINEAR_FLUID:
  - Prior to R11, the tangent stiffness matrix resulting from a pressure-volume relationship in simple airbag models was merely an approximation and sometimes resulted in poor convergence. A justification of the approximation is that a rigorous treatment reveals that coupling

terms between all nodes in bag result in a dense stiffness matrix and slow execution. Exploiting the low rank structure of this matrix contribution and the use of Sherman-Morrison formula, the correct (or at least close to correct) stiffness matrix is now implemented without sacrificing speed and at the same time obtaining much better convergence.

- ***ALE**
  - *ALE_STRUCTURED_MESH_CONTROL_POINTS:
    - If the S-ALE mesh has different mesh sizes and transition zones, suggest new lists of control points to create optimal mesh transitions (the new list is output in the messag file).
  - *ALE_STRUCTURED_MESH:
    - 2D version of the S-ALE code.
  - *ALE_INJECTION:
    - Inject materials in an ALE mesh (i.e. add a group to some elements and prescribe the velocities of the related nodes).
  - *ALE_PRESCRIBED_MOTION:
    - Prescribe or initialize velocities by ALE group.
  - *ALE_FSI_TO_LOAD_NODE:
    - Use the 2nd line for a directory path where to read or write the files with the fsi data (alefsi2ldnd*.tmp*). Implement the restart.
  - *CONTROL_ALE and *SECTION_ALE2D_SMOOTHING
    - mpp version of the AFAC, BFAC, CFAC and DFAC mesh smoothings in the 2D ALE code.
  - *CONTROL_ALE (END < 0, 2nd line, 2nd column):
    - If END < 0 in *CONTROL_ALE, remove the ALE mesh after |END|.
  - *CONTROL_ALE (IALEDR = 1, 4th line, 2nd column) and *CONTROL_DYNAMIC_RELAXATION:
    - Exclude ALE computations if IDRFLG = 1 unless IALEDR = 1.
  - *MAT_ADD_EROSION (IDAM > 0, 1st line, 3rd column):

        - Implement the GISSMO damage model in ALE.
    - *DATABASE_ALE_MAT:
        - Output the volume averaged pressures of each ALE groups
    - *INITIAL_DETONATION and *CONTROL_EXPLOSIVE_SHADOW:
        - Compute the lighting times by ALE explosive groups.
    - *DATABASE_ALE_BINARY:
        - Output ALE data in a binary file that can be post-treated.
    - *CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_ALE_ELEMENTS (ALECOMM = 1, 1st line, 2nd column):
        - Create a MPP communicator for processors involved in ALE applications.
    - Added *ALE_STRUCTURED_MESH_TRIM so initial mesh can be trimmed to better fit the domain of interest.
    - S-ALE mesh starts from a rectangular box and the elements away from the domain of interest are then deleted based on the distance to certain geometry or part/element set. This way S-ALE mesh could be of irregular shape. Fewer elements leads to less running time.
    - Added *ALE_STRUCTURED_MESH_MOTION so S-ALE mesh can be made to follow the motion of the mass center of certain ALE material material(s).
    - Add variable TDEATH in *ALE_STRUCTURED_MESH so S-ALE mesh can be deleted during the run to save running time. All related FSI and nodal coupling cards are automatically deleted too.
    - Fix bugs affecting S-ALE (*ALE_STRUCTURED_MESH):
        - Fix sometimes improper volume fraction initialization by *INITIAL_VOLUME_FRACTION_GEOMETRY when using with ESORT = 1 in *CONTROL_SOLID.
        - Fix sometimes incorrect effect of *INITIAL_HYDROSTATIC_ALE and *ALE_AMBIENT_HYDROSTATIC when using with ESORT = 1 in *CONTROL_SOLID.

- ***BOUNDARY**
    - Speedup the input error checking for *BOUNDARY_PRESCRIBED_MOTION.

- Fix *BOUNDARY_PRESCRIBED_ORIENTATION_RIGID_DIRCOS which did not orientate the rigid body when angles are close to PI when using double precision.
- *BOUNDARY_CYCLIC is supported in selective mass scaling (*CONTROL_TIMESTEP).
- *BOUNDARY_SPC_SYMMETRY_PLANE:
  - Add a new option _SET.
  - Allow more than two definitions of symmetric planes.
  - Fix core dump when *BOUNDARY_SPC_SYMMETRY_PLANE, and *ALE_MULTI-MATERIAL_GROUP are used together.

- **Blast**
  - For *LOAD_BLAST_ENHANCED BLAST = 4, apply blast pressure to segments which reside below the ground plane with new parameter FLOOR. This allows blast pressure to be applied to a deformable floor which deflects below the ground plane, and accommodates floors which are not planar.
  - Implement blast particle-SPH coupling algorithm as invoked by variable NODID in *DEFINE_PARTICLE_BLAST (SMP). The SPH smoothing length is taken into consideration.

- **CESE**
  - Added a new prescribed boundary condition card that allows a normal velocity to be specified in the inlet boundary.
  - Added a positivity-preserving strategy for the spatial derivatives calculations to make the solver more stable (currently only CESE 2D, 3D, and CESE-FSI-IBM 2D solvers are supported).
  - Made it a fatal error to attempt to use *LOAD_BLAST_ENHANCED as a CESE boundary condition with other than a type-2 blast.
  - Improved error tolerances in the conjugate heat transfer method solver used with the immersed-boundary method FSI solver, and corrected other small related errors.
  - Any unused nodes specified in a standalone CESE problem are now treated as a fatal error. This fixes an issue with d3plot output when such orphan nodes were passed on to the d3plot file.
  - Corrected some weightings for the MPP CESE moving mesh solvers. This could have been an issue in cases where an MPP CESE shared node is next to a moving boundary.
  - Adjusted the information output by the implicit ball-vertex mesh motion solver to reflect that the absolute error tolerance is no longer used, only the relative error tolerance. This applies to both the ICFD and CESE solvers that use this mesh motion solver.
  - For the *CESE_DATABASE cards, corrected these issues:

        - Any used segments that are not in the CESE mesh are reported.
        - Element sets look up is now guaranteed to work.
        - Drag calculation output that is attempted for the incorrect FSI method, is now reported. Here are the illegal cases:
            - *CESE_DATABASE_FSIDRAG is only available with the CESE immersed boundary FSI solvers.
            - *CESE_DATABASE_SSETDRAG is not available with the CESE immersed boundary FSI solvers. In other words, it only works with the non-FSI solvers and moving mesh FSI solvers.
        - Failure to find an internal node number in *CESE_DATABASE commands is now reported.
        - Output was not being performed for the initial conditions. Instead, it is now done after the first time step.
        - Warning is given when illegal IDs are given in *CESE_DATABASE... cards. Such IDs are then ignored.

    - Changed behavior for the *CESE_DATABASE cards includes:

        - Output times are now selected in a manner similar to CESE d3plot output, meaning when the CESE simulation time has reached at least the requested output times. Also, output never occurs more than once per CESE time step.
        - Cycle number was reported in some outputs as the 'time step'. The actual solver time step is now used instead.

    - When performing d3plot output for the immersed boundary CESE FSI solver, take into account what structural elements overlay CESE elements for the Schlieren number and chemical species mass fractions.
    - Formation enthalpy concept is added to the CESE Navier-Stokes solver.
    - Many restart-related bugs were fixed in various CESE solvers.

- ***CHEMISTRY**

    - The chemistry solvers are working with the following CESE solvers:

        - 2D, 3D, and axi-symmetric Euler and Navier-Stokes solvers.
        - Immersed boundary method FSI 2D, 3D, and axi-symmetric Euler solvers.

    - Added a restart capability for the CESE chemistry solvers.

- **CONTACT**

    - Fix initialization error related to *CONTACT_GENERAL_INTERIOR that resulted in every subsequent *CONTACT_GENERAL also being treated as INTERIOR.

- Fix for spotwelds improperly deleted due to rigid body conflict when an IPBACK contact interface is in effect. The failure of the constraint-based contact to tie should not cause the weld to be deleted if the penalty-based contact ties.
- Fix reported contact forces and energies for *CONTACT_-TIED_SHELL_-EDGE_TO_SOLID.
- Fix bug for *CONTACT_ERODING_NODES_to_SURFACE. The slave nodes' thickness was ignored, which was problematic for SPH simulations, for example. SST is now taken into account for this contact.
- Fix a problem with SMOOTH contact during implicit springback.
- Enhance implicit processing of tied contact and rotational dofs on slave nodes for special cases with *CONTACT_..._CONSTRAINED_OFFSET.
- Adjust logic for unconstraining rigid body slave nodes for SMOOTH contact to be compatible with deformable to rigid switching.
- Enable the use of *CONTACT_FORMING_..._SMOOTH for implicit.
- Fix the problem of tied contact in MPP having a slave node from another process working with new approach for tied contact.
- Correct initialization of MPP tied contact with implicit mechanics when explicit is running dynamic relaxation followed by implicit.
- Fix a bug in assignment of contact thickness for null beams. This bug was introduced at r89658/R9.
- Add variable 2DBINR (Card F) for surface-to-surface contact involving 2D seatbelt elements initially inside a retractor. This is only available for SOFT = 2 contact.
- Fix a bug for contact involving high order shell elements that occurs when 8-node shell elements are generated by SHL4_TO_SHL8, or when using large part id like 100000001.
- Add an alternative implementation of ICOR (coefficient of restitution) for contact. The algebraic sign of ICOR determines which implementation is used.
- Command line option, soft = 1to2 converts all possible contacts from soft = 1 to soft = 2
- Command line option, soft = 2to1 converts contacts from soft = 2 to soft = 1
- Fix *CONTACT_AUTOMATIC_GENERAL for spotweld beams when using SSID = 0, i.e. all parts included in the contact, and CPARM8 = 2.
- Implement unloading curve, UNLCID, for options FCM = 2/3 in *CONTACT_RIGID_(OPTION).
- Fix zero frictional energy output to glstat and sleout when using *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_ORTHO_FRICTION.
- Implement SMP consistency mode, i.e. ncpu < 0, for:
  - *CONTACT_SURFACE_TO_SURFACE_CONTRACTION_JOINT
  - *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_COMPOSITE

- Fix seg fault when using *CONTACT_AUTOMATIC_NODES_TO_-SURFACE for SPH elements impacting on shell plate.
- Fix *DEFORMABLE_TO_RIGID switching using contact forces, CODE = 2 & 4, when the contact type is *CONTACT_FORCE_TRANSDUCER.
- Fix zero contact stiffness if *EOS_TABULATED is using curve LCC instead of tabulated input cards.
- Allow *CONTACT_TIED_SURFACE_TO_SURFACE to use MAXPAR in Optional Card A. It was previously hardcoded to 1.01.
- Implement edge treatment option SRNDE = 1,2 (Optional Card E) for *CONTACT_AUTOMATIC_NODES_TO_SURFACE.
- Fixed MPP segment based (SOFT = 2) contact when used with 2-surface force transducers. Output data may have been incorrect due to errors in accessing arrays. This error occurred when different processors participate in different contact interfaces.
- Fixed MPP implicit SOFT = 2 contact which was failing to properly reset the segment and node data from a converged state leading to possible "floating invalid" error or possible convergence failure.
- Fixed an MPP SOFT = 2 contact problem that could occur if a contact interface used SBOXID to eliminate slave segments. This could cause a segmentation fault during initialization.
- Fixed a possible memory error during initialization of SOFT = 2 contact, when using DEPTH = 5, 15, 25, or 35 or SBOPT = 4 or 5.
- Fixed an error in MPP SOFT = 2 eroding contact that could cause force spikes and inappropriate contact detection after solid elements erode.
- Fixed an error in SOFT = 2 eroding contact that caused the contact to fail to create new segments on interior elements when there were no active segments at the start of the run. This error was most likely to occur in MPP runs when a decomposition can result in a process that has no active segments at the start of the run.
- Changed the behavior of SOFT = 2 contact when the contact keyword indicates a surface to surface contact, but the master surface has no segments. In older versions, the contact would use the slave segments and do a single surface contact with them. Going forward, the contact will not do anything because the slave surface has nothing to contact.
- Fixed some contact options when using linear 3D solids or linear shell elements in implicit analysis. These element were causing a zero explicit time step, and some contacts use this explicit step in the denominator of the stiffness matrix. These include SOFT = 1, SOFT = 2, and tied, penalty-based contacts.
- Added a gap calculation to SOFT = 2 contact. The gaps are written to the binary interface force file. This is supported for both SMP and MPP. Overlaps are reported as negative gaps.
- Fixed a flaw in the support of SSF on *PART_CONTACT when using SOFT = 2 contact with DEPTH = 5. The consequence was to sometimes

choose the wrong part when looking up the scale factor so the stiffness was not predictable.

- Added variable SSFTYP on card F of *CONTACT which affects how SSF on *PART_CONTACT works when used with SOFT = 2 contact. By default, the contact chooses a master segment for each pair of segments in contact. The SSF factor is then taken from the slave segment. When SSFTYP is set to 1 (or any nonzero value), it changes the behavior so the maximum SSF value of the 2 segments in contact will be used. The contact stiffness is therefore independent of how the contact chooses master and slave segments.
- Fixed MPP *PART_CONTACT when used with SSF. It was possible for SSF to be incorrectly taken as zero, so penetration would occur.
- Improved the accuracy of *CONTACT_2D_AUTOMATIC contact. For problems where penetration depths are small, there was an accuracy issue that could cause contact forces to be set to zero in cycles when they should not have been, which could cause a loss of contact history. Because the penetrations are small, the results look about the same, but the contact pressure history is smoother.
- Fixed *CONTACT_2D_AUTOMATIC so it will correctly add new segments when elements using *MAT_081 or*MAT_082 are used for an eroding part.
- Fixed *CONTACT_2D_AUTOMATIC_TIED which could could fail if more than 1 tied contact was used in a model.
- Fixed the sliding option, ISLIDE, of *CONTACT_2D_AUTOMATIC type contacts in both SMP and MPP.
- Fixed MPP *CONTACT_2D_AUTOMATIC_SINGLE_SURFACE and *CONTACT_2D_AUTOMATIC_SURFACE_TO_SURFACE which had a problem in the bucket sort where the buckets may have been too small if segments passed from other processors were larger than the segments already in the processors. This could cause some contact to be missed. It could also cause the job to terminate with Error SOL+1274 if the passed segments are large enough such as can occur with shooting nodes.
- Added an option to offset the contact surface segments attached to 2D solid elements in *CONTACT_2D_AUTOMATIC. The option is controlled by two new parameters, SLDSOS and SLDSOM, on new optional card 5. If the card is omitted, or SLDSOS or SLDSOM are input as zero, then there is zero offset which has always been assumed for surfaces of solids. If input with a value greater than zero, then the offset is set equal to the input value. This behavior is not consistent with the 3D SLDTHK option, which uses half the input value, but it is consistent with the negative value option of SOS and SOM on card 2 which uses the input value, not half of it.
- Add option NEHIS to *USER_INTERFACE_FRICTION:

    - With NEHIS = 0 (default), special choice of element history variables is provided in subroutine usrfrc, see comments there.
    - With NEHIS > 0, plastic strain and element history variables up to NEHIS-1 are provided in original order in subroutine usrfrc.

- Add new *CONTACT_AUTOMATIC_..._TIEBREAK model OPTIONs 13 and 14, which are based on *MAT_240.
- Allow unlimited number of history variables for user-defined tiebreak, *CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIE-BREAK_USER.
- IGNORE = 2 on *CONTACT_..._MORTAR is set to default to avoid unnecessary bad behavior.
- If ISYM < 0 on *CONTROL_CONTACT, this will point to a node set containing all nodes on symmetry planes in the model, which will be picked up by the mortar contact and treat edge treatment accordingly.
- If MPAR1 < 0 on *CONTACT_..._MORTAR for IGNORE = 3, this will govern the penetration reduction as a function of a curve.
- If SLDTHK < 0 on *CONTACT_..._MORTAR, the contact surface is offset "inwards", previously only a positive value was supported.
- Implicit tied contacts (strong objective) supported for groupable option, which is necessary when running a coupled thermal/mechanical simulation.
- User friction supported in mortar contact, see *USER_INTERFACE_-FRICTION. The subroutine is called mortar_usrfrc and found in dyn21.F.
- FS = 2 on *CONTACT_..._MORTAR supported, allowing friction as function of sliding velocity and contact pressure in mortar contact.
- For large penetrations in mortar contact during implicit analysis, the step will be abandoned and a retried with a smaller time step.
- *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR_TIED_-WELD supported, SMP and MPP, particularly intended for implicit.
- When mortar tied contact is used with shells, offsets are accounted for to induce a moment from tangential tractions in the interface.
- In mortar contact, let PENMAX and SLDTHK take over the meanings SST and TKSLS have in R9 and earlier, although in a different way. Now PENMAX corresponds to the maximum penetration depth for solids. SLDTHK is used to offset the contact surface from the physical surface of the solid element, instead of playing with SST and TKSLS, which was rather awkward. This update also saves the pain of having to treat shells and solids in separate interfaces if these features are desired.
- A "shooting node logic" algorithm is implemented for mortar contact and is always active. This should reduce the presence of negative sliding energies when run in explicit and also improve initial penetration situations in implicit.
- The MPP groupable contacts include all eroding contacts, i.e.

    - *CONTACT_ERODING_NODES_TO_SURFACE
    - *CONTACT_ERODING_SURFACE_TO_SURFACE
    - *CONTACT_ERODING_SINGLE_SURFACE.

- The MPP groupable contacts include beam-to-beam treatment in *CONTACT_AUTOMATIC_GENERAL. It supports rectangular beams, and output of contact forces to rcforc for an accompanying 2-sided force transducer.
- The MPP *CONTACT_AUTOMATIC_SINGLE_SURFACE_TIED is implemented and supports parameter CLOSE.
- MPP's *CONTACT_AUTOMATIC_BEAMS_TO_SURFACE_ID now supports the contact of slave beam nodes from both sides of the master surface.
- Fix incorrect *INITIAL_STRESS data written to dynain in MPP when np > 1.
- *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE:
  - Improve SOFT = 6 behavior. In guide pin contact, consider the pin's curved edge, therefore overcome the false penetration problem.
- *CONTACT_FORMING_NODES_TO_SURFACE_SMOOTH:
  - Allow segment definition, in addition to part or part set ID.

- ***CONSTRAINED**
  - Fix MPP message passing error that could occur if a node involved in *CONSTRAINED_SHELL_TO_SOLID is shared between more than 2 processors.
  - *CONSTRAINED_GLOBAL: Added user-defined tolerance parameter TOL in length units. If non-zero, the internal mesh-size dependent tolerance gets replaced by this value.
  - Added option to continue a calculation with constrained interpolation after an independent node is deleted using INDSW in *CON-STRAINED_INTERPOLATION.
  - Fix to exactly singular constraint matrix for *CONSTRAINED_-INTERPOLATION running in fast/vector mode.
  - Correct MPP communication during the detection of co-linear nodes in *CONSTRAINED_INTERPOLATION.
  - Add additional error checking on coincident nodes for revolute and screw joints.
  - Promote linear algebra processing for *CONSTRAINED_INTERPOLATION in explicit single precision to real*8 to remove round-off accumulation errors.
  - A more robust solution to the processing of birth and death times for prescribed motion constraints for the LaGrange Multiplier Formulation of joints for explicit.
  - Add implicit capabilities pertaining to UNITCELL:
    - Always unconstrain the last 3 nodes in input and output if they are referenced in *CONSTRAINED_MULTIPLE_GLOBAL constraints. These are control points for UNITCELL.
    - At the end of implicit time step always go through the computation to compute the resultant forces. If there are *CONSTRAINED_-MULTI-

PLE_GLOBAL constraints, output the resultant forces on the last 3 nodes.

- Enhance nodal constraint handling for superelements using explicit to properly handle the implicit/explicit switching case. I also extended the code to recognize *BOUNDARY_SPC definitions instead of just those on the *NODE cards.
- The logic to handle *CONSTRAINED_INTERPOLATION with large number of independent nodes extended for *CONTROL_IMPLICIT_MODES.
- Implicit was enforcing birth and death times on *BOUNDARY_SPC during dynamic relaxation contrary to the manual. So such times are now ignored with dynamic relaxation.
- Added a warning about the combined use of rigid body stoppers and the lagrange multiplier formulation of joints for explicit recommending switching to the penalty formulation.
- Corrections to get implicit to work with *CONSTRAINED_-INTERPOLATION with lots of independent nodes especially in MPP.
- *CONSTRAINED_BEAM_IN_SOLID:
  - Add _PENALTY option to invoke a penalty-based formulation (implicit and explicit).
  - Implicit support for IDIR = 1 (allow sliding along axial direction).
  - Implicit support for AXFOR (user prescribed debonding force between beam and solid).
  - Thermal solver recognizes *CONSTRAINED_BEAM_IN_SOLID by constraining temperature fields between beam and solid nodes.
  - Write LSDA format output file named "cbisfor" containing debonding force (constraint-based) or penalty force (penalty-based).
- Add two keywords *CONSTRAINED_SHELL_IN_SOLID and *CONSTRAINED_SOLID_IN_SOLID, which are similar to *CONSTRAINED_-BEAM_IN_SOLID, but are used to couple shells immersed in solids and solids immersed in solids, respectively.
- Fix a bug affecting *CONSTRAINED_LOCAL whereby z-translation was mistakenly constrained when IRC = 0.
- Fix a bug for PIDCTL of *DEFINE_CURVE_FUNCTION, that occurs when using "0" as sampling rate.
- *CONSTRAINED_SPOTWELD:
  - Enable the normal and shear forces at spotweld failures to be temperature-dependent functions.
- Allow the same part to be used in SPR connections, i.e., MID and SID can now match in *CONSTRAINED_SPR2 or rather PID1 and PID2 can match in *CONSTRAINED_INTERPOLATION_SPOTWELD. The requirement for

this is that the SPR node lies in between the shell elements to be self-connected.

- *CONSTRAINED_INTERPOLATION_SPOTWELD, MODEL = 1, can now be used as connection of two beam nodes.
- Several updates for *CONSTRAINED_INTERPOLATION_SPOTWELD (new card 5):
  - Incorporate torsion mode with GAMMA > 0.
  - Allow definition of separate stiffnesses STIFF, STIFF2, STIFF3, and STIFF4 for tension, shear, bending, and torsion.
  - Optional exponential damage law via LCDEXP.
  - Alternative shear kinematics treatment, parameter SROPT.
  - Output of history variables with NEIPB = 7 on *DATA-BASE_EXTENT_BINARY.
- Add GISSMO damage as failure variable for *CONSTRAINED_TIED_NODES_FAILURE.
- Fixed bug in processing *CONSTRAINED_NODAL_RIGID_BODY and *PART_INERTIA so code does not abort with a bogus "Error 10144".
- *CONSTRAINED_COORDINATE:
  - Fix a machine dependent error when the input coordinates are far away from the part.
  - Extend to rotational constraints. The constraint will be appled to the closest node.
    When IDIR > 10, IR = IDIR-10:
    IR = 1, constrain rx
    IR = 2, constrain ry
    IR = 3, constrain rz
    IR = 4, constrain rx+ry
    IR = 5, constrain ry+rz
    IR = 6, constrain rz+rx
    IR = 7, constrain rx+ry+rz
  - Fix a segmentation fault problem when IDIR is greater than 10.
- *CONSTRAINED_RIGID_BODY_STOPPERS:
  - Extend to have multiple rigid body stoppers for one single rigid body.

- **CONTROL**
  - *CONTROL_REFINE_SOLID and *SECTION_SOLID (ELFORM = 2):
    - Support fully integrated S/R solids.
  - *CONTROL_REFINE_... (IBOX, 1st line, 5th column):

- Implement *DEFINE_BOX_LOCAL and *DEFINE_BOX_ADAPTIVE to refine elements checking criteria provided by these box keywords.

- *CONTROL_ADAPTIVE (ADPTYP = 8, 1st line, 3rd column) and *SECTION_SHELL (ELFORM = 12):

  - Map the plain stress shell thicknesses for the 2D adaptive remeshing

- Staged construction (*CONTROL_STAGED_CONSTRUCTION, *DEFINE_STAGED_CONSTRUCTION_PART):
- Change the behaviour when a part is added.
  Previously, the stiffness and strength of the part would ramp up gradually according to ramp time ATR on *DEFINE_CONSTRUCTION_STAGES. Now, the stiffness and strength have their full value immediately at the start of the stage when the part becomes active (STGA). The reason for the change is to prevent unrealistic deformations occurring while the part is only partially stiff. The same change applies if a part is added using STGA on *LOAD_STIFFEN_PART. There is no change to gravity loading associated with *DEFINE_STAGED_CONSTRUCTION_PART: when a part is added, the gravity load still ramps up according to ramp time ATR. Nor is there any change to the behaviour during part removal.
- Other updates to Staged Construction are:

  - Enabled _TITLE option for *DEFINE_CONSTRUCTION_STAGES and *DEFINE_STAGED_CONSTRUCTION_PART. The titles are ignored by LS-DYNA and are used only in pre-processing. Previously, adding _TITLE would have caused an input error.
  - Fixed bugs in energy balance output for staged construction (*DEFINE_STAGED_CONSTRUCTION_PART and also *LOAD_STIFFEN_PART and *LOAD_GRAVITY_PART). The internal energy was wrongly calculated for dormant parts, and the gravity loading could sometimes be missing from the external work calculation, depending on the other contents of the model. These bugs affected the energy outputs (e.g. in glstat file) but did not affect the other results (stress, displacement, etc).
  - Fix bug in dynain file related to the format of *INITIAL_PWP_NODAL_DATA card, which is written if the model contains *CONTROL_PORE_FLUID. The resulting dynain file could not be read into LS-DYNA.
  - *DEFINE_CONSTRUCTION_STAGES have option inputs RTS, RTE ("real time" at start and end of stage). This is intended to enable an "accelerated analysis" in which processes that really take days or weeks can be modelled in seconds of analysis time. These inputs previously had no effect, they were present only to help the user understand the

times in the input file. Now, "real times" will be written to the output files in place of analysis time.
- Fixed bug that occurred with *CONTROL_STAGED_CONSTRUCTION if Dynamic Relaxation was also switched on. Staged construction is compatible with D.R. only if the analysis begins at the first stage (i.e. time = 0). If not, D.R. now gets switched off automatically and a warning is issued.
- Enabled *LOAD_GRAVITY_PART for tshells.

- **CONTROL_ADAPTIVE**

  - Fix to avoid seg fault in R-adaptivity if 2*(number of shells) > 3*(number of nodes).
  - Fix problem with 2d adaptivity and boundary merging. Some boundary points between materials weren't merged in some cases, depending on where the program thought the 2d contours started. This only applies for *CONTROL_ADAPTIVE ADPTYP = 8 with mmm2d = 1.
  - Fix excessive memory growth during adaptive problems, and reduce memory requirements overall.
  - Generate input error message if *DEFINE_FILTER is used together with *CONTROL_ADAPTIVE, because these filters just won't work with adaptivity.
  - Increase the size of some statically allocated arrays so that larger 2d adaptive problems can be run.
  - *CONTROL_ADAPTIVE:

    - Added Card 5 with only one input variable called INMEMORY.
      EQ.0: conventional out of core shell adaptivity
      EQ.1: in-core shell adaptivity with load rebalancing.

  - *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS:

    - The VID of the rotating axis can now be defined by both *DEFINE_VECTOR and *DEFINE_VECTOR_NODES. It enables the movement of the rotating axis. Previous verion only use *DEFINE_VECTOR to define the VID.
    - The rotational dynamics can work in MPP now.

  - Added variable ICRFILE in *CONTROL_OUTPUT so that nodes sets and element sets associated with *DATABASE_CROSS_SECTION are written to a file to facilitate checking of the cross-section definition.
  - The adaptive element size range defined by RMIN/RMAX in *DEFINE_BOX_ADAPTIVE can now be out of the range defined in *CONTROL_REMESHING for 3D adaptivity.
  - *CONTROL_ADAPTIVE:

        - Add warning message that IREFLG is not supported in 3D adaptivity (ADPTYP = 7).

    - *CONTROL_ADAPTIVE:

        - Add a new feature to the adaptivity of sandwich part: allow multi-layers of solid core to be refined.
        - Support the refinement of 6-node solid elements in the refinement.
        - Fix a bug in the output of 'adapt.msh': an extra blank line was output in *ELEMENT_SHELL_THICKNESS.
        - Fix a duplicate beam error with adaptivity involving beam elements.

    - *CONTROL_ADAPTIVE_CURVE:

        - Fix a bug where the refinement width control was not functioning properly.

- **Discrete Element Method**

    - Switch material type from rigid to elastic for DEM.
    - Enhance MPP's particle-DEM coupling algorithm for *PARTICLE_BLAST.
    - Fix bug if de_massflow_plane and interface force file for *DEFINE_DE_TO_SURFACE_COUPLING are both defined.
    - Fix MPP bug for *PARTICLE_BLAST if some processors contain solid elements while other processors have no solid elements.
    - Fix bug for *PARTICLE_BLAST if solids are used as geometry for HE particles.
    - Implement rebalancing algorithm for *PARTICLE_BLAST, the performance of particle-particle contact and particle-structure contact is increased by ~10~30 times for hundreds of cores----MPP only.
    - Fix bug for *DEFINE_DE_MASSFLOW_PLANE output error if multiple planes are defined.
    - Fix bug for *DEFINE_DE_INJECTION if multiple injection planes are defined.
    - Implement eroding coupling between particle and structure (shell/solid) for *PARTICLE_BLAST. New surfaces of eroded solid parts are taken into consideration.
    - Fix MPP bug when detonation point is defined using a node for *PARTICLE_BLAST.
    - Fix wear depth calculation error for DEM interface force file (MPP only).
    - Skip *PARTICLE_BLAST calculation during dynamic relaxation phase.
    - Fix MPP bug when there are multiple *PARTICLE_BLAST definitions.
    - Add calculation of coordination number for DEM in MPP.
    - Add automatic bucket sort for *DEFINE_DE_TO_SURFACE_COUPLING.
    - Reformulate particle injection algorithm for MPP such that particles with different radii can be injected.

- Add birth time and death time for *CONTROL_DISCRETE_ELEMENT.
- Fix bug in calculation of capillary force for *DEFINE_DE_-TO_SURFACE_-COUPLING.
- Fix bug for capillary force calculation if DEM model has zero potential contact pairs but non-zero capillary force.
- Implement DEM mass output to interface force file for *DEFINE_DE_TO_-SURFACE coupling.
- Add mass output for demrcf.
- Add moment output to demrcf (SMP only).
- Report damping energy for DE non-reflecting boundary conditions.
- Implement explicit thermal modeling of DES (SMP only).
- Implement user defined curve to get mass flow rate for *DEFINE_DE_IN-JECTION.
- Fix minor bug for *DEFINE_DE_TO_SURFACE_COUPLING when the thickness of shell is much larger than segment size.

- **EFG (Element Free Galerkin)**

  - Variables STRFLG and INTOUT in *DATABASE_EXTENT_BINARY can now be turned on when using 3D adaptivity on EFG solid.
  - Special decomposition is implemented for EFG shell formulation 41 to avoid the memory error in MPP.
  - Automatically set IPS = 0 (no pressure smoothing) for EFG solid formulation 41.
  - *MAT_076 is now supported for EFG shell formulation 44.
  - Fixed incorrect stresses in:

    - Plane strain EFG formulation (shell type 43) in both explicit and implicit,
    - Axisymmetric EFG formulation (shell type 44) in explicit.

- ***ELEMENT**

  - *INTEGRATION_BEAM with different PIDs at each integration point: this was an existing capability, but the time step calculation was overly conservative for cases where the section contained a small proportion of a stiffer material, such as the reinforcement in reinforced concrete. For the same reason, LS-DYNA could add large amounts of mass-scaling unnecessarily. The time step calculation has been improved to remedy this.
  - Fixed bug for beam elements ELFORM = 2: with certain combination of inputs only, the output forces and moments could be wrongly rotated about the beam axis. This affected the output forces only, not the solution inside LS-DYNA. The error could take two forms: (a) if IST on *SECTION_BEAM is non-zero, the output forces and moments are supposed to be rotated into the beam's principal axis system, but this rotation could be applied to the

wrong beam elements; and (b) when no ELFORM = 2 elements have IST, but the model also contains beams with ELFORM = 6 and RRCON = 1 on the SECTION_BEAM card, some of the ELFORM = 2 elements could have their output forces and moments rotated by one radian. These bugs are now fixed.

- Speed up keyword for some models that use lots of *ELE-MENT_SOLID_-TET4TOTET10 due to too many memory allocation calls.
- *SECTION_BEAM: Added a flag ITORM for improved representation of torsional modes which can be activated (ITORM = 1) only if an eigenvalue analysis is performed and which applies only to beam type 13. If ITORM is not active (ITORM = 0) the torsional inertia from structural analysis is used which may result in too large eigenvalues related to torsional modes.
- Added cubic solid element formulations 27,28,29 (*SECTION_SOLID).
- Added section forces for higher order solid elements.
- Added element deletion capability for higher order elements.
- Correct issue with prescribed motion on superelements for explicit mechanics.
- Enhance the application of damping to superelements for explicit.
- Tune up output of consistent elemental mass matrices. Needed to capture the lumped mass terms that had been removed. This code changes output of the elemental mass matrices to include the lumped terms.
- Enhance *ELEMENT_DIRECT_MATRIX_INPUT where the matrices for the same superelement do not match in order.
- SEATBELT:

    - Fix MPP bug that could occur where there is more than one type-9 seatbelt pretensioner.
    - Fix misprinted section number and material number for 2D belt error message.
    - Limit the bending stiffness of *MAT_SEATBELT to implicit analysis only. Warning will be issued when non-zero bending stiffness is defined for explicit analysis.
    - Fix a MPP bug whereby incorrect belt material length information is output to d3hsp.
    - Fix a bug that occurs when time-dependent slipring friction is used for 2D belts.
    - Fix erroneous 1d seatbelt slipring message that has been there since version R8.0.0.
    - Enhance *DATABASE_RECOVER_NODE so that it works for shell form 23 with 3x3 integration.

- *USER_NONLOCAL_SEARCH:

    - Provides an interface for gathering the history data of specified elements that surround a “master” element to average (or smooth) the

history data of the master element. The surrounding elements are determined using a user defined strategy. The type of averaging is also user specified. Currently this keyword only works for solid elements.
- supports solid form 1, 16, 19, 21
- supports _ORTHO to search in material local abc directions
- enables user to define a nonlocal search in ellipsoid shape

- Added cohesive element formulation -29 that defines the cohesive midlayer from the average of surrounding shell normals. This fomulation is better suited for simulating normal shear.
- Fixed absence of part mass in d3hsp for cohesive shell element formulation 29.
- Fix memory error when using *NODE_THICKNESS_SET and also fix node set not found error when using *NODE_THICKNESS_SET with *SET_-NODE_INTERSECT.
- Make *TERMINATION_DELETED_SOLIDS work with hex spot weld failures.
- Fix seg fault when using shell type 15, axisymmeteric volume weighted, with *MAT_EROSION and also materials with equation-of-states.
- Fixed implicit accuracy when using higher order shell form 23. The element was
  forced to use 3x3 integration but now supports both 2x2 and 3x3.
- Modified discrete beam form 6 when it is defined with rotational stiffness, but no rotational damping. This change adds a small amount of damping to prevent beams from excessive oscillations which can cause error in the element strain measure.
- Fixed the NREFUP option (*CONTROL_OUTPUT) when the ORIENTATION option of *ELEMENT_BEAM is not active and some other options are not active. The NREFUP option is available for beam types 1, 2, 11, 12, and 14.
- Fixed the thinning of shell form 24 which was thinning about 33% more than it should under large tensile strain.
- Enabled adaptive tet meshing (ADPTYP = 7 on *CONTROL_ADAPTIVE) to work for any reasonable solid element form at the start of the calculation. Previously, the part could only be tet meshed with form 13 elements, or else EFG solid elements 41 or 42, or the job would crash at the first remap step. Now it should work with any structural element form.
- Improved the accuracy of tetrahedral solid form 13. During rigid body translation, some pressure could develop. Now it can translate pressure free, and therefore stress free.
- Fixed beam elements when some elements in a part use *ELE-MENT_-BEAM_ORIENTATION, and some do not. The affected beam forms are 1, 2, 11, and 14.
- Modified the behavior of isotropic materials that are used in composites that are modeled with tshell form 5. The oscillation check on the thickness stress

was modified to directly check stress rather than a total strain. For nonlinear materials, this is more reliable as it was possible to miss the oscillations when checking strains. This should have little effect on most solutions.

- Fixed tshell forms 5 and 7 when used with total Lagrangian material models such as *MAT_002. Large rotations were leading to incorrect strains and stresses.
- Fixed tshell form 3 when used with the hyperelastic materials. The L matrix was in the global coordinate system instead of the local system.
- Changed the d3hsp output of 3-node triangular shell elements so that zero thickness is reported for node 4. The inputted node 4 value was being output and included in the element thickness calculation, but now it is ignored.
- Fixed output of membrane shell form 5 when used with materials other than 34 and 134. The stress and history data written to the d3plot file was wrong.
- Fixed the behavior of CDL and TDL on *SECTION_DISCRETE when one of the nodes is constrained by an SPC. Also, corrected the deforc output when CDL and TDL limits are reached.
- Fixed the strain output in eloutdet for higher order shell form 23.
- Improvement of error checking of cohesive elements (solid forms 19/20/21/22). In addition to checking for adjacent elements (shells, tshells or solids), we now check for being part of a tied contact definition. This eliminates a lot of unnecessary warning messages.
- Fixed adaptivity (and restart) for tetrahedral solid formulation 13 by porting nodal averaged data between adaptive steps. Before this fix, spurious peaks in cross-section forces could occur and be mistaken for contact pressure peaks.
- Add new option for *PART_STACKED_ELEMENTS to deal with in-plane composed reference mesh parts. Must be used together with *NODE_-MERGE_-SET.
- Add cross section forces (*DATABASE_SECFORC) for 20-node and 27-node hexas, i.e., solid forms 23 and 24.
- Add variable ITOFF in *SECTION_BEAM to control torsion behavior for spotweld beams (beam form 9).
- Improve time step estimate for 10-noded tet form 16 with "curved" edges to improve robustness.
- Add variable ICRQ = 2 on *CONTROL_SHELL to only treat thickness continuously across element edges. This is an alternative to ICRQ = 1 which treats both thickness and plastic strain continuously across element edges.
- For higher order shells, the body loads account for shape functions when assembling nodal forces.
- The kinematics for warped/hourglassed cohesive solid forms 20/22 are now corrected so that rigid body motion should give zero eigenvalues.
- If IACC = 1 on *CONTROL_ACCURACY, 6-node quadratic shell form 24 is treated
- According to Martin & Breiner for alleviating membrane and shear locking.

- If IBEAM on *CONTROL_IMPLICIT_EIGENVALUE is set to 2 or 13, then beam formulations 1, 4 and 5 undergo section conversion from an integration rule to resultant properties.
- Fixed error for reading *ELEMENT_SHELL_OFFSET_COMPOSITE.
- Fix parsing errors in *SECTION_BEAM_AISC.
- Fix error in reading of user-defined shell elements.
- A new 4-node tetrahedral solid element (ELFORM = 60) is implemented to support mixed materials. The volumetric locking is eliminated without nodal averaging.

- **EM (Electromagnetic Solver)**

  - EM Analysis developments are divided into several subcategories below.
  - Batteries

    - Added 2 extra variables in d3plot in EM_FEMSTER_NODE for batteries:
      D3PL_RAND_areaCircuit_EM
      D3PL_RAND_areaCell_EM
    - For local area of each Randle circuit and global area of the cell.
    - Added meshless Randle model, see *EM_RANDLES_MESHLESS.
    - Fixed bugs for addition of joule heat rate in meshless Randle.
    - Added battery model with composite tshells.
    - Switched from *EM_CIRCUIT_RANDLE to *EM_BATTERY_-RANDLES for solids and *EM_RANDLE_LAYERED for composite tshells.
    - In *EM_BATTERY_RANDLES, *EM_RANDLE_LAYERED and *EM_-RANDLE_SHORT, Randle Area = 2 is now the default, and the old Randle Area = 0 ("as is") is now Randle Area = 3.
    - Added cylindrical cells.
    - Fix bug in build of the layered (composite tshells) circuits when layers end up by a separator (like in cylindrical cells).
    - Addition of RANDLES instead of RANDLE in *EM_RANDLE_... keywords to be consistent with the manual (the old RANDLE still works).
    - Fix bug in building layer mesh for addition of different composite tshell parts.
    - Addition of Randle Area in randles circuit for composite tshells.
    - Addition of Randles circuit in connection with new LS-PrePost battery packaging for solid elements, in serial and MPP.
    - Addition of optional joule heating from a meshless Randle circuit to a set of parts (uniformly). This is triggered using *EM_ISO-POTENTIAL_CONNECT.

  - II. Electrophysiology

- Added Monodomain (EPMD) and bidomain (EPBD) solvers for electrophysiology.
- Addition of bath loading in EP models, both in EPBD, and in EPMD, using an augmented monodomain approach. This should work both in serial and MPP.
- Added calcium concentration at nodes vector in EP so that it can be used in mechanical models. It can be visualized using d3plot in relative permeability for now.
- Added PCG in EP: the user can choose between MF2 and PCG using EM_SOLVER_FEM.
- Added tetrahedrons in EPMD and EPBD.
- Addition of *EM_EP_TENTUSSCHER_STIMULUS2 to create stimulus on a node set where the amplitude is time dependent given by a load curve (amplitude vs time). Several such stimuli can be created at the same time.
- Addition of user cards for *EM_EP_TENTUSSCHER and *EM_EP_-TENTUSSCHER_STIMULUS for user to input parameters for electrophysiology.
- Addition of beta and Cm in *EM_MAT_003 and *EM_MAT_005.
- Added Godunov method using MF2 in MPP for EP bidomain.
- Addition of *EM_MAT_005 with 2 conductivity tensors for EP bidomain model.
- Addition of implicit and first order operator split (+ combination of the 2) in monodomain method.
- Added activation time as a d3plot output as well as an ASCII file (x,y,z,time) at each node. In d3plot, the activation time is at the ohm heating power for now.
- Added transmembrane potential in d3plot output: it is in the scalar potential for now.

◦ III. Resistive Spot Welding

- Addition of resistive spot welding in 2D (rsw2d).
- Addition of contact Joule Heat Rate for contact resistance in rsw2d.
- Addition of resistive heating solver in 2D, for rsw in 2D.
- Added zero out of em_nodeJHrate in em_zeroEMFieldsOut, so that no more JHR from the contact resistance is added after EM is switched off.

◦ IV. Eddy current

- Added option to use *DEFINE_FUNCTION in LCID for the imposed scalar potential circuit type in EM_CIRCUIT. Allows users to use their own circuit equation as input.

◦ V. Inductive heating

- Added option to define NUMLS, F and A with a Load Curve function of the macro time if a negative integer value is entered.

◦ VI. Miscellaneous EM

- Creation of d3p_bemDecomp file if gmv > 0 in *EM_OUTPUT with BEM face domains.
- Corrected an MPP issue for the EM solver that could occur in problems where some solid and shell elements have the same element number.

- **Forming Analysis**

A special form of shell h-adaptivity called "tube adaptivity" can now be invoked using *DEFINE_BOX_NODES_ADAPTIVE. Here, fission and fusion occurs in shells located inside a "tube", that is, a torus-shaped volume, based on the path of a moving tool. This form of adaptivity can help reduce simulation time for incremental forming or roller hemming.

◦ *ELEMENT_BLANKING:

- Fix corner trimming problem of a flat blank, where the corner elements would not follow the trim line when trimmed.

◦ *CONTROL_FORMING_ONESTEP:

- Improve support to-be-unfolded part as a dynain file, by accepting *ELEMENT_SHELL_THICKNESS, *INITIAL_STRESS_SHELL, and *INITIAL_STRAIN_SHELL.
- Add *MAT_123 to onestep method.
- Fix friction force calculation error.
- Improvements: some of the executables were not able to use multiple CPU in SMP before, now it is possible.

◦ *CONTROL_FORMING_TRIMMING, *DEFINE_CURVE_TRIM:

- Fix bug in trimming: some of the history variables were lost during trimming.
- Fix bug: some SPC nodes were mistakenly removed.
- Fix bug in trimming of sandwiched part with multi-layerd core: shells were wrongly created for every layer of the sandwiched core.
- Improve trimming of solid elements: allow the corner to be trimmed exactly as the trim curve.

◦ *CONTROL_FORMING_TRIMMING, *DEFINE_CURVE_TRIM_3D:

- Improve trimming with _3D option: if a vector id is provided (by mistake) with 3D trimming, the code will set the vector to be zero, as 3D trimming does not require a vector.

- *DEFINE_CURVE_TRIM_2D:
  - Change from *DEFINE_CURVE_TRIM_NEW to *DEFINE_CURVE_-TRIM_2D.
- *CONTROL_FORMING_REMOVE_ADAPTIVE_CONSTRAINTS:
  - Fix segmentation fault.
  - Extend to triangular elements, in addition to quadrilateral elements.
- *CONTROL_IMPLICIT_FORMING:
  - For IOPTION = 2, fix a truncation error that prevented completion of the analysis.
  - Fix a bug that prevented application in dynamic implicit analysis.
  - Fix kinetic energy calculation error.
- *DEFINE_FORMING_CLAMP:
  - Add error message: "Vector: xx was not defined" in case vector's direction is defined incorrectly.
  - Check constraints for the rigid clamper and free the constraints from the moving clampers.
- *DEFINE_PART_FROM_LAYER:
  - Add *CONTACT_SURFACE_TO_SURFACE between layers generated by this keyword.
- *CONTROL_FORMING_AUTOPOSITION_PARAMETER:
  - If separation distance cannot be found, for example, when the MPID is not found when calculating the separation distance, or out of position, or the DIR is not input correctly, instead of returning a very large number, the value of PREMOVE will be returned.
  - Support *DEFINE_COORDINATE_VECTOR.
- *CONTROL_FORMING_OUTPUT:
  - Enable the variable NOUT not only in punch drawing but also in binder closing.
  - Allow output of d3plot according to NOUT without using y1,y2,... or a curve id.
  - Fix a bug to prevent excessive intfor output.
- *DEFINE_FORMING_BLANKMESH:

- Fix X, Y shifting problem (not working) for NPLANE = 2 and 3.

- *INCLUDE_AUTO_OFFSET:
  - Extend to beam and solid elements.
  - Fix a beam offset problem when adaptivity is turned on.
  - Add a new option _USER. User can now control how much the node and shell element are offset. In addition, with this option, the offset can be used for sheet blank part. Without this option, the auto offset can only be used for rigid bodies.
  - Extend _USER option to include solid and beam parts.

- *CONTROL_FORMING_TIPPING:
  - Improve this keyword to allow three source coordinates and the corresponding three target coordinates for the tipping. Use NMOVE = -6 to activate this feature.

- *CONTROL_FORMING_UNFLANGING:
  - Fix a segmentation fault when writing the result file 'unflanginfo.out'.

- *DEFINE_MULTI_DRAWBEADS_IGES:
  - Fix a duplicate node set issue when SMOOTH contact is used with automatic draw beads generation from IGES.

- *CONTROL_FORMING_PRE_BENDING:
  - Add a warning message that the keyword must be placed at the end of the input file.

- *DEFINE_BOX_DRAWBEAD:
  - Fix a bug in calculating the box size.

- *CONTROL_FORMING_STONING:
  - Allow the element set to be defined with *SET_SHELL_GENERAL and *DEFINE_BOX.

- *DEFINE_FIBERS, and *CONTROL_FORMING_ONESTEP:
  - Add a new keyword (*DEFINE_FIBERS) to define carbon fibers and their related properties for one-step inverse forming simulations of carbon fiber reinforced composites.
  - Output initial flat part, which is re-orientated by aligning node N1 and N2 in x-direction.

- Output element fiber information, including orientation and width.
- When N1 or N2 is zero or undefined, another line of input is required for the target coordinates for N1 and N2, and the code will find the nearest nodes.
- Outputs:
  1st history variable: the angle between two fibers.
  2nd history variable: the angle between the first fiber with respect to the element direction.
  3rd history variable: the angle between the second fiber with respect to the element direction.
- Up to three major fiber reorientations are allowed.

◦ *CONTROL_FORMING_STRAIN_RATIO_SMOOTH:

- Change keyword name from *CONTROL_FORMING_TOLERANCE to *CONTROL_FORMING_STRAIN_RATIO_SMOOTH.

◦ *CONTROL_FORMING_AUTOCHECK:

- Add a new variable IFSHARP. When IFSHARP = 0, check the sharp edge and delete the elements; when IFSHARP = 1, ignore sharp edge.
- Check for and fix for triangular elements incorrectly defined with four unique nodes.

◦ *INTERFACE_COMPENSATION_FLANGE:

- Added this new keyword to handle flanging die compensation.

◦ *DEFINE_PART_FROM_LAYER:

- Add a new keyword to generate multi-layers of shells for a composite structure (carbon fiber material, for example).

◦ *ELEMENT_LANCING:

- Add lancing of multi-layered solid elements.

◦ *CONTROL_FORMING_BESTFIT:

- Add some bestfit statistics in the "messag" file after best fit. The first column is the percentage of nodes within the range indicated; the second column is the percentage of nodes within the upper limit of the range indicated.
- Output the maximum gap.

◦ *DEFINE_CURVE_FLD_FROM_TRIAXIAL_LIMIT, and *DEFINE_CURVE_TRIAXIAL_LIMIT_FROM_FLD:

        - Added these two new keywords.

    - *INCLUDE_COMPENSATION_TRIM_NODE:

        - Add a new option which will include a file containing all the nodes near the trimming line. This file should be generated from *INTERFACE_COMPENSATION_NEW_REFINE_RIGID (bndnd0.tmp).

    - *INTERFACE_COMPENSATION_3D:

        - Add a new option _REFINE_RIGID to automatically identify the nodes near the trimming curves, so surface compensation later will be smoother.
        - Add a new variable TANGENT. TANGENT = 1 maintains the boundary tangency from the addendum to the binder.
        - Combine rigid refinement along trimming curve into the main compensation in one single run.
        - Change keyword *INTERFACE_COMPENSATION_NEW to *INTERFACE_COMPENSATION_3D.

- ***FREQUENCY_DOMAIN**

    - Added logic for some frequency response computations so that the amount of drilling rotation control is the same as for eigenvalue computations.
    - *DATABASE_FREQUENCY_ASCII_OPTION:

        - Added modal contribution fraction output to NODOUT_SSD and ELOUT_SSD.
        - Added option NODFOR_SSD as an option to *DATABASE_FREQUENCY_ASCII.
        - Added options NODOUT_PSD and ELOUT_PSD for random vibration analysis.

    - *DATABASE_FREQUENCY_BINARY_OPTION:

        - Added D3ZCF binary database to fringe plot zero-crossing frequencies (with positive slope) in random vibration analyis.
        - Added D3ACC binary database to fringe plot acoustic pressure contribution from boundary elements in BEM acoustic computation.

    - *FATIGUE:

        - Implemented this keyword to run time domain fatigue analysis based on stress or strain.
        - Added new mean stress correction methods: Goodman-tension-only and Gerber-tension-only to provide conservative analysis for compression mean stress.

- Added an option EN to *MAT_ADD_FATIGUE to define material's EN curve.
- Improvement to skip fatigue computation if the local strain is less than 1.e-6.
- Improved strain based fatigue analysis when using Maximum Shear Strain and using Signed Von Mises strain.
- Added restart option RESTRT to fatigue analysis, if the stress/strain time history has been precomputed.

◦ *FREQUENCY_DOMAIN_ACOUSTIC_BEM:

- Added half space option to dual BEM based on Burton-Miller formulation.
- Implemented incident wave to Kirchhoff method.
- Implemented incident wave to Burton-Miller BEM.
- Implemented incident wave to Rayleigh method.
- Fixed bug in running acoustic analysis with multiple boundary conditions in MPP.
- Enabled running BEM restart (ibemrest = 6) based on atv matrix computed previously. SMP only.
- Generating D3ACS database for collocation bem (method = 3) and dual collocation bem (method = 4) only.

◦ *FREQUENCY_DOMAIN_PATH:

- Added option _NOJOBID, so that users can run restart based on the same eigenvector database for each CASE (otherwise, LS-DYNA will add different prefix to the file name in each CASE automatically).

◦ *FREQUENCY_DOMAIN_RANDOM_VIBRATION:

- Added the following new load types for random vibration analysis:
  VAFLAG = 9 base velocity
  10 base displacement
  11 enforced acceleration by large mass method
  12 enforced velocity by large mass method
  13 enforced displacement by large mass method
- Fixed a bug in running PSD interpolation when log-log interpolation is used and the PSD includes both magnitude and phase delay (for cross PSD).
- Implemented Lalanne method for frequency domain fatigue analysis.
- Added option LCTYP2 to define phase difference in cross psd by degrees and radians.

◦ *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM:

- Changed the rule of dumping nodal displacement results to D3SPCM. Now the state variable of nodal displacement results is the displacement peak value itself, without adding original nodal coordinates. LS-PrePost has been updated to accomodate this change.
- Added xyplot file spectrum_curve_print. This file saves the intermediate base acceleration spectrum, converted from base motion time history (LCTYP = 10, 11, 12).
- Added the following new load types for response spectrum analysis:
  LCTYP = 5 (base velocity vs natural period)
  6 (base acceleration vs natural period)
  7 (base displacement vs natural period)
  8 (nodal force vs natural period)
  9 (pressure vs natural period)
  10 (base velocity time history)
  11 (base acceleration time history)
  12 base displacement time history)
- For group force computation, now we calculate the group force for each mode first and then run the mode combination on them. Previously we calculate the group force as the sum of the nodal force, after the mode combination.
- Added Von Mises stress output for beams for response spectrum analysis.
- Updated response spectrum analysis so that it can work with intermittent eigenvalue analysis.
- Added nodal force and group force output (NODFOR_SPCM) for response spectrum analysis.

◦ *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM_DDAM:

- Implemented DDAM for navy ship shock response analysis.
- Implemented CSM (Closely Spaced Modes) treatment for DDAM.
- Added mcomb = -14 to run DDAM with user defined CSM.
- Added a new parameter EFFMASS, to define a required minimum percentage for total modal mass, to decide the modes to be used in DDAM analysis. The default value is 80 (80%).
- Added a parameter UNIT, to define the unit system in the input deck, as the NAVSEA constants are only valid with the BIN unit system.

◦ *FREQUENCY_DOMAIN_SSD:

- Implemented mean stress correction for SSD fatigue analysis.
- Implemented option restmd = 2 to restart with old scratch file modeshp to save time.
- Implemented an option _FRF to *FREQUENCY_DOMAIN_SSD, to provide FRF results in SSD.

- Added option _MODAL_CONTRIBUTION to output modal contribution fraction for nodes and elements.
- Enabled combination of modal damping and local damping in SSD computation.
- Added the following new load types with rotational degree-of-freedom.
  VAD = 9 (base angular velocity)
  10 (base angular acceleration)
  11 (base angular displacement)

- **ICFD (Incompressible Fluid Solver)**

  - New ICFD features and major modifications:

    - Major rework of the boundary layer mesh generation capabilities. See MESH_BL keyword.
    - Major rework on the wave generation capabilities. Added 2D and 3D solitary waves as well as a irregular wave model (JONSWAP spectra). See *ICFD_BOUNDARY_FSWAVE keyword.
    - Added an option so that pmin and pmax in MESH_SIZE_SHAPE can be defined using *ICFD_DEFINE_POINT. The big advantage is that *ICFD_DEFINE_POINT can move and therefore *MESH_-SIZE_-SHAPE as well. Also added new Shape name: SPOL as well as birth and death times.
    - Added keyword to define a volumetric heat source. See *ICFD_-DEFINE_HEATSOURCE.
    - Added keyword which allows the user to define an initial plane for level set rather than building the initial interface mesh. See *ICFD_-INITIAL_LEVELSET.
    - Added keyword to control gap size in embed shell cases. See *ICFD_-CONTROL_EMBEDSHELL.

  - Small feature additions in ICFD and modifications to existing keywords:

    - Output frequency of d3plot in steady state in now controlled by sixth flag of *ICFD_CONTROL_OUTPUT.
    - Added output frequency for *ICFD_DATABASE_TEMP.
    - *ICFD_DEFINE_POINT : can now be made to follow a surface part's displacements.
    - Allowing *DEFINE_FUNCTION to be used for R and LCID in *ICFD_-DEFINE_NONINERTIAL.
    - *ICFD_CONTROL_GENERAL : potential flow solver can now be used in transient analysis (which can for example be useful in cases like conjugate heat transfer).

        - *ICFD_MAT : added the option to scale the surface tension by using a load curve or a *DEFINE_FUNCTION.

    - Bug fixes in ICFD:

        - Fix temperature SUPG stabilizing parameter for Conjugate Heat Transfer problem.
        - Fix the viscosity as a function of temperature when using Non-Newtonian fluids with NNID = 6,7,8 in Free-Surface problems.
        - Fix the surface tension force term.
        - Fix issue in multiphase algorithm. Stability and accuracy greatly improved.
        - Improved stability of k-epsilon model in steady state solver.

    - Minor ICFD improvements:

        - Change the nodal assembly by an element integration and assembly in anisotropic porous media solver. This way, forces at porous media interfaces are better described for coarse meshes and thin porous media domains.
        - Split the mesh statistics in icfd_mstats.xxx.dat into bulk mesh and boundary layer.
        - Added 'wetness' variable for free surface cases that shows how much a surface has touched the water.
        - Support of icfd_timeiter.dat for the steady state solver.
        - Added timer for potential flow solver.
        - Added a spatial smoothing for the surface shear stress calculation.
        - Added ICFD endtime in d3hsp initial keyword reading.
        - Accelerated heat transfer calculation.
        - Added a small warning that ICFD does not scale in SMP with ncpu higher than 1.
        - Change in unreference node detection criteria. Before, it was stopping with an error message, now it proceeds with a warning.
        - Added warning when porous media model or non newt model not detected.
        - Added avg pre and avg flux to ICFD_DATABASE_FLUX output.

- **Implicit (Mechanical) Solver**

    - *CONTROL_IMPLICIT_MODAL_DYNAMIC:

        - Support output to elout for modal dynamic analysis.
        - Make performance enhancements for transient modal analysis including the implicit Newmark scheme for time integration and a node set for loads in *CONTROL_IMPLICIT_MODAL_DYNAMIC.

- When using a direct solver for implicit (LSOLVR = 2 or 6 in *CONTROL_-IMPLICIT_SOLVER), the system of linear equations is reordered (permuted) to reduce the solution cost. Up to and including version R10, two options were available: MMD (Multiple Minimum Degree) and METIS (external package from University of Minnesota). These two options are serial algorithms, and they might run out of memory or consume a large fraction of total run time for very large models. As of version R11, a parallel, distributed-memory algorithm, LS-GPart, is introduced. It scales in both memory and time and should only be attempted for very large MPP implicit models and with the guidance of implicit support staff at LSTC (support@lstc.com). LS-GPart can be used by setting variable ORDER to 4 in *CONTROL_IMPLICIT_SOLVER). A new keyword *CON-TROL_IMPLICIT_ORDERING was also introduced to fine-tune ordering options.
- Correct a number of minor issues with memory access for implicit.
- Enhance implicit handling of nodal inertia for special cases.
- Fix divide by zero in power iteration for buckling problems with inertia relief.
- Enhancements for matrix dumping left out the special case of matrix dumping for intermittent eigenvalue problems which is now corrected.
- Adjust output to d3hsp for implicit linear equation solver options to match keyword manual.
- Correct the MPP implementation for the new stiffness control on implicit rotational dynamics.
- Adjust shift logic for lanczos eigensolver for a special case.
- Enhance implicit treatment of sense switch sw1 to avoid issues in SMP.
- Apply correction for a problem that computed way too many eigenmodes in one iteration of the MPP eigensolver.
- Add the new feature for the specification of stiffness types for *CONTROL_-IMPLICIT_ROTATIONAL_DYNAMICS.
- Lower the implicit dynamic memory greed factor from 0.85 to 0.80.
- Put end-of-file tag on d3eigv after writing stresses for MCMS eigensolver. Normalize MCMS computed eigenvectors to have unit norm.
- Correct the dumping of matrices from implicit when MTXDMP > 1.
- Correct a misalignment of statements in flxinit causing SMP to fail with *PART_MODES and the use of the PARTM feature from *CONTROL_-RIGID.
- Implement handling of failure of *CONSTRAINED_TIEBREAK for implicit. Required saving of the failure flag to use when constraint matrix structure has to be the same as the last analyze phase.
- Fix long standing potential memory clobber for single precision SMP implicit. (Nevertheless, single precision is not recommended for implicit.)
- Improve implicit logic for determining which DOFs are active for 2D problems in MPP.
- Enhance the modal stress scaling to be more responsive to model features to make the computation more robust.

- Enhance implicit key point logic during dynamic relaxation phase. We were using the incorrect end time which led to a zero time step.
- Add error test for when dynamic relaxation is using implicit (idrflg = 5 or 6) but DRTERM is not specified.
- Correct the MPP implementation of *PART_MODES so that the part can now be distributed across processes.
- Enable implicit to collect resultant forces for SPC constraints in local coordinates.
- Fix *CONTROL_IMPLICIT_MODES to correctly build superelements in MPP.
- For implicit MPP, correct tagging of the end of each d3eigv* file.
- Reduce memory requirements for MPP Lanczos.
- Enhance implicit to recognize superelement mass in the mass matrix multiplication.
- Enhance *CONTROL_IMPLICIT_MODES to be able to create a superelement for a model that was already using a superelement.
- Enhance the specification of IMFLAG < 0 for *CONTROL_IMPLICIT_GENERAL. The old approach only allowed toggling between 0 and 1 using a curve. This was extended to allow ordinate values of 0, 1, 4, or 5 in the curve controlling implicit/explicit switching.
- Enhance processing of rotational inertias for implicit, especially discrete elements and rigid body inertias.
- Add additional implicit debugging by checking the ends of beam elements and what they are or are not connected to.
- Reset more arrays to get the nonlinear elements to work correctly for implicit linear multi-step (NSOLVR = -1).
- If two independent nodes for *CONSTRAINED_INTERPOLATION have the same coordinates then a divide by zero could happen. That has been corrected.
- Add INTERFACE_SPRINGBACK to the cases where implicit collects and processes damping terms instead of suppressing them as is the case for implicit statics.
- Update implicit's collection of damping terms for discrete elements to account for user specified coordinate system and the case of no second node.
- Patch up reporting of bad pivots in MPP.
- For MPP, implement the checking for rigid body node replication, which was already in SMP. Also added proper error termination for analyzing the constraint matrix in MPP.
- Correct dynamic memory allocation for the implicit case for cases with *CONSTRAINED_INTERPOLATION with a large number of independent nodes but no inertia relief.
- Adjust the output value for IMFLAG to be the user specified value instead of the internally adjusted value. Also make sure the user cannot input IMFLAG = 3 which is an internal value that should not be used as input.
- Enhance linear implicit for prescribed motion data on deformable nodes.

- Correct reading of constraint mode aux vectors used by modal dynamics to impose prescribed motion constraints.
- Change typing of integer back to integer*4 to get proper output to binary format of superelement file generated by *CONTROL_IMPLICIT_STATIC_-CON-DENSATION.
- Finish migration of implicit eigensolver using Power Method for Inertia Relief + Buckling to dynamic memory.
- Enhance the separable component report to include rigid bodies.
- Enhance Implicit Usage Alert message so that for SMP it only outputs the recommended value for memory and not the memory2 setting.
- Correct the memory management for the stiffness matrix in SMP as it was freed too early when using implicit modes.
- Made a number of enhancements and corrections for the feature to apply boundary prescribed motion constraints during implicit modal dynamics.
- Added a user supplied linear equation solver capability for implicit mechanics.
- Extend changes for implicit nodal rotational inertia scaling to include *CONTROL_IMPLICIT_MODES.
- Account for rotational nodal inertia terms in implicit computations for discrete nodal inertia matrices.
- Remove double booking of rotational nodal inertia and discrete inertias that have had the rotational nodal inertia added. This will change the eigenvalues computed by implicit by making them more correct.
- Adjust implicit's treatment of inertia's so that implicit intermittent eigenvalue computations will match an implicit non-intermittent eigenvalue computation.
- Add control for the accuracy output to eigout.
- Apply patches to implicit mechanics from the development code as part of our work on solving very large implicit problems.
- Fix a deep and long hidden bug in implicit inertia relief.
- Correct underallocation of storage for inertia relief workspace for problems with more than 6 rigid body modes.
- Convert all of the implicit linear algebra to F95 dynamic memory. Added additional tracking statistics on the use of dynamic memory used by implicit. Enhance output with an Implicit Usage Alert to tell users how to set memory and memory2 for this model.
- Fix the marking of the end of the d3mode file when writing stresses.
- Fix a problem marking the end of the d3eigv file when modal stresses are written.
- Add detection of bad beam input for implicit.
- Enhance keypoint logic to enforce keypoints at the initial time step and on restart from explicit.
- Fix a problem with the timing for when "dead" nodes are incorporated into implicit.
- Added features to allow tighter coupling between implicit and USA.

- Correct output of eigenvalues and frequencies for the nonsymmetric eigenvalue problem to match that of rotational dynamics.
- Improve error message for reading d3eigv file for *PART_MODES for the case when the user input a d3eigv file from a different model than intended.
- Enhance implicit inertia relief to be optional for any explicit phase.
- Added MCMS (LSTC's name for AMLS) approximate eigensolver.
- Corrected the computation of reduced mass matrix for *PART_MODES when the nodes for the part are distributed in MPP. Also corrected the computation of total kinetic energy for the same situation.
- Earlier enhancements to adjust for poorly scaled implicit mechanical problems negatively affected the direct linear equation solver used in the implicit treatment of joints for explicit in single precision. The pivot tolerance was inappropriately being reduced. Now fixed.
- Migration of shell arrays to dynamic storage broke d3iter. Also had to reset i/o address for d3iter on restart.
- When implicit springback was following an explicit transient step the implicit keywords with the _SPR were not properly handled. Now corrected.
- Added the feature of resetting implicit geometry at the start of each time step to enable implicit linear multiple load analysis.
- Fix an implicit problem where a linear implicit analysis follows inertia relief computation.
- Enabled tshells to use the consistent mass matrix option of *CONTROL_IMPLICIT_CONSISTENT_MASS.
- Sense switch sw4 is now supported in implicit, in both SMP and MPP.
- If IMASS = 0 on *CONTROL_IMPLICIT_DYNAMICS, i.e., the analysis is static, the kinetic energy is output as zero to make physical sense.
- If HGEN = 1 on *CONTROL_ENERGY, energy from drilling constraint is included in hourglass energy and thus accounted for in energy balance.
- A nonzero start time of initial velocities is supported in implicit dynamics, see *INITIAL_VELOCITY_GENERATION_START_TIME.
- If IRATE = -1 on *CONTROL_IMPLICIT_DYNAMICS, rate effects are active even in implicit statics, which is sensible if viscoelastic effects are used in quasi-static analyses.
- Rotational prescribed motion on rigid bodies induce a fictitious residual force to avoid initial zero loads, which is a way to prevent stalling of the analysis. Translational prescribed motion was supported in this way in prior versions.
- Four variables (GJADSTF/GJADVSC/TJADSTF/TJADVSC) in *CONTROL_-RIGID automatically add joint stiffnesses to all joints, primarily for use in implicit in models with many joints (e.g., dummies) to stabilize the overall behavior.
- NLNORM = 4 on *CONTROL_IMPLICIT_SOLUTION mixes rotational and translational degrees of freedom for computing residual forces by weighing the rotational contribution with a length scale internally calculated to avoid

a units problem. The length scale used is reported in the output and can be overwritten by NLNORM < 0.

- Implemented a chained *CASE treatment for implicit, for splitting a "complicated" process into several "simple" simulations allowing for transfer of state between each such simulation. This makes use of writing and reading dynain.lsda (*INTERFACE_SPRINGBACK_LSDYNA/*INCLUDE) between cases, and in addition to element stresses, etc. that are the common state constituents, we support

  - mortar contact friction, tied, tiebreak and tied weld
  - tied contact slave node and master segment pairs
  - stabilization history of elements (hourglass and drilling)

- This is an ongoing project which is intended to be supported in an Implicit GUI in LS-PrePost for facilitating its setup.
- If IACC = 1 on *CONTROL_ACCURACY, "bad" implicit element formulations are automatically switched to type 2 (solid) or type 16 (shells).
- Fixed bug in d3eigv output for model with *CONTROL_IMPLICIT_-INERTIA_RELIEF.

- ***INITIAL**

  - *INITIAL_LAG_MAPPING (NELANGL = -1, 2nd line, 6th column):
    If NELANGL = -1, no mesh are generated or projected; just map the data if the 2nd run mesh geometry matches the 1st run one at its final cycle
  - *INITIAL_SOLID_VOLUME:
    Recalculate and reset initial volume of solid elements using material models with EOS before analysis if the original nodal position has been moved by nodal projections in contact initialization. This option eliminates calculation of non-physical initial hydrostatic pressure due to the nodal repositioning.
  - Fix ineffective *INITIAL_VELOCITY_GENERATION for part defined with *PART_INERTIA when ID = 0, STYPE = 0 and IRIGID = 1.
  - Fix incorrect initial velocity when ICID.ne.0 in *INITIAL_VELOCITY_-GENERATION, and rotational velocity, omega, is not zero and *PART_INERTIA is also present.
  - Fixed *INITIAL_STRESS_SHELL and *INITIAL_STRESS_TSHELL when used with *INTEGRATION_SHELL. The integration rule was getting lost leading to unnecessary interpolation of data.
  - Fixed dynain writing and reading of *INITIAL_STRESS_SHELL for the fully integrated C0 shell (shell form 20).
  - Enable multiple *INITIAL_VELOCITY_GENERATION keywords to be used with *ELEMENT_SHELL_COMPOSITE or *ELEMENT_TSHELL_-COMP-OSITE. Only one velocity generation keyword was supported previously.

- With the new parameter IVADD, the *INITIAL_VEHCILE_KINEMATICS velocity field can be superimposed on pre-defined nodal velocities.
- IZSHEAR = 2 on *INITIAL_STRESS_SECTION gets a special treatment for preloading bolts, each bolt is seen as an entity and the constraint is to prescribe the mean stress in the section and not in each element, meaning that the bolt is capable of take bending resistance, currently applies to the common low order elements (type -2,-1,1,2,10,13,15) for explicit and implicit

- Isogeometric Elements

  - Addition of HAZ (heat affected zone) features to IGA shells. No new keywords were added. The capability works identically to standard FE shells.
  - Reduce unit system sensitivity of *CONSTRAINED_NODE_TO_-NURBS_-PATCH_SET.
  - *ELEMENT_SOLID_NURBS_PATCH:

    - Isogeometric solid analysis is now available in both SMP (with consistency flag turned on) and MPP.
    - Activate user defined materials for isogeometric solids.

  - *ELEMENT_SHELL_NURBS_PATCH:

    - Isogeometric shell analysis is now available in SMP with consistency flag turned on. (MPP was already available.)
    - Add a power iteration method to get the maximum eigen-frequency for each isogeometric shell element. This will be used to set a reasonable scale factor for trimmed element.
    - Modify the time step scale factor for IGA trimmed shell element so that the overall time step will not be unreasonably small due to very small trimmed elements.

  - *ELEMENT_SHELL_NURBS_PATCH:

    - Fixed problem in decomposition for heavily trimmed NURBS-patches.
    - The problem may have occurred if most parts of a NURBS-patch are trimmed (not actually part of the geometry). In such cases the MPP decomposition could have gone wrong.

  - Write element information for NURBS shells to d3hsp (Element ID, Part ID, number of nodes and connectivity). This is invoked by setting NPOPT = 1 in *CONTROL_OUTPUT.
  - Fix bug when NURBS shells are present in a model and extra DOFs where assigned (*NODE_SCALAR, or shell forms 24/25/26).
  - Fix for *ELEMENT_SHELL_NURBS_PATCH when applying body force using *LOAD_BODY_GENERALIZED or *LOAD_BODY_PARTS. Apply the body force on the control points.

- Add support for initialization of shell thickness at in-plane int. point for *ELEMENT_SHELL_NURBS_PATCH(_TRIMMED) using *INITIAL_-STRAIN_SHELL_NURBS_PATCH (SMP and MPP).
- Add support for initialization of stresses, plastic strain, history variables and strains for *ELEMENT_SHELL_NURBS_PATCH(_TRIMMED) using *INITIAL_STRESS/STRAIN_SHELL_NURBS_PATCH.
- Add support of writing *ELEMENT_SHELL_NURBS_PATCH_TRIMMED to ASCII dynain file.
- Add support of *PART_COMPOSITE for isogeometric shells.
- *ELEMENT_SHELL_NURBS_PATCH & *CONTROL_ADAPTIVE:
  Allow adaptivity for regular shell elements if NURBS patches are in the model.
- Add possibility to define a negative real value for NISR and NISS to define a desired size of the automatically created interpolation shell elements. This may be especially useful when using NURBS elements for rigid tools in forming applications.
- Allow *CONTROL_FORMING_AUTOPOSITION_PARAMETER with IGA NURBS shells.
- Allow *PART_MOVE with IGA NURBS shells.
- Write stresses of interpolation elements to elout for *ELEMENT_SOLID_-NURBS_PATCH.
- Add support for initialization of stresses, plastic strain, history variables and strains for *ELEMENT_SOLID_NURBS_PATCH using *INITIAL_-STRESS/STRAIN_SOLID_NURBS_PATCH.

- ***LOAD**

  - Fix INCLUDE_TRANSFORM offset for coordinate systems in *LOAD_-NODE_POINT which were using the wrong offset.
  - Added support for *LOAD_THERMAL for higher order (quadratic and cubic) solids. The temperature at the nodes is interpolated from the nodes to the integration points so that the temperature is not the same at all integration points.
  - Correct the issue where use of *LOAD_BODY_ is applied to a model with rigid bodies to avoid null elemental stiffness matrices.
  - Fixed *LOAD_THERMAL_VARIABLE_ELEMENT_TSHELL. It was not working.
  - Fixed *LOAD_THERMAL_VARIABLE when used with shell form 2 that has default warping stiffness (BWC = 2 on *CONTROL_SHELL), and when OSU = 1 on *CONTROL_ACCURACY to activate an objective stress update.
  - *LOAD_SEGMENT_CONTACT_MASK is now supported for mortar contact in both SMP and MPP, in both implicit and explicit.
  - Fix bug in accessing ground motion ID (*DEFINE_GROUND_MOTION) from *LOAD_SEISMIC_SSI.
  - Allow *DEFINE_FUNCTION for *LOAD_THERMAL_LOAD_CURVE.

- *LOAD_SURFACE_STRESS:
  Fix a bug when there are more than 1 contact on one side of the blank, the area calculation was larger and the pressure smaller than it should be.
- *LOAD_BODY_VECTOR:
  Fix a bug in writing binary dynain (MPP).

- ***MAT and *EOS**

  - Fix bug in *MAT_079. The equations giving the influence of pressure on stiffness and strength were not exactly as written in the manual. PREF had been used in place of (PREF-P0). The code has been corrected to match the manual. This change will affect results from existing models, but usually P0 would be given a very small value so in most cases the difference should not be significant.
  - *MAT_089:

    - Now works with Tetrahedron ELFORM = 13. Previously the behavior was the same as for ELFORM = 10 (volumetric locking could occur).
    - Fixed bug affecting solid elements only - timestep calculation was wrong. Response could be unstable especially for higher values of Poisson's ratio, e.g. 0.4. Workaround was to reduce the timestep.

  - *MAT_119 unload option 3 - very small displacements followed by unloading could result in excessive unload stiffness and unexpectedly large mass-scaling, arising from small numerical rounding errors in the interpolated version of the load curves LCIDTR, LCIDTS, etc. Now fixed.
  - *MAT_169 (*MAT_ARUP_ADHESIVE) - enabled for implicit analysis.
  - *MAT_172 (*MAT_CONCRETE_EC2):

    - Fixed bug for combination of MAT_172 with Staged Construction (*CONTROL_STAGED_CONSTRUCTION). While elements were dormant, crushing damage could occur that persisted after the element became active.
    - Through-thickness strain was wrongly calculated when cracks are opening or closing. This strain is only an output parameter and does not affect the other results, but could potentially have led to unexpected element deletion if used with *MAT_ADD_EROSION.
    - Enabled CMPFLG (*DATABASE_EXTENT_BINARY).

  - *MAT_197 (MAT_SEISMIC_ISOLATOR)
  - Added optional rotational stiffness (new optional Card 7). This is useful when multiple isolator elements are stacked on top of each other.
  - Added new TYPE = 3 Lead Rubber Bearing. Includes cavitation in tension, buckling in compression, degradation of shear strength due to heating of the lead core.
  - *MAT_203

- Added history variables 10 & 11 for post-processing: high-tide tensile strains in the two local reinforcement directions.
- Enabled CMPFLG (*DATABASE_EXTENT_BINARY).
- Fix bug in hysteresis behaviour that could occasionally cause error terminations.
- Elements are now eroded when existing input parameter EPDAM2 is reached. If EPDAM2 and EPDAM1 are not defined, or if DRESID is non-zero, the element never erodes.

◦ *MAT_208 (*MAT_BOLT_BEAM):

- Now the element erodes when it reaches failure criteria. Previously, the forces and moments were set to zero but the element did not get deleted.
- Added new input field AXSHFL to control whether shear displacements (excluding sliding within the clearance gap) are capable of lengthening the bolt and increasing axial tension. By default (as in R10 and previous versions), shear displacements can increase axial tension. This is reasonable if the shear deformation is associated with rotation or bending of the bolt itself while the plates remain a fixed distance apart. But if the shearing is largely due to deformation of the bearing surfaces then (in real life) the bolt length does not increase and the tension is unaffected. This latter behaviour can now be invoked by setting AXSHFL to 1. This effect will be more significant as shear displacements become large. Note that displacements associated with sliding across the clearance gap are always ignored for purposes of calculating the axial load.

◦ *MAT_211 (*MAT_SPR_JLR) fixed bug - load curve IDs 8 or 9 digits long not read correctly from *MAT card in single precision version
◦ GISSMO and DIEM damage models now work with higher order solid elements.
◦ Instead of using a number or percentage of failed integration points to trigger erosion of higher order solids in *MAT_ADD_EROSION, use volume fraction of failed material. The reason for this approach is that the volume associated with each integration point varies widely within the higher order solids.
◦ Fix a bogus error message for *MAT_ADD_PORE_AIR that occurs when PERMX is defined as "0", while PERMY and/or PERMZ are not zero
◦ *MODULE feature for user-defined materials is built in with "sharelib" binaries.
◦ *MAT_153/*MAT_DAMAGE_3: Extended to up to 10 backstresses that can be determined
◦ from stress-strain data for solid/shell elements. This extension also supports implicit dynamics.

- Added support for cohesive shells in *MAT_240.
- Fix the convergence issue with plasticity algorithm in *MAT_260A/*MAT_-STOUGHTON_NON_ASSOCIATED_FLOW.
- Fix incorrect stress initialization when using *MAT_005/*MAT_-SOIL_-AND_FOAM with vol. strain vs pressure defined using load curve LCID, together with *LOAD_DENSITY_DEPTH.
- Fix seg fault or incorrect stresses when initializing stresses using *INITIAL_-STRESS_SOLID for *MAT_107/*MAT_MODIFIED_JOHN-SON_COOK.
- Fix strain rate effects on *MAT_157/*MAT_ANISOTROPIC_ELASTIC_-PLASTIC for implicit static analysis.
- Fix seg fault when using *MAT_157/*MAT_ANISOTROPIC_ELASTIC_-PLASTIC and MAT_ANISOTROPIC_ELASTIC_PLASTIC for 2D analysis.
- Fix incorrect results when using *MAT_TABULATED_JOHN-SON_-COOK/*MAT_224 with table LCKT defined and the first abscissa value set to a negative temperature.
- Increase robustness of *MAT_BARLAT_ANISOTROPIC_PLAS-TICI-TY/*MAT_033 for solids.
- Fix input error when using *MAT_ELASTIC_WITH_VISCOSITY_-CURVE/*MAT_060c when LCID = 0.
- Store computed yield strength as history variable #6 for *MAT_-PIECE-WISE_LINEAR_PLASTIC_THERMAL/*MAT_255.
- Fix to work-energy sums when *MAT_090/*MAT_ACOUSTIC material is used. If kinematics are not requested via *CONTROL_ACOUSTIC (the default), then acoustic element energies are not included in the solution sums. If kinematics are requested, then the energies are included. Previously, acoustic elements contributed to the work, but not the kinetic energy. Note - computing acoustic element kinematics is not required to calculate acoustic pressures and roughly doubles the cost of the acoustic elements. This correction has no affect upon the computed solution.
- Fixed brick material *MAT_089 with hourglass form 6. The hourglass scaling was bad which caused bad results.
- Modified shell *MAT_214 to prevent dividing by zero in some cases.
- Fixed *MAT_091 when used with shell form 16. The material directions were being calculated incorrectly causing the stress to be wrong.
- Fixed conflict between RTCL damage in *MAT_123 and heat affected zones. The TRIAX parameter was being overwritten causing possibly excessive damage.
- Node and connectivity data for elements that use *MAT_FABRIC/*MAT_-034 has been restored to the the dynain file. It had been removed along with stress and strain data which was removed because the fabric material cannot be prestressed by dynain.
- Fixed laminated shell theory with shell *MAT_172. It was calculating wrong shear strain.

- Fixed *MAT_023, *MAT_072, *MAT_083, *MAT_153, *MAT_223, *MAT_-229, and *MAT_259 when used with linear solid form 18. Some material constants were not passed correctly.
- Fixed *MAT_024 plastic strain failure for beam element forms 4 and 5. The elements were not failing.
- Fixed *MAT_077 for tetrahedral solid form 13. Some newer options were not working.
- Fixed *MAT_244 (shells and solids) when LCY1, LCY2, LCY3, LCY4, or LCY5 was left equal to zero. In this case, the code attempted to use nonexistent data, and it's unclear how this affected results. This caused the Windows executable, to error terminate with a "Program Exception - access violation" message.
- Fixed a problem where *MAT_172 was used to model 100% reinforcement and TYPEC was 3 or 6, and Young's Modulus of concrete (ET36) was input as zero. For steel only, this value should not matter, but it caused a divide by zero error during initialization. This is now prevented by having ET36 default to a small positive number for 100% reinforcement.
- Fixed shell form 17 when used with *MAT_077. There was no call to the stress update routine.
- Fixed ESORT > 0 when used with shell form 18 and *MAT_077. The triangular elements are now switched to triangular shell form 17 to be compatible with quad shell form 18.
- Fixed various errors in *MAT_NONLOCAL:

  - When both incremental and non-incremental data are requested for smoothing.
  - When used with shell materials with more than one in-plane point, or brick elements with more than 1 integration point. When coefficients are calculated for nearby points, the sum of coefficients was excluding other points within the same element or layer. The sum is used to normalize the weighted average. Since it was too small, the function that is smoothed would tend to grow.
  - Fixed an MPP only bug in the *MAT_NONLOCAL material averaging. A buffer could be overwritten if there was more than one nonlocal definition in the model. The same error was fixed for *MAT_CODAM2, *MAT_GURSON_RCDC, or *MAT_PLASTICITY_-WITH_DAMAGE with the RCDC option and the characteristic element length or nonlocal radius was defined.
  - The nonlocal search messages to screen and message files were modified to be more informative. During the search, a progress message is printed with each 100 million points added to the lists. This is intended to combat the perception that the code has hung.

- Added new options for *MAT_SPOTWELD_DAMAGE-FAILURE failure by OPT 6. There are 2 new TFLAG options:

  - TFLAG = 2 causes the max sheet thickness to be used.
  - TFLAG = 3 causes the sum of thicknesses to be used.

- A sheet thickness scale factor was added which scales the sheet thickness calculated by the TFLAG options.
- Fixed *MAT_126 when used with tshell forms 3, 5, or 7. The angle initialization was incorrect leading to bad stress values.
- Enabled *MAT_025, *MAT_173, *MAT_193, and *MAT_198 to be used with tshell forms 3, 5, and 7.
- Enabled *MAT_123 to work with tshell forms 3, 5, and 7 using options EPSTHIN and LCTSRF, and also NUMINT < 0 option. All 3 options were previously only available for thin shells and tshell forms 1, 2, and 6.
- Fixed the stress from *EOS_GASKET model when used with tshell form 2. Also fixed the compressive failure strain (CFS) for *EOS_GASKET with bricks or tshell forms 5 and 7. It was setting CFS = TFS.
- Fixed the behavior of NUMFIP on *MAT_ADD_EROSION when used with shell or tshell composite sections. When counting failed layers, the zeroing of the counter did not happen unless the first layer of the composite used *MAT_ADD_EROSION. This would have caused elements to fail that should not have failed. All 3 options, NUMFIP > 0, -100 < NUMFIP < 0, and NUMFIP < -100 are now working.
- Fixed the eigenvalue calculation in the first cycle when the model has solids or tshell forms 3, 5, or 7, and these elements are used with *MAT_022, *MAT_054, *MAT_055, *MAT_059, or *MAT_213.
- Fixed thermal strains in *MAT_021 tshells. The material directions were not processed correctly causing incorrect thermal strains. Both deformation and output were fixed and are now working for all tshell forms.
- Fixed the material direction when using shell *MAT_091. Also enabled output in the material direction when CMPFLG = 1 on *DATA-BASE_EXTENT_BINARY.
- If EPSR and EPSF are defined in *MAT_054, correct computation of transverse shears strains for solids and tshells.
- Add possibility to use failure criterion in *MAT_054 for solids in a transversal isotropic manner. It is assumed that the material 1-direction is the main axis and that the behavior in the 2-3 plane is isotropic. This feature is invoked by setting TI = 1 (card 2, column 7) in *MAT_054.
- Fix bug for shear stiffness behavior in *MAT_058 when using a table definition for GAB and only providing stress-strain-curves for positive shear.
- Fix bug for strain-rate dependent stiffness behavior in *MAT_058 when using a table definition for EA, EB or GAB under compressive loading.
- Add history variable for ellipsoidal failure surface for *MAT_059 (SC.lt.0), shells only. Now history variable 8 is the failure surface "f", which is similar to the Tsai-Wu criterion.

- *MAT_100_DA(*MAT_SPOTWELD_DAIMLERCHRYSLER),*DEFINE_-CONNECTION_PROPERTIES:Add the possibility to define a yield curve or table for DSIGY, SIGY in case of using PRUL = 1.
- For *MAT_100 (*MAT_SPOTWELD), OPT = 0/-1: Add the possibility to define force/moment resultants as a function of the effective strain rate, by defining an appropriate load curve. This will be indicated by a negative value for NRR, NRS, NRT, MRR, MSS, MTT. This functionality is implemented for beam, hex and hex-assembly spotwelds.
- Extended capability of initializing *MAT_157 solids using input variable IHIS and *INITIAL_STRESS_SOLID.
  Blocks of material parameters that can be initialized in this way are:

  - material direction (q11,...,q33) - 6 values
  - stiffnesses (c11,c12,c13,...,c66) - 21 values
  - anisotropic constants (F,G,H,L,M,N) - 6 values
  - curve/table - ID (LCSS) - 1 value
  - strengths (XC,XT,YC,YT,ZT,ZC,SXY,SYZ,SZX) - 9 values << NEW

  See User's Manual for details.
- Add value of failure criterion (Tsai-Wu or Tsai-Hill) to history variable 10 for postprocessing in *MAT_157. Shell elements only.
- Fix bug in *MAT_261 when table definition is used to define the non-linear in-plane shear behavior (LCSS). This applies to shells/tshells/solids.
- Add default strength limits (XC, ... 1.e+16) if they are not defined for *MAT_-261/*MAT_262.
- Added a criterion to avoid possible snapback behavior in *MAT_262 by only allowing certain "softening" modulus with respect to the elastic stiffness. This might be important when using rate-dependent strength limits (*DEFINE_CURVE) and the values for the fracture toughnesses are not properly set.
- *MAT_4A_MICROMEC /*MAT_215:
  Add strength limit XC for failure in fiber compression.
- *MAT_GENERALIZED_PHASE_CHANGE/*MAT_254:

  - Added latent heat algorithm to *MAT_254. Input follows the same phase transformation matrix as the other transformation related parameters.
  - Added user-defined history variables. Up to 8 history variables can be defined using *DEFINE_FUNCTION. Parameter list for functions includes time, user histories, phase distribution, temperature, peak temperature, temperature rate, stresses, and plastic strains.

- New parameter dtemp in *MAT_CWM/*MAT_270 that can invoke a subcycling in the material formulation, if the temperature jump within a time step exceeds the limit defined by dtemp.

- Activated latent heat algorithm for thermal material *MAT_THERMAL_-CWM/*MAT_T07.
- *MAT_CORUS_VEGTER/*MAT_136:
  - Renamed material from *MAT_CORUS_VEGTER to *MAT_VEGTER, as Corus no longer exists.
  - Tabular input for strain rate dependency implemented.
  - New option *MAT_VEGTER_STANDARD:
    --expects a parameter alpha_ps,theta instead of the second component of the plane strain point
    --input consistent with most literature data
    --material routine itself is unchanged
    --temperature dependent strain rate dependency also possible with the Bergstrom equation
  - New option *MAT_VEGTER_2017:
    --uses a simplified input
    --Input of tensile strengths (Rm0,Rm45,Rm90), uniform elongation (Ag0,Ag45,Ag90) and plastic anisotropy (R0,R45,R90)
    --based on a model provided by TATA steel, the standard input data for MAT_VEGTER is reproduced
    --material routine itself is unchanged
    --temperature dependent strain rate dependency also possible with the Bergstrom equation

- *MAT_REINFORCED_THERMOPLASTIC/MAT_249:
  Changed handling of post-processing data in history values. User can define the post-processing data to be written into histories.
- Add new failure criterion DTMIN (minimum time step) to *MAT_ADD_-EROSION.
- Add new failure criterion MXTMP (maximum temperature) to *MAT_-ADD_EROSION for solid and shell elements.
- Add new option LCFLD < 0 to *MAT_ADD_EROSION. In this case, |LCFLD| refers to a table where FLD curves are shell thickness dependent (in contrast, existing LCFLD > 0 provides rate dependence).
- Fix for combination of *MAT_ADD_EROSION and tshell form 2 or beams. Strain-based criteria (e.g. MXEPS) did not work correctly before.
- Several changes for *MAT_ADD_EROSION with IDAM = 1 (GISSMO):
  - If LCSDG < 0, then |LCSDG| refers to a *DEFINE_FUNCTION with arguments triaxiality and Lode parameter.
  - New option LCREGD < 0, where |LCREGD| refers to a table that contains regularization factor vs. element size curves for different triaxialities.
  - Compute element size for LCREGD not only once at t = 0 (SIZFLG = 0), but also after each adaptive refinement step.

  - New option REFSZ < 0 of GISSMO provides a plastic strain value, that corresponds to that reference size, written to history variable ND+17.
  - Improve robustness if DMGEXP < 1 is used.

- Fix for GISSMO to be used in adaptive remeshing. Evaluation of damage coupling flag could go wrong due to averaging of history variables in rezone step.
- Support DIEM (*MAT_ADD_EROSION with IDAM < 0) for beam form 1.
- Add new keywords *MAT_ADD_DAMAGE_GISSMO and *MAT_ADD_-DAMAGE_DIEM. The idea is to separate these damage models from *MAT_ADD_EROSION, where only pure element erosion criteria remain. That should simplify understanding the manual. Old input is still supported.
- Add new MIDFAIL options 2 and 3 to *MAT_ADD_DAMAGE_GISSMO.
- Add new keyword option _STOCHASTIC for *MAT_ADD_DAM-AGE_-GISSMO to allow spatially varying failure behavior when used together with *DEFINE_STOCHASTIC_VARIATION.
- Add new option HISVN to *MAT_ADD_DAMAGE_GISSMO: A user-defined history variable (e.g. hardness) can be used to modify the failure. LCSDG is in this case a TABLE_3D with the arguments triaxiality, Lode parameter, and that history variable.
- Add option to *MAT_ADD_GENERALIZED_DAMAGE that allows defining the number of failed integration points (to trigger element erosion) for each history variable separately. Only applicable for shells.
- Add new MIDFAIL options 2, 3, and 4 to *MAT_ADD_GENERAL-IZED_-DAMAGE.
- Add NUMINT option to *MAT_089 for shell elements.
- Add two nonlocal failure criteria to *MAT_280. The first one works similar to the ENGCRT/RADCRT criterion of *MAT_ADD_EROSION. The second is similar to the SOFT option of *MAT_054, where tensile strength is reduced in next-to-failed (crashfront) elements.
- Add new material model *MAT_BARLAT_YLD2004/*MAT_199 for solid elements in explicit analysis.
- New option ITERS < 0 in *MAT_143 invokes an alternative plasticity algorithm. It also comes with a new logarithmic rate dependence option, IRATE = 2.
- Allow initial temperatures for *MAT_224_GYS to be set via *INITIAL_-STRESS_SOLID. Also, enable *MAT_224_GYS to be used in coupled thermal-mechanical analyses.
- Modified materials *MAT_234 and *MAT_235 so that they work with angles on the *SECTION_SHELL card to define material directions for layers.
- Add option HISOUT = 1 to store principal strains as history variables 25-27 for *MAT_181 (available for solid elements).
- New options for *MAT_240/*MAT_COHESIVE_MIXED_MODE_ELASTO-PLASTIC_RATE, invoked by adding _THERMAL, _3MODES, or _THER-

MAL_3MODES to the keyword. Allows temperature dependent material data and/or inclusion of a third deformation and fracture mode.

- Add new optional hardening rule HR = 10 to *MAT_036 and *MAT_243: table with pre-strain dependence.
- Variable BETA < 0 of *MAT_224 can now refer to a *DEFINE_TABLE_3D, where the dissipation factor can be defined as a function of temperature (TABLE_3D), strain rate (TABLE), and plastic strain (CURVE).
- Add principal strains as new history variables 18-20 in *MAT_083.
- Add new option IHYPO to *MAT_023. IHYPO = 1 switches the material model formulation from hyperelastic to hypoelastic for solids, which allows stress initialization through *INITIAL_STRESS_SOLID.
- Fix for *MAT_190 when used together with *DAMPING_PART_STIFFNESS and RYLEN = 2. Premature failure due to FLD was likely to occur.
- Allow the Material Model Driver (Appendix K) to be used in batch mode: If a file called "mmd.bat" exists in the working directory, then the commands contained therein get executed sequentially. Supported commands are print, cross, time, and quit.
- Algorithmically consistent tangent modulus implemented for *MAT_024 and *MAT_123.
- Add flag for allowing nonsymmetric tangent moduli in user materials. Currently supports only solid forms -1, -2 and 2.
- Fix bug whereby encrypted *MAT_075 data was echoed in d3hsp.
- For the case where an encrypted material model referenced load curve(s), the material type was revealed by d3hsp in the load curve usage summary. That is no longer the case.
- Change the stress update in *MAT_PML_ELASTIC_FLUID to make it more stable. Viscous damping is still needed to achieve stability.
- *MAT_232/*MAT_BIOT_HYSTERETIC is now supported in all solid element formulations.
- Added *MAT_293/*MAT_COMPRF.
  This material model simulates the behavior of pre-impregnated (prepreg) composite fibers during the high temperature preforming process. In addition to providing stress and strain, it also provides warp and weft yarn directions and stretch ratios after the forming process. The major applications of the model are for materials used in light weight automobile parts.
- Added *MAT_296/*MAT_ANAND_VISCOPLASTICITY. This visco-plastic model uses a set of evolution equations instead of loading-unloading criterion to describe dislocation motion and hardening or softening behavior of materials. This model can be applied to simulate solders used in electronic packaging.
- Added 2-way option for tshell formulation 5 in *MAT_054.
- *MAT_260B:

  - Set default value for P12 = -0.5, p22 = 1.0, p33 = 3.0.
  - Set default value for G12 = -0.5, G22 = 1.0, G33 = 3.0.

- Correct shear stress calculation error.
- Set default value for DEPSO to 0.001, so as to avoid division by zero.

- *MAT_260A:

  - Set default value for R00 = 1.0, R45 = r00, R90 = r00
  - Set default value for sig0, sig45, sig90, and sigb to make sure that the non-associated flow will be degenerated to associated flow.
  - Add Equation of State.
  - If SIGB is zero, then it is assumed that all the SIGS' are equal.
  - Add Xue's failure model.

- *MAT_123:
  When major strain is used as a failure criteria, the equivalent major strain is added to the current step by using the current strain ratio and the previous deformation strain carried over from the previous (forming) stage.
- *DEFINE_CURVE_STRESS:
  Add new options to *DEFINE_CURVE_STRESS, add ITYPE = 1,2,3,4,5,11.
- *MAT_036:

  - Output the optimized material parameters when using both R-values and the A, C, H, P parameters as input.
  - Add an error message when the material model is attempted for tshells.
  - Turn off the output of material parameters if encryption is used.

- **MPP**

  - Suppress output of pfile information to d3hsp and messag if the *CONTROL_MPP_PFILE line itself is encrypted.
  - Fix automatic setting of "decomp { bagref }" in the pfile, which was broken in revision 101313.
  - Add MPP contact timing calls around force transducer initialization and net force calculations, so they are better represented in the contact timing table.
  - Adjusted initialization of *PART_MODE for MPP so that certain processing only happens on processor 0.
  - Correct problems with using MPP predecomposition when using jobid specifications. There were issues with initializing the file ids.
  - Enhance MPP eigensolver to have a kinder, gentler termination when no eigenmodes found.
  - For MPP, register the part in *PART_MODES to not be split across processes.
  - Allow parameter expression in keyword *CONTROL_MPP_PFILE.
  - MPP load balancing profiles are output to both .csv and .xy files.
  - pfile directive "decomp { defgeo }" in a full deck restart causes decomposition to be re-done using the current deformed geometry. This can keep

elements in contact in the same processor and helps the MPP performance of models with large deformation for example SPH bird strike, car wading, etc.

- **Output**
  - *DATABASE_ELOUT, *DATABASE_HISTORY_BEAM: Fix old typo in beam history collection routine, the effect of which is not obvious but could possibly have led to incorrect output of some beam data in elout.
  - Do a better job deleting scratch LSDA files from the file system, including removing all %XXX extensions. This may help with some customer file system issues during large adaptive problems.
  - Add rotations (moments) for nodes in the bndout file if the problem has 6 degrees of freedom.
  - Implement new force collection routines for bndout data, which should do a better job of reporting just those forces/energies that are due to the boundary conditions applied.
  - Adjust implicit logic for secforc output for arclength method.
  - Fix a problem in reporting tied contact resultant forces in implicit.
  - Enhance logic that determines when to write out the last state to d3plot for implicit.
  - Fix an MPP bug for nodal stress/strain output, which could occur when more than one part share a node where stress/strain output is requested.
  - Fix missing plastic strain tensors in d3plot when STRFLG in *DATA-BASE_-EXTENT_BINARY is set and INTSTRN = 1 in *INTERFACE_-SPRING-BACK.
  - Fixed stress output for shell forms 13, 14 and 15 when NIP = 4 on *SEC-TION_SHELL and MAXINT < 0 on *DATABASE_EXTENT_BINARY. The stress outputted was incorrect.
  - Fixed issues when reporting eroded hourglass energy to glstat and matsum. For brick elements, the eroded energy was counted twice, and for thick shells, eroded energy was not counted at all. Both issues caused energy to not balance in the glstat data.
  - Enabled secfor output for higher order shell forms 23 and 24.
  - The 'Effective Stress' option is supported in *DEFINE_MATERIAL_HIS-TO-RIES, meaning that the material dependent equivalent stress is output to the d3plot database. Currently only *MAT_036 and *MAT_133 honors this option, all other materials will output the von Mises stress for now.
  - Variable NTIED of *DATABASE_EXTENT_INTFOR can be used to output the tied status on the slave side of tied mortar contact, including tiebreak and tied weld.
  - Fixed intfor database for SMP if the file size is larger than 7M byte.
  - Echo *DATABASE_EXTENT_COMP flags in d3hsp.
  - Fixed bug for d3plot if both DECOMP = 5 or 6 in *DATABASE_-EXTENT_-BINARY, and PSETID is specified in *DATABASE_BINARY_-D3PLOT.

- Fixed bug for *DATABASE_HISTORY_DISCRETE if BEAM = 1 in *DATABASE_BINARY_D3PLOT.
- Fixed bug in writing *SECTION_*_TITLE to d3prop file.
- Fixed legend of ssstat in binout.
- Fixed wrong cross-section ID in secforc if dyna.str is used.
- Write dynain file in I10 or long format is keyword input includes those formats.
- Fixed bug affecting d3plot when analysis includes dynamic relaxation.
- Added one additional significant digit to *NODE coordinates in dynain.
- Fix bug in d3plot when both higher order and ALE elements are in the model.
- *DATABASE_HISTORY_NODE_LOCAL_ID:
  Fix bad node labels in nodout when long input format is used.
- Fixed bug where HEADING in *DATABASE_HISTORY_NODE_ID was limited to 10 characters in free (comma-delimited) format.

- **Restarts**

  - Correct implicit memory pointers to work correctly on restart.
  - Also corrected dump and restart lengths for implicit restart.
  - Properly start up explicit LaGrange Multiplier treatment of joints at restart.
  - Fix seg fault when using *DELETE_CONTACT for restart when running with SMP.
  - Fix error termination for full deck restart that includes *DEFINE_ELEMENT_DEATH.
  - Fix input error during structured input when using *INITIAL_VELOCITY_GENERATION and *CHANGE_VELOCITY_GEN-ERATION together in a full deck restart.
  - Fix incorrect full deck restart analysis if initial run was implicit and the full deck restart run is explicit. This affects MPP only.
  - *CHANGE_CURVE_DEFINITION in a restart was not working properly to modify curve LCDT in *DATABASE_BINARY_D3PLOT.
  - Fix corrupt d3part database affect a small restart with *DELETE_PART and *DELETE_FSI.
  - Fix bug in full deck restart of tied contact that resulted in force discontinuities across the restart.

- ***SENSOR**

  - Fix a bug for *SENSOR_DEFINE_FORCE when FTYPE = JOINT, which occurs when joint id > 9999999.
  - Fix a bug for *SENSOR_CONTROL for type = SPC, that was introduced in r115453 & r115457.
  - The bug occurs when a SPC boundary condition was initially off and then turned on later.

- Fix a bug for *SENSOR_DEFINE_..._SET that can occur if sensor command is defined before the definition of the related *SET commands.
- Add MTYPE = BNDOUT to *SENSOR_DEFINE_MISC to trace energy reported in bndout.
- Add MTYPE = MATSUM to *SENSOR_DEFINE_MISC to trace energy reported in matsum.
- Fix a sensor bug that occurs when *SENSOR_DEFINE_FORCE is used to trace the force associated with prescribed motion.
- Fix a sensor bug that occurs when *SENSOR_DEFINE_MISC has MTYPE = CURVE that refers to a load curve of *DEFINE_CURVE_FUNCTION. The bug was introduced in r115362.
- Couple thermal-only analysis with general sensor so that sensor can be used to terminate the analysis.
- Add TYPE = ELESET to *SENSOR_CONTROL to erode elements.
- Add MTYPE = NFAILE to *SENSOR_DEFINE_MISC to trace number of failed elements.
- Fix a bug affecting *SENSOR_DEFINE_FORCE with FTYPE = JOINTSTIF.
- Fix bug in spotweld-constraint handling in MPP when TYPE = SPOTWELD in *SENSOR_CONTROL.
- Fix a bug in *SENSOR_CONTROL when TYPE = SPC. The bug occurs when a node is involved in more than one SPC definition.
- Add MTYPE = CURVE for *SENSOR_DEFINE_MISC so that sensor can trace the value of a time-dependent curve or a *DEFINE_CURVE_-FUNCTION.

- **SPG (Smooth Particle Galerkin)**

  - Added *CONSTRAINED_IMMERSED_IN_SPG for composite analysis.
    This keyword applies to immersion of beam or shell elements in SPG solids. This is a new feature of SPG method for failure analysis of some particular composites such as rebar in concrete and fiber-reinforced composites.
  - Added *CONTACT_SPG for self-contact in SPG method.
    This feature is useful in studying some self-contact for high velocity impact/penetration applications where failed particles may still interact in compression modes.
  - Optimize the SMP performance of SPG solid formulation 47.
  - *CONSTRAINED_IMMERSED_IN_SPG now works in MPP.
  - *MAT_181 is now supported for SPG solid formulation 47.

- **SPH (Smooth Particle Hydrodynamics)**

  - *CONTACT_2D_NODE_TO_SOLID:

- Contact was not robust when using master surface with sharp angles or thin structure, like a needle. It has been revised to handle better this kind of geometry, and take into account the thickness of slave nodes.
- Add a maximum parametric coordinate parameter MAXPAR for segment search (default = 1.05).
- Change format when transferring values from keyword format to structured format and pfile format. This change greatly improves precision.

- *CONTROL_SPH:
  Add IEROD = 3 to enforce zero deviatoric stress to eroded SPH particles, and conserve volumetric response if an EOS is defined.
- *DEFINE_SPH_To_SPH_COUPLING:
- Allow negative values of SRAD. In that case, we compute a contact distance based on volume instead of smoothing length.
- Fix bug for SPH parts using *MAT_147 (*MAT_FHWA_SOIL). History variables were improperly initialized, rendering the whole damage evolution aspect of the material inoperative with SPH.
- Implement enhancement for fluid formulations in SPH so that interaction between multiple SPH fluid parts is more robust.
- Fix bug affecting *DEFINE_BOX_SPH. This feature was broken.
- Fix bug for *DEFINE_ADAPTIVE SOLID_TO_SPH. History variables were not transmitted to the SPH particles properly for some materials.
- Add option to automatically compute the contact thickness of slave SPH particles using ITHK in *CONTROL_SPH. The thickness calculated by ITHK = 1 is used only if SST (*CONTACT_-AUTOMATIC_NODES_TO_-SURFACE) or OFFD (*CONTACT_2D_NODE_-TO_SOLID) are set to zero. All default behaviors remain unchanged.
- Enable SPH in full deck restart.
- SPH part is now identified as element type 4 in d3hsp like this, "element type ..... = 4"
- *ELEMENT_SPH_VOLUME specifies volume instead of mass for SPH particle.
- Added in adaptive SPH formulation (ASPH) with anisotropic smoothing tensor (FORM = 9, SMP only) and renormalization approximation for adaptive SPH formulation with anisotropic smoothing tensor (FORM = 10, SMP only). The axes of those forms evolve automatically to follow the mean particles spacing as it varies in time, space and direction based on the strain rate tensors. These forms have better accuracy and stability than the standard SPH formulation.
- Added a new function ISHOW = 1 in *CONTROL_SPH whereby SPH particles generated by *DEFINE_ADAPTIVE_SOLID_TO_SPH will be shown as points instead of spheres before activating them, i.e., before erosion of parent solid.

- Added in a new variable ISPHKERN in *SECTION_SPH for higher order kernel option: with ISPHKERN = 1, a quintic spline kernel function (smoother and more accurate) will be used instead (supported in FORM = 0,1,4,9,10 in *CONTROL_SPH for both SMP and MPP version of executables).
- Added binout support for SMP rcforc file with *CONTACT_2D_NODE_-TO_SOLID. Write user id (instead of internal ID) in rcforc for *CONTACT_-2D_NODE_TO_SOLID. Fixed rcforc output in the case of multiple *CON-TACT_2D_NODE_TO_SOLID contacts (bug 13454).
- Added in _SPH_VARIATION option (SMP only) for *DEFINE_STOCHAS-TIC_ELEMENT with SPH particles.
- Supported *DEFINE_STOCHASTIC_VARIATION option for SPH particles (combined with *MAT....._STOCHASTIC option) with material models *MAT_010, *MAT_015, and *MAT_024.
- Support conventional mass scaling (negative DT2MS in *CONTROL_-TIMESTEP) for SPH.
  This feature works for both SPH 3D and 2D cases.

- **Thermal Solver**

  - *CONTROL_EXPLICIT_THERMAL_... and *CONTROL_ADAPTIVE (ADPTYP = 8, 1st line, 3rd column): For the explicit thermal solver, map the temperatures after each adaptive restart for ADPTYP = 7,8.
  - *CONTROL_EXPLICIT_THERMAL_...: Implement the explicit thermal solver in ALE 2D.
  - *CONTROL_EXPLICIT_THERMAL_CONTACT:
  - If part id < 0 in the *SET_PART called by *CONTROL_-EXPLICIT_THER-MAL_CONTACT, the autocontact is activated for that part. Otherwise, by default, the thermal contact is only searched between different parts.
  - Added death time TDEATH and birth time TBIRTH to *BOUNDARY_TEM-PERATURE_NODE/SET in order to activate and deactivate temperature constraints.
  - Add iterative solution option for the thermal radiation boundary condition linear equation solver. Correct logic used in determining the acceptable thermal solver options for SMP.
  - Fixed bug where dynain was missing thermal history variables.
  - New keyword *BOUNDARY_TEMPERATURE_RSW:

    - Prescribe nodal temperatures within a (possibly moving) ellipsoidal region of the structure.
    - Temperatures for the center and the boundary of the ellipsoid have to be input. In between there is a quadratic approximation.
    - Outside of the ellipsoid, no temperature values are prescribed.
    - Position and axis of symmetry are defined by to nodes.
    - Applicable to solid and thermal thick shell elements.

- Modification of variable time stepping in thermal solver:
  - Ensure that the step size of the last time step before a breakpoint is not smaller than half the previous step. If necessary, the last two time step sizes are averaged. The breakpoints are still hit exactly. This avoids drastic step size reductions (sometimes by some orders of magnitude) that slow down the further simulation.
  - Accept load curve input for dtmin, dtmax and dtemp in *CONTROL_-THERMAL_TIMESTEP. As usual if a negative integer number is given its absolute value refers to the load curve ID.

- *LOAD_HEAT_CONTROLLER now implemented for MPP.
- *BOUNDARY_THERMAL_WELD_TRAJECTORY:
  - Additional option for heat source definition. With IFORM.eq.5, the energy rate distribution does not have a pre-defined form, but can be given as a function of the local coordinates r,s,t, the time and the current weld velocity. The formula is input with a *DEFINE_-FUNCTION keyword.
  - Fixed d3hsp output. Now external IDs of used load curves instead of internal ids are written and cross reference for the curves' usage is output

- Thermal edge contact:
  - Models heat transfer from and to a shell edge onto a surface (solid facet or shell).
  - Shell edges have to belong to thermal thick shells (THSHEL = 1 in *CONTROL_SHELL).
  - Shell edges are on the slave side.
  - Activated if parameter ALGO is larger than 1 (2 = two_way, 3 = one_way).
  - Available in both MPP and SMP.

- Composite thick shells:
  - Added composite thick shell functionality to the structure heat transfer solver.
  - Up to this point the lay-up defined by *PART_COMPOSITE_TSHELL has not been taken into account by the thermal solver. Now, additional degrees of freedom are generated and the element is split into virtual elements in the element routine. The implementation is very similar to what has been done for thin composite shells defined by *PART_-COMPOSITE.

- Fixed error in reading *SECTION_SHELL_THERMAL

- *DEFINE_CURVE_FUNCTION is now supported in the thermal solver.

- **XFEM (eXtended Finite Element Method)**

  - Added erosion option for XFEM shells.

- **Miscellaneous**

  - *DAMPING_FREQUENCY_RANGE_DEFORM can now be applied to tshells.
    In previous versions it worked only for solids, beams, shells, and discrete elements.
  - Fixed bug in *DAMPING_FREQUENCY_RANGE_DEFORM.
  - The damping's contribution to internal energy was wrongly calculated. This did not affect the solution (stresses, displacements, etc), only the output values of internal energy.
  - Update to external case driver to support LSDA based includes in the keyword input.
  - Fix incorrect handling of symmetric load curves when checking discretization errors, which resulted in incorrect and misleading error messages.
  - Fix initialization problem that could arise if more than one *INTERFACE_-LINKING instance references the same *INTERFACE_-COMPONENT.
  - Fix some memory allocation and initialization related to *INTER-FACE_-LINKING.
  - Improve reporting of seatbelt input errors in nastran reader.
  - Added *DEFINE_DRIFT_REMOVE to provide a correction to curves to compensate for errors in accelerometers.
  - Fix a bug that occurs when *INCLUDE_TRANSFORM is used together with *DEFINE_BOX and/or *PART_INERTIA.
  - Fix a bug that generates duplicate parts even when *PART_DUPLICATE is never defined.
  - Automatically merge DEFORMABLE_TO_RIGID_AUTOMATIC cards with the same options for better performance.
  - *DEFINE_PRESSURE_TUBE: Added 2nd keyword input line for viscosity, step size, and damping. Added support for automatically generated shell/solid tubes.
  - Fix wrong pointer used for section id/properties when generating part for visualization of rigid wall during adaptivity. This caused error message, KEY+137, during adaptivity.
  - Fix input error for duplicate part if multiple *RIGIDWALL_-GEOMET-RIC_..._DISPLAY keywords are used, some with part id PID specified and some not.
  - Fix non-effective OPTIONs DBOX, DVOL, DSOLID, DSHELL, DTSHELL, DSEG for for deleting segments in *SET_SEGMENT_GENERAL.

- Add failure function terms (normal, bending, shear) as arguments of functions in *DEFINE_CONNECTION_PROPERTIES with PRUL.ge.2
- Add new option DGTYP = 5 to *DEFINE_CONNECTION_PROPERTIES.
- Fix for *DEFINE_CONNECTION_PROPERTIES with PRUL.ge.2 (*DEFINE_FUNCTION). The function IDs were not working with *INCLUDE_TRANSFORM and large IDs > 2**24 also failed.
- Add warning message for *DEFINE_FUNCTION: if the function name starts with i, j, k, l, m, n, I, J, K, L, M, or N, it will return an integer value.
- Removed the echo of each *CONTACT data and load curve data in d3hsp if that data are encrypted.
- Fixed bug in reading *CONTROL_REQUIRE_REVISION if free format is used.
- Fix a number of issues related to long format input:

  - Corrected legend that is written in nodout if long format is used.
  - Fixed bug in reading long format if *KEYWORD long = yes is used in include file.
  - Fixed bug in reading long format input for *INCLUDE_STAMPED_PART if optional 4 or 5 card doesn't exist
  - Fixed bug for long format bug for the following keywords:
    *MAT_EMMI
    *PERTURBATION_NODE
    *DEFINE_TABLE_MATRIX
    *INTERFACE_SPRINGBACK_LSDYNA
    *EOS_013
    *ALE_FSI_TO_LOAD_NODE
    *INITIAL_VOLUME_FRACTION
    *CONTROL_ADAPTIVE (3d)
    *CONTACT_AUTOMATIC_GENERAL_INTERIOR_MPP
    *CONTACT_ERODING_SINGLE_SURFACE_MPP
    *PERTURBATION_NODE
    *CONSTRAINED_GENERALIZED_WELD_FILLET
    *AIRBAG_HYBRID_ID
    *MAT_ADD_EROSION
    *FREQUENCY_DOMAIN_FRF
    *PARAMETER
    *DEFINE_HEX_SPOTWELD_ASSEMBLY
    *DEFINE_SPH_TO_SPH_COUPLING
    *ELEMENT_BEARING
    *SPH_COUPLING
    *ALE_2D
    *ELEMENT_BEAM_PIPE
    *BOUNDARY_PRESCRIBED_FINAL_GEOMETRY
    *PARAMETER_EXPRESSION
    *NODE_MERGE

*NODE_MERGE_SET
*ELEMENT_NURB_SOLID_PATH
*INITIAL_STRAIN_*
*BOUNDARY_THERMAL_BULKNODE
*CONSTRAINED_SHELL_TO_SOLID
*MAT_RIGID if geometry contact entity is used
*MAT_VISCOELASTIC_HILL_FOAM
*MAT_002

- Fixed bug in reading multiple entries of any of the following commands:
  *CONTROL_REQUIRE_REVISION
  *SECTION_SHELL_EFG
- Fixed bug for *INCLUDE_TRANSFORM in the case where the material ID is in alpha (non-numeric).
- Fixed bug in reading *SECTION_SHELL and *SECTION_SOLID if multiple sections are entered under one keyword.
- Correct the application of reaction forces from *INTERFACE_SSI_AUX_EMBEDDED in *INTERFACE_SSI (MPP only).
- Fix bug in running SSI problems in single precision.
- 3D adaptivity now partially supports *INCLUDE_TRANSFORM: a transformation of model geometry can now be specified using TRANID.
- *PART_MOVE:
  Extend to support *SET_PART_COLLECT and *SET_PART_ADD.
- Enable support of parametric filename in *INCLUDE when adaptivity is used.
- *INTERFACE_SPRINGBACK_LSDYNA, and *INCLUDE_BINARY:
  Fix missing SPCs output in binary dynain files in both SMP and MPP

Capabilities added to create LS-DYNA R12:

See release notes (published separately) for further details.

- ***AIRBAG**

  - Fix a bug for the output of area and leakage information for all parts constituting a control volume airbag. The bug occurred when an airbag was comprised of more than 10 parts.
  - *AIRBAG_HYBRID_CHEMKIN: fix an MPP bug introduced in r117881 that results in incorrect airbag pressure.
  - Remove the interaction between *AIRBAG_REFERENCE_GEOMETRY and *INITIAL_FOAM_REFERENCE_GEOMETRY so that they can only be used to define the reference geometry of shell and solid elements respectively.
  - *AIRBAG_PARTICLE (CPM):

- New keyword *DEFINE_CPM_NPDATA to support more part-specific input for *AIRBAG_PARTICLE. Invoked by NPDATA > 0 and STYPEH = 2 or 3. Among other things, this new feature allows user to control smoothing algorithm for applying particle to fabric impulse.
- Add new limit checking and self adjusting algorithm for 4th order polynomial nonmonotonic function of nonlinear CP to avoid incorrect result.
- Support inflator mass flowrate curve (LCTi) using *DEFINE_CURVE, *DEFINE_CURVE_FUNCTION and *DEFINE_FUNCTION.
- New feature for *DEFINE_CPM_VENT for pushout vent to allow user to apply the ambient pressure when internal parts extend out from the external vent.
- Support C23 (discharge coefficient) as function of vent area.
- Support Autoliv porous leakage model (FVOPT = -1,-2) under CPM and CPM+UP switch capabilities.
- Add tire inflation capability under CPM method to maintain the target tire pressure during the initial setup.
- Support inflator volume evaluated from current geometry while using user-defined inflator chamber.
- Fix bug for airbag with solid parts inside. The volume from those parts are excluded from bag volume.

◦ New keyword *CONTROL_AIRBAG for CV (Control Volume) closed volume check.
◦ Support multiple airbags when not all airbags have a reference geometry (*AIRBAG_REREFERENCE_GEOMETRY).

- ***ALE**

◦ *INITIAL_ALE_MAPPING: Add a parameter SYM to apply specific mapping rules to elements and nodes outside the mesh of the previous run that wrote the mapping file to be used in the current run.
◦ *ALE_MAPPING: Add new keyword to map data during a run (not just initially like with *INITIAL_ALE_MAPPING). A particular state from the mapping file is read.
◦ *INITIAL_VOLUME_FRACTION_GEOMETRY and CNTTYP = 7: Allow the user to define the geometry using *DEFINE_FUNCTION.
◦ *INITIAL_DETONATION: If PID < -1, |PID| is the ID of a *SET_PART.
◦ *INITIAL_HYDROSTATIC_ALE, *ALE_AMBIENT_HYDROSTATIC: Account for the compaction to compute the initial and ambient hydrostatic pressure for *EOS_MIE_GRUNEISEN.
◦ *ALE_PRESCRIBED_MOTION and *BOUNDARY_AMBIENT: Add a new parameter SIDR in both keywords to control their use during the dynamic relaxation phases (similar to SIDR in *DEFINE_CURVE).

- *BOUNDARY_AMBIENT: Set birth and death times with the first and last abscissa of *DEFINE_CURVE for the internal energy and relative volume time curves (LCID1 and LCID2).
- *CONTROL_ALE: Add a new variable BNDFLX to select only the ALE groups (*SET_MULTI-MATERIAL_GROUP_LIST) that can flux in when these groups are in the ALE elements along the mesh boundaries. Set BNDFLX = -1 to forbid any influx along free mesh boundaries.
- *ALE_BURN_SWITCH_MMG: Implement this keyword to allow the user to implement his own burn models.
- *ALE_MESH_INTERFACE: Implement this new keyword to mesh material interfaces with triangular shells (the material volume can also be meshed with tetrahedra).
- *CONSTRAINED_LAGRANGE_IN_SOLID: Implement a 2D version of the implicit thermal ALE coupling.
- *CONSTRAINED_LAGRANGE_IN_SOLID_EDGE with CTYPE = 5: Renew the coupling interface along the outside shell edges involved in the ALE coupling after shell erosion.
- *CONSTRAINED_LAGRANGE_IN_SOLID with 4 =< CTYPE <= 6 : Write in and read back from d3full the FSI relative displacements and other coupling arrays.
- *CONTROL_SEGMENTS_IN_ALE_COUPLING: New keyword that deactivates segments in the ALE penalty coupling (CTYPE = 4,5,6 in *CONSTRAINED_LAGRANGE_IN_SOLID) if the segments are face to face. If variable SYM = 1, a segment normally constrained is excluded from the coupling (similar to ISYM in *CONTROL_CONTACT).
- *DATABASE_BINARY_FSIFOR and *CONTROL_MPP_DECOMPOSITION_NUMPROC: Prevent fsifor from being corrupted by a MPP job starting right after MPP decomposition.
- *DATABASE_BINARY_FSIFOR and *SECTION_ALE2D: Output the interface force file (fsifor) in 2D (meshfringe in LS-PrePost should be used to see the coupling force and pressure distributions along the segment edges).
- *DATABASE_FSI: Output the center of pressure at fx-lc,fy-lc,fz-lc (or gx,gy,gz) in dbfsi if a node set (NDSETID) is provided in *DATABASE_FSI.
- *SECTION_ALE1D and *DATABASE_EXTENT_BINARY BEAMIP > 0: Access auxiliary and history variables in d3plot for ALE 1D elements (like NEIPH for solids and NEIPS for shells).
- *DATABASE_TRACER and TRACK = 2: The tracer moves with the ALE mesh.
- *DATABASE_TRACER and ALE mapping: Output the tracer final locations in a keyword format (to be included in the next run initialized by a mapping).
- A new ellipsoid geometry option is added in *INITIAL_VOLUME_FRACTION_GEOMETRY.
- *INITIAL_HYDROSTATIC_ALE now supports ALE single material with void formulation, that is, ELFORM 12 in *SECTION_SOLID.

- Structured ALE (S-ALE):
  - Support *EOS_MURNAGHAN to model weakly incompressible water.
  - *ALE_STRUCTURED_MESH_VOLUME_FILLING implementeded to fill ALE fluids into the initial S-ALE mesh and sidestep *INITIAL_VOLUME_FRACTION_GEOMETRY.
  - *ALE_STRUCTURED_FSI implemented to perform ALE fluid-structure interaction with structured ALE mesh. It could effectively stop the leakage often observed when using *CONSTRAINED_LAGRANGE_IN_SOLID.

- ***BATTERY (Electrochemistry Solver)**

  (See also "Battery module Release" in the "EM (Electromagnetic Solver)" section.)

  The *BATTERY family of keywords invokes the new electrochemistry solver, which is only available in double precision executables. *BATTERY keywords are documented in Volume III of the LS-DYNA Keyword User's Manual.

  The keywords starting with *BATTERY refer to and control the problem set up for detailed one-dimensional electrochemistry modeling of battery cells. This is intended to be used for battery-thermal-structure-interaction problems.

  Two Lithium Ion Battery (LIB) models are available via two one-dimensional full cell models.

  - Single insertion which has this structure: Anode Lithium metal electrode/Separator/Cathode composite electrode
  - Dual insertion which has this structure: Anode composite electrode/Separator/Cathode Composite electrode

  These two cell models are based on an electrochemical model with various anode, separator, and cathode material properties. Therefore, the user can select a material property for their anode and cathode including an open-circuit potential (OCP). For the separator, the user can also select a material property among the different electrolytes which include all of the transport properties necessitated in battery simulation. Note that all transport properties are uniquely designed for each battery type.

  The selection of the single insertion or dual insertion model is done in keyword *BATTERY_ECHEM_CONTROL_SOLVER. Here, users can select the

battery run mode such as Galvanostatic or Potentiostatic, the number of cycles, and termination controls. Please see Vol III of the keyword manual for more details.

With the *BATTERY_ECHEM_CELL_GEOMETRY keyword, users can choose the length of each layer in a single cell including both sides of the current collectors, and the corresponding total number of mesh elements can also be input.

After this is done, then users need to set up their own values of all variables in the material cards for all layers: anode, cathode, and separator. The three main keywords are,

*BATTERY_ECHEM_MAT_ANODE

*BATTERY_ECHEM_MAT_CATHODE

*BATTERY_ECHEM_MAT_ELECTROLYTE

Here, first the OCP ID must be carefully selected (please refer to the keyword manual) and then Coulomb capacity, initial state of charge, thermodynamics data, and porous media data, respectively.

In the *BATTERY_ECHEM_THERMAL keyword card, the user can set the initial temperature and other thermal properties. However, please note that this card is ignored when the battery solver is coupled to the thermal and thermal-mechanical solvers.

Please note that the purpose of these 1D solvers is give the user a tool to test their OCP, material properties, and transport battery properties. For coupling the electrochemical battery solver to the thermal-mechanical solver, users must design their own mesh system with a different part number and must assign the individual part numbers for each solver. For example, if the electrochemical battery solver needs to solve within a specific part (all battery regions), then the user must assign that part number in the first variable column in each of these material keywords: *BATTERY_ECHEM_MAT_ANODE, *BATTERY_ECHEM_MAT_CATHODE, and *BATTERY_ECHEM_MAT_ELECTROLYTE. The same part number should be assigned for use by the structural thermal and mechanical solvers. Structural parts outside of the battery would have other part numbers. Please note that the 1D electrochemistry solver solves all elements assigned to the part numbers for the battery, and also note that this battery solver has its own 1D mesh system in each battery structural element, while the thermal-mechanical solver has its own 3D mesh system.

Currently however, only the dual insertion model is coupled with the LS-DYNA thermal-mechanical solvers. This model covers all Lithium-Ion batteries used by the battery manufacturers of cellular phones, and automotive industries batteries.

So, in version R12.0.0, users can simulate how the Lithium-Ion battery responds thermally and/or mechanically when external heat sources or impacting forces are applied to the battery pack. The battery model can be a single battery cell, a cell stack which has multiple cells connected (over 100 cells), and even multiple cell stacks connected in parallel. By controlling the solution scheme of the structural solvers, users can calculate the structural effects for a certain period of time of battery operation such as initial, middle, and end of state of battery discharging or charging.

For more detail about electrochemical battery theory, please refer to the LS-DYNA multiphysics theory manual. For keyword setup, please refer to the multiphysics (Vol III) keyword manual. In addition, for interested users, please request some sample keyword decks from LS-DYNA technical support, or email directly to kyoungsu.im@ansys.com.

- ***BOUNDARY**
  - Fix bug in *BOUNDARY_PRESCRIBED_MOTION which could cause velocity boundary conditions to be incorrectly handled for dof=+/- 4 or 8 if the node has more than one velocity boundary condition, e.g., one during dynamic relaxation and another during transient analysis.
  - Corrected MPP communication error associated with Implicit loading constraints for *BOUNDARY_PRESCRIBED_MOTION_FINAL_GEOMETRY.
  - For convection, flux and radiation boundary conditions, the parameter PSEROD on *BOUNDARY_... specifies a part set for which new segments exposed to the environment due to solid element erosion will inherit the boundary condition data.
  - New option BNDOUT2DYNAIN on *BOUNDARY_PRESCRIBED_MOTION_RIGID, allows for output of reaction force to dynain for use in subsequent simulations.
  - SPC2BND on *CONTROL_OUTPUT which will convert constraints on *MAT_RIGID to prescribed motions, for access to reaction forces in bndout.
  - Fix *BOUNDARY_NON_REFLECTING to have the correct velocity averaging and force redistribution for triangular segments.
  - *CONTROL_ADAPTIVE: Boundary conditions *BOUNDARY_RADIATION_SET and *BOUNDARY_CONVECTION_SET are updated in accordance with mesh changes due to 3D tet adaptivity under the condition that the segment set(s) are defined using *SET_SEGMENT_GENERAL with OPTION = PART.

- ***BLAST**
    - Fix blast wind velocity field for *LOAD_BLAST_ENHANCED BLAST = 4. Previously velocity was always the ground-reflected wave. Now, if a segment is not in the Mach stem region, the blast wind comes from both the incident-only and ground-reflected waves.
    - Fix a bug which could potentially affect results for models which contained both *LOAD_BLAST and *LOAD_BLAST_ENHANCED with TBO.ne.0. The time offsets could get mixed up or ignored.

- ***CESE** (Compressible Fluid Solver)
    - For the solvers not performing chemistry calculations, a switch has been made to a positivity-preserving method. For most problems, this will lead to a smaller time step, depending upon the shape of the smallest mesh element. Note that this method guarantees that density and internal energy remain positive.
    - Several bug fixes were made that make these solvers more stable.
    - For the CESE moving mesh conjugate heat transfer solver, fixed several bugs, including some MPP bugs that depended upon the mesh decomposition.

- ***CHEMISTRY**
    - The inflator model can be extended up to a 5 chamber model. Previously, it was limited to only a 3 chamber model which consists of the combustion chamber, gas chamber, and tank. In this version, we added two more gas plenum chambers to control both the speed of the gas and pressure into the tank.
    - Resolved issues with back flows when the pressure of the downstream gas chamber is higher than the upper chamber by correcting the pressure equation.
    - Updated the procedure for computing/loading an initial blast profile as an initial condition of a detonation or deflagration.
    - Fixed some problems in the axisymmetric combustion solver.
    - Chemically-reacting FSI flow problems using the Euler equation solver now work for any problem up to 60 species in the combustion gas. FSI with this Euler solver is strong and stabilized.

- ***DUALCESE (Dual CESE Compressible Fluid Solver)**
    - The *DUALCESE family of keywords invokes the new dual Conservation Element/Solution Element (dual CESE) compressible fluid solver. This solver is only available in double precision executables.
    - The *UNIT family of keywords is introduced which provides a coherent way to specify units in an LS-DYNA problem. For now, these keywords only

work with the dual CESE solver but may be extended to other solvers in the future.

- Dual CESE Solver Characteristics:
  - Explicit
  - Double precision
  - Dynamic memory handling
  - SMP and MPP
  - 3D solver / special case 2D solver and 2D axisymmetric solver. Note: 2D axisymmetric solver is only done for the CFD solver, not yet for FSI-ibm or FSI-mmm solver cases.
  - Automatic coupling with the LS-DYNA structural solver
  - Eulerian fixed mesh or moving mesh (Either type input with *DUALCESE_ELE2D or *DUALCESE_ELE3D cards, or via *MESH cards for a tetrahedral mesh)

- Dual CESE Solver Main Features:
  - CFD solver is based upon the dual CESE (Conservation Element / Solution Element) method that is a new version of CESE technology with enhanced accuracy and robustness
  - Highly accurate shock wave capturing
  - Embedded (immersed) boundary approach or moving mesh (fitted) approach for FSI problems
  - Mesh can be broken up into regions/parts with a different solver per region, with the intent to minimize the region where a moving mesh FSI technique is used, or where an immersed boundary FSI method is used. This capability is intended to help optimize solver performance.
  - Complex fluid equations of state (EOS) are now available through the REFPROP and COOLPROP EOS libraries. This is only supported with *DUALCESE models.
  - Bi-cubic table look-up systems are now available for the REFPROP and COOLPROP libraries to dramatically speed up the evaluation of thermodynamic quantities.

- Dual CESE Solver Applications (Non-exhaustive):
  - FSI problems
  - Shock wave capturing
  - Shock/acoustic wave interaction

- Planned future features of Dual CESE Solver:
  - FSI with material erosion (as done in the *CESE immersed boundary FSI solver)
  - Coupled stochastic fuel spray solver (See *STOCHASTIC keywords)

- Coupling with chemistry (See *CHEMISTRY keywords) solver
- Multi-species transport
- Conjugate heat transfer
- Cavitation model

- ***CONTACT**

  - Fix old issue for *CONTACT_ENTITY type 9 to properly handle rotations when the entity is not centered on (0,0,0).
  - Fix for spotwelds improperly deleted due to rigid body conflict when an IPBACK *CONTACT interface is in effect. The inability of the constraint-based contact interface to tie should not cause the weld to be deleted if the penalty side ties. (MPP only.)
  - Fix SMP *CONTACT_2D_NODE_TO_SOLID. Friction was being ignored.
  - Added a warning that *CONTACT_TIEBREAK_NODES_TO_SURFACE_-ID is not supported for implicit computations.
  - *CONTACT_2D_..._THERMAL is now available in MPP.
  - Fix an SMP bug for ERODING contact of solid elements, which could result in erroneous contact thickness.
  - Fix seg fault or incorrect frictional behavior when using _THERMAL_FRIC-TION option for *CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_-SURFACE and *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE (SMP only).
  - Fix instability when using *CONTACT_TIEBREAK_NODES_TO_SUR-FACE (SMP only).
  - Fix incorrect *CONSTRAINED_TIE-BREAK behavior when the master node is the last node in the input after sorting.
  - Fix failure to detect contact between beam and shell edge when using *CON-TACT_AUTOMATIC_BEAMS_TO_SURFACE and the beam diameter is large compared to the segment size (SMP only).
  - Fix *CONTACT_AUTOMATIC_GENERAL for spot weld beams when us-ing SSID = 0, i.e. all parts included in the contact, and CPARM8 = 2.
  - Implement unloading curve, UNLCID, for options FCM = 2/3 in *CON-TACT_RIGID_(OPTION).
  - FTORQ = 1 and 2 (Opt. Card E in *CONTACT), affecting transmittal of mo-ments, are now implemented in SMP for *CONTACT_AUTOMATIC_SUR-FACE_TO_SURFACE_TIEBREAK and *CONTACT_AUTOMATIC_ONE_-WAY_SURFACE_TO_SURFACE_TIEBREAK.
  - FTORQ = 2 is now implemented in SMP for *CONTACT_AUTOMATIC_-SURFACE_TO_SURFACE and *CONTACT_ONE_WAY_SURFACE_TO_-SURFACE.
  - Added contact energy density to the intfor database for segment-based (SOFT = 2) contact. This option is invoked by NENG = 1 on *DATABASE_-EXTENT_INTFOR.

- Added support for ORTHO_FRICTION option for segment-based (SOFT = 2) contact. This option is available for all versions, SMP, Hybrid, and MPP with and without the groupable option, and for all supported CONTACT keywords.
- Added options to limit the scope the DPRFAC option of segment-based (SOFT = 2) contact. When DPRFAC is set to a value greater than or equal to 1.0, then DPRFAC is the ID of either a shell set, a segment set, or a part set. When both segments are in the set, then the DPRFAC option is active for that segment pair. If either segment is not in then set, the DPRFAC is inactive. When searching for the set, the search will proceed in the order of shell set, then segment set, and finally part set. The first set that is found with a matching ID will be used. The set attribute DA1 will be read and used as the DPRFAC value.
- Added support for VSF parameter on Card 3 of *CONTACT when using SOFT = 2 contact.
- Added support for FTORQ = 2 (*CONTACT, Card E) for SMP and MPP segment-based (SOFT = 2) contact. Setting FTORQ = 2 adds torque to master nodes to counteract the moment that is created by frictional contact forces due to the contact surface being offset from the mid-plane of the element. This added torque reduces the net moment from contact to zero.
- Added keyword *DEFINE_FRICTION_SCALING which allows shell segments to have friction coefficients on the inner and outer face (SOFT = 2 contact only). Independent scale factors on the inner and outer face scale the nominal friction coefficient. This was motivated by airbags which have liners on the inside of the bag thus creating a smoother (slicker) surface on the inside as compared to the outside.
- Added a new variable EDGEK on Card C of *CONTACT which scales edge-to-edge contact stiffness for SOFT = 2 contact having DEPTH = 5, 15, 25, or 35.
- Added control of thick segment checking using the SNLOG flag on *CONTACT. A thick segment check has been done quietly throughout the history of segment-based (SOFT = 2) contact. A search along the contact surface is made looking for thick pairs that are too close, and those pairs are removed from contact. This is done to prevent possible unstable behavior that could occur if the offsets of nearby thick segments come into contact at a bend in the mesh. When SNLOG = 0 or 1, the thick segment check will be done quietly as before. Set to 2, the check will be done and a warning 21465 will be written to report the segment pairs that are removed from contact. Set to 3, the thick segment check will be omitted.
- Enabled segment-based contact (SOFT = 2) to work with segments attached to cohesive elements with zero volume.
- Enabled *CONTACT_ENTITY to work with thick shell elements. It was previously error terminating in the input phase.

- Enabled SINGLE_SURFACE segment-based (SOFT = 2) contact to output gap values to the intfor output database. Previously, output of the gap values worked only for the non-SINGLE_SURFACE contact types.
- Enabled the SPOTHIN and SWRADF variables on *CONTROL_CONTACT to work when spot welds are modeled by sharing nodes with the shell parts that are welded. This has not worked until now because the search for affected shells was based on tied contact, and tied contact is not needed when nodes are shared.
- Enabled *CONTACT_2D_AUTOMATIC to work with erosion of 2D solid elements that use *MAT_081 or *MAT_082.
- Enabled multiple instances of *CONTACT_2D_AUTOMATIC_TIED to be reliably used in a model.
- Improved the PSTIFF option of segment-based contact to make the segment mass better match the nodal masses. The main effect is to increase the stiffness for segments on the edge of the mesh. For a regular mesh with no mass scaling or lumped nodal masses, the PSTIFF option now calculates the same segment mass as the default method based on segment volume and density.
- Fixed segment-based contact for adaptive remeshing and full deck restarts.
- Fixed the coefficient of restitution option (ICOR) in segment-based contact when it is used along with DPRFAC (Depth of Penetration Reduction FACtor).
- Fixed *CONTACT_2D_FORCE_TRANSDUCER with both slave and master sides defined when they are used with *CONTACT_2D_AUTOMATIC in MPP. A memory clobber was likely and also output was incorrect.
- Fixed MPP wear calculation in segment-based contact. A mix-up of ID numbers means that the wear was only working when contact interfaces were numbered sequentially from 1.
- Fixed the THERMAL option of *CONTACT in MPP when some MPP partitions do not participate in all the contact definitions.
- Fixed *CONTACT_2D_AUTOMATIC_TIED when used with selective mass scaling, which is made active by setting IMSL = 1 and DT2MS < 0 on *CONTROL_CONTACT. The problem occurred when selective mass scaling was applied to the nodes that are tied. Prior to the change, kinematic constraints were failing.
- Fixed MPP *CONTACT_2D_AUTOMATIC when beams were in contact, or when solids were used with nonzero values of solid surface offset(s) (variables SLDSOS or SLDSOM). Both cases could lead to using invalid memory space and a segmentation fault.
- Add new option ICNEP = 1 to *DEFINE_FRICTION with which those lines with non-existent parts or part sets will be ignored.
- Variable ENGOUT on *CONTROL_OUTPUT added to write minimum (wherever occurring) contact energy densities to d3plot (MORTAR contact only).
- Variable NENG on *DATABASE_EXTENT_INTFOR added to write contact energy densities to intfor (MORTAR contact only).

- Variable PENOUT on *CONTROL_OUTPUT added to write maximum (wherever occurring) penetrations across interfaces to d3plot (MORTAR contact only).
- Variable NPEN on *DATABASE_EXTENT_INTFOR to write absolute and relative penetrations to intfor (MORTAR contact only).
- Variable NTWELD on *DATABASE_EXTENT_INTFOR writes user tied weld history variables to intfor file (MORTAR contact only).
- Variable VC on *CONTACT_... supported for MORTAR contact.
- Added variable TDPEN on *CONTACT_2D_AUTOMATIC_SURFACE_-TO_SURFACE_MORTAR. This is the analogue to interference option MPAR1 for IGNORE = 3 in 3D automatic MORTAR contact.
- Mortar contact supports erosion, that is, any solid segment or shell edge segment belonging to parts involved in the contact definition will become active in the contact when exposed to the environment due to erosion.
- IGNORE = 4 on *CONTACT_..._MORTAR supports a curve of relative interference reduction vs. time. When MPAR1 < -1.0, |MPAR1| is the curve ID.
- *LOAD_THERMAL_CONSTANT is supported in mortar contact, in those situations where the contact properties depend on temperature.
- In eigenvalue analysis, nonzero mortar contact stress will not influence rigid body modes, i.e., you should see the proper rigid body modes among the available output.
- TEMP < 0 on *CONTACT_..._MORTAR_TIED_WELD calls a user tied weld interface, allowing implementation of "arbitrary" tied condition in weld simulations.
- *CONTACT_TIED_..._THERMAL supported for (spotweld) beams.
- The THERMAL option can now be used for the following tied contacts:

  *CONTACT_TIED_NODES_TO_SURFACE_OFFSET_THERMAL

  *CONTACT_TIED_NODES_TO_SURFACE_CONSTRAINED_OFFSET_THERMAL

  *CONTACT_TIED_NODES_TO_SURFACE_THERMAL

  *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_OFFSET_THERMAL

  *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET_THERMAL

  *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET_THERMAL

  *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_THERMAL

  BUT the slave set type can NOT be a node set, at least not yet.
- Now implemented for MPP are *CONTACT_AUTOMATIC_SURFACE_-TO_SURFACE_TIEBREAK and *CONTACT_AUTOMATIC_SURFACE_-TO_SURFACE_TIED_WELD.

- Segment-based contact (SOFT = 2) now supports groupable and non-blocking features.
- Option FTORQ for transmittal of moments across the contact interface is implemented in the groupable node-to-surface contacts, surface-to-surface contacts, and tied contacts.
- *CONTACT_AUTOMATIC_GENERAL supports options SOFT = 1 and SRNDE for shell edge treatment.
- *CONTACT_AUTOMATIC_GENERAL supports options SOFT = 1 and SRNDE for the shell edge treatment.
- A new orthogonal friction model is developed for the constraint and penalty *RIGIDWALL_ORTHO. A RIGIDWALL_ORTHO with equal friction coefficients in all directions now behaves as a regular RIGIDWALL with a single friction coefficient.
- *CONTACT_RIGID_TO_RIGID is enhanced to support unloading curve, FCM = 1/2/3.
- *CONTACT_CONSTRAINT_NODES_TO_SURFACE is enhanced to support variable PENSF on MPP Card 2 of *CONTACT and recover contact forces that existed before solid remeshing associated with 3D solid adaptivity.
- *CONTACT_AUTOMATIC_GENERAL is improved to stabilize short beams with small rotational inertias.
- ERODING contacts are now supported in full deck restarts.
- *CONTACT_AUTOMATIC_BEAMS_TO_SURFACE supports beam to shell_edge contact and detects the contact between shell edges and phantom nodes.
- A new built-in variable IDRFLG added to *DEFINE_CURVE_FUNCTION, *DEFINE_FUNCTION. IDRFLG carries a value of 1 during dynamic relaxation and 0 in the transient phase.
- Multiple *DEFINE_FRICTION tables with the same ID are merged.
- Effect of variable I2D3D is correctd in MPP to avoid duplicated contact segments when the attached shell and solid are not assigned to the same processor.
- ERODING contact in MPP is fixed to compute the stiffness of newly-exposed solid nodes and segments and apply the optional thickness SLDTHK to the newly-exposed solid segments.
- The contact thickness in *PART_CONTACT is applied to *CONTACT_AUTOMATIC_GENERAL.
- *CONTACT_AUTOMATIC_GENERAL is corrected by reducing the contact stiffness to half.

- ***CONSTRAINED**

  - Fix ordering issue during initialization of *CONSTRAINED_INTERPOLATION in MPP that could have resulted in incorrect "colinear" warnings or possibly deadlock

- Fix MPP message passing error that could occur if a node involved in *CONSTRAINED_SHELL_TO_SOLID is shared between more than 2 processors.
- Enhanced processing of an exactly singular constraint matrix for *CONSTRAINED_INTERPOLATION.
- Corrected error in the checking for massless *CONSTRAINED_INTERPOLATION constraints in single precision.
- Enhance *CONSTRAINED_INTERPOLATION in the explicit solver so the linear algebra of the constraint equation processing always operates in double precision to reduce loss of precision in single precision executables.
- Add implicit support to *CONSTRAINED_SHELL_IN_SOLID.
- *CONSTRAINED_BEAM_IN_SOLID:
  - Add support for IDIR = 1. This means the beam is allowed to freely slip longitudinally inside solid elements.
  - Add implicit support for the AXFOR option. Debonding between beams and solids may now be simulated using the implicit solver.
  - Add implicit support for CONSTRAINED_BEAM_IN_SOLID_PENALTY.
- Fix incorrect *CONSTRAINED_INTERPOLATION motion of the dependent nodes if the number of constrained dof is less then the total dof, i.e., DDOF.ne.123456.
- Fix ineffective PNODE in *CONSTRAINED_NODAL_RIGID_BODY when PNODE < 0.
- Fix kinetic energy dependence on MPP core count when using *CONSTRAINED_JOINT_(OPTION) with LMF = 1 in *CONTROL_RIGID.
- Added swforc file output for welds modeled by *CONSTRAINED_GENERALIZED_WELD. Output values are the brittle failure forces, axial and shear, and the failure function.
- Improved temperature-dependent failure curve option of spot welds defined by * CONSTRAINWED_SPOTWELD. Curve interpolation was using the wrong segment of the curve. Also, changed swforc output to show zero axial and shear forces after a weld has failed.
- Add correct torsion to SPR3 (*CONSTRAINED_INTERPOLATION_SPOTWELD with STIFF4 > 0).
- Small modification for PIDVB < 0 of *CONSTRAINED_SPR2/SPR3: Beams get deleted after failure (they were just separated before).
- Fix for *CONSTRAINED_SPR2/SPR3: part id of internally generated beams has to take Nodal Rigid Bodies into account.
- Ctl. Add error trap if INTPERR = 1 is set on *CONTROL_SHELL and data interpolation would be done with *INITIAL_STRESS_SHELL.
- *CONSTRAINED_JOINT_STIFFNESS_CYLINDRICAL now available to model cylindrical/revolute connections with play
- *CONSTRAINED_COORDINATE now supports part set ID in addition to part ID.

- *CONSTRAINED_COORDINATE: When IDIR is negative, the constraint is applied at the nearest node, not at the coordinate.
- For nodes which are not attached to any elements, turn off the automatic global constraint normally applied to such nodes if those nodes are involved in *CONSTRAINED_MULTIPLE_GLOBAL.

- ***CONTROL**

  - *CONTROL_REFINE_... with NTOTRF = -1: Refine solids or shells with elements dynamically added during the run (as opposed to NTOTRF > 0 for which the user must estimate the number of child elements required for the refinement and these elements are added during the initialization).
  - *CONTROL_REFINE_SHELL: Support contact for the case of NTOTRF = -1, i.e., dynamically add contact segments due to mesh refinement.
  - In *CONTROL_REFINE_... keywords:

    - If CRITRF < 0, reverse the refinement conditions
    - If CRITRM < 0, reverse the coarsening conditions

  - *CONTROL_STAGED_CONSTRUCTION:

    - Added support for *ELEMENT_SOLID ELFORMs 4, 13, 16, 17.
    -
    - Added new input field IDYNAIN to suppress output of dynain file at end of each stage. This can be done for all stages using IDYNAIN on *CONTROL_STAGED_CONSTRUCTION, or for individual stages using IDYNAIN on *DEFINE_CONSTRUCTION_STAGES.
    - Fix bug affecting *MAT_021 and *MAT_021 solids with Staged Construction (*DEFINE_STAGED_CONSTRUCTION_PART). When a part became active, the stresses were wrongly initialized. Bug affected solid elements only.

  - *CONTROL_PORE_FLUID: Fixed bug in internal energy calculation for solid element types with more than one integration point. This affected only models containing *CONTROL_PORE_FLUID.
  - *CONTROL_ADAPTIVE: Small change to 2d adaptive remeshing that should improve behavior for meshes with bad boundaries.
  - Fix problem with 2d adaptivity and boundary merging. Some boundary points between materials weren't merged in some cases, depending on where the program thought the 2d contours started. This only applies for *CONTROL_ADAPTIVE adpopt = 8 with mmm2d = 1.
  - Implement idrflg = -3 for *CONTROL_DYNAMIC_RELAXATION which invokes the version R7 (and earlier) implementation of idrflg = 3. Now idrflg = 3 means the parts not included in the part set are eliminated from the computation, and idrflg = -3 means all parts are included in the explicit

computation but only those in the part set are included in the distortional-kinetic-energy-based convergence check in the dynamic relaxation phase.

- Ignore *CONTROL_SPOTWELD between parts that are inactive during implicit dynamic relaxation phase.
- Fix a bug whereby SHLTRW in *CONTROL_SHELL was ignored when ISTUPD > 0.
- Add variable MLKBAG to *CONTROL_OUTPUT to include accumulated airbag gas leakage in abstat.
- Fix wrong pointer used for section id/properties when generating part for visualization of rigidwall during adaptivity. This cause error message KEY+137.
- *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS:

  - Add a stiffness option (ISTFNS) to *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS.
    EQ.1: no stiffness is added.
    EQ.2: only spin softening is added which keeps stiffness symmetric.
    EQ.3: both spin softening and gyroscopic effects are added which makes the matrix skew-symmetric.

    Default is 3.
  - Add the whirling direction to the output eigout.

- DISPLAY option in *RIGIDWALL_PLANAR will be ignored for stationary rigid walls when SKIPRWG = 1 in *CONTROL_CONTACT.
- Added options to the ERODE parameter on *CONTROL_TIMESTEP. The original options were 0 and 1 where 1 causes solid and thick shell elements to be eroded if their time step dropped below TSMIN*DT0 where TSMIN is specified on *CONTROL_TERMINATION, and DT0 is the solution time step that is calculated in the first cycle. The new options are to check and delete shell elements and beam elements having small time steps. The control of shells is in the 'tens' place and the beams is in the 'hundreds' place. The valid options for ERODE are now 1, 10, 11, 100, 101, 110, and 111. For ERODE = 111, beams, shells, and solids are all checked. For ERODE = 11, shells and solids are checked. The original options of 0 and 1 still behave exactly as they did.
- Added support of *CONTROL_SUBCYCLE for segment-based (SOFT = 2) contact. Contact forces are calculated for all nodes of a segment pair only if any node of the pair is due to have a force calculated.
- Fixed some issues so that solid elements and thick shell elements will work as advertised with respect to DTMIN on *CONTROL_TERMINATION, ERODE on *CONTROL_TIMESTEP, and PSFAIL on *CONTROL_SOLID. These variables control whether we terminate the analysis or fail elements when their time step becomes small or their volume becomes negative.

- Add an option TET13V on *CONTROL_SOLID to choose between the efficient and a more accurate version of the tet type 13 implementation.
- Lagrangian multiplier joints, LMF = 1 on *CONTROL_RIGID, are supported for consistent mass scaling (RBSMS = 1 on *CONTROL_RIGID).
- *CONTROL_ADAPTIVE:Fix bug in 3D tet adaptivity when there are rigid parts with a tetrahedral mesh and ELFORM = 10. Before the bug fix, the rigid parts with ELFORM = 10 were not properly written out during adaptive restart, resulting in an error termination.
- *CONTROL_REMESHING: 3D tet adaptivity is able to handle the remeshing of multiple bodies in a single adaptive parts. Preserving of feature lines is controlled by the variable SEGANG.

- **Discrete Element Method**

  - New keyword *DEFINE_DE_FLOW_DRAG to support DES interacting with external flow field.
  - Add a moving system with birth/death times in *DEFINE_DE_ACTIVE_-REGION.
  - Fix bug of generation failure and uneven distribution of injected DES particles (*DEFINE_DE_INJECTION) when the radius of injected DES particles is very small.
  - Fix segmentation fault when using simple and small restarts in DEM.
  - Add the keyword *DEFINE_DE_COHESIVE to enable the capillary force in specified DES node set or parts.
  - Add the keyword *INITIAL_STRESS_DES to initialize stress in discrete element spheres (DES).
  - Output the DES initial stress and geometry information into dynain_ini and dynain_geo files (FSPLIT = 1 in *INTEFACE_SPRINGBACK_LS_DYNA).
  - Fix incorrect behavior when using *DEFINE_DE_ACTIVE_REGION with itype = 1, i.e. BOX, with *DEFINE_TRANSFORMATION. The box was not rotated.

- **Element Free Galerkin (EFG)**

  - *SECTION_SOLID_EFG: Volume of 6-noded solid elements using element formulation 41 (EFG) was calculated incorrectly. That bug is now fixed.

- ***ELEMENT**

  - For triangular shells with thickness stretch (*SECTION_SHELL, ELFORM = 27) the option IDOF = 1 is made available allowing a continuous thickness field between them and quadrilateral shells with thickness stretch, ELFORM = 25,26.
  - For the Belytschko-Tsay shell with thickness stretch (*SECTION_SHELL, ELFORM = 25) an improved representation of stresses over the thickness may be obtained with the new option IDOF = 11 instead of IDOF = 1 (for

continuous thickness fields) or with the new option IDOF = 12 instead of IDOF = 2 (for discontinuous thickness fields).

- Changed *DEFINE_ELEMENT_EROSION to be more compatible with the original FE options and added support for IGA elements via *DEFINE_ELEMENT_EROSION_IGA.
- Added calculation of implicit tangent for shell formulation 46, a 2D cohesive element.
- *ELEMENT_DIRECT_MATRIX_INPUT:
  - Enhanced the reading of superelement files to support connections using nodes, scalar nodes, internal dofs, and the label of "0" for scalar nodes.
  - Added MPP logic for collecting nodes associated with superelements for use in decomposition for the reading of binary formatted files for superelements.
  - Fix an error associated with using superelements in MPP explicit. Two arrays should have been initialized to zero, but the bug did not manifest itself until the user used 12 processes. The arrays are now properly initialized to zero.
  - Corrected the initialization of superelements involving nodes with SPC constraints.
- *ELEMENT_SEATBELT_PRETENSIONER: make type-8 pretensioner available for 2D belt.
- *ELEMENT_SEATBELT_SENSOR: add type-5 sensor for tracing retractor payout.
- Restructure nodal volume data communication for solid tet formulation 13 for better parallel performance.
- Added new more conservative time step calculation (independent of shell thickness) for improved stability in cohesive shell formulation 29.
- Fix incorrect stress output to d3plot and ASCII files when using tetrahedron solid types 10 and 13 with orthotropic materials and when CMPFLG = 1 in *DATABASE_EXTENT_BINARY.
- Fixed a bug that caused axisymmetric elements (shell ELFORMs 14,15) to instantly fail when DTMIN > 0 in *MAT_ADD_EROSION.
- Shell elements with *MAT_NULL can be deleted by TIME in *DEFINE_ELEMENT_DEATH_SHELL.
- Added a check for invalid ELFORM values on *SECTION cards. Invalid values were leading to terminations without clear error termination messages.
-
- Added an optional modification to the time step calculation that is done for solid elements. See variable IHDO in *CONTROL_TIMESTEP. Setting IHDO to 1 causes the time step calculation to be modified such that it does not have a discontinuity between expansion and compression. With the default

time step calculation, the solution time step can jump up or down about 6% when an element controlling the time step switches from compression to expansion. The size of the jump depends on the linear bulk viscosity coefficient. These jumps may not occur if multiple elements are controlling the time step as it is unlikely for all to be expanding at the same time, so the smaller time step is used consistently. Setting IHDO to 1 prevents this discontinuity from occurring.

- Added support for shell form 23 in output file eloutdet (*DATABASE_ELOUT). When shell form 23 is used, the code can now output stress and strain at 2x2 or 3x3 integration points and extrapolate to all 8 nodes.
- Added a bulk viscosity option for thick shell (TSHELL) elements (See variable TSTYPE on *CONTROL_BULK_VISCOSITY).
- Enabled plane strain and axisymmetric elements (*SECTION_SHELL ELFORM 13, 14, 15) to include stress initialization by *INITIAL_STRESS_SHELL for materials that use equations of state.
- Enabled solid spot weld assemblies to use 8 node and 6 node cohesive elements with *MAT_240. There is no assembly failure calculation, but the resultant forces and moments are calculated and can be output to the swforc file. This works with solid element formulations 19, 20, 21, and 22.
- Enabled variables CDL and TDL on *SECTION_DISCRETE to be used when one of the discrete beam nodes is constrained by an SPC.
- Improved the accuracy of pressure loading on fully integrated, volume-weighted axisymmetric solid elements (ELFORM = 15/NIP = 4 on *CONTROL_SHELL), particularly along the axis of symmetry.
- Improved the post-failure behavior of integrated beam elements by adding an option (NAUDP on *SECTION_BEAM) to update the neutral axis when one or more integration points fail so that nodal moments are correctly calculated. This option is available for the integrated beam formulations 1, 9, 11, and 14 when used with *MAT_003, *MAT_098, *MAT_100, *MAT_124, and *MAT_158.
- Improved mass scaling of beam element formulations 4 and 5. A dimensional problem was causing erratic behavior which could cause unstable behavior.
- Fixed bug affecting simultaneous use of ERODING contact with cohesive pentahedral solids, which through use of ESORT = 1, are changed to formulations 21/22. Prior to this fix, this combination of keywords could have lead to error termination due to negative volume.
- Add check if two or more parts use solid element formulation 13 (tetrahedron with pressure averaging) and those parts share some nodes. Write a warning in that case because such a condition could lead to instabilities.
- COHOFF on *SECTION_SOLID allows for adjusting the reference layer for cohesive element formulations 20 and 22.
- Fixed bug in plane strain, 8-node shell formulation 55 to show correct stresses when 4 in-plane points are required for d3plot output. Restored writing out stress components at all integration points in elout. Shell

formulation 55 is for implicit analysis only and requires 4, 9 or 16 integration points (default 4) since it is meant to simulate the singular stress field around a crack tip.
- For thick shell (TSHELL) formulations 1 and 2, fixed incorrect stress output in elout when used for composite materials and CMPFLG = 1.

- ***EM (Electromagnetic Solver)**

  - *EM_SOLVER_BEM: Option PRECON = 4 (line 1 field 4), LLT factorization of the BEM matrix, can now be used in MPP. It could only be used in serial/SMP up to now.
  - Eddy current / inductive heating solver:

    - Addition of monolithic solver for FEM+BEM solve (higher time steps and improved stability for ferromagnetic materials) (*EM_SOLVER_FEMBEM).
    - Optimization of memory/CPU cost in BEM solve.
    - Improved accuracy of solution on prismatic elements.
    - Addition of LLT factorization as a preconditioner for BEM solver in MPP (*EM_SOLVER_BEM).
    - Added 2D and 2D axi capability for RSW and other applications (*EM_CONTROL and *EM_MAT_004).
    - Support of eroding conductors (*EM_CONTROL_EROSION and *EM_MAT_...).
    - Improved accuracy of thermal coupling for tetrahedral elements.

  - EM contact:

    - Optimize contact search and robustness => reduced calculation times and memory cost
    - Added capability in RSW to specify electric contact law (*EM_CONTACT_RESISTANCE).

  - Battery Module Release:

    - Equivalent circuit model (ECM): Implementation of Randles circuits as simplified electro-chemistry model
    - Dynamic EM-mechanical-thermal coupling for external and internal short circuit (battery crush) (see in particular *EM_RANDLES_SHORT).
    - Bath loading, coupling mono-bi and bath in same domain.
    - Purkinje network (*EM_EP_MECACOUPLING).
    - Current defined stimuli (*EM_EP_TENTUSSCHER_STIMULUS).

- ***FATIGUE**

- Added using *DEFINE_TABLE to define SN curves for multiple mean stress.
- Added new mean stress correction method (METHOD = 5): Morrow equation (SN curve).
- Extended thick shell element fatigue analysis (including multiaxial) to MPP.
- Extended solid element fatigue analysis (including multiaxial) to MPP.
- Extended shell element fatigue analysis (including multiaxial) to MPP.
- Fixed a bug in running *FATIGUE_SUMMATION. This function is now working as a standalone module. Previously it was used inside fatigue analysis.
- Added warning message MSG_FTG+5 in case the calculated stress value is higher than the stress of the first point on SN curve, to remind user to check the SN curve or stress calculation. If the stress value is higher than the stress of the first point on SN curve, extrapolation is used and this may not be accurate, especially if the first point is the UTS (Ultimate Tensile Strength).
- Added a parameter (DMGMIN in *FATIGUE) to allow user to define base damage ratio for elements with zero stress or strain.
- Added a new option _D3PLOT to allow running time domain fatigue analysis based on d3plot.
- Implemented *FATIGUE_FAILURE to remove failed elements from model.
- Implemented *FATIGUE_MULTIAXIAL to run multiaxial fatigue analysis.
- Implemented *FATIGUE_LOADSTEP to run fatigue analysis with multiple load steps.
- Added warning message MSG_FTG+4 if fatigue properties are not defined for the current element under fatigue analysis.
- Implemented definition of initial fatigue damage ratio by part or part set (PID/SID in *INITIAL_FATIGUE_DAMAGE_RATIO).
- Added semi-log SN curve definition. This can be used both in time domain and frequency domain fatigue analysis.
- Added exposure time TEXPOS for fatigue analysis, in case it is different from endtim in *CONTROL_TERMINATION.
- Added an option D3PLOT to *INITIAL_FATIGUE_DAMAGE_RATIO to allow using damage variables from transient preload cases as initial fatigue damage ratio.
- Fixed a bug in defining mean stress correction methods. The UTS/yield strength should be defined on material model, not part ID, according to the Manual.

- **Forming Analysis**

  - *DEFINE_BOX_NODES_ADAPTIVE now supports more than 2 levels of mesh refinement for tube adaptivity. Maximum level is specified by variable LEVEL.

- ONESTEP simulations with triangular elements used to produce misleading effective plastic strain results in regions with high curvatures. This is now fixed.
- Fix bug in ONESTEP method that produces false minor and major strain in the output file onestepresult
- Fix bug in *CONTROL_FORMING_ONESTEP, OPTION = 6.
- Fix MPP bug for ONESTEP output files repositioned.k and onestepresult.
- Fixed the problem of lacking temperatures at the lancing line in MPP lancing simulations.
- Fixed a memory access problem which resulted in error termination of simulations of unflanging process.
- *CONTROL_FORMING_MAXID is supported by 3d tet adaptivity (*CONTROL_ADAPTIVE).
- *INCLUDE_STAMP_PART: Improvement to support *DEFINE_TRANSFORMATION.
- *DEFINE_CURVE_TRIM_3D: Projection of curve to blank is now allowed when the trimming curve is far away from the blank. This was previously disallowed.
- *CONTROL_FORMING_ONESTEP:
  - Add a CPU time report for onestep method to record the time spent on initial unfolding.
  - Allow user to output specific part to the file of 'onestepresult'.
  - The fracture curve LCSDG can be automatically found from *MAT_ADD_EROSION.
- *CONTROL_FORMING_PRE_BENDING(_LOCAL): New option allows user to define a vector based on a local coordinate system. If the LOCAL option is used, then coordinate system ID is input on Card 2.
- *ELEMENT_LANCING: Allow multi-curve lancing with different starting times. Previously, only one starting time was allowed. With this new feature, all the lancing curves will be used to cut at the same time, but the nodes will not be able to separate until the lancing time is reached.
- *CONTROL_FORMING_AUTOPOSITION_PARAMETER
  - Support 2D elements.
  - When CID is a negative value, its absolute value refers to a vector ID (*DEFINE_VECTOR) rather than a coordinate system ID.
- *DEFINE_FORMING_ONESTEP_MASTER: This new keyword allows a second blank to be welded to a master blank. The two blanks are connected by using spot welds.
- Add keyword *CONTROL_FORMING_TRIM_SOLID_REFINEMENT to homogeneously refine elements along a trim curve. Supports *DEFINE_CURVE_TRIM_2D and *DEFINE_CURVE_TRIM_3D.

- *DEFINE_CURVE_TRIM_2D allows refinement of a sandwiched part along trimming curves. The sandwich core comprised of multiple layers of solid elements can now be refined. In addition, the trimming curve can be in any direction (2D trimming only).
- *CONTROL_FORMING_ONESTEP_ORTHO uses 2 nodes in the final part to define the rolling direction of the anisotropic material.
- *DEFINE_FIBERS:
  - User can perform carbon fiber simulation without the matrix (fibers only).
  - No need to define material property for the matrix.

- ***FREQUENCY_DOMAIN**
  - Correction to rotational inertia for *FREQUENCY_DOMAIN_SSD.
  - *con Extend logic for implicit constraint handling to tied contact with _CONSTRAINED_OFFSET to skip any SPC constraints on the rotational dofs of the SPC slave nodes. We already have such logic to skip the constraints on the translational dofs for the slave nodes for all tied contacts.
  - *loa: Correct the issue where use of *LOAD_BODY is applied to a model with rigid bodies. If the vector of nodes having the load applied belong to a rigid body, then the vector of elemental stiffness matrices is null. So logic was added to skip the call to the implicit matrix assembly subroutine for that case.
  - *DATABASE_FREQUENCY_BINARY_*{OPTION}*:
    - Added a new option SUMMATION to *DATABASE_FREQUENCY_BINARY_D3PSD and *DATABASE_FREQUENCY_BINARY_D3RMS to get total PSD and RMS response from multiple loading resources.
    - Update to support *INCLUDE_TRANSFORM.
    - Added NFSPACE = 3 to define output frequency as eigenfrequencies.
    - Added an option (BINARY = 2) to dump out individual mode response to d3spcm (*FREQUENCY_DOMAIN_RESPONSE_SPECTRUM).
  - *DATABASE_FREQUENCY_ASCII_*{OPTION}*:
    - Update to support *INCLUDE_TRANSFORM.
    - Added NFSPACE = 3 to define output frequency as eigenfrequencies.
  - *FREQUENCY_DOMAIN_ACOUSTIC_BEM:
    - Update to support *INCLUDE_TRANSFORM.
    - Added radiated power computation to Rayleigh method.
  - *FREQUENCY_DOMAIN_ACOUSTIC_FEM:

- Update to support *INCLUDE_TRANSFORM.
- Update to use mixed elements (tet, hex and pentahedrons).
- Fixed a bug in running with combined boundary conditions (transient vibration and impedance).
- Added a flag (RESTRT) to run restart from transient analysis results. LS-DYNA will read an existing binary database to extract the velocity boundary condition.
- Added defining impedence boundary condition by *DEFINE_CURVE.
- Added a flag "idump" in *FREQUENCY_DOMAIN_ACOUSTIC_-FEM_EIGENVALUE to dump out acoustic stiffness and mass matrices.

◦ *FREQUENCY_DOMAIN_FRF:

- Update to support *INCLUDE_TRANSFORM.
- Enabled using structural damping (*DAMPING_STRUCTURAL).

◦ *FREQUENCY_DOMAIN_LOCAL:

- Implemented this keyword to run frequency domain analysis on part of model.
- Implemented options SOLID_SET, SHELL_SET, BEAM_SET and TSHELL_SET.
- Implemented option EXCLUDE to exclude specified sets of elements or nodes.
- Enabled using this feature on response spectrum analysis (*FREQUENCY_DOMAIN_RESPONSE_SPECTRUM).

◦ *FREQUENCY_DOMAIN_MODE:

- Implemented option LOAD_PROJECTION, to select the normal modes based on load projection ratio.
- Implemented option MODAL_COEFFICIENT to select the participating modes based on relative significance of the modal coefficients.
- Enabled this keyword to FRF (*FREQUENCY_DOMAIN_FRF) and SSD (*FREQUENCY_DOMAIN_SSD).

◦ *FREQUENCY_DOMAIN_RANDOM_VIBRATION:

- Update to support *INCLUDE_TRANSFORM.
- Added parameters ICOARSE and TCOARSE in *FREQUENCY_DOMAIN_RANDOM_VIBRATION to reduce points in PSD curve to save CPU time.
- Added parameter TOL_INTG to allow user to define the relative tolerance for integration. The default is 1.e-5.
- Updated PSD curve input so that loading types 9 (base velocity), 10 (base displacement), 11 (enforced acceleration), 12 (enforced velocity),

and 13 (enforced displacement) can be defined through time history curve.
- Added structural damping (*DAMPING_STRUCTURAL) to random vibration analysis.

◦ *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM

- Enabled running response spectrum analysis with CASE.
- Added beam elements stress/strain components in elout_spcm when applicable. Previously only resultant forces and moments are provided.
- Fixed a bug in reading d3eigv family files for multipoint response spectrum analysis.
- Update to support *INCLUDE_TRANSFORM.
- Fixed a bug in running response spectrum with base excitation defined in time domain.

◦ *FREQUENCY_DOMAIN_SSD

- Fixed a bug in reading d3eigv for restart option (RESTMD = 1) when both 4-noded shells and 8-noded shells (like ELFORM 23) are present in the model.
- Update on SSD to use the current geometry of model if SSD is performed after dynamic analysis. Previously SSD is always performed based on the initial geometry.
- Implemented radiated acoustic power computation with Rayleigh integral.
- Added radiation efficiency computation for ERP (*FREQUENCY_DOMAIN_SSD_ERP).
- Enabled sense switch for direct SSD (ctrl-c).
- Updated *FREQUENCY_DOMAIN_SSD_FATIGUE by adding scale factor for each load. Added MSG_KEY+1232, MSG_KEY+1233 to remind user about the changes.
- Added torque and rotational dof excitation for SSD (VAD = 8, 9, 10, 11), with local damping (DMPFLG = 1).
- Update to support *INCLUDE_TRANSFORM.
- Extended *FREQUENCY_DOMAIN_MODE_LOAD_PROJECTION to the computation of nodfor_ssd, nodfor_ssd and elout_ssd.
- Added option _FREQUENCY_DEPENDENT to run direct SSD with frequency dependent material properties.
- Added option _FRF to run SSD with FRF setting. Changed the output filename to d3frf. With this option, one can get fringe plot for FRF (previously only xyplot results were given by FRF).
- Added rotational dof output in nodout_ssd, when applicable.

- Added new loading options vad = 12, 13, 14 for direct SSD (*FREQUENCY_DOMAIN_SSD_DIRECT), for prescribed velocity, acceleration, and displacement.

- ***ICFD (Incompressible Fluid Solver)**

  - Navier Stokes solve/free surface flows:

    - *ICFD_BOUNDARY_FSWAVE: Added Stokes wave of fifth order, solitary wave model and irregular waves using JONSWAP spectrum. Add a complete check of wave generation settings and the validity of the parameters within each wave theory. *ICFD_BOUNDARY_PRESCRIBED_VEL can be used jointly to model the interaction of any wave theory and any prescribed velocity at inlets.
    - *ICFD_BOUNDARY_PERIODIC: Addition of periodic, reflective and sliding mesh boundary conditions.
    - *ICFD_CONTROL_TIME: Maximum and minimum time step definitions can now be made functions of time.
    - *ICFD_CONTROL_OUTPUT_SUBDOM: Supports output to d3plot (before only supported VTK and VTU formats).
    - *ICFD_DEFINE_SOURCE: Allows the user to specify a generic volumetric force entering the velocity solve. Can be useful in various applications, for example, when coupling ICFD with the EM solver.
    - *ICFD_INITIAL: *DEFINE_FUNCTION can now be used to define an initial velocity profile.
    - *ICFD_INITIAL_LEVELSET: Extended the number of initial surfaces which can be generated; boxes and spheres are now possible on top of surface plane.
    - *ICFD_MAT: Variable CA specifies the contact angle for the liquid-vapor interface, for use in surface tension problems.
    - *ICFD_MODEL_POROUS: Added new porous models, pmid = 11 and pmid = 10, for parachute fluid flow. To be used with thin shells (See *MESH_EMBEDSHELL).
    - Bug Fix: Removed pressure outlet smoothing technique after noticing it could cause disruption of results. Results of internal flow problems might be especially affected.
    - Bug fix: Added more digits to icfd_fluidmesh.key output to avoid round off errors.

  - Turbulence models:

    - *ICFD_CONTROL_TURBULENCE, SUBMOD = 2: Added LES Dynamic turbulence model originally proposed by DK Lilly (1991) with localization on coefficient CS by Piomelli and Liu (1995).

- *ICFD_DEFINE_TURBSOURCE: new keyword which allows addition of turbulent source terms for RANS models.
- *ICFD_CONTROL_TURB_SYNTHESIS: now supports *DEFINE_-FUNCTIONs.
- Bug fix: Fixed incorrect calculation of stresses in laws of the wall.

◦ FSI, DEM coupling and remeshing:

- *ICFD_CONTROL_ADAPT: Variable KIS may be used to diminish the excessive coarsening that can potentially occur when remeshing by keeping the nodal mesh size distribution of the initial volume mesh.
- *ICFD_CONTROL_ADAPT: Variable VAR gives the user more control on the error calculation triggering a remesh.
- *ICFD_CONTROL_DEM_COUPLING: Variable MAXVEL is a 'max velocity' term for the DEM force calculation intended to avoid spurious high velocities which could cause the fluid solver to diverge.
- *ICFD_CONTROL_DEM_COUPLING: Variable DTYPE = 1 invokes option to use Morrison formula for Drag calculation to apply on DEM particles.
- *ICFD_CONTROL_FSI: Added control on the number of FSI fluid subiterations. This avoids the sometimes unneeded excessive number of FSI subiterations when the fluid and very light structures (like parachutes) develop a resonance-like mode inside the FSI subiterations (coupling iterations). See variable NSUB.

◦ Thermal and Conjugate heat transfer (CHT):

- *ICFD_BOUNDARY_FLUX_TEMP: Modified boundary condition so that the prescribed value is equivalent to quantity prescribed in BOUNDARY_HEAT_FLUX.
- *ICFD_BOUNDARY_CONJ_HEAT: Added option to impose a temperature drop between solid and fluid (see variables VAL and SFLCID). Also added an alternative penalty based (mortar) coupling method (CTYPE = 1). This can be beneficial in cases with large mesh size discrepancies but is typically associated with higher solve times.
- *ICFD_BOUNDARY_CONVECTION_TEMP: Added keyword to prescribe a convection boundary condition for thermal problems.
- *ICFD_CONTROL_CONJ: TSF feature added in ICFD solver for thermal and CHT problems.
- *ICFD_CONTROL_TURBULENCE: Added thermal law of the wall; see variable TWLAW.
- Bug fix: Previously, all FSI surfaces were taken into account for the thermal and fluid coupling. Now only the boundaries to which the keyword

        - *ICFD_BOUNDARY_CONJ_HEAT is applied will be coupled to the solid.
        - Bug fix: HCLCID and TCLCID in *ICFD_MAT were incorrectly read in MPP.
        - Bug fix: icfd_thermal.dat now keeps getting output in CHT cases after the Navier-Stokes equations have reached steady state.

- **Implicit (Mechanical Solver)**

    - New LSOLVR options in *CONTROL_IMPLICIT_SOLVER:

        - 17 (SMP only): iterative solver with a preconditioner based on a local incomplete factorization.
        - 27 (MPP only): ditto.

    - *CONTROL_IMPLICIT_ORDERING: Made various improvements to LS-GPart (ORDER = 4).

        - Significant improvements in MPP;
        - Added hybrid parallelism (OpenMP);
        - Added a progress report ("heartbeat") for large problems.

    - New option where ILIMIT in *CONTROL_IMPLICIT_SOLUTION can vary with time. If ILIMIT < 0, |ILIMIT| is taken as the curve ID which defines the iteration limit between automatic stiffness reformations (ordinate) vs. time (abscissa).
    - Implemented an approximate constitutive matrix for implicit analysis of *MAT_187/*MAT_SAMP-1.
    - New implicit feature for automatic generation of solution key points through examination of load curves for points of particular interest, e.g., times at which maximum load occurs. Set DTMIN < 0 in *CONTROL_IMPLICIT_AUTO to invoke this option.
    - Enhanced the performance of the output to d3* files for *CONTROL_IMPLICIT_EIGENVALUE and *CONTROL_IMPLICIT_MODES. This saves 15% of the wall clock time for large eigenvalue problems where hundreds of eigenmodes are written to d3eigv.
    - Corrected the use of load curve specifications for the following implicit control variables:

        - IAUTO < 0 in *CONTROL_IMPLICIT_AUTOMATIC_DYN,_SPR
        - IMASS < 0 in *CONTROL_IMPLICIT_DYNAMICS_DYN,_SPR
        - ISTIF < 0 in *CONTROL_IMPLICIT_SOLUTION_DYN,_SPR

    - *CONTROL_IMPLICIT_INERTIA_RELIEF:

- Corrected the processing of some kinds of contact during the implicit inertia relief computation.
- Disabled use of iterative linear equation solvers in *CONTROL_IMPLICIT_SOLVER when *CONSTRAINED_IMPLICIT_INERTIA_RELIEF is active.
- Needed to account of inertia relief modes in MPP for the computation of resulting forces from constraints.
- Enhance explicit's use of *CONTROL_IMPLICIT_INERTIA_RELIEF by adding a second orthogonalization step for the accelerations.

◦ *CONTROL_IMPLICIT_MODES:

- Fixed application of implicit constraint modes in MPP for the case where a constraint mode is also a shared node.
- Added a switch on *CONTROL_IMPLICIT_MODES to not write d3mode file when generating superelements.
- Improved the creation of superelement files in MPP.
- Correct dynamic memory allocation issue that was causing problems with computing the reduced stiffness matrix in MPP for implicit modes.
- Corrected output to d3mode in MPP.
- Added error checking on nodes for *CONTROL_IMPLICIT_MODES to make sure they are deformable.

◦ *CONTROL_IMPLICIT_MODAL_DYNAMICS:

- Allow the use of shell formulation 18 in modal dynamics when reading from d3eigv.
- Correct a typo in the computation of the explicit time step for modal superposition. Also applies to *CONTROL_IMPLICIT_DYNAMICS with imass = 2 or 3.
- Adjusted reading of d3eigv for modal dynamics for the case where the modes are computed and then immediately used -- all with stresses included.
- Correct the implicit modal dynamics stress output for beams using non-default value for BEAMIP.

◦ *CONTROL_IMPLICIT_EIGENVALUE:

- Freed allocated memory that was not free at the end of subroutine im_mode_stress.
- Adjusted the logic for intermittent eigenvalue computation to deal with explicit not quite getting to the end time.
- Properly handle the output of 10 noded tets to the d3eigv database.
- Reduce size of d3eigv by not adding rotational dofs for solid element only models.

- The computation of the i/o address for writing the d3eigv database in MPP for models with 8 noded shell elements was wrong. The d3eigv database would probably fill the i/o system causing an abnormal termiation. The i/o address computation is now correct.
- Enable the computation of Campbell diagrams for Implicit Rotational Dynamics as part of the Intermittent Eigenvalue capabilities.
- Enable the use of intermittent eigenvalues during both dynamic relaxation and regular transient phase.
- For eigenvalue analyses where there are lots and lots of zero eigenmodes where the eigensolver fails we will now output the computed modes to the d3eigv database for model debugging purposes.
- Extend the cost logic for Lanczos Eigensolvr, both SMP and MPP, to be more aggressive about staying with the current shift. Improves performance for large problems as the cost function is not necessarily monotonic.
- Added shift and scaling to the standard eigenvalue problem to make the solution methodology more robust. This is the same shift and scaling as used for MCMS.
- Corrected output to d3eigv for implicit MPP eigensolver for large number of integration points.
- Add logic so that for some frequency response computations the amount of drilling rotation control is the same as for eigenvalue computations.
- Added Sectoral Symmetry to *CONTROL_IMPLICIT_EIGENVALUE as an implicit eigensolver option for SMP DP. Sectoral Symmetry is an eigensolver for models with a large degree of rotational symmetry such as fan blades.
- Adjust zero shift for Lanczos eigensolver.
- Fix up MPP storage issues in MPP implementation of Lanczos. Increased minimum storage of eigenvalues from 500 to 2500. Restricted eigenvector checking due to MPI buffer length.
- Add additional tag at end of d3eigv for MCMS that was missing. Normalize MCMS computed eigenvectors to have unit norm.

- Correct joint constraint processing in implicit mechanics which should improve the reporting of joint forces (*DATABASE_JNTFORC) in implicit.
- Enhance implicit's processing of nodal mass matrices to include the local coordinate transformation.
- *CONTROL_IMPLICIT_SOLUTION with NSOLVR = 1: Fixed problem in which Implicit Linear Analysis used the forces at the end of the linear step to compute resultant forces. This did not match expectations of the users. Computation of resultant forces, such as those in bndout, were changed to use the force at the beginning of the linear step.
- *CONTROL_IMPLICIT_SOLVER:

- Correct the removal of ordering reuse logic for the MPP implementation of implicit mechanics. This is an important time saving feature for very large models with multiple time steps.
- For intermittent eigenvalue analysis the direct solvers used by the eigenvalue analysis were forced for the entire execution. We now save and restore the solver option selected by the user to use during the non-eigenvalue execution of the run. This enables the use of iterative solvers iterative solvers.
- Fix the implicit logic to properly deal with NEGEV = 1 in *CONTROL_IMPLICIT_SOLVER and IAUTO.ne.0 in *CONTROL_IMPLICIT_AUTO.
- Disabled the use of ORDER = 1 in *CONTROL_IMPLICIT_SOLVER for MPP as this is a really bad choice in MPP.
- Adjusted output to d3hsp for implicit linear equation solver options to match keyword manual. (*CONTROL_IMPLICIT_SOLVER)
- Adjust implicit logic for dumping matrices (MTXDMP in *CONTROL_IMPLICIT_SOLVER). Correct the dumping of matrices from implicit when MTXDMP > 1.

- *CONTROL_IMPLICIT_STATIC_CONDENSATION: Correct indexing of array involved in implicit static condensation.
- Echo the input for *CONTROL_IMPLICIT_RESIDUAL_VECTOR to d3hsp.
- Fix an issue of the implicit linear algebra filenames being inconsistent between Linux and Windows.
- Add an implicit-only option for processing *CONSTRAINED_INTERPOLATION which is referred to as force-geometry-mass (fgm). Forces are moved from the dependent node to the independent nodes, geometry of the dependent node is computed from the independent nodes, and the mass on the dependent node is moved to the independent nodes. All without using a constraint matrix or LaGrange Multiplier approach.
- No longer automatically increase nodal DOF from 3 to 6 due to the presence of *CONSTRAINED_INTERPOLATION. This is unnecessary for solid element models and increases the cost of large solid element models for implicit by 15% due to huge increase in constraint processing to constrain out all of the rotational dofs.
- Correct implicit's handling of SPC constraints on shared nodes in MPP that are also involved in tied contact.
- Enhance Implicit constraint processing to accept function definitions for motor joint movement (*CONSTRAINED_JOINT_***_MOTOR).
- *CONTROL_IMPLICIT_SOLUTION: Added NSOLVR = -1 so that the initial geometry is used for each step of a multistep linear analysis.
- Added implicit time stamps and additional performance tracking for MPP Lanczos eigensolver. Extended command Line Option impcon = 1.
- Added a command line directive of impcon = 1 which tracks events during implicit simulation to analyze performance for large implicit jobs. This is

also a useful debugging tool as it helps identify the particular part of implicit is being executed at an abnormal termination.

- Single precision executables are now disallowed for implicit mechanics (both MPP and SMP).
- Restored final memory report for implicit SMP runs. Logic was based on old memory allocation scheme instead of new dynamic memory allocation.
- Turned on Mumps, a new linear solver option for implicit mechanics, to be included for double precision SMP on XEON64 and AMD64 systems.
- Corrected an inefficiency for implicit when there are many many AutoSPC constraints in MPP. A linear search through the AutoSPC constraints was replaced with a binary search.
- Corrected the collection of resultant forces when using implicit mechanics for tied contact using _OFFSET. Other tied contact such as _CONSTRAINED_OFFSET were OK.
- Added SMP implementation of new keyword *CONTROL_IMPLICIT_RESIDUAL_VECTORS.
- Apply logic that was in R9 and R10 but had not made it into R11 and R12 to check for incorrect values in nodal inertia array for implicit dynamics and eigenvalue analysis.
- Fixed divide by zero in power iteration for buckling problems with inertia relief. (*CONTROL_IMPLICIT_BUCKLING, *CONTROL_IMPLICIT_INERTIA_RELIEF)
- Correct problem where solution control was inappropriately returned to implicit after issuing sense switch sw1.
- Added *CONTROL_IMPLICIT_RESIDUAL_VECTOR. Purpose: Activate and control the computations of residual vectors. Residual vectors are the linear response of a model to a specified load which is then orthogonalized to a set of eigenmodes and any previously computed residual vectors. The eigenmodes can either be computed during the execution or read from an input file. The computation of residual vectors is the same as multi-step linear (NSOLVR = -1 on *CONTROL_IMPLICIT_SOLUTION) but has the additional step of orthogonalization.
- Add a stiffness option to *CONTROL_IMPLICIT_ROTATIONAL_DYNAMICS. The stiffness terms are suppressed to keep the stiffness matrix symmetric but the force terms are added.
- *MAT_ELASTIC_FLUID/*MAT_001_FLUID usage with *CONTROL_IMPLICIT_EIGENVALUE: Warning added to highlight the absence of enforcement of irrotationality in solid elements that use this fluid material model. In eigenvalue analyses this absence will often lead to the prediction of numerous spurious rotational fluid modes. This material model should therefore be used with caution in modal analyses.
- Fixed implicit element stiffness of shell elements when used with laminated shell theory, and when also using anisotropic materials *MAT_022, *MAT_034, *MAT_040, *MAT_054, *MAT_055, or *MAT_058. In certain cases, the shear stiffness was too small.

- Lagrangian multiplier joints, LMF = 1 on *CONTROL_RIGID, are supported for implicit analysis.
- Fixed bug with d3eigv when using TET10S8 = 1 on *CONTROL_OUTPUT.

- ***INITIAL**

  - *INITIAL_LAG_MAPPING:

    - Thick shell data from a previous run can be mapped to a new thick shell mesh.
    - *INITIAL_LAG_MAPPING with NELANGL = -3: For the Lagrangian mapping, project the boundary nodes of the current mesh onto the boundary faces of the previous mesh.
    - In a solid-to-solid mapping, map the strain array output by STRFLG = 1.
    - Map the nodal pressures for ELFORM = 13 tetrahedra.
    - If NELANGL = -2 in a 3D to 3D mapping, the data from the previous run are rotated around the axis of an angle ANGLE before mapping.
    - *INITIAL_LAG_MAPPING_WRITE3DAXI: For a 3D axisymmetric Lagrangian model, add the option WRITE3DAXI to *INITIAL_LAG_MAPPING to output the mapping file as if it came from a 2D axisymmetric model.

  - Fix bug in the *INITIAL_STRESS_TSHELL module of the dynain output file. For Thick Shells with 6-10 integration points through the thickness, the z-coordinates of the integration points were incorrect.
  - Added new option ISTIFF to *INITIAL_STRESS_SECTION for enhanced stability.
  - Added new ISTIFF option for artificial stiffness in *INITIAL_STRESS_SECTION.
  - Fix *INITIAL_STRESS_TSHELL output to dynain for thick shell form 7. Output stresses for all 4 in-plane integration points instead of just 1.
  - Fix incorrect rotational axis when using *PART_INERTIA and *INITIAL_VELOCITY_GENERATION with IRIGID = 1 and the rotational axis is defined using nodes by setting NX = -999 and defining the nodes with NY and NZ.
  - Make *MAT_GENERAL_NONLINEAR_1DOF_DISCRETE_BEAM / *MAT_121 work with *INITIAL_STRESS_BEAM.
  - Disable *INITIAL_AXIAL_FORCE_BEAM and *INITIAL_STRESS_SECTION when IDRFLG = -999 in *CONTROL_DYNAMIC_RELAXATION.
  - Fix seg fault or incorrect stresses when initializing stresses using *INITIAL_STRESS_SOLID with *MAT_107/*MAT_MODIFIED_JOHNSON_COOK.
  - Fixed a bug that made *INITIAL_VELOCITY_GENERATION_START_TIME not work for rigid parts.

- STRFLG in *DATABASE_EXTENT_BINARY will be automatically set to unity when using *INITIAL_STRAIN_SOLID.
- Fixed the writing of dynain files that use beam element formulations 7 or 8. They were writing the wrong number of integration points.
- Fixed a problem that occurred when when initializing stress in thick shells using a dynain file created by a previous run that used a different number of integration points per layer than the new run. In this case, when reading the dynain data to initialize the element, the stress tensor was being properly averaged or extrapolated as needed, but the material extra history variables were not, which for some materials caused wrong material behavior.
- Fixed the reading of initial strain data for thick shell formulations 2, 3, 5, 6, and 7. A strain transformation was missing.
- Add new keyword *INITIAL_HISTORY_NODE(_SET) to initialize select history variables at node locations. These nodal values are internally interpolated to the element integration points using the finite element shape functions. A main difference to using *INTIAL_STRESS_SHELL/SOLID, where you would need to initalize ALL history variables up the ones you really need/want to initialize is that *INITIAL_HISTORY_NODE(_SET) allows you to just pick the few variables you would like to initialize without touching the others.
- *INITIAL_AXIAL_FORCE_BEAM now supported for beam formulation 1 (H-L beam) and any material. Previously, only beam formulation 9 with *MAT_SPOTWELD was allowed.
- Selective mass scaling is not applicable to beam formulation 1 (Hughes-Liu beam).
- *CONTROL_ADAPTIVE: Users are able to use *INITIAL_VELOCITY_GENERATION for the 3D adaptive parts as long as STYP = 3 (node set) and the corresponding node set is defined using *SET_NODE_GENERAL with OPTION = PART. (This would apply only to the unusual situation in which initial velocities were invoked AFTER the mesh is adapted.)

- **Isogeometric Analysis (IGA)**

  - *ELEMENT_SHELL_NURBS_PATCH:

    - Include initial parameterization check for isogeometric shells.
    - Include automatic removal of trimming loops fully contained within a single element.

  - Updated *DEFINE_SPOTWELD_RUPTURE to work with isogeometric shell elements.
  - Added IGA shell and IGA solid element erosion due to the material failure strain, *MAT_ADD_DAMAGE, and *MAT_ADD_EROSION.

- Contact for IGA in implicit is now available using the automatically generated interpolation elements. The IGACTC option in *CONTROL_CONTACT, however, is not currently supported for implicit.
- Added *INITIAL_VELOCITY_GENERATION support for IGA elements using parts and part sets.
- Added support for checking element stiffness matrices for IGA through the LPRINT option in *CONTROL_IMPLICIT_SOLVER.
- Both IGA solids and IGA shells now work with *MAT_RIGID. Previously, only IGA shells were supported for rigid material.
- IGA now works for implicit springback.
- Added the ISTUPD thickness change options (*CONTROL_SHELL) to ELFORM = 3 IGA shell elements.
- Added drilling stiffness type 4 (see DRCM in *CONTROL_IMPLICIT; DRCPSID and DRCPRM in *CONTROL_SHELL) to the IGA shells.
- Improved the time centering for IGA shells for improved convergence rates in implicit analysis.
- *ELEMENT_SHELL_NURBS_PATCH: Enabled keyword *LOAD_NURBS_SHELL for trimmed elements.
- *ELEMENT_SOLID_NURBS_PATCH:
  - IINT defines the integration rule.
    - EQ.0: reduced Gauss integration rule (default)
    - EQ.1: full Gauss integration rule.
    - EQ.2: patch-wise reduced integration rule.
    - EQ.3: non-uniform Gauss integration rule uses full integration for exterior elements and reduced integration for interior elements.
  - Add conventional mass-scaling for isogeometric solids
- These material models are now supported for shells in isogeometric analysis:
  - *MAT_224/*MAT_TABULATED_JOHNSON_COOK
  - *MAT_054-055/*MAT_ENHANCED_COMPOSITE_DAMAGE
- Laminated shell theory is now supported for shells in isogeometric analysis. This option can be activated for shell formulations that allow for transverse shear deformability by:
  - Setting LAMSHT = 1,3 or 5 in *CONTROL_SHELL, and
  - Using *INTEGRATION_SHELL to specify an integration rule, which is referenced in *SECTION_SHELL.
- *INITIAL_STRAIN_SHELL_NURBS_PATCH: Fixed output for thickness in case ISTUPD = 0 in *CONTROL_SHELL.

- *INITIAL_(STRESS/STRAIN)_SHELL_NURBS_PATCH: Fixed error in writing of *DEFINE_NURBS_CURVE to dynain file (*INTERFACE_SPRINGBACK_LSDYNA).
- Fixed bugs that arose from improper merging of interpolation nodes at patch boundaries. This could have lead to errors such as "Zero Normal Vector".
- Remove the limitation to have NURBS patches and related trimming curves defined in a normalized parameter space as this is not common in CAD-files.
- Fix bug when using IGA-shells (*ELEMENT_SHELL_NURBS_PATCH) together with user defined elements (ELFORM = 100-105).

- ***LOAD**

  - There were unexpected error terminations when *LOAD_THERMAL_LOAD_CURVE was used in an adaptive analysis. This has been fixed.
  - *LOAD_THERMAL_D3PLOT reads temperature data from a file in d3plot format. The file name is specified as an option on the command line. If this file does not exist in the working directory, LS-DYNA now gives a reasonable message and exits gracefully.
  - *LOAD_BODY_GENERALIZED: fix a bug that happens when CID > 0 and the CID doesn't have its origin at (0,0,0).
  - Fix incorrect results when using *DEFINE_CURVE_FUNCTION with AX/AY/AZ for *LOAD_SEGMENT.
  - Fix output to nodfor when using *LOAD_SSA.
  - Fix ineffective *LOAD_THERMAL_CONSTANT when used with *MAT_ELASTIC_VISCOPLASTIC_THERMAL/*MAT_106.
  - Fix seg fault when using *LOAD_MOVING_PRESSURE due to uninitialized variable.
  - Fixed a bug preventing *LOAD_BLAST_ENHANCED from working for 2D analysis.
  - Added line-of-sight feature (LSFLG) to *LOAD_MOVING_PRESSURE: When LSFLG.EQ.1, the pressure will be applied to the first-hit segments from the nozzle.
  - When IDIR = 3 in *LOAD_MOVING_PRESSURE, the pressure is in the direction from NODE1 to NODE2, but only the normal component of the pressure is applied on the segments.
  - Enabled *LOAD_THERMAL to work for beam nodes when nodal releases are defined at those nodes. The thermal loading was previously incorrect.
  - New keyword *LOAD_THERMAL_RSW: Prescribes nodal temperatures within a (possibly moving) ellipsoidal region of the structure in mechanical-only simulations. So there is no heat transfer available to the surroundings. Input is comparable to thermal boundary condition *BOUNDARY_TEMPERATURE_RSW. Features include:

        - Temperatures for the center and the boundary of the ellipsoid have to be input. Inbetween, there is a quadratic approximation.
        - Outside of the ellipsoid, no temperature values are prescribed.
        - Position and axis of symmetry are defined by two nodes
        - Optional definition of a heat affected zone (HAZ) around the weld nugget. Temperatures at its boundary are to be given and a linear interpolation from the boundary of the nugget to the boundary of the HAZ is used. Outside the HAZ a default temperature is applied.

    - Implement *LOAD_SPCFORC in MPP.
    - Reduce memory usage and computation time for *LOAD_SEISMIC_SSI_-NODE when ground motions are specified at every node on the soil-structure interface.
    - New keyword *LOAD_EXPANSION_PRESSURE applies a uniform pressure (e.g., from explosive detonation) on the internal surfaces of a chamber while one wall of the chamber moves (as a piston) so that the loaded area increases.

- ***MAT and *EOS**

    - Added *MAT_295/*MAT_ANISOTROPIC_HYPERELASTIC.

        - This is a collection of (nearly-in)compressible, (an)isotropic, hyperelastic material models primarily aimed at describing the mechanical behavior of biological soft tissues. Some of the material models may also be used to analyze a wider class of materials including fiber-reinforced elastomers and stretchable fabrics.
        - Modules include isotropic, anisotropic, and active anisotropic.
        - Allows for electrophysiology-fluid-structure interaction (EFSI).
        - Available for solid element formulations 1, 2, and 10.

    - *MAT_079/*MAT_HYSTERETIC_SOIL: New option for cyclic degradation. See input fields SIGTH, SIGR and CHI on Card 5.
    - *MAT_119/*MAT_GENERAL_NONLINEAR_6DOF_DISCRETE_BEAM: New failure option FCRIT (Field 7, Card 6, see also Remark 1). The pre-existing failure algorithm uses two separate criteria: one that considers only negative displacements and rotations of all six degrees of freedom, and a second criterion considering only positive displacements and rotations. Thus, positive x-displacement and positive y-displacement could combine to cause failure while positive x-displacement and negative y-displacement could not. The new option FCRIT = 1 offers a single criterion that considers both positive and negative displacements/rotations.
    - *MAT_169/*MAT_ARUP_ADHESIVE bugfix: The "interfacial failure" option (TMAXE, SMAXE) was not propagating from element to element as it should.

- Fixed bugs in *MAT_172/*MAT_CONCRETE_EC shear capacity calculation (TYPESC > 0):

  - This capability did not work with fully-integrated shell elements such as ELFORM = 16.
  - Incorrect results or error terminations could occur if material types other than 172 were mixed with MAT_172 in PART_COMPOSITE and the MAT_172 definition had TYPESC > 0.

- *MAT_197/*MAT_SEISMIC_ISOLATOR: New option for sliding isolator with rim failure (TYPE = 5).
- *MAT_203/*MAT_HYSTERETIC_REINFORCEMENT: Fixed bug in MAT_203 affecting beam elements with EPDAM1, EPDAM2 non-zero, and DRESID equal to zero. When the beam reached its erosion limit, error termination or unexpected erosion of neighboring elements could occur.
- *MAT_209/*MAT_HYSTERETIC_BEAM: New material model for modelling buildings in earthquakes. A significantly extended version of *MAT_191 (*MAT_SEISMIC_BEAM) with lumped plastic hinges at both ends of the beam and many additional capabilities.
- Add heat generation factor QCURE to *MAT_ADHESIVE_CURING_VISCOELASTIC/*MAT_277 which relates the heat generated in one time step with the increment of the degree of cure in that step.
- *MAT_296/*MAT_ANAND_VISCOPLASTICITY:

  - Correct the deformation resistance S calculation.
  - Fix floating point exception related bug when compiling with FPE option active.

- Add keyword *MAT_ADD_CHEM_SHRINKAGE.

  - The inputs and features are same as those of *MAT_ADD_THERMAL_EXPANSION except for the usage of curve LCID.
  - The physical chemical shrinkage rate is calculated as

    $$\beta = (1.0 - \alpha)^3 - 1.0$$

    where curve LCID defines alpha (ordinate) vs. temperature (abscissa).
  - When defining curve LCID in *DEFINE_CURVE, the variable DATTYP should be set to -100.

- Extension of THERML variable in *MAT_077_H to allow C11, C20, C02, and C30 to also be specified as a function of temperature.
- Add calculation of internal energy to *EOS_019/*EOS_MURNAGHAN.
- Make *EOS_019/*EOS_MURNAGHAN compatible with *INCLUDE_TRANSFORM.

- Add support for optional EOS in *MAT_COMPOSITE_FAILURE_SPH_-MODEL/*MAT_059.
- Variable PHEL in *MAT_JOHNSON_HOLMQUIST_CERAMICS/*MAT_-110 can be specified equal to 0.0 by default or by user input. In this case PHEL is calculated internally. This value is now echoed as "phel" in d3hsp.
- *MAT_ADD_PERMEABILITY: allow the permeability to be a function of volumetric strain, plastic strain rate, or pressure.
- *MAT_ADD_PORE_AIR: fix an MPP bug triggered when input format is long = s, write standard keyword input and write long structured input deck.
- *MAT_FABRIC: make strain restoration factor TSRFAC available for linear liner.
- *MAT_GENERAL_NONLINEAR_6DOF_DISCRETE_BEAM/*MAT_119:

  - Allow unloading option of "2" for crushable beam, IFLAG = 2.
  - Add the stiffness matrix to enable implicit for crushable beam.

- *MAT_SEATBELT:

  - Enhance 2D belt by offering choice of element formulations and material properties along transverse direction for 2D belt.
  - Enable 2D belt material to have loading curve, LLCID, defined as a table.
  - Issue error message when the edge nodal set of 2D belt part is not on the edge of the related 2D belt part

- Added isotropic plasticity to *MAT_030/*MAT_SHAPE_MEMORY.
- Added new material model *MAT_291/*MAT_SHAPE_MEMORY_ALLOY for shape memory alloys. This is a micromechanics-inspired constitutive model for shape-memory alloys that accounts for initiation and saturation of phase. This model is based on Kelly, Stebner, Bhattacharya (2016) and is available for solid elements only.
- Added support for curves defining thermal properties vs. mechanical history variables in *MAT_THERMAL_ISOTROPIC_TD_LC.
- Fixed the problem in *MAT_244/*MAT_UHS_STEEL where redundant table look-up operations in the plasticity algorithm increased the computational cost.
- Added history variable (at the 8th position) in *MAT_133/*MAT_BARLET_YLD2000 to allow user input of a effective plastic strain shift which can be used to account for stored energy in sub-structures after heat treatment. This option is only applicable to the case of HARD < 0 (curve/table input of hardening curves).
- Added 3D table option to hardening curve input of *MAT_233/*MAT_CAZACU_BARLAT so that the material model is applicable to simulations of hot/warm forming of materials such as magnesium.

- Fix incorrect initial strains when using *MAT_MOONEY-RIVLIN_RUBBER/*MAT_027 with *INITIAL_FOAM_REFERENCE_GEOMETRY and running in single precision.
- Fix problem of solution hanging when using *MAT_PIECEWISE_LINEAR_PLASTICITY_STOCHASTIC and *DEFINE_HAZ_PROPERTIES (MPP only).
- Fix incorrect behavior for *MAT_GENERAL_JOINT_DISCRETE_BEAM/*MAT_097 when BEGTIM in *CONTROL_START is set > 0.0.
- Fix incorrect stresses for *MAT_ANISOTROPIC_VISCOPLASTIC/*MAT_103 and *MAT_ANISOTROPIC_PLASTIC/*MAT_103P when using BETA for *ELEMENT_SHELL_BETA or BETA in the *MAT input or material integration point angles input on *SECTION_SHELL.
- Fix seg fault when using *MAT_PIECEWISE_LINEAR_PLASTICITY/*MAT_024 for Hughes-Liu beam with implicit analysis.
- Output fitted data to curveplot for *MAT_HYPERELASTIC_RUBBER/MAT_77_H when N > 1.
- Fix effect of FBRT on tensile strength, XT, for *MAT_ENHANCED_COMPOSITE_DAMAGE/*MAT_055. FBRT should only affect the tensile strength upon compressive maxtrix mode failure.
- If FAILTM < 0.0 in *MAT_ADD_EROSION, skip erosion failure evaluation during dynamic relaxation phase.
- The calculation of Q12 for *MAT_SPECIAL_ORTHOTROPIC/MAT_130 and *MAT_RESULTANT_ANISOTROPIC/MAT_170 is incorrect. It should be Q12=(v21p*E11p)/(1-v12p*v21p).
- Fix ineffective curves LCSRA, LCSRB, LCSRC, LCSRAB, LCSRBC, LCSCA in *MAT_MODIFIED_HONEYCOMB/*MAT_126.
- Error terminate with message, INI+484, if LOG_INTERPOLATION is invoked for *MAT_PIECEWISE_LINEAR_PLASTICITY/*MAT_024 and the strain rate for the table is defined by LCSS is negative.
- Fix ineffective user-define failure subroutine (FAIL < 0) for *MAT_MODIFIED_PIECEWISE_LINEAR_PLASTICITY/*MAT_123.
- Fix output to elout for solids using *MAT_PAPER/*MAT_274 and CMPFLG > 0 in *DATABASE_EXTENT_BINARY.
- Allow *MAT_065/*MAT_MODIFIED_ZERILLI_ARMSTRONG to compute the flow stress using a more general form by using power exponent, m, of the effective plastic strain instead of the square root of the effective plastic strain in the case of an FCC metal.
- Fix seg fault when using *MAT_ADD_EROSION for *PART_COMPOSITE when the first layer of the *PART_COMPOSITE is not using *MAT_ADD_EROSION.
- Fix incorrect direction of thermal expansion when using *MAT_NONLINEAR_ORTHOTROPIC / *MAT_040 with *MAT_ADD_THERMAL_EXPANSION.
- Fix contact penetration after element erosion when using *MAT_110 / *MAT_JOHNSON_HOLMQUIST_CERAMICS with eroding contact.

- Fix incorrect stress/strain output to d3plot when using *MAT_023 / *MAT_TEMPERATURE_DEPENDENT_ORTHOTROPIC and running 2D analysis with MAXINT > 3 in *DATABASE_EXTENT_BINARY.
- Fix incorrect stress initialization when using *LOAD_DENSITY_DEPTH in combination with *MAT_005/*MAT_SOIL_AND_FOAM where the material's volumetric strain vs. pressure is input using curve LCID.
- Fix strain rate effects on *MAT_157/*MAT_ANISOTROPIC_ELASTIC_-PLASTIC for implicit static analysis.
- Fix seg fault when using *MAT_278/*MAT_CF_MICROMECHANICS.
- Fixed a bug causing 2WAY = 1 in *MAT_ENHANCED_COMPOSITE_-DAMAGE/*MAT_054 not to be recognized.
- Added rate sensitivity to *MAT_S04/*MAT_SPRING_NONLINEAR_-ELASTIC: LCD can point to a table (*DEFINE_TABLE) which gives loading rates (relative velocity values). There is then defined a corresponding curve of force vs. displacement for each loading rate.
- Added PRESTRAIN keyword option for *MAT_MODIFIED_PIECEWISE_-LINEAR_PLASTICITY/*MAT_123. When PRESTRAIN is used, the variable IPS on Card 5 is used to control the prestrain option. If IPS is set to 1, then the strain tensor defined by *INITIAL_STRAIN_SHELL will be used as prestrain when checking major strain failure, EPSMAJ.
- Added a new option called TTOPT to *MAT_SPOTWELD which is used by solid and solid assembly spot welds. The option controls the behavior of TRUE_T making it possible to revert the TRUE_T behavior back to how it worked in R8 and previously. If TTOPT = 0 or if the TTOPT is not input, then the behavior is unchanged with this update. If TTOPT = 1, then R8 and earlier behavior happens. TTOPT = 2 is like TTOPT = 1, but the average top and bottom values of forces and moments are used for failure making failure invariant with respect to element numbering.
- Added support for user-defined spot weld failure in *MAT_100_DAMAGE-FAILURE with individual solid elements. Previously, only beam elements and solid weld assemblies were supported.
- Enabled *MAT_ADD_THERMAL_EXPANSION to work in thick shell elements when the solutions is mechanical only. Some code was missing causing bad behavior.
- Enabled *MAT_128/*MAT_HEART_TISSUE for thick shell forms 3, 5, and 7. Initialization of the F tensor was missing causing a 1st cycle termination.
- Enabled *MAT_145, *MAT_244, and *MAT_254 to work with thick shell formulations 3, 5, and 7.
- Enabled multiple instances of nonlocal material averaging to be used in MPP. This change affects *MAT_NONLOCAL, and also *MAT_CODAM2, *MAT_GURSON_RCDC, or *MAT_PLASTICITY_WITH_DAMAGE with the RCDC option.
- Enabled the variable EC of *MAT_058/*MAT_LAMINATED_COMPOS-ITE_FABRIC to be used with thick shell formulations 1, 2 and 6. If a positive value is input, then it will be used. f EC is left blank or set to zero or a

negative number, then the minimum of EA and EB will continue to be used. Also, *MAT_058 will now echo to d3hsp EC = 0 when used with thin shells because the EC value is ignored.

- Improved hourglass form 6 when use with *MAT_089/*MAT_PLASTICITY_POLYMER. A poor choice of the material parameter used to scale the hourglass stiffness made it difficult to use.
- Fixed spot weld assemblies that use user defined failure option 12 in *MAT_100. An error was causing OPT = 12 to not work at all.
- Fixed the use of *MAT_ADD_DAMAGE_DIEM with *MAT_024 and tetrahedral element formulation 13. The damage calculation used bad data leading to a wrong result.
- Fixed the initialization of the material direction for orthotropic materials when used with AOPT = 2 in 2D plane strain, plane stress, and axisymmetric elements.
- Fixed implicit beam spot weld elements (*SECTION_BEAM ELFORM = 9) when used with NF > 0 on *MAT_100/*MAT_SPOTWELD. The averaging of the stress was causing the model to converge to the wrong solution with beam forces too low.
- *MAT_296/*MAT_ANAND_VISCOPLASTICITY: Solved a problem that caused discrepancies between material parameters provided in the input keyword and the values reported in the d3hsp file. Analysis results were not impacted.
- *MAT_097/*MAT_GENERAL_JOINT_DISCRETE_BEAM: Solved a problem that may have caused analysis termination due to fatal error when a simulation switched from implicit to explicit.
- *MAT_261/*MAT_LAMINATED_FRACTURE_DAIMLER_PINHO: Solved a problem that may have prevented accumulation of back stress for in-plane shear plasticity model.
- *MAT_LAMINATED_FRACTURE_DAIMLER_CAMANHO/*MAT_262:

    - Fixed bug in in-plane shear behavior for tshells if curves are used to define strain rate dependency of SIGY and ETAN.
    - Corrected warning messages in case of tshell formulations 1/2 and adjusted the computation of element length for fracture toughness to match with thin shells.
    - Added flag MSG in *MAT_262 to control the writing of warning messages.
    - Added transverse shear damage similar to *MAT_054/*MAT_058.
    - Added shell-only option to use nonlinear (elastic) stress-strain curves instead of constant moduli (EA, EB, GAB). This allows asymmetric tension-compression.
    - Added flag DSF that controls the failure of an integration point based on in-plane shear failure. This was added to be able to reinstate the in-plane shear failure behavior prior to revision 117876 (DSF = 1).

- Fixed incorrect behavior of *MAT_262 when first layer in *PART_-COMPOSITE used a non-262 material model (shells only).
- Fixed bug when using table (2D) for defining strain rate dependent fracture toughnesses values with respect to characteristic element length.

◦ *MAT_LAMINATED_COMPOSITE_FABRIC/*MAT_058:

- Fixed an error in calculation of the initial time step when curves define the stiffness values for EA, EB, GAB (shells only).
- Add the SOLID option to support *MAT_058 for solid elements.
- Fixed bug when using curve LCEFS to define ERODS failure strain as a function of strain rate (shells only).
- Add option to define direction-dependent failure strains. For this, define a curve LCDFAIL that has 5 (for shells) or 9 (for solids) data points and has LCINT set to the number of data points. The ordinate values define the failure strains in the different directions as follows: 1: ef_11t ; 2: ef_11c ; 3: ef_22t ; 4: ef_22c ; 5: ef_12 ; (and additionally for solids) 6: ef_33t ; 7: ef_33c ; 8: ef_23 ; 9: ef_31, The curve's abscissa values must be ascending to meet input requirements but are otherwise ignored.

◦ *MAT_ANISOTROPIC_ELASTIC_PLASTIC/*MAT_157: Output the history variable that tracks failure (according to the Tsai-Wu or Tsai-Hill criterion) as history variable #10.
◦ *MAT_ENHANCED_COMPOSITE_DAMAGE/*MAT_054: Correct the computation of transverse shear strains for solids and tshells when EPSR and EPSF are defined.
◦ *MAT_VISCOPLASTIC_MIXED_HARDENING/*MAT_225: Fix issues when a table to account for strain-rate dependency is used together with kinematic hardening (BETA < 1).
◦ Add support of IORTHO = 1 for cohesive user-define materials.
◦ *MAT_106/*MAT_ELASTIC_VISCOPLASTIC_THERMAL: Added possibility to specify up to 8 user-defined history variables for output. The values of these history variables are computed via *DEFINE_FUNCTION. These values can, for example, be used to evaluate the hardness of the material.
◦ *MAT_254/*MAT_GENERALIZED_PHASE_CHANGE:

- New transformation laws (PTLAW = 5,6,7,8,9) which are tailored for titanium (Ti-6Al-4V).
  - EQ.5: Recovery of alpha martensite based on JMAK, using Koistinen-Marburger equation to estimate equilibrium concentration. Transformation of recovered phase partially to to-phase/
  - EQ.6: Associated with 5; transformation of remaining recovered phase to this to-phase.

EQ.7: Parabolic growth rate calculating the step-wise dissolution of two or more phases into one other phase. This law calculates the sum of remaining phase concentrations. The from-phase is the first to be dissolved.

EQ.8: Associated with 7; additional phases to be dissolved according to 7. Phases are dissolved one after the other.

EQ.9: Extensions of Koistinen-Marburger; threshold of fr-phase and incomplete transformation within a certain range of temperature rates.

EQ.12: JMAK transformation law (same as 2), but active within the temperature range from start and end temperature, i.e. it is active in heating and cooling.

- Read PTTAB6 for JMAK transformation law to account for accelerated phase transformation due to plastic strain in the material.
- Account for TSF (*CONTROL_THERMAL_SOLVER) in phase kinetics.
- History data only written for phases that are actually defined.
- Added variable POSTV which allows user to specify additional history variables (accumulated thermal strain, accumulated strain tensor, plastic strain tensor, equivalent strain) for output. When the temperature is in the annealing range, these values are reset.
- New input variable for initial plastic strain to initialize a constant nonzero equivalent plastic strain value in the whole part.
- Added enhanced annealing option that controls the reset of plastic strains above a certain critical temperature. The anneal process can be described by a time and temperature dependent approach (JMAK, tabular input, load curve inputs).
- Add a cut-off temperature for the thermal expansion.

◦ *MAT_270/*MAT_CWM:

- New option ANOPT (annealing option) that allows cutting the thermal expansion above a temperature limit (e.g. annealing temperature).
- Added variable POSTV which allows user to specify additional history variables (accumulated thermal strain, accumulated strain tensor, plastic strain tensor, equivalent strain) for output. When the temperature is in the annealing range, these values are reset.

◦ *MAT_277/*MAT_ADHESIVE_CURING_VISCOELASTIC:

- Implemented Arrhenius shift function as alternative to the WLF shift function.
- Heat generation due to curing can be accounted for.

◦ *MAT_278/*MAT_CF_MICROMECHANICS:

- Added curing induced heating.
- Fixed the solid formulation to give comparable results as the shell formulations.
- For the solid formulation, added input for the elastic properties of the fiber contribution in the direction that is orthogonal to the fiber plane.

- Fix for combination of *MAT_ADD_PORE_AIR and *MAT_ADD_EROSION with solid element formulations 1, 10, 43, 60, 61, and 99. History variables could have been mixed up.
- Increase accuracy for rate curves SIGVM < 0 and MXEPS < 0 of *MAT_ADD_EROSION. The original input curve is used instead of the rediscretized one.
- Add new variable P4 for *MAT_ADD_DAMAGE_DIEM to define if transverse shear stresses are included in the stress invariant computations (e.g triaxiality) or not. Useful for shells with corresponding “plane stress” material models, such as *MAT_024_2D, *MAT_036, ...
- Add new option MIDFAIL = 4 to GISSMO (*MAT_ADD_DAMAGE_GISSMO) and "eGISSMO" (*MAT_ADD_GENERALIZED_DAMAGE).
- Add new option LP2BI to *MAT_ADD_DAMAGE_GISSMO (shells only): failure becomes a function of triaxiality and a new bending indicator (adopted from *MAT_258).
- Fixes for GISSMO damage when used together with an equation-of-state (*EOS).
- Take IRATE flag from *CONTROL_IMPLICIT_DYNAMICS into account for GISSMO.
- Add new keyword *MAT_ADD_SOC_EXPANSION for geometric expansion due to State Of Charge from EM solver (currently only available for isotropic, hypoelastic materials with solid element formulations -2, -1, 1, 2, and 10).
- Add option to *MAT_024 with VP = 3, where yield stress can now be a function of plastic strain, strain rate, and up to five history variables that can be set using *INITIAL_HISTORY_NODE. That means LCSS refers to *DEFINE_TABLE_XD up to a level of 7.
- Add *MAT_024's option VP = 3 (filtered total strain rate) for solid elements.
- Enhancement when using log interpolation of strain rate data with VP = 1 in shell elements in *MAT_024, *MAT_123, or *MAT_251: eliminate numerical noise for very low strain rates by internally adding lower limits for strain rate and yield stress.
- Add effective strain as history variable #28 for *MAT_034/*MAT_FABRIC with FORM = 14, 24, or -14.
- Fix problem with internal computation of E0 for *MAT_036/*MAT_3-PARAMETER_BARLAT if hardening rule HR = 2 or HR = 5 is used AND E0 is zero in the input AND E is lessthan zero (curve for Young's modulus).
- Add new options to *MAT_068/*MAT_NONLINEAR_PLASTIC_DISCRETE_BEAM: translational and rotational stiffnesses TK{R,S,T} and

RK{R,S,T} can now be assigned negative values referring to curve IDs for load/moment vs. displacement/twist to get nonlinear elastic behavior.

- Fix for *MAT_105/*MAT_DAMAGE_2 with large curve IDs for LCSS (only solids).
- Make *MAT_133/*MAT_BARLAT_YLD2000 available for solid elements (currently only for explicit analysis and without C-R kinematic hardening).
- Fix for *MAT_169/*MAT_ARUP_ADHESIVE with variables referring to *DEFINE_FUNCTIONs: function ID offsets from *INCLUDE_TRANSFORM (IDFOFF) did not work.
- *MAT_187/*MAT_SAMP-1: instability criterion now available as history variable #28.
- Modifications for *MAT_187L/*MAT_SAMP_LIGHT:
  - log interpolation for table (optional) and no extrapolation
  - improved tolerance for plane stress iteration procedure
  - add viscoelasticity (defined by LCEMOD and BETA)
  - add flag to control curve treatment, either using discretized (0, default) or original (1).
- Fix thermal expansion in *MAT_188/*MAT_THERMO_ELASTO_VISCOPLASTIC_CREEP for solid elements: double precision version could show no expansion at all.
- Enable *MAT_199/*MAT_BARLAT_YLD2004 to be used with shell element formulations 25,26,27 and tshell element formulations 3,5,7. Set default values (1.0) for the transformation matrix coefficients.
- Add option to *MAT_224/*MAT_TABULATED_JOHNSON_COOK: variable BETA < 0 can now refer to a *DEFINE_TABLE_4D for triaxiality (TABLE_4D), temperature (TABLE_3D), strain rate (TABLE) and plastic strain (CURVE) dependence.
- Allow *MAT_224 to be used with Lode parameter dependent tables even for shell elements, i.e., in cases where LCF refers to *DEFINE_TABLE and/or LCI refers to *DEFINE_TABLE_3D.
- Allow *MAT_224 implicit to be used with EFG and MEFEM (ELFORMs 41, 42, 43, 45; see *SECTION_SOLID).
- Change behavior of NUMINT > 1 for *MAT_224 if used with multi-integration point solid elements. Integration points that reach damage = 1 still update stresses and therefore carry load. Only if NUMINT integration points reach damage = 1, the element gets eroded. The old way (single IPs got zero stresses before the element was deleted) just led to severe deformations and instabilities.
- Fix floating invalid problem in *MAT_224 (solids and LCG > 0): plastic strain rate could have become negative in rare cases.
- Make *MAT_251/*MAT_TAILORED_PROPERTIES available for solid elements.

- Enable numerical tangent for *MAT_252/*MAT_TOUGHENED_ADHESIVE_POLYMER allowing implicit analysis i^{th} moderate nonlinearities.
- Fixed problem using *MAT_258/*MAT_NON_QUADRATIC_FAILURE and *DAMPING_PART_STIFFNESS together with RYLEN = 2 in *CONTROL_ENERGY.
- Modification for *MAT_280/*MAT_GLASS: Parameter NIPF now also applies to the EPSCR failure criteria, i.e., elements get deleted when NIPF integration points failed due to reaching EPSCR.
- *MAT_ADD_INELASTICITY introduced for low order solids and shells. This keyword can be used to add inelastic behaviors, including plasticity, viscoelasticity, and creep, to any material model whose stress is calculated incrementally.
- *MAT_ADD_DAMAGE_DIEM now supports Hughes-Liu beams, thick shell type 2, and axisymmetric elements.
- All parameters on first two cards of *MAT_ADD_EROSION are supported for Instability on *DEFINE_MATERIAL_HISTORIES.
- *MAT_EXTENDED_3-PARAMETER_BARLAT/*MAT_036E now supports tables to define stress vs. plastic strain and strain rate. Viscoplastic consistency is mandatory.
- Enchanced message SOL+737. “Strain range of stress-strain input for *MAT_031 has been exceeded.”
- In checking for fixed nodes for PML boundary (*MAT_PML_...), correctly merge translational constraints from *NODE and *BOUNDARY_SPC, in case both are used at the same node.
- Calculate internal energy correctly for PML elements. *MAT_PML_NULL may have issues.
- Implement *DAMPING_FREQUENCY_RANGE_DEFORM for solid PML elements.
- Introduce new label “shl2d” for user materials in plane stress elements, distinguishing them from shells.
- Add keyword "*MAT_ADD_CHEM_SHRINKAGE_TITLE", with which the chemical shrinkage effect can be simulated.
- *MAT_242/*MAT_KINEMATIC_HARDENING_BARLAT2000:
  - Define Young's modulus with a curve. If EA is less than zero, the absolute value of EA is the curve ID defining Young's modulus as a function of plastic strain.
  - Add option for modified Yoshida formulation with two variables SC1, SC2 (same as *MAT_125).

- **MPP**
  - When MPP predecomposition is done for more processors than the calculation, and the model contains airbags, the airbag ownership was not being

properly handled leading to problems including possibly segfault. This has been fixed.

- Improvements and fixes for MPP handling of decomposition regions and processor subsets.
- Fix MPP contact initialization issue that was segfaulting in some models if parts were being excluded from the d3plot output.
- Add new pfile option "transform_keyword" to the "decomp" section. Including this new flag will cause the global decomposition transformations to apply to all the decomposition regions created by these keywords:

  *PARTS_DISTRIBUTE

  *PARTSET_DISTRIBUTE

  *ARRANGE_PARTS

  *CONTACT_DISTRIBUTE

  Before r86885, and after that was reverted in r102224, these regions were decomposed without any coordinate transformation at all. Between those versions, the global transformation applied to all these regions. I think this behavior makes sense, but someone complained that r86885 changed behavior, so it was removed in r102224. Then someone ELSE complained that r10224 changed the behavior that THEY wanted, so this option is now added.
- Fix missing initialization that broke d3plot files when MPP predecomposition was used with models having *DEFINE_CURVE_FUNCTIONs that used the PIDCTL function.
- Corrected MPP processing of *PART_MODES option of ANSID .ne. 0. The node list for this option needed to be sorted and logic adjusted so that all processes, even those with no such nodes, are involved in the communication.

- **Output**

  - *DATABASE_TRACER_GENERAL: In this keyword, tracers are nodes that output histories for any solids or beams or shells or thick shells with the tracers in their volumes.
  - *DATABASE_TRACER_GENERAL and *CONTROL_REFINE_SHELL: Implement the tracers in the shell refinement.
  - *DATABASE_TRACER_GENERAL and *CONTROL_REFINE_SOLID: Implement the tracers in the solid refinement.
  - *DATABASE_PROFILE: Implement TYPE = 6 to output the distribution (along a given direction) of thick shell data.
  - *DATABASE_PROFILE: Output strain profiles if STRFLG = 1 in *DATABASE_EXTENT_BINARY.

- MPP fix for frictional work output to intfor (*DATABASE_BINARY_INTFOR) when soft = 2 contact is being used
- "Interface Pressure" output to intfor is now returned to always being positive. There is no clear way to distinguish between compression and tension at this point in the code, so restoring the old behavior seems best.
- Fix issue with reported time step controlling element in glstat.
- Reaction forces for superelements (*ELEMENT_DIRECT_MATRIX_INPUT) using explicit time integration are now available in spcforc.
- SPCs in *CONSTRAINED_NODAL_RIGID_BODY_SPC are now internally converted to equivalent *BOUNDARY_PRESCRIBED_ MOTION_RIGID if SPC2BND is set to 1 on *CONTROL_OUTPUT. This allows output of reactions to bndout.
- New stress extrapolation from gauss points to nodes for shells (similar to the SOLSIG option for solids). Enable by setting the SHLSIG variable to 1 in *CONTROL_OUTPUT. Applies to shell element formulations 16, 20, and 21.
- *DATABASE_RECOVER_NODE:
  - Fix an MPP bug for the nodal stress calculation of 10-node tetrahedron element.
  - Add 3 more nodal stress components to be recovered by using the velocity vector.
  - Add elemental extrapolation method for stress recovery.
- Error terminate with KEY+501 message if different BEAMIP settings are used in duplicate *DATABASE_EXTENT_BINARY.
- *ele: Eliminate order dependency of IDOF in *SECTION_SHELL in which the IDOF in the first shell part became the default for the other shell parts with the same formulation instead of being independent.
- Fix incorrect rigid body velocities output to matsum for axisymmetric analysis with eroding elements.
- Fix incorrect rigidwall forces & stonewall energy reported for *RIGIDWALL_PLANAR_ORTHO.
- Shell reference surface offset NLOC in *SECTION_SHELL will now properly affect moment calculation for output to secforc (*DATABASE_SECFORC).
- Eliminated output of nodes having zero mass to massout (*DATABASE_MASSOUT).
- Fixed a bug that caused inconsistencies in strains output to d3plot and d3part.
- Fixed a bug that caused discrepancies in elout and disbout for discrete beams using *MAT_121/*MAT_GENERAL_NONLINEAR_1DOF_DISCRETE_BEAM.
- Fixed a bug that caused zero forces in nodfor for discrete beams (beam ELFORM 6).

- Fixed a bug that caused incorrect stresses in d3plot and elout for shell ELFORM 23.
- Fixed a bug that caused discrepancy in rigid body velocity output to glstat and matsum.
- Fixed a bug that caused segfault when using LCUR in *DATABASE_DISBOUT.
- Added missing report of triggered failure criterion when solid elements fail due to *MAT_ADD_EROSION.
- Fixed a bug that caused incorrect filtered results in ncforc when using *DATABASE_NCFORC_FILTER in MPP.
- Enabled the change in beam length to be viewed when fringe plotting discrete beams.
- Enabled variable ENGFLG on *DATABASE_EXTENT_BINARY to apply to thick shells as well as thin shells. This allows internal energy density of tshells to be written to d3plot.
- Fixed a thick shell output problem affecting d3plot that occurred when MAXINT on *DATABASE_EXTENT_BINARY was larger than the number of layers in the element. For the nonexistent layers, we were reading data from the next element in memory. Now data for the last existing point is repeated.
- Fixed two issues when reporting eroded hourglass energy to glstat and matsum. For solid elements, the eroded energy was not removed from the regular hourglass energy, so it was counted twice causing a poor energy balance in the glstat data. Also, thick shells were not reporting eroded hourglass energy.
- Fixed bug in which DECOMP = 2 or 4 in *DATABASE_EXTENT_BINARY corrupts d3drlf.
- Fixed bug whereby a simple restart corrupted the d3part database.
- Echo *DATABASE_EXTENT_BINARY_COMP variables to d3hsp.

- **Restarts**

  - *DAMPING_FREQUENCY_RANGE_DEFORM now works smoothly with full deck restarts (*STRESS_INITIALIZATION). Applies to solids, beams, shells, thick shells. Previously, a stress-jump would occur at the beginning of the restart run.
  - Fix conditional so that node rotational masses are properly synchronized when initializing *CONTACT_TIED_..._BEAM_OFFSET during MPP full deck restart.
  - Fix MPP full deck restart issue that caused hanging if the new input file contained encrypted input.
  - Correct the handling of restarting implicit after full restart.
  - Fix bug affecting restarts in implicit.
  - Support the following for full deck restart and consequently, *CONTROL_MPP_DECOMPOSITION_REDECOMPOSITION.

- SPH active region with local coordinate system (*DEFINE_SPH_ACTIVE_REGION, ICID).
- SPH injection (*DEFINE_SPH_INJECTION)
- Explicit joints (*CONSTRAINED_JOINT).
- LMF joint formulation (*CONTROL_RIGID, LMF = 1).

◦ Fix seg fault when using *DELETE_CONTACT for restart when running with SMP.
◦ Fix error termination for full deck restart using *DEFINE_ELEMENT_DEATH.
◦ Added new option COMP to *DELETE_PART for simple restart.

*DELETE_PART_COMP

This option eliminates data pertaining to deleted parts from d3plot thereby reducing the size of the d3plot database.

- ***SENSOR**

◦ Limit the usage of *SENSOR to transient analysis only, not dynamic relaxation.
◦ *SENSOR_DEFINE_CALC-MATH: fix a bug triggered when CALC = SUM and any of involved sensors, SENSi, are negative for subtraction.
◦ *SENSOR_DEFINE_ELEMENT: fix a bug triggered when trying to trace the stress/strain of a failed element.
◦ *SENSOR_DEFINE_FORCE: fix an MPP bug for TYPE = CONTACT2D.
◦ *SENSOR_DEFINE_MISC: fix a bug in which incorrect kinetic energy of a rigid body was sensed.
◦ *SENSOR_SWITCH_CALC-LOGIC: allow as many switches as needed for logic calculation.
◦ *SENSOR_CONTROL:

- Fix a bug for TYPE = BAGVENTPOP in which venting is not turned off for *AIRBAG_HYBRID.
- Fix a bug for TYPE = PRESC-MOT triggered when the referenced node or rigid part has a big ID.
- Fix a bug for TYPE = BELTPRET that fails to turn on the pretensioner.
- Fix a bug for TYPE = BELTRETRA that fails to lock the retractor when NEWLEG of *CONTROL_OUTPUT > 0 and no SBTOUT output is requested.
- Add CNRB option to control *CONSTRAINED_NODAL_RIGID_BODY.
- Add TYPE = LOADTHM to control *LOAD_THERMAL_VARIABLE and *LOAD_THERMAL_VARIABLE_NODE
- Add optional time delay.

- Fix order dependency problem when using *DEFORMABLE_TO_RIGID activated by *SENSOR_CONTROL TYPE = "DEF2RIG".

- **SPG (Smooth Particle Galerkin)**

  - Volume of 6-noded solid elements using element formulation 42 (SPG) was calculated incorrectly. That bug is now fixed.
  - Fix SPG bug in MPP whereby the time step size varies with different number of MPP processes.
  - *CONSTRAINED_IMMERSED_IN_SPG: Fix fatal memory issue if the number of immersed nodes is much larger than the number of nodes of the SPG part.
  - Enabled additional material models for SPG application, some of which include orthotropic behavior: *MAT_110, *MAT_122, *MAT_123, *MAT_143, *MAT_199, *MAT_260A, *MAT_269.
  - *SECTION_SOLID_SPG now automatically sets element formulation to 47.
  - If FAIL is set greater than 0 in *MAT_003 or *MAT_024, it is used in the SPG bond failure.
  - Added SPG bond failure criteria corresponding to *MAT_ADD_DAMAGE_GISSMO and *MAT_ADD_EROSION (1st principal stress, max shear strain, 3rd principal strain).

- **SPH (Smooth Particle Hydrodynamics)**

  - Incompressible SPH (FORM = 13) is available in beta form.
  - Add two material models for implicit SPH formulation (FORM = 13):

    - *MAT_300/*MAT_SPH_02/*MAT_SPH_IMPLICIT_FLUID: Input includes surface tension coefficient and surface area minimization coefficient.
    - *MAT_301/*MAT_SPH_03/*MAT_SPH_IMPLICIT_STRUCTURE: Used for boundary particles. Input includes surface adhesion coefficient.

  - Add *DATABASE_SPHMASSFLOW and *DEFINE_SPH_MASSFLOW_PLANE to measure SPH mass flow rate across a defined plane. This feature is to SPH as *DATABASE_DEMASSFLOW is to DEM.
  - Add option to move *DEFINE_SPH_ACTIVE_REGION around by following a moving coordinate system.
  - Add option for buffer zone in *DEFINE_SPH_ACTIVE_REGION.
  - Add an error message when a *DEFINE_BOX_SPH is referenced in *CONTROL_SPH boxid. This should point to a regular *DEFINE_BOX.
  - Add option to reactivate particles, and add an optional buffer zone in *DEFINE_BOX_SPH.
  - *DEFINE_BOX_SPH gets a special treatment with FORM = 13. Particles outside of the activation box get frozen in space, and deactivated particles can

become active when entering the box. This allows calculating only particles surrounding the region of interest.

- Reduce d3plot size for incompressible SPH by trimming down irrelevant variables.
- *DEFINE_ADAPTIVE_SOLID_TO_SPH:
  - Zero out increment of internal energy for eroded particles.
  - Bug fix in SMP: Results were inconsistent in SMP when ncpu was greater than one.
  - Bug fix in stress calculation of embedded SPH particles when ICPL = 1. Internal energy of these particles was also inconsistent.
  - When elements erode, distribute their internal energy to their child particles.
  - Reset IOPT = 0 if ICPL = 0.
  - Fix the MPP 3D strain calculation when adaptive with pure thermal analysis is used. Remove contribution of adaptive particles to strain rate calculation.
  - Properly update density of embedded particles based on element current volume. When particles became active, they used to still carry the rest density.
  - Enforce embedded SPH particles to output zero internal energy, for energy conservation.
- *DEFINE_SPH_INJECTION:
  - Speed-up initial smoothing length calculation when *DEFINE_SPH_-INJECTION is present. It used to be very slow for models containing a large number of injected particles.
  - Add option to define a variable speed of injection. If the injection speed scale factor is defined as negative, it refers to a *DEFINE_-CURVE defining the velocity magnitude vs. time.
  - Use yet-to-be injected particles as ghost particles on the other side of the injection plane.
  - If the coordinate system is updated in time (IFLAG = 1 in *DEFINE_-COORDINATE_NODES), we also update the injection direction.
  - If the injection plane follows a node (NID in *DEFINE_SPH_INJEC-TION), and IFLAG = 1 in *DEFINE_COORDINATE_NODES, we also continously rotate the whole stack of particles to be injected with the plane.
- Added SPH support for *MAT_193/*MAT_DRUCKER_PRAGER.
- Bug fix in psetid option of *DATABASE_BINARY_D3PLOT if psetid contains SPH parts.
- Fix ASCII output of SPH neighbor count, which was always zero.

- Bug fix in SPH neighbor search when variable smoothing length is employed. The neighbor list was created based on minimum smoothing length instead of maximum. As a result, some neighbors were potentially omitted.
- Add option in *CONTROL_MPP_DECOMPOSITION_REDECOMPOSITION to remove dead SPH particles from the model at each redecomposition step.
- Improve MPP load balancing when a *CONTROL_MPP_DECOMPOSITION_REDECOMPOSITION is present and a moving box defines the activation region of SPH.
- Create MPP variants of 2D plane-strain and 2D axisymetric SPH formulations with thermal coupling.
- Add support for *LOAD_THERMAL_LOAD_CURVE in SPH.
- Fix bug for SPH thermal formulation in MPP. Artificial viscosity calculation was incorrect.
- Fix bug in MPP with ERODING contact and SPH. In some MPP decompositions, some processors were ignoring contact between SPH and Lagrangian parts.
- Restored TEROD and CEROD parameters for *MAT_NULL with SPH particles (these two parameters were not applied from R9).
- Material models added for SPH:

  - *MAT_COMPOSITE_DAMAGE/MAT_022 for SPH plane strain.
  - *MAT_MODIFIED_CRUSHABLE_FOAM/*MAT_163 for SPH axisymmetric, plane strain, and 3D.
  - *MAT_ENHANCED_COMPOSITE/*MAT_054,_055 for SPH axisymmetric and 3D.

- *CONTROL_SPH:

  - Improvements in adaptive smoothed particle hydrodynamics formulations (FORMs 9,10) with an anisotropic kernel. Speed up SMP operationsr; optimize bucket cycle; update principle direction and scale factor.
  - Renamed MEMORY variable to NMNEIGH and added error/warning messages to help clarify meaning for users.

- New kernel functions (SPHKERN in *SECTION_SPH) for 3D SPH.

  - SPHKERN = 1 (quintic spline kernel function) now supports FORMs 5,6. (Previously only supported for FORMs 0,1,9,10.
  - Added SPHKERN = 2 for FORMs 0,1,5,6. This quadratic spline kernel function mainly aims for high velocity impact to relieve the problem of compressive instability.

- Added SPHKERN = 3 for FORMs 0,1,5,6. This quartic smoothing kernel function (G.R.Liu 2003) is similar to the standard cubic spline kernel function but should be more stable and accurate.

- *DEFINE_SPH_INJECTION: (both SMP and MPP):

  - Add injection plane moving with a node NID.
  - Add injection velocity based on a local coordinate system CID.

- Fix inexplicable penetration when using *CONTACT_AUTOMATIC_NODES_TO_SURFACE with SPH elements. This affects SMP only.

- **Thermal Solver**

  - *CONTROL_EXPLICIT_THERMAL_SOLVER and *ELEMENT_TSHELL: Implement heat conduction for thick shells in the explicit thermal solver.
  - *CONTROL_EXPLICIT_THERMAL_SOLVER can use *INITIAL_TEMPERATURE to initialize the element temperatures (it averages the initial nodal temperatures at element centers).
  - *CONTROL_EXPLICIT_THERMAL_INITIAL with ID < 0 allows initialization of temperature by element instead of element set (ID > 0).
  - New SOLVER options in *CONTROL_THERMAL_SOLVER:
    EQ.18: preconditioner based on a local incomplete factorization;
    EQ.19: preconditioner based on a block low-rank factorization of the global problem.
  - *CONTROL_THERMAL_SOLVER:

    - Fixed the echo of thermal solver options to d3hsp.
    - Enhanced the setting of default for GMRES parameters when nonsymmetric iterative was internally chosen over the input value for thermal linear equation solver.
    - Migrated the linear algebra data structures in thermal mechanics to Fortran 95 dynamic storage as part of the storage modernization effort. Reduces requirement of user on setting the memory command line parameter.
    - Declare all old SMP linear equation solvers for thermal as obsolete. Automatically switch to the new solvers with an appropriate warning. This is a step towards modernization of linear algebra for thermal.
    - Added nonsymmetric problem support to the modern linear algebra path in thermal. This is mostly the THERMAL_BULK feature.
    - Turned off support for direct linear equation solvers for thermal in single precision. In single precision change direct solver options to appropriate iterative solvers. Symmetric (11) goes to modified Incomplete Choleski PCG (16) which is the strongest symmetric iterative solver. Nonsymmetric (20) goes to GMRES (17).

- Correct the case where cgtol is specified on *CONTROL_THERMAL_-SOLVER but reltol is not.
- Corrected testing of linear equation solver option for thermal. The addition of GMRES option for conjugate heat transfer problems had to be properly dealt with.

- Turn off all implicit mechanics if a thermal-only solution.
- *CONTROL_THERMAL_SOLVER: Fix a conflict associated with using the nonsymmetric direct solver (SOLVER = 30) for the thermal side of a coupled thermal/mechanical analysis when the mechanical analysis is implicit.
- *BOUNDARY_RADIATION_<option>_VF_READ requires a view factor file. An input trap was added if this view factor file is missing.
- There was a limit on *BOUNDARY_TEMPERATURE_NODE and *INITIAL_TEMPERATURE_NODE keyword appearances. This limit was removed, and the speed of the keyword reader was improved.
- Added new keyword *CONTROL_THERMAL_FORMING for easy setup of hot/warm forming simulations. This keyword sets default values for thermal control keywords so that there is no need to include *CONTROL_SOLUTION, *CONTROL_THERMAL_SOLVER and *CONTROL_THERMAL_TIMESTEP in the input deck unless fine tuning of simulation parameters is needed. This keyword can also be used to set up default thermal parameters for forming contact pairs.
- Added new keyword *BOUNDARY_TEMPERATURE_TRAJECTORY to apply a temperature boundary condition on nodes enclosed in either a cylindrical or rectangular prism volume moving along a trajectory. The center of the volume moves along the trajectory defined by a nodal path at a prescribed velocity. The geometry of the enclosing volume can be time-variant. This keyword applies only to solid elements.
- New keyword *BOUNDARY_FLUX_TRAJECTORY defines a moving flux surface boundary condition along a nodal path. Based on the shape of the heat source and its aiming direction, the projection onto the surface is calculated and used for application of the flux. Additional features include:

  - Propagation to newly exposed surfaces after element erosion.
  - Option to balance the change in projected area by modifying the surface density.
  - Total amount of heat input as resulting from the numerical integration of the surface densities can be enforced to coincide with the input.
  - Various heat distributions are available:
    - Constant distribution within a double elliptic region
    - Gaussian distribution within a double elliptic region
    - User-defined function (*DEFINE_FUNCTION) based on local coordinates, time, and temperature

- *LOAD_HEAT_GENERATION: Added variable REFNODE to define a reference node for the function definition. The current nodal coordinates can be referred to in the function definition as “xref”, “yref”, and “zref”. It allows defining a heat source motion associated with the motion of the reference node.
- Thermal contact for 'edge' contact of composite tshell elements now considers the composite stacking sequence by way of an internally constructed mesh of stacked tshell elements.

- **XFEM (eXtended Finite Element Method)**

  - *BOUNDARY_PRECRACK: Adjusted the location of pre-crack to avoid passing through nodal points.
  - Recoded neighbors list to handle triangular mesh better.
  - Added support of GISSMO damage model for XFEM. Set FAILCR = 0 in *SECTION_SHELL_XFEM to activate GISSMO model.
  - 2D XFEM shell (ELFORM = 52 in *SECTION_SHELL_XFEM) is a fully integrated form and so NIP = 4 is now hardwired.
  - Second order stress update can now be specified for 2D XFEM shell form 52 (OSU = 1 in *CONTROL_ACCURACY).

- **Miscellaneous**

  - *DAMPING_FREQUENCY_RANGE and *DAMPING_FREQUENCY_-RANGE_DEFORM had an error trap related to the time step being too large to compute damping at frequency FHIGH. The trap was unnecessary for *DAMPING_FREQUENCY_RANGE_DEFORM and has been removed. The trap was previously necessary for *DAMPING_FREQUENCY_RANGE to avoid instability, but now the code has been modified to remain unconditionally stable and the error trap has been removed. The code modification will result in some change of results for *DAMPING_FREQUENCY_-RANGE (but not for the _DEFORM option). The difference will be most noticeable when the product of the timestep with FHIGH is large, such as in Implicit calculations.
  - Added new command line option to run only a subset of the cases defined in the input deck via *CASE. As before, if all cases in a model should be run, the single word “CASE” should appear as a command line argument. But if only some cases should be run, those case ids can be listed on the command line like:

    ```
    CASE=17,22,147
    ```

    There should be NO spaces before or after the =, and the list following the = should be a comma delimited list of case ids, with no spaces.
  - LS-DYNA now returns an exit code of 1 to the system in case of non-normal termination. Previously, we always returned 0 (no error) no matter what, which could be misleading if a user's job script made use of the exit code.

- Suppress d3hsp output of any *PARAMETER that was encrypted in the input.
- Fix old bug in *INTERFACE_LINKING that would cause incorrect behavior for displacements scaled via a *DEFINE_FUNCTION if (and only if) the function was defined in terms of 3 variables (spatial displacement dependence only).
- The third variable in *PART_ADAPTIVE_FAILURE now does this:
  EQ.1: disable adaptivity of THIS part after it is split into two pieces
  EQ.2: disable ALL adaptivity after this part is split into two pieces
  The default value is 0, which does nothing.
- Add keyword *DEFINE_DRIFT_REMOVE to restore periodicity to specified curve(s) that physically should exhibit periodicity. For example, accelerometer data collected as a car drives one circuit around a track should exhibit periodicity such that when integrated to get displacement, that displacement is zero. However, noise in the data leads to nonphysical drift. This keyword activates an algorithm that approximately restores periodicity.
- *INTERFACE_LINKING_NODES: Interface nodes that were shared between processes were not properly dealt with for implicit.
- *DEFINE_CURVE_FUNCTION:
  - Fix a bug for SENSOR or SENSORD that may result in erroneous information in CURVOUT.
  - Fix a bug for function PIDCTL that occurred in a thermal-only analysis.
- *PART_DUPLICATE:
  - Fix a bug in which 10-noded tet elements were not duplicated.
  - Add option of BOXID to assure that the transformed configuration falls inside the box
- *SET_PART_TREE: Define a branch in a tree structure. A branch is a part set that can be defined using parts and/or sub-branches. With this keyword, the whole model can be modeled as a hierarchical tree structure.
- *SET_SHELL: allow *SET_SHELL_LIST_GENERATE to generate a set of 2D belts.
- New keyword *DEFINE_QUASAR_COUPLING to enable coupling of LS-DYNA and Cadlm's QUASAR ROM (Reduced Order Model). Supports multiple ROMs attached to LS-DYNA FEM model.
- Madymo coupling:
  - Support TASS Madymo coupling using Intel MPI.
  - Support Madymo 7.7 and above.
- Fixed outdated argument lists for user subroutines. Before this fix user-defined features using *MODULE may not work correctly.

- *DEFINE_PRESSURE_TUBE now supports decomposition of automatically generated solid/shell tubes in MPP.
- Added support for user element history variables in *USER_NONLOCAL_-SEARCH.
- Implement *DEFINE_DRIFT_REMOVE for MPP.
- Fix empty *SET_SEGMENT error, KEY+140, when using *SET_SEGMENT_-GENERAL with OPTION set to SET_SOL-ID/SET_SLDI0/SET_SLDF#/SET_TSHELL/SET_TSHIO.
- Fix seg fault when using *INTERFACE_LINKING_NODE_SET.
- New functions AX2, AY2, and AZ2 for *DEFINE_CURVE_FUNCTION. The difference compared to AX, AY, and AZ is that if n2 = 0, then return component relative to axes fixed in n1.
- New function DIST() in *DEFINE_CURVE_FUNCTION, which is used to calculate the distance traveled by a node
- Add feature to *DEFINE_MATERIAL_HISTORIES, LABEL="History" whereby if the first attribute A1 is negative, its absolute value points to a curve. The first ordinate value of that curve defines an operation to be performed on a list of history variables. The subsequent ordinate values give the history variable numbers in the list. See the User's Manual for details and an example.
- Add keyword *DEFINE_ELEMENT_EROSION_(SHELL/TSHELL) to allow more flexible control of when to actually delete an element.
- Add two new OPTIONs for *DEFINE_TRANSFORMATION.

  - TRANSL2ND: translation given by two nodes and a distance
  - ROTATE3NA: rotation given by three nodes and an angle (two nodes provide rotation axis, going through the third node)

- Add new option DTYPE = 1 to *PERTURBATION_NODE to allow uniform distribution between SCL × [−AMPL, AMPL] for TYPE = 8.
- Add runtime output to "Open include file: ..." instance.
- Removed the echo of encrypted data to d3hsp for the following keywords: *PARAMETER, *DEFINE_FRICTION, *ELEMENT_DISCRETE, *CONTACT, and *DEFINE_CURVE.
- Added three sense switches swb, swc and swd, all of which will create dynain data. *INTERFACE_SPRINGBACK_LSDYNA must be defined in the input deck.

  swb: a dynain is written and the analysis continues.
  swc: a restart and dynain are written and the analysis continues.
  swd: a restart and dynain are written and the analysis terminates.

  The first dynain file created by one of these sense switches is named dynain.1, and the filename is incremented by 1 (dynain.2, dynain.3, etc.) each time one of the sense switches is submitted.
- Replace keyword *SET_SPRING with *SET_DISCRETE.

- Changed the default of plabel to plabel = no for faster input processing. If the input contains non-numeric (character) ID(s), an error message will be issued, in which case the user would need to include "plabel = yes" on the execution line so that the non-numeric ID(s) could be properly read.
- Fix bug in which message announcing loading of an include files appeared twice.
- Fixed bug in madymo coupling in which the restart dump was called twice.
- Improve check for empty or duplicate *SETs and issue appropriate warnings/errors.
- Can now use an environment variable to set the default memory: setenv LSTC_DEFMEM n where n is the memory size
- Can now suppress almost all output by including "benchmark = y" on either the execution line or on the *KEYWORD line in the input deck. It will also remove part, node and element output in d3hsp.
- Fixed bug in reading long format if *KEYWORD long = yes is used in include file.
- A new flag TOL in *INCLUDE_UNITCELL is introduced for users to define the tolerance for identifying the pairs of nodes in the periodic positions.
- New keywords: *COSIM_FMI_CONTROL and *COSIM_FMI_INTERFACE: Adds capability to remotely co-simulate with other software supporting FMI standard.
- Deliver model order reduction (MOR) *CONTROLLER_PLANT for the linear structural and piezo-electric system. The state space matrices are exported based on the modal truncation or Krylov subspace.
- *PART_DUPLICATE: Add a new optional variable ZMIN. Transformed part(s) will have a minimum z-coordinate equal to ZMIN.
- *INCLUDE_STAMPED_PART_SOLID_TO_SOLID: This keyword extends the idea of *INCLUDE_STAMPED_PART to solid elements. Information about a solid part is mapped from one analysis (e.g., stamping) to another analysis (e.g., crash).

    - Maps the stress tensor, effective plastic strain, and strain tensor.
    - Calculates the thickness from the first analysis and modifies the coordinates of the nodes in the second model to conform to that thickness.
    - When PID is a negative number, it means that the top surface of the solid needs to be reversed to match the forming result. Otherwise, the mapping will be wrong.
    - When the element orientation is defined in *ELEMENT_SOLID_ORTHO, the angles are mapped to the new mesh.

- *PART_MOVE:

    - Maximum number of parts moved in one input increased from 400 to 1000.

- When CID is a negative value, it defines a vector id or VID pointing to the direction of the part move and the variable ZMOV is the move distance.

Capabilities added to create LS-DYNA R13:

See release notes located at https://ftp.lstc.com/anonymous/outgoing/support/FAQ/ReleaseNotes/Release_Notes_LS-DYNA_R13_0_0_rev2.pdf.

Capabilities added to create LS-DYNA R14:

See release notes located at https://ftp.lstc.com/anonymous/outgoing/support/FAQ/ReleaseNotes/Release_Notes_LS-DYNA_R14_0_0_rev0.html.

MATERIAL MODELS

Some of the material models presently implemented are:

- elastic,
- orthotropic elastic,
- kinematic/isotropic plasticity [Krieg and Key 1976],
- thermoelastoplastic [Hallquist 1979],
- soil and crushable/non-crushable foam [Key 1974],
- linear viscoelastic [Key 1974],
- Blatz-Ko rubber [Key 1974],
- high explosive burn,
- hydrodynamic without deviatoric stresses,
- elastoplastic hydrodynamic,
- temperature dependent elastoplastic [Steinberg and Guinan 1978],
- isotropic elastoplastic,
- isotropic elastoplastic with failure,
- soil and crushable foam with failure,
- Johnson/Cook plasticity model [Johnson and Cook 1983],
- pseudo TENSOR geological model [Sackett 1987],
- elastoplastic with fracture,
- power law isotropic plasticity,

- strain rate dependent plasticity,
- rigid,
- thermal orthotropic,
- composite damage model [Chang and Chang 1987a 1987b],
- thermal orthotropic with 12 curves,
- piecewise linear isotropic plasticity,
- inviscid, two invariant geologic cap [Sandler and Rubin 1979, Simo et al, 1988a
- 1988b],
- orthotropic crushable model,
- Mooney-Rivlin rubber,
- resultant plasticity,
- force limited resultant formulation,
- closed form update shell plasticity,
- Frazer-Nash rubber model,
- laminated glass model,
- fabric,
- unified creep plasticity,
- temperature and rate dependent plasticity,
- elastic with viscosity,
- anisotropic plasticity,
- user defined,
- crushable cellular foams [Neilsen, Morgan, and Krieg 1987],
- urethane foam model with hysteresis,

and some more foam and rubber models, as well as many materials models for springs and dampers. The hydrodynamic material models determine only the deviatoric stresses. Pressure is determined by one of ten equations of state including:

- linear polynomial [Woodruff 1973],
- JWL high explosive [Dobratz 1981],
- Sack "Tuesday" high explosive [Woodruff 1973],
- Gruneisen [Woodruff 1973],
- ratio of polynomials [Woodruff 1973],
- linear polynomial with energy deposition,

- ignition and growth of reaction in HE [Lee and Tarver 1980, Cochran and Chan 1979],
- tabulated compaction,
- tabulated,
- TENSOR pore collapse [Burton et al. 1982].

The ignition and growth EOS was adapted from KOVEC [Woodruff 1973]; the other subroutines, programmed by the authors, are based in part on the cited references and are nearly 100 percent vectorized. The forms of the first five equations of state are also given in the KOVEC user's manual and are retained in this manual. The high explosive programmed burn model is described by Giroux [Simo et al. 1988].

The orthotropic elastic and the rubber material subroutines use Green-St. Venant strains to compute second Piola-Kirchhoff stresses, which transform to Cauchy stresses. The Jaumann stress rate formulation is used with all other materials with the exception of one plasticity model which uses the Green-Naghdi rate.

SPATIAL DISCRETIZATION

The elements shown in Figure 1-1 are presently available. Currently springs, dampers, beams, membranes, shells, bricks, thick shells and seatbelt elements are included.

The first shell element in DYNA3D was that of Hughes and Liu [Hughes and Liu 1981a, 1981b, 1981c], implemented as described in [Hallquist et al. 1985, Hallquist and Benson 1986]. This element [designated as HL] was selected from among a substantial body of shell element literature because the element formulation has several desirable qualities:

- It is incrementally objective (rigid body rotations do not generate strains), allowing for the treatment of finite strains that occur in many practical applications.
- It is compatible with brick elements, because the element is based on a degenerated brick element formulation. This compatibility allows many of the efficient and effective techniques developed for the DYNA3D brick elements to be used with this shell element;
- It includes finite transverse shear strains;
- A through-the-thickness thinning option (see [Hughes and Carnoy 1981]) is also available.

All shells in our current LS-DYNA code must satisfy these desirable traits to at least some extent to be useful in metalforming and crash simulations.

The major disadvantage of the HL element turned out to be cost related and, for this reason, within a year of its implementation we looked at the Belytschko-Tsay [BT] shell [Belytschko and Tsay 1981, 1983, 1984] as a more cost effective, but possibly less accurate

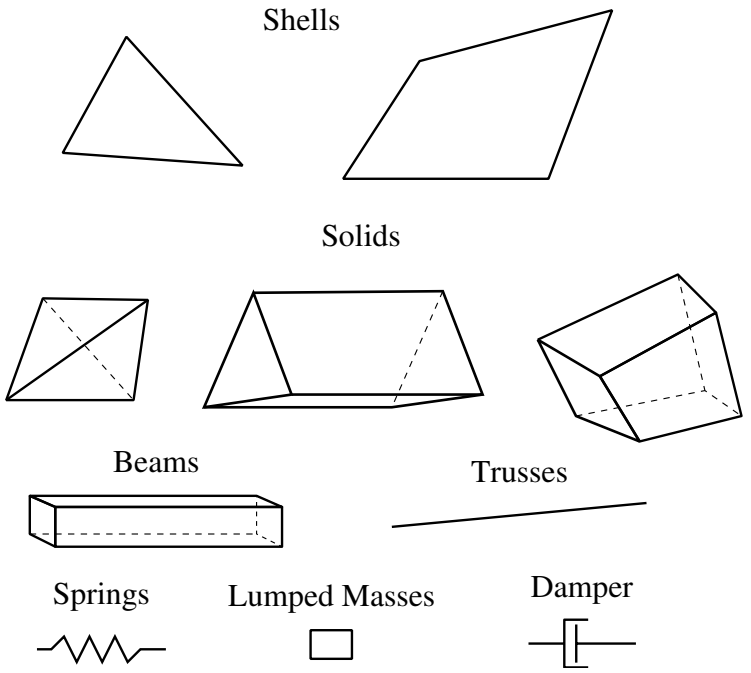

Figure 1-1. Elements in LS-DYNA. Three-dimensional plane stress constitutive subroutines are implemented for the shell elements which iteratively update the stress tensor such that the stress component normal to the shell midsurface is zero. An iterative update is necessary to accurately determine the normal strain component which is necessary to predict thinning. One constitutive evaluation is made for each integration point through the shell thickness.

alternative. In the BT shell the geometry of the shell is assumed to be perfectly flat, the local coordinate system originates at the first node of the connectivity, and the co-rotational stress update does not use the costly Jaumann stress rotation. With these and other simplifications, a very cost effective shell was derived which today has become perhaps the most widely used shell elements in both metalforming and crash applications. Results generated by the BT shell usually compare favorably with those of the more costly HL shell. Triangular shell elements are implemented, based on work by Belytschko and co-workers [Belytschko and Marchertas 1974, Bazeley et al. 1965, Belytschko et al. 1984], and are frequently used since collapsed quadrilateral shell elements tend to lock and give very bad results. LS-DYNA automatically treats collapsed quadrilateral shell elements as C^0 triangular elements.

Since the Belytschko-Tsay element is based on a perfectly flat geometry, warpage is not considered. Although this generally poses no major difficulties and provides for an efficient element, incorrect results in the twisted beam problem and similar situations are obtained where the nodal points of the elements used in the discretization are not coplanar. The Hughes-Liu shell element considers non-planar geometries and gives good results on the twisted beam. The effect of neglecting warpage in a typical application cannot be predicted beforehand and may lead to less than accurate results, but the latter is only speculation and is difficult to verify in practice. Obviously, it would be better to

use shells that consider warpage if the added costs are reasonable and if this unknown effect is eliminated. Another shell published by Belytschko, Wong, and Chiang [Belytschko, Wong, and Chiang 1989, 1992] proposes inexpensive modifications to include the warping stiffness in the Belytschko-Tsay shell. An improved transverse shear treatment also allows the element to pass the Kirchhoff patch test. This element is now available in LS-DYNA. Also, two fully integrated shell elements, based on the Hughes and Liu formulation, are available in LS-DYNA, but are rather expensive. A much faster fully integrated element which is essentially a fully integrated version of the Belytschko, Wong, and Chiang element, type 16, is a more recent addition and is recommended if fully integrated elements are needed due to its cost effectiveness.

Zero energy modes in the shell and solid elements are controlled by either an hourglass viscosity or stiffness. Eight node thick shell elements are implemented and have been found to perform well in many applications. All elements are nearly 100% vectorized. All element classes can be included as parts of a rigid body. The rigid body formulation is documented in [Benson and Hallquist 1986]. Rigid body point nodes, as well as concentrated masses, springs and dashpots can be added to this rigid body.

Membrane elements can be either defined directly as shell elements with a membrane formulation option or as shell elements with only one point for through thickness integration. The latter choice includes transverse shear stiffness and may be inappropriate. For airbag material a special fully integrated three and four node membrane element is available.

Two different beam types are available: a stress resultant beam and a beam with cross section integration at one point along the axis. The cross section integration allows for a more general definition of arbitrarily shaped cross sections taking into account material nonlinearities.

Spring and damper elements can be translational or rotational. Many behavior options can be defined, e.g., arbitrary nonlinear behavior including locking and separation.

Solid elements in LS-DYNA may be defined using from 4 to 8 nodes. The standard elements are based on linear shape functions and use one point integration and hourglass control. A selective-reduced integrated (called fully integrated) 8 node solid element is available for situations when the hourglass control fails. Also, two additional solid elements, a 4 noded tetrahedron and an 8 noded hexahedron, with nodal rotational degrees of freedom, are implemented based on the idea of Allman [1984] to replace the nodal midside translational degrees of freedom of the elements with quadratic shape functions by corresponding nodal rotations at the corner nodes. The latter elements, which do not need hourglass control, require many numerical operations compared to the hourglass controlled elements and should be used at places where the hourglass elements fail. However, it is well known that the elements using more than one point integration are more sensitive to large distortions than one point integrated elements.

The thick shell element is a shell element with only nodal translations for the eight nodes. The assumptions of shell theory are included in a non-standard fashion. It also uses hourglass control or selective-reduced integration. This element can be used in place of any four node shell element. It is favorably used for shell-brick transitions, as no additional constraint conditions are necessary. However, care has to be taken to know in which direction the shell assumptions are made; therefore, the numbering of the element is important.

Seatbelt elements can be separately defined to model seatbelt actions combined with dummy models. Separate definitions of seatbelts, which are one-dimensional elements, with accelerometers, sensors, pretensioners, retractors, and sliprings are possible. The actions of the various seatbelt definitions can also be arbitrarily combined.

CONTACT-IMPACT INTERFACES

The three-dimensional contact-impact algorithm was originally an extension of the NIKE2D [Hallquist 1979] two-dimensional algorithm. As currently implemented, one surface of the interface is identified as a reference surface and the other as a tracked surface. Each surface is defined by a set of three or four node quadrilateral segments, called reference and tracked segments, on which the nodes of the tracked and reference surfaces, respectively, must slide. In general, an input for the contact-impact algorithm requires that a list of segments be identified for two surfaces. In nonsymmetric contact, these are the tracked and reference surfaces. For symmetric contact, the algorithm is run twice so that each surface acts as both the tracked and reference surfaces. For the single surface algorithm only one surface is defined and each node in the surface is checked each time step to ensure that it does not penetrate through the surface. Internal logic [Hallquist 1977, Hallquist et al. 1985] identifies a reference segment for each tracked node and a tracked segment for each reference node and updates this information every time step as the tracked and reference nodes slide along their respective surfaces. Note that for general automatic definitions only parts/materials or three-dimensional boxes must be given. Then the possible contacting outer surfaces are identified by the internal logic in LS-DYNA. More than 20 types of interfaces can presently be defined including:

- sliding only for fluid/structure or gas/structure interfaces
- tied
- sliding, impact, friction
- single surface contact
- discrete nodes impacting surface
- discrete nodes tied to surface
- shell edge tied to shell surface

- nodes spot welded to surface
- tiebreak interface
- one way treatment of sliding, impact, friction
- box/material limited automatic contact for shells
- automatic contact for shells (no additional input required)
- automatic single surface with beams and arbitrary orientations
- surface to surface eroding contact
- node to surface eroding contact
- single surface eroding contact
- surface to surface symmetric constraint method [Taylor and Flanagan 1989]
- node to surface constraint method [Taylor and Flanagan 1989]
- rigid body to rigid body contact with arbitrary force/deflection curve
- rigid nodes to rigid body contact with arbitrary force/deflection curve
- edge-to-edge
- draw beads

Interface friction can be used with most interface types. The tied and sliding only interface options are similar to the two-dimensional algorithm used in LS-DYNA2D [Hallquist 1976, 1978, 1980]. Unlike the general option, the tied treatments are not symmetric; therefore, the surface which is more coarsely zoned should be chosen as the reference surface. When using the one-way slide surface with rigid materials, the rigid material should be chosen as the reference surface.

For geometric contact entities, contact has to be separately defined. Note that that for the contact of a rigid body with a flexible body, either the sliding interface definitions as explained above or the geometric contact entity contact can be used. Currently, the geometric contact entity definition is recommended for metal forming problems due to high accuracy and computational efficiency.

INTERFACE DEFINITIONS FOR COMPONENT ANALYSIS

Interface definitions for component analyses are used to define surfaces, nodal lines, or nodal points (*INTERFACE_COMPONENTS) for which the time histories of nodal coordinates and if applicable (*INTERFACE_LINKING_NODE/EDGE) and available (beams, shells), nodal rotations, are saved at some user specified frequency (*CONTROL_OUTPUT). This data may then be used to drive interfaces (*INTERFACE_LINKING) in subsequent analyses. This capability is especially useful for studying the detailed

response of a small member in a large structure. For the first analysis, the member of interest need only be discretized sufficiently that the displacements and velocities on its boundaries are reasonably accurate. After the first analysis is completed, the member can be finely discretized and interfaces defined to correspond with the first analysis. Finally, the second analysis is performed to obtain highly detailed information in the local region of interest.

When starting the analysis, specify a name for the interface segment file using the Z = parameter on the LS-DYNA command line. When starting the second analysis, the name of the interface segment file (created in the first run) should be specified using the L = parameter on the LS-DYNA command line.

Following the above procedure, multiple levels of sub-modeling are easily accommodated. The interface file may contain a multitude of interface definitions so that a single run of a full model can provide enough interface data for many component analyses. The interface feature represents a powerful extension of LS-DYNA's analysis capability.

PRECISION

The explicit time integration algorithms used in LS-DYNA are in general much less sensitive to machine precision than other finite element solution methods. Consequently, double precision is not generally required. The benefits of this are greatly improved utilization of memory and disk. When problems have been found we have usually been able to overcome them by reorganizing the algorithm or by converting to double precision locally in the subroutine where the problem occurs. Particularly sensitive problems (e.g. some buckling problems, which can be sensitive to small imperfections) may require the fully double precision version, which is available on all platforms. Very large problems requiring more than 2 billion words of memory will also need to be run in double precision, due to the array indexing limitation of single precision integers.

GETTING STARTED

DESCRIPTION OF KEYWORD INPUT

The keyword input provides a flexible and logically organized database that is simple to understand. Similar functions are grouped together under the same keyword. For example, under the keyword *ELEMENT are included solid, beam, shell elements, spring elements, discrete dampers, seat belts, and lumped masses. Many keywords have options that are identified as follows: "*OPTIONS*" and "*{OPTIONS}*". The difference is that "*OPTIONS*" requires that one of the options must be selected to complete the keyword command. The option <BLANK> is included when {} are used to further indicate that these particular options are not necessary to complete the keyword.

The LS-DYNA User's Manual is alphabetically organized in logical sections of input data. Each logical section relates to a particular input. There is a control section for resetting LS-DYNA defaults, a material section for defining constitutive constants, an equation-of-state section, an element section where element part identifiers and nodal connectivities are defined, a section for defining parts, and so on. Nearly all model data can be input in block form. For example, consider the following where two nodal points with their respective coordinates and shell elements with their part identity and nodal connectivity's are defined:

```
$define two nodes
$
*NODE
10101x y z
10201x y z
$    define two shell elements
$
*ELEMENT_SHELL
10201pidn1n2n3n4
10301pidn1n2n3n4
Alternatively, acceptable input could also be of the form:
$     define one node
$
*NODE
10101x y z
$    define one shell element
$
*ELEMENT_SHELL
10201pidn1n2n3n4
$
$     define one more node
$
*NODE
10201x y z
$ define one more shell element
$
*ELEMENT_SHELL
10301pidn1n2n3n4
```

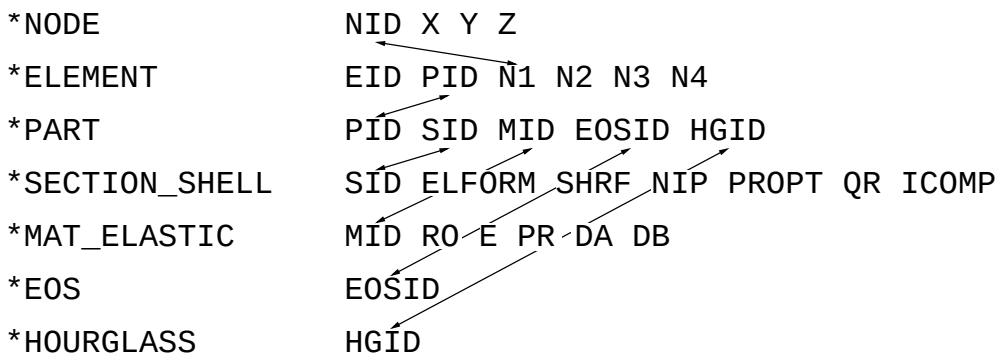

Figure 2-1. Organization of the keyword input.

A data block begins with a keyword followed by the data pertaining to the keyword. The next keyword encountered during the reading of the block data defines the end of the block and the beginning of a new block. A keyword must be left justified with the "*" contained in column one. A dollar sign "$" in column one precedes a comment and causes the input line to be ignored. Data blocks are not a requirement for LS-DYNA, but they can be used to group nodes and elements for user convenience. Multiple blocks can be defined with each keyword if desired as shown above. It would be possible to put all nodal points definitions under one keyword *NODE, or to define one *NODE keyword prior to each node definition. The entire LS-DYNA input is order independent with the exception of the optional keyword, *END, which defines the end of input stream. Without the *END termination is assumed to occur when an end-of-file is encountered during the reading.

Figure 2-1 highlights how various entities relate to each other in LS-DYNA input. In this figure the data included for the keyword, *ELEMENT, is the element identifier, EID, the part identifier, PID, and the nodal points identifiers, the NID's, defining the *element connectivity*: N1, N2, N3, and N4. The nodal point identifiers are defined in the *NODE section where each NID should be defined just once. A part defined with the *PART keyword has a unique part identifier, PID, a section identifier, SID, a material or constitutive model identifier, MID, an equation of state identifier, EOSID, and the hourglass control identifier, HGID. The *SECTION keyword defines the section identifier, SID, where a section has an element formulation specified, a shear factor, SHRF, a numerical integration rule, NIP, among other parameters.

Constitutive constants are defined in the *MAT section where constitutive data is defined for all element types including solids, beams, shells, thick shells, seat belts, springs, and dampers. Equations of state, which are used only with certain *MAT materials for solid elements, are defined in the *EOS section. Since many elements in LS-DYNA use uniformly reduced numerical integration, zero energy deformation modes may develop. These modes are controlled numerically by either an artificial stiffness or viscosity which resists the formation of these undesirable modes. The hourglass control can optionally be user specified using the input in the *HOURGLASS section.

During the keyword input phase where data is read, only limited checking is performed on the data since the data must first be counted for the array allocations and then reordered. Considerably more checking is done during the second phase where the input data is printed out. Since LS-DYNA has retained the option of reading older non-keyword input files, we print out the data into the output file d3hsp (default name) as in previous versions of LS-DYNA. An attempt is made to complete the input phase before error terminating if errors are encountered in the input. Unfortunately, this is not always possible and the code may terminate with an error message. The user should always check either output file, d3hsp or messag, for the word "Error".

The input data following each keyword can be input in free format. In the case of free format input the data is separated by commas, i.e.,

```
*NODE
10101,x ,y ,z
10201,x ,y ,z

*ELEMENT_SHELL
10201,pid,n1,n2,n3,n4
10301,pid,n1,n2,n3,n4
```

When using commas, the formats *must not* be violated. An I8 integer is limited to a maximum positive value of 99999999, and larger numbers having more than eight characters are unacceptable. The format of the input can change from free to fixed anywhere in the input file. The input is case insensitive and keywords can be given in either upper or lower case. *The asterisks "*" preceding each keyword must be in column one.*

To provide a better understanding behind the keyword philosophy and how the options work, a brief review of the keywords is given below.

*AIRBAG

The geometric definition of airbags and the thermodynamic properties for the airbag inflator models can be made in this section. This capability is not necessarily limited to the modeling of automotive airbags, but it can also be used for many other applications, such as tires and pneumatic dampers.

*ALE

This keyword provides a way of defining input data pertaining to the Arbitrary-Lagrangian-Eulerian capability.

*BOUNDARY

This section applies to various methods of specifying either fixed or prescribed boundary conditions. For compatibility with older versions of LS-DYNA it is still possible to specify some nodal boundary conditions in the *NODE card section.

*CASE

This keyword option provides a way of running multiple load cases sequentially. Within each case, the input parameters, which include loads, boundary conditions, control cards, contact definitions, initial conditions, etc., can change. If desired, the results from a previous case can be used during initialization. Each case creates unique file names for all output results files by appending CID*n* to the default file name.

*COMPONENT

This section contains analytical rigid body dummies that can be placed within vehicle and integrated implicitly.

*CONSTRAINED

This section applies constraints within the structure between structural parts. For example, nodal rigid bodies, rivets, spot welds, linear constraints, tying a shell edge to a shell edge with failure, merging rigid bodies, adding extra nodes to rigid bodies and defining rigid body joints are all options in this section.

*CONTACT

There are numerous options in the *CONTACT section for treating interaction between disjoint parts.

*CONTROL

Options available in the *CONTROL section allow the resetting of default global parameters, such as the hourglass type, the contact penalty scale factor, shell element formulation, numerical damping, and termination time.

*DAMPING

Defines damping either globally or by part identifier.

*DATABASE

This keyword with a combination of options can be used for controlling the output of ASCII databases and binary files output by LS-DYNA. With this keyword the frequency of writing the various databases can be determined.

*DEFINE

This section allows the user to define curves for loading, constitutive behaviors, etc.; boxes to limit the geometric extent of certain inputs; local coordinate systems; vectors; and orientation vectors specific to spring and damper elements. Items defined in this section are referenced by their identifiers throughout the input. For example, a coordinate system identifier is sometimes used on the *BOUNDARY cards, and load curves are used on the *AIRBAG cards.

*DEFORMABLE_TO_RIGID

This section allows the user to switch parts that are defined as deformable to rigid at the start of the analysis. This capability provides a cost efficient method for simulating events, such as rollover events. While the vehicle is rotating the computation cost can be reduced significantly by switching deformable parts that are not expected to deform to rigid parts. Just before the vehicle comes in contact with ground, the analysis can be stopped and restarted with the part switched back to deformable.

*ELEMENT

Define identifiers and connectivities for all elements which include shells, beams, solids, thick shells, springs, dampers, seat belts, and concentrated masses in LS-DYNA.

*EOS

This section reads the equations of state parameters. The equation of state identifier, EOSID, points to the equation of state identifier on the *PART card.

*HOURGLASS

Defines hourglass and bulk viscosity properties. The identifier, HGID, on the *HOURGLASS card refers to HGID on *PART card.

*INCLUDE

To make the input file easy to maintain, this keyword allows the input file to be split into sub-files. Each sub-file can again be split into sub-sub-files and so on. This option is beneficial when the input data deck is very large.

*INITIAL

Initial velocity and initial momentum for the structure can be specified in this section. The initial velocity specification can be made by *INITIAL_VELOCITY_NODE card or *INITIAL_VELOCITY cards. In the case of *INITIAL_VELOCITY_NODE nodal identifiers are used to specify the velocity components for the node. Since all the nodes in the system are initialized to zero, only the nodes with non-zero velocities need to be specified. The *INITIAL_VELOCITY card provides the capability of being able to specify velocities using the set concept or boxes.

*INTEGRATION

In this section the user defined integration rules for beam and shell elements are specified. IRID refers to integration rule number IRID on *SECTION_BEAM and *SECTION_SHELL cards, respectively. Quadrature rules in the *SECTION_SHELL and *SECTION_BEAM cards need to be specified as a negative number. The absolute value of the negative number refers to user defined integration rule number. Positive rule numbers refer to the built in quadrature rules within LS-DYNA.

*INTERFACE

Interface definitions are used to define surfaces, nodal lines, and nodal points for which the displacement and velocity time histories are saved at some user specified frequency. This data may then be used in subsequent analyses as an interface ID in the *INTERFACE_LINKING_DISCRETE_NODE as constraining nodes, in *INTERFACE_LINKING_SEGMENT as constraining segments, and in *INTERFACE_LINKING_EDGE as the constraining edge for a series of nodes.

This capability is especially useful for studying the detailed response of a small member in a large structure. For the first analysis, the member of interest need only be discretized sufficiently that the displacements and velocities on its boundaries are reasonably accurate. After the first analysis is completed, the member can be finely discretized in the region bounded by the interfaces. Finally, the second analysis is performed to obtain highly detailed information in the local region of interest.

When beginning the first analysis, specify a name for the interface segment file using the Z=parameter on the LS-DYNA execution line. When starting the second analysis, the name of the interface segment file created in the first run should be specified using the

L=parameter on the LS-DYNA command line. Following the above procedure, multiple levels of sub-modeling are easily accommodated. The interface file may contain a multitude of interface definitions so that a single run of a full model can provide enough interface data for many component analyses. The interface feature represents a powerful extension of LS-DYNA's analysis capabilities. A similar capability using *INTERFACE_SSI may be used for soil-structure interaction analysis under earthquake excitation.

*KEYWORD

Flags LS-DYNA that the input deck is a keyword deck. To have an effect this must be the very first card in the input deck. Alternatively, by typing "keyword" on the execution line, keyword input formats are assumed and the "*KEYWORD" is not required. If a number is specified on this card after the word KEYWORD, it defines the memory size to be used in words. The memory size can also be set on the command line.

> **NOTE:** The memory specified on the execution line overrides memory specified on the *KEYWORD card.

*LOAD

This section provides various methods of loading the structure with concentrated point loads, distributed pressures, body force loads, and a variety of thermal loadings.

*MAT

This section allows the definition of constitutive constants for all material models available in LS-DYNA including springs, dampers, and seat belts. The material identifier, MID, points to the MID on the *PART card.

*NODE

Define nodal point identifiers and their coordinates.

*PARAMETER

This option provides a way of specifying numerical values of parameter names that are referenced throughout the input file. The parameter definitions, if used, should be placed at the beginning of the input file following *KEYWORD. *PARAMETER_EXPRESSION permits general algebraic expressions to be used to set the values.

*PART

This keyword serves two purposes:

1. Relates part ID to *SECTION, *MATERIAL, *EOS and *HOURGLASS sections.

2. Optionally, in the case of a rigid material, rigid body inertia properties and initial conditions can be specified. Deformable material repositioning data can also be specified in this section if the reposition option is invoked on the *PART card, that is, *PART_REPOSITION.

*PERTURBATION

This keyword provides a way of defining deviations from the designed structure, such as buckling imperfections.

*RAIL

This keyword provides a way of defining a wheel-rail contact algorithm intended for railway applications but can also be used for other purposes. The wheel nodes (defined on *RAIL_TRAIN) represent the contact patch between wheel and rail.

*RIGIDWALL

Rigid wall definitions have been divided into two separate sections, PLANAR and GEOMETRIC. Planar walls can be either stationary or moving in translational motion with mass and initial velocity. The planar wall can be either finite or infinite. Geometric walls can be planar as well as have the geometric shapes, such as rectangular prism, cylindrical prism and sphere. By default, these walls are stationary unless the option MOTION is invoked for either prescribed translational velocity or displacement. Unlike the planar walls, the motion of the geometric wall is governed by a load curve. Multiple geometric walls can be defined to model combinations of geometric shapes available. For example, a wall defined with the CYLINDER option can be combined with two walls defined with the SPHERICAL option to model hemispherical surface caps on the two ends of a cylinder. Contact entities are also analytical surfaces but have the significant advantage that the motion can be influenced by the contact to other bodies, or prescribed with six full degrees-of-freedom.

*SECTION

In this section, the element formulation, integration rule, nodal thicknesses, and cross sectional properties are defined. All section identifiers (SECID's) defined in this section must be unique; that is, if a number is used as a section ID for a beam element, then this number cannot be used again as a section ID for a solid element.

*SENSOR

This keyword provides a convenient way of activating and deactivating boundary conditions, airbags, discrete elements, joints, contact, rigid walls, single point constraints, and constrained nodes. The sensor capability is new in the second release of version 971 and will evolve in later releases to encompass many more LS-DYNA capabilities and replace some of the existing capabilities, such as the airbag sensor logic.

*SET

A concept of grouping nodes, elements, materials, etc., in sets is employed throughout the LS-DYNA input deck. Sets of data entities can be used for output. So-called surfa nodes used in contact definitions, surfa segment sets, surfb segment sets, pressure segment sets, and so on can also be defined. The keyword, *SET, can be defined in two ways:

1. Option LIST requires a list of entities in which eight entities are defined per card and as many cards as needed are used to define all the entities.

2. Option COLUMN, where applicable, requires an input of one entity per line along with up to four attribute values which are used by other keywords to specify, for example, the failure criterion input that is needed for *CONTACT_CONSTRAINT_NODES_TO_SURFACE.

*TERMINATION

This keyword provides an alternative way of stopping the calculation before the termination time is reached. The termination time is specified on the *CONTROL_TERMINATION input and will terminate the calculation whether or not the options available in this section are active.

*TITLE

In this section a title for the analysis is defined.

*USER_INTERFACE

This section provides a method to provide user control of some aspects of the contact algorithms including friction coefficients via user defined subroutines.

RESTART

This section of the input is intended to allow the user to restart the simulation by providing a restart file and optionally a restart input defining changes to the model, such as

deleting contacts, materials, elements, switching materials from rigid to deformable, and deformable to rigid.

*RIGID_DEFORMABLE

This section switches rigid parts back to deformable in a restart to continue the event of a part impacting the ground which may have been modeled with a rigid wall.

*STRESS_INITIALIZATION

This is an option available for restart runs. In some cases there may be a need for the user to add contacts, elements, etc., which are not available options for standard restart runs. A full input containing the additions is needed if this option is invoked upon restart.

SUMMARY OF COMMONLY USED OPTIONS

The following table gives a list of the commonly used keywords related by topic.

Topic	Component	Keywords
Geometry	Nodes	*NODE
	Elements	*ELEMENT_BEAM *ELEMENT_SHELL *ELEMENT_SOLID *ELEMENT_TSHELL
	Discrete Elements	*ELEMENT_DISCRETE *ELEMENT_SEATBELT *ELEMENT_MASS

Topic	Component	Keywords
Materials	Part	PART cards glues the model together: *PART → { *MAT, *SECTION, *EOS, *HOURGLASS }
	Material	*MAT
	Sections	*SECTION_BEAM *SECTION_SHELL *SECTION_SOLID *SECTION_TSHELL
	Discrete sections	*SECTION_DISCRETE *SECTION_SEATBELT
	Equation of state	*EOS
	Hourglass	*CONTROL_HOURGLASS *HOURGLASS
Contacts & Rigid walls	Defaults for contacts	*CONTROL_CONTACT
	Definition of contacts	*CONTACT_*OPTION*
	Definition of rigid walls	*RIGIDWALL_*OPTION*
Boundary Conditions & Loadings	Restraints	*NODE *BOUNDARY_SPC_*OPTION*
	Gravity (body) load	*LOAD_BODY_*OPTION*
	Point load	*LOAD_NODE_*OPTION*
	Pressure load	*LOAD_SEGMENT_*OPTION* *LOAD_SHELL_*OPTION*
	Thermal load	*LOAD_THERMAL_*OPTION*
	Load curves	*DEFINE_CURVE
Constraints and spot welds	Constrained nodes	*CONSTRAINED_NODE_SET
	Welds	*CONSTRAINED_GENERALIZED_WELD *CONSTRAINED_SPOT_WELD
	Rivet	*CONSTRAINED_RIVET

Topic	Component	Keywords
Output Control	Items in time history blocks	*DATABASE_HISTORY_*OPTION*
	Default	*CONTROL_OUTPUT
	ASCII time history files	*DATABASE_OPTION
	Binary plot/time history/restart files	*DATABASE_BINARY_OPTION
	Nodal reaction output	*DATABASE_NODAL_FORCE_GROUP
Termination	Termination time	*CONTROL_TERMINATION
	Termination cycle	*CONTROL_TERMINATION
	CPU termination	*CONTROL_CPU
	Degree of freedom	*TERMINATION_NODE

Table 2.1. Keywords for the most commonly used options.

EXECUTION SYNTAX

The execution line for LS-DYNA, sometimes referred to as the command line, is as follows:

LS-DYNA I=**inf** O=**otf** G=**ptf** D3PART=**d3part** D=**dpf** F=**thf** T=**tpf** A=**rrd** M=**sif** S=**iff** H=**iff** Z=**isf1** L=**isf2** B=**rlf** W=**root** E=**efl** X=**scl** C=**cpu** K=**kil** V=**vda** Y=**c3d** BEM=**bof** {**KEYWORD**} {**THERMAL**} {**COUPLE**} {**CASE**} {**PGPKEY**} {**FLUIDS**} MEMORY=**nwds** MODULE=**dll** NCPU=**ncpu** PARA=**para** ENDTIME=**time** NCYCLE=**ncycle** JOBID=**jobid** D3PROP=**d3prop** GMINP=**gminp** GMOUT=**gmout** MCHECK=**y** MAP=**map** MAP1=**map1** LAGMAP=**lagmap** LAGMAP1=**lagmap1**

where,

inf = input file (user specified)

otf = high speed printer file (default = d3hsp)

ptf = binary plot file for postprocessing (default = d3plot)

d3part = binary plot file for subset of parts; see *DATABASE_BINARY_D3PART (default = d3part)

dpf = dump file to write for purposes of restarting (default = d3dump). This file is written at the end of every run and during the run as requested by *DATABASE_BINARY_D3DUMP. To stop the generation of this dump file,

specify "d=nodump" (case insensitive). Sense switch "sw1" will trigger writing of a dump file and overrides "d=nodump".

thf = binary plot file for time histories of selected data (default = d3thdt)

tpf = optional temperature file

rrd = running restart dump file (default = runrsf)

sif = stress initialization file (user specified)

iff = interface force file (user specified). See *DATBASE_BINARY_INTFOR and *DATABASE_BINARY_FSIFOR.

isf1 = interface segment save file to be created (default = infmak)

isf2 = existing interface segment save file to be used (user specified)

rlf = binary plot file for dynamic relaxation (default = d3drlf)

efl = echo file containing optional input echo with or without node/element data

root = root file name for general print option

scl = scale factor for binary file sizes (default =70)

cpu = cumulative cpu time limit in seconds for the entire simulation, including all restarts, if cpu is positive. If cpu is negative, the absolute value of cpu is the cpu time limit in seconds for the first run and for each subsequent restart run.

kill = if LS-DYNA encounters this file name it will terminate with a restart file (default = d3kil)

vda = VDA/IGES database for geometrical surfaces

c3d = CAL3D input file

bof = *FREQUENCY_DOMAIN_ACOUSTIC_BEM output file

nwds = Number of words to be allocated. A word is 4 bytes in single precision and 8 bytes in double precision. This number overwrites the memory size specified on the *KEYWORD card at the beginning of the input deck. This option is necessary if the default memory allocation is insufficient, in which case LS-DYNA will write an error message stating such.

dll = The dynamic library for user subroutines. Only one dynamic library can be loaded via "module=dll". See *MODULE_LOAD command for loading multiple dynamic libraries.

ncpu = Overrides NCPU and CONST defined in *CONTROL_PARALLEL. A positive value sets CONST = 2 and a negative values sets CONST = 1. See the *CONTROL_PARALLEL command for an explanation of these parameters. The *KEYWORD command provides an alternative way to set the number of CPUs.

para = Overrides PARA defined in *CONTROL_PARALLEL.

time = Overrides ENDTIM defined in *CONTROL_TERMINATION.

ncycle = Overrides ENDCYC defined in *CONTROL_TERMINATION.

jobid = Character string which acts as a prefix for all output files. Maximum length is 72 characters. Do not include the following characters:) (* / ? \.

d3prop = See *DATABASE_BINARY_D3PROP input parameter IFILE for options.

gminp = Input file for reading recorded motions in *INTERFACE_SSI (default = gmbin).

gmout = Output file for writing recorded motions in *INTERFACE_SSI_AUX (default = gmbin).

map = Output/Input file for writing/reading data in ALE mappings controlled by *INITIAL_ALE_MAPPING or *BOUNDARY_ALE_MAPPING.

map1 = Output file for writing data in ALE mappings controlled by *INITIAL_ALE_MAPPING or *BOUNDARY_ALE_MAPPING if MAP= is used to read data from a different file.

lagmap = Output/Input file for writing/reading data in Lagrangian mappings controlled by *INITIAL_LAG_MAPPING.

lagmap1 = Output file for writing data in Lagrangian mappings controlled by *INITIAL_LAG_MAPPING if LAGMAP= is used to read data from a different file.

These command line options can be in any order.

To avoid undesirable or confusing results, each LS-DYNA run should be performed in a separate directory, unless using the command line parameter "jobid" described above. If rerunning a job in the same directory, old files should first be removed or renamed to avoid confusion since the possibility exists that the binary database may contain results from both the old and new run.

By including "keyword" anywhere on the execute line or instead if *KEYWORD is the first card in the input file, the keyword formats are expected; otherwise, the older structured input file will be expected.

To run a coupled thermal analysis the command "couple" must be in the execute line. A thermal only analysis may be run by including the word "thermal" in the execution line.

The execution line option "pgpkey" will output the current public PGP key used by LS-DYNA for encryption of input. The public key and some instructions on how to use the key are written to the screen as well as a file named "lstc_pgpkey.asc".

Setting "ncycle=1" on the execution line causes the calculation to run just one cycle followed by termination with restart files. No editing of the input deck is required. The calculation can then be restarted with or without any additional input.

If the word "case" appears on the command line, then *CASE statements will be handled by the built in driver routines. Otherwise they should be processed by the external "lscasedriver" program, and if any *CASE statements are encountered, it will cause an error.

If "mcheck=y" is given on the command line, the program switches to "model check" mode. In this mode the program will run only 10 cycles – just enough to verify that the model will start. For implicit problems, all initialization is performed, but execution halts before the first cycle. If the network license is being used, the program will attempt to check out a license under the program name "LS-DYNAMC" so as not to use up one of the normal DYNA licenses. If this fails, a normal execution license will be used.

SENSE SWITCH CONTROLS

The status of an in-progress LS-DYNA simulation can be determined by using the sense switch. On UNIX versions, this is accomplished by first typing a "^C" (Control-C). This sends an interrupt to LS-DYNA which is trapped and the user is prompted to input the sense switch code. LS-DYNA has a number of terminal sense switch controls that are tabulated below:

Type	Response
SW1	A restart (dump) file is written, and LS-DYNA terminates.
SW2	LS-DYNA responds with time and cycle numbers.
SW3	A restart file is written, and LS-DYNA continues.
SW4	A plot state is written, and LS-DYNA continues.
SWA	Flush ASCII file buffers.
SWB	A dynain file is written and LS-DYNA continues. For SWB, SWC and SWD (see below), *INTERFACE_SPRINGBACK_LSDYNA must be defined in the input deck. The file name is dynain.# where # is incremented by 1 each time SWB, SWC, or SWD is issued.
SWC	A restart file and a dynain file are written, and LS-DYNA continues.
SWD	A restart file and a dynain file are written, and LS-DYNA terminates.

Type	Response
SWE	Terminate explicit dynamic relaxation and proceed with the transient analysis.
conv	Temporarily override nonlinear convergence tolerances.
endtime=*t*	Change the termination time to *t* (*t* is a real number).
iter	Enable/Disable output of binary plot database "d3iter" showing mesh after each equilibrium iteration. Useful for debugging convergence problems.
lprint	Enable/Disable printing of equation solver memory, cpu requirements.
nlprint	Enable/Disable printing of nonlinear equilibrium iteration information.
prof	Output current timing information to messag (SMP) or prof.out (MPP).
stop	Halt execution immediately, closing open files.

On UNIX/LINUX and Windows systems the sense switches can still be used if the job is running in the background or in batch mode. To interrupt LS-DYNA simply create a file called d3kil containing the desired sense switch, for example, "sw1". LS-DYNA periodically looks for this file and if found, the sense switch contained therein is invoked and the d3kil file is deleted. A null d3kil file is equivalent to a "sw1".

When LS-DYNA terminates, all scratch files are destroyed: the restart file, plot files, and high-speed printer files remain on disk. Of these, only the restart file is needed to continue the interrupted analysis.

PROCEDURE FOR LS-DYNA/MPP

As described above the serial/SMP code supports the use of the SIGINT signal (usually Ctrl-C) to interrupt the execution and prompt the user for a "sense switch." The MPP code also supports this capability. However, on many systems a shell script or front end program (generally "mpirun") is required to start MPI applications. Pressing Ctrl-C on some systems will kill this process, and thus kill the running MPP-DYNA executable. On UNIX/LINUX systems, as workaround, when the MPP code begins execution it creates a file named, “bg_switch”, in the current working directory. This file contains the following single line:

rsh **<machine name>** kill -INT **<PID>**

where < machine name > is the hostname of the machine on which the root MPP-DYNA process is running, and <PID> is its process id. (on HP systems, "rsh" is replaced by "remsh"). Thus, simply executing this file will send the appropriate signal. For Windows, usually the d3kil file is used to interrupt the execution.

For more information about running the LS-DYNA/MPP Version see Appendix O.

Files: Input and Output

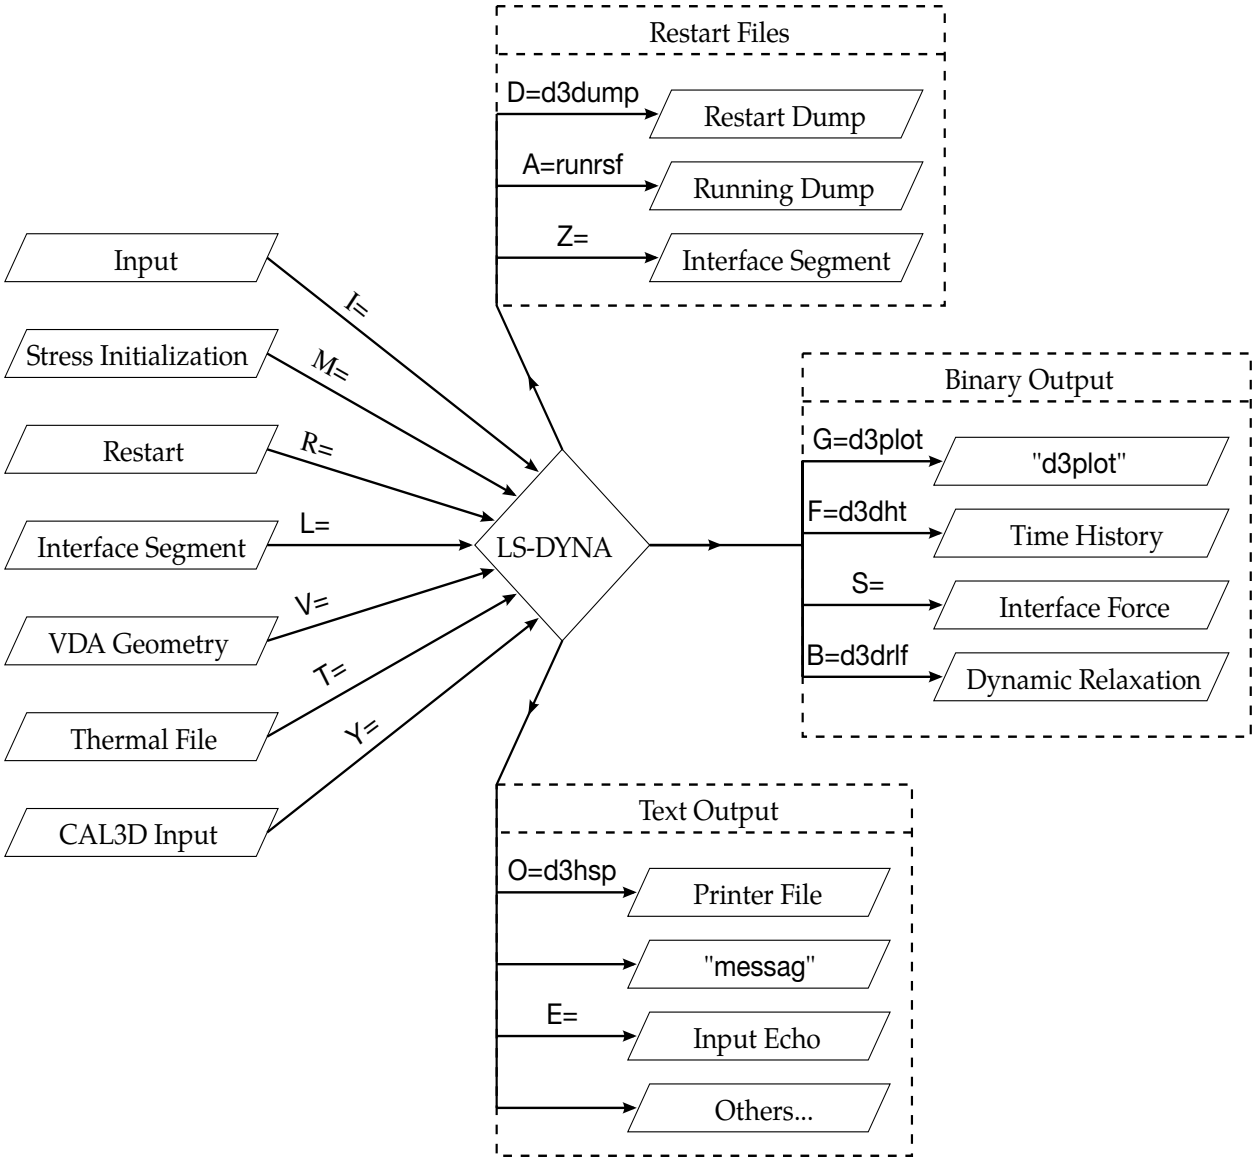

Figure 2-2. Files Input and Output.

FILES

1. **Uniqueness.** File names must be unique.

2. **Interface forces.** The interface force file is created only if it is specified on the execution line "S=**iff**".

3. **File size limits.** For very large models, the default size limits for binary output files may not be large enough for a single file to hold even a single plot state, in

which case the file size limit may be increased by specifying "X=**scl**" on the execution line. The default file size limit (X=70) is 70 times one-million octal words or 18.35 Mwords. That translates into 73.4 Mbytes (for 32-bit output) or 146.8 Mbytes (for 64-bit output).

4. **CPU limits.** Using "C=**cpu**" defines the maximum CPU usage allowed. When the CPU usage limit is exceeded, LS-DYNA will terminate with a restart file. During a restart, **cpu** should be set to the total CPU used up to the current restart plus whatever amount of additional time is wanted.

5. **File usage in restart.** When restarting from a dump file, the execution line (except of a full deck restart in MPP) becomes

   LS-DYNA I=**inf** O=**otf** G=**ptf** D=**dpf** R=**rtf** F=**thf** T=**tpf** A=**rrd** S=**iff** Z=**isf1** L=**isf2** B=**rlf** W=**root** E=**efl** X=**scl** C=**cpu** K=**kill** {KEYWORD}

   where

   rtf=[name of dump file written by LS-DYNA]

   The root names of the dump files written by LS-DYNA = are controlled by dpf (default = d3dump) and rrd (default = runrsf). A two-digit number follows the root name, for example, d3dump01, d3dump02, etc., to distinguish one dump file from another. Typically, each dump file corresponds to a different simulation time.

   The adaptive dump files contain all information required to successfully restart so that no other files are needed except when CAD surface data is used. When restarting a problem that uses VDA/IGES surface data, the vda input file must be specified, e.g.:

   LS-DYNA R=**d3dump01** V=**vda**

   No stress initialization is possible at restart. Also the VDA files and the CAL3D files must not be changed.

6. **Default file names.** File name dropouts are permitted; for example, the following execution lines are acceptable:

   LS-DYNA I=**inf**

   and

   LS-DYNA R=**rtf**

7. **Interface segments.** For an analysis using interface segments, the execution line in the first analysis is given by:

LS-DYNA I=**inf** Z=**isf1**

and in the second by:

LS-DYNA I=**inf** L=**isf1**

8. **Batch execution.** In some installations (e.g., GM) calculations are controlled by a file called "names" on unit 88. The names files consists of two lines in which the second line is blank. The first line of names contains the execution line, for instance:

I=**inf**

For a restart the execution line becomes:

I=**inf** R=**rtf**

RESTART ANALYSIS

The LS-DYNA restart capability allows analyses to be broken down into stages. After the completion of each stage in the calculation, a "restart dump" is written that contains all information necessary to continue the analysis. The size of this "dump" file is roughly the same size as the memory required for the calculation. Results can be checked at each stage by post-processing the output databases in the normal way, so the chance of wasting computer time on incorrect analyses is reduced.

The restart capability is frequently used to modify models by deleting excessively distorted elements, materials that are no longer important, and contact surfaces that are no longer needed. Output frequencies of the various databases can also be altered. Often, these simple modifications permit a calculation that might otherwise not continue on to a successful completion. Restarting can also help diagnose why a model is giving problems. By restarting from a dump that is written before the occurrence of a numerical problem and obtaining output at more frequent intervals, it is often possible to identify where the first symptoms appear and what aspect of the model is causing them.

The format of the restart input file is described in this manual. If, for example, the user wishes to restart the analysis from dump state *nn*, contained in file D3DUMP*nn*, then the following procedure is followed:

1. Create the restart input deck, if required, as described in the Restart Section of this manual. Call this file restartinput.

2. Start dyna from the command line by invoking:

LS-DYNA I=**restartinput** R=**D3DUMP*nn***

3. If no alterations to the model are made, then the execution line:

LS-DYNA R=**D3DUMP*nn***

will suffice. Of course, the other output files should be assigned names from the command line if the defaults have been changed in the original run.

The full deck restart option allows the user to begin a new analysis, with deformed shapes and stresses carried forward from a previous analysis for selected materials. The new analysis can be different from the original, such as more contact surfaces and different geometry (of parts which are not carried forward). Examples of applications include:

- Crash analysis continued with extra contact surfaces.
- Sheet metal forming continued with different tools for modeling a multi-stage forming process.

The following procedure is followed for full-deck restart:

1. Create the restart input deck using *STRESS_INITIALIZATION, as described in the Restart Section of this manual. Call this file restartinput.

2. For SMP, start dyna from the command line by invoking:

LS-DYNA I=**restartinput** R=**D3DUMP*nn***

3. For MPP, start dyna from the command line by invoking:

LS-DYNA I=**restartinput** N=**D3FULL*nn***

A typical restart file scenario:

LS-DYNA is run using an input file named "job1.inf", and a restart dump named "d3dump01" is created. A new input file, "job2.inf", is generated and submitted as a restart with, "R=d3dump01", as the dump file. The input file job2.inf contains the entire model in its original *undeformed* state but with more contact surfaces, new output databases, and so on.

Since this is a restart job, information must be given to tell LS-DYNA which parts of the model should be initialized in the full deck restart. When the calculation begins, the restart database contained in the file d3dump01 is read, and a new database is created to initialize the model in the input file, job2.inf. The data in file job2.inf is read, and then LS-DYNA proceeds through the entire input deck and initialization. At the end of the initialization process, all the parts selected are initialized from the data saved from d3dump01. This means that the deformed position and velocities of the nodes on the elements of each part, and the stresses and strains in the elements (and, if the material of the part is rigid, the rigid body properties) will be assigned.

It is assumed during this process that any initialized part has the same elements, in the same order, with the same topology, in job1 and job2. If this is not the case, the parts cannot be initialized. However, the parts may have different identifying numbers.

For discrete elements and seat belts, the choice is all or nothing. All discrete and belt elements, retractors, slip rings, pretensioners, and sensors must exist in both files and will be initialized.

Materials which are not initialized will have no initial deformations or stresses. However, if initialized and non-initialized materials have nodes in common, the nodes will be moved by the initialized material causing a sudden strain in the non-initialized material. *This effect can give rise to sudden spikes in loading.*

Points to note are:

- Time and output intervals are continuous with job1; that is, the time is not reset to zero.
- Don't try to use the restart part of the input to change anything since this will be overwritten by the new input file.
- Usually, the complete input file part of job2.inf will be copied from job1.inf, with the required alterations. We again mention that there is no need to update the nodal coordinates since the deformed shapes of the initialized materials will be carried forward from job1.
- Completely new databases will be generated with the time offset.

VDA/IGES DATABASES

VDA surfaces are surfaces of geometric entities which are given in the form of polynomials. The format of these surfaces is as defined by the German automobile and supplier industry in the VDA guidelines, [VDA 1987].

The advantage of using VDA surfaces is twofold. First, the problem of meshing the surface of the geometric entities is avoided and, second, smooth surfaces can be achieved which are very important in metal forming. With smooth surfaces, artificial friction introduced by standard faceted meshes with corners and edges can be avoided. This is a big advantage in springback calculations.

A very simple and general handling of VDA surfaces is possible allowing arbitrary motion and generation of surfaces. For a detailed description, see Appendix L.

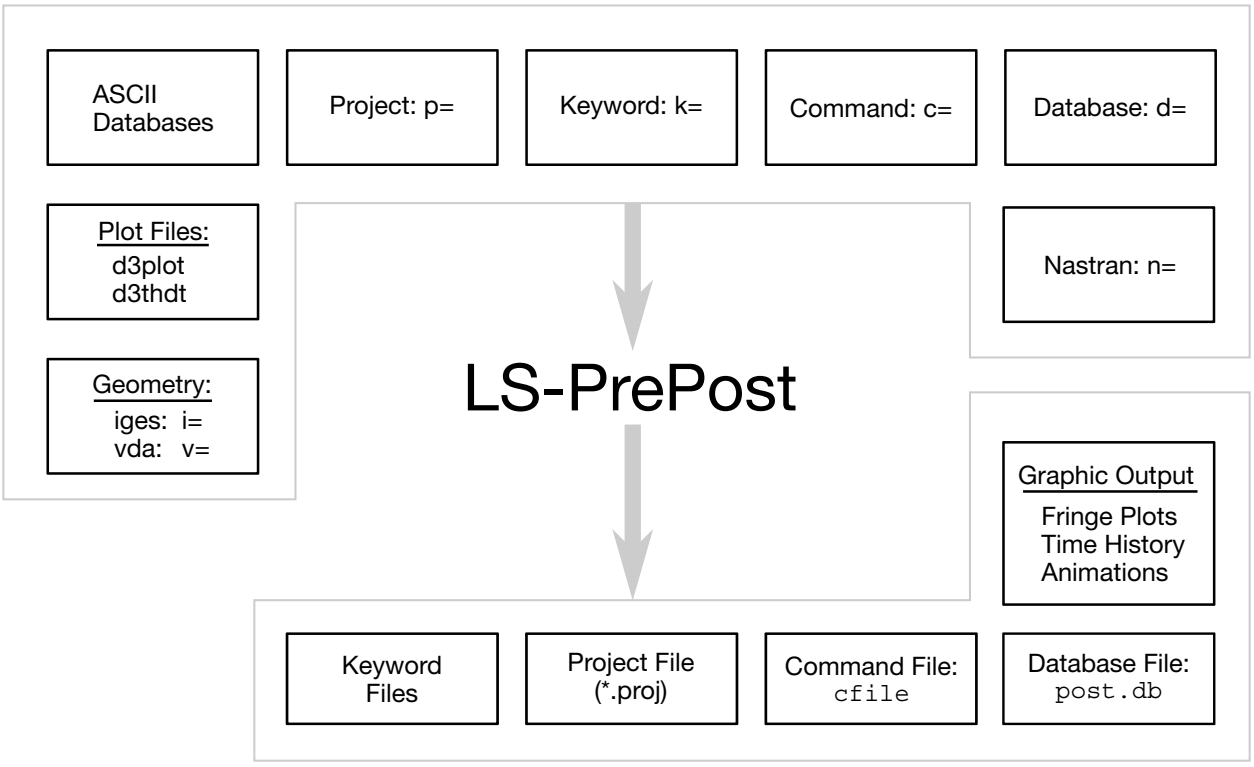

Figure 2-3. File Organization

LS-PrePost®

LS-DYNA is designed to operate with a variety of commercial pre- and post-processing packages. Currently, direct support is available from TRUEGRID, PATRAN, eta/VPG, HYPERMESH, EASi-CRASH DYNA and FEMAP. Several third-party translation programs are available for PATRAN and IDEAS.

Alternately, the pre- and post-processor LS-PrePost is available from Ansys and is specialized for LS-DYNA. LS-PrePost is an advanced pre- and post-processor that is delivered free with LS-DYNA. The user interface is designed to be both efficient and intuitive. LS-PrePost runs on Windows, Linux, and Unix, utilizing OpenGL graphics to achieve fast model rendering and XY plotting.

Some of the capabilities available in LS-PrePost are:

- Complete support for all LS-DYNA keyword data.
- Importing and combining multiple models from many sources (LS-DYNA keyword, IDEAS neutral file, NASTRAN bulk data, STL ASCII, and STL binary formats).
- Improved renumbering of model entities.
- Model Manipulation: Translate, Rotate, Scale, Project, Offset, Reflect

- LS-DYNA Entity Creation: Coordinate Systems, Sets, Parts, Masses, CNRBs, Boxes, Spot welds, SPCs, Rigidwalls, Rivets, Initial Velocity, Accelerometers, Cross Sections, etc.
- Mesh Generation: 2Dmesh Sketchboard, nLine Meshing, Line sweep into shell, Shell sweep into solid, Tet-Meshing, Automatic surface meshing of IGES and VDA data, Meshing of simple geometric objects (Plate, Sphere, Cylinder)
- Special Applications: Airbag folding, Dummy positioning, Seatbelt fitting, Initial penetration check, Spot weld generation using MAT_100
- Complete support of LS-DYNA results data file: d3plot file, d3thdt file, All ASCII time history data file, Interface force file

LS-PrePost processes output from LS-DYNA. LS-PrePost reads the binary plot-files generated by LS-DYNA and plots contours, fringes, time histories, and deformed shapes. Color contours and fringes of a large number of quantities may be interactively plotted on meshes consisting of plate, shell, and solid type elements. LS-PrePost can compute a variety of strain measures and reaction forces along constrained boundaries.

LS-DYNA generates three binary databases. One contains information for complete states at infrequent intervals; 50 to 100 states of this sort is typical in a LS-DYNA calculation. The second contains information for a subset of nodes and elements at frequent intervals; 1000 to 10,000 states is typical. The third contains interface data for contact surfaces.

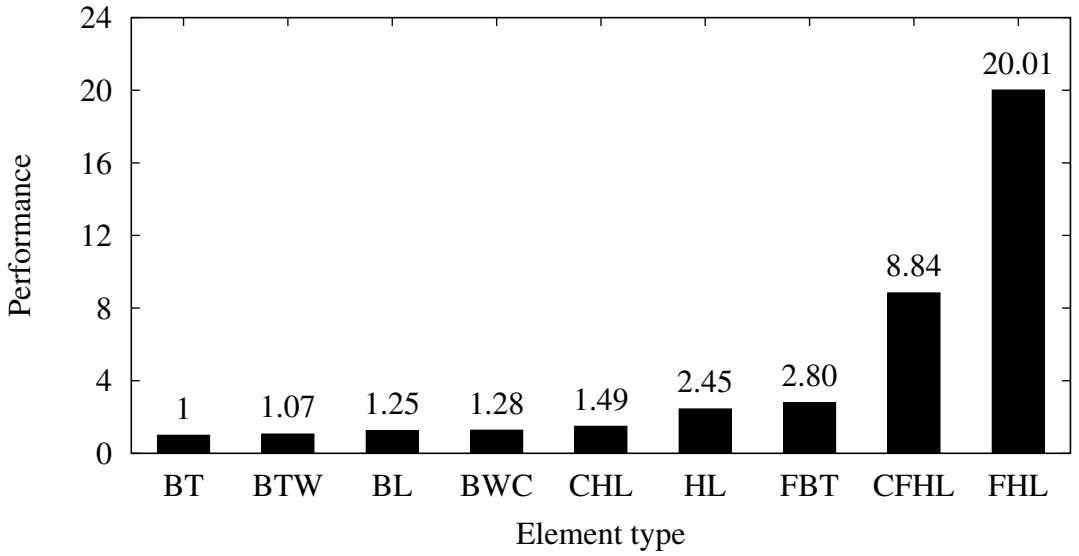

Figure 2-4. Relative cost of the four noded shells available in LS-DYNA where BT is the Belytschko-Tsay shell, BTW is the Belytschko-Tsay shell with the warping stiffness taken from the Belytschko-Wong-Chiang, BWC, shell. The BL shell is the Belytschko-Leviathan shell. CHL denotes the Hughes-Liu shell, HL, with one point quadrature and a co-rotational formulation. FBT is a Belytschko-Tsay like shell with full integration, FHL is the fully integrated Hughes-Liu shell, and the CFHL shell is its co-rotational version.

EXECUTION SPEEDS

The relative execution speeds for various elements in LS-DYNA are tabulated below:

Element Type	Relative Cost
8 node solid with 1 point integration and default hourglass control	4
as above but with Flanagan-Belytschko hourglass control	5
constant stress and Flanagan-Belytschko hourglass control, i.e., the Flanagan-Belytschko element	7
4 node Belytschko-Tsay shell with four thickness integration points	4
4 node Belytschko-Tsay shell with resultant plasticity	3

Element Type	Relative Cost
BCIZ triangular shell with four thickness integration points	7
C^0 triangular shell with four thickness integration points	4
2 node Hughes-Liu beam with four integration points	9
2 node Belytschko-Schwer beam	2
2 node simple truss elements	1
8 node solid-shell with four thickness integration points	11

These relative timings are very approximate. Each interface node of the sliding interfaces is roughly equivalent to one-half zone cycle in cost. Figure 2-4. illustrates the relative cost of the various shell formulations in LS-DYNA.

UNITS

The units in LS-DYNA must be consistent. One way of testing whether a set of units is consistent is to check that:

$$[\text{force unit}] = [\text{mass unit}] \times [\text{acceleration unit}]$$

and that

$$[\text{acceleration unit}] = \frac{[\text{length unit}]}{[\text{time unit}]^2}.$$

Examples of sets of consistent units are tabulated below. For a more comprehensive table, see http://ftp.lstc.com/anonymous/outgoing/support/FAQ/consistent_units .

	(a)	(b)	(c)
Length unit	meter	millimeter	millimeter
Time unit	second	second	millisecond
Mass unit	kilogram	tonne	kilogram
Force unit	Newton	Newton	kiloNewton
Young's Modulus of Steel	210.0E+09	210.0E+03	210.0
Density of Steel	7.85E+03	7.85E–09	7.85E–06
Yield stress of Mild Steel	200.0E+06	200.0	0.200
Acceleration due to gravity	9.81	9.81E+03	9.81E-03
Velocity equivalent to 30 mph	13.4	13.4E+03	13.4

GENERAL CARD FORMAT

The following sections specify, for each keyword command, the cards that must be defined and those cards that are optional. Each card is described in its fixed format form and is shown as a number of fields in an 80 character string. With the exception of "long format input" as described later in this section, most input cards consist of 8 fields with a field length of 10 characters. A sample card is shown below. The card format is clearly stated if the format is different than 8 fields of 10 characters. See also notes on a special "I10 format" at the end of this section.

As an alternative to fixed format, a card may be in free format with the values of the variables separated by commas. When using comma-delimited values on a card, the number of characters used to specify a value must not exceed the field length for fixed format. For example, an I8 number is limited to a value of 99999999 and a larger number with more than 8 characters is unacceptable. A further restriction is that characters beyond column 80 of each line are ignored by the code. Fixed format and free, comma-delimited format can be mixed throughout the deck and even within different cards of a single command but not within a card.

The limits on number of characters per variable and number of characters per line as stated above are raised in the case of long format input. See the description of long format input below.

Example Card.

Card [N]	1	2	3	4	5	6	7	8
Variable	NSID	PSID	A1	A2	A3	KAT		
Type	I	I	F	F	F	I		
Default	none	none	1.0	1.0	0	1		
Remarks	1			2		3		

In the example shown above, the row labeled "Type" gives the variable type and is either F, for floating point or I, for an integer. The row labeled "Default" reveals the default value set for a variable if zero is specified, the field is left blank, or the card is not defined. The "Remarks" row refers to enumerated remarks at the end of the section.

Optional Cards:

Each keyword card (line beginning with "*") is followed by a set of data cards. Data cards are either,

4. *Required Cards.* Unless otherwise indicated, cards are required.

5. *Conditional Cards.* Conditional cards are required provided some condition is satisfied. The following is a typical conditional card:

ID Card. Additional card for the ID keyword option.

ID	1	2	3	4	5	6	7	8
Variable	ABID	HEADING						
Type	I	A70						

6. *Optional Cards.* An optional card is one that may be replaced by the next keyword card. The fields in the omitted optional data cards are assigned their default values.

Example. Suppose the data set for *KEYWORD consists of 2 required cards and 3 optional cards. Then, the fourth card may be replaced by the next keyword card. All the fields in the omitted fourth and fifth cards are assigned their default values.

> **WARNING:** In this example, even though the fourth card is optional, the input deck may *not* jump from the third to fifth card. The *only* card that card 4 may be replaced with is the next keyword card.

Long Format Input:

To accommodate larger or more precise values for input variables than are allowed by the standard format input as described above, a "long format" input option is available. One way of invoking long format keyword input is by adding "long=**y**" to the execution line. A second way is to add "long=**y**" to the *KEYWORD command in the input deck.

long=**y**: read long keyword input deck; write long structured input deck.
long=**s**: read standard keyword input deck; write long structured input deck.
long=**k**: read long keyword input deck; write standard structured input deck.

The "long=**s**" option may be helpful in the rare event that the keyword input is of standard format, but LS-DYNA reports an input error and the dyna.str file (see *CONTROL_-STRUCTURED) reveals that one or more variables is incorrectly written to dyna.str as a series of asterisks due to inadequate field length(s) in dyna.str.

The "long=**k**" option really serves no practical purpose.

When long format is invoked for keyword input, all variables that are less than or equal to 20 characters in standard format are expanded to or remain at 20 characters. There is one exception to the previous rule for alphanumeric variables of 20 characters in length. A20 in standard format becomes A40 in long format. Alphanumeric variables that are longer than A20 in standard format are extended to A160 in long format. The number of input lines in long format is unchanged from standard format, rather only the length of each line changes. For example, long format for the card corresponding to the _ID option of a keyword becomes (I20,A160) whereas standard format is (I10,A70).

Allowing a 20-character field for a numerical variable does not mean that it will allow for 20 significant digits. There are more fundamental limitations at work, particularly when running in single precision. The absolute value of an integer in single precision cannot be larger than $2^{31} - 1 = 2{,}147{,}483{,}647$. The mantissa of a floating point value cannot exceed 2^{23} in single precision and cannot exceed 2^{52} in double precision.

To convert a standard format input deck to a long format input deck, run LS-DYNA with "newformat = long" on the execution line. For example, if standard.k is a standard format input deck,

LS-DYNA i=**standard.k** newformat=**long**

will create a long format input deck called standard.k.long.

You can mix long and standard format within one input deck by use of "+" or "-" signs within the deck. If the execution line indicates standard format, you can add "+" at the end of any keywords to invoke long format just for those keywords. For example, "*NODE +" in place of "*NODE" invokes a read format of (I20,3F20,2F20).

Similarly, if the execution line indicates long format, you can add "-" at the end of any keywords to invoke standard format for those keywords. For example, "*NODE –" in place of "*NODE" invokes the standard read format of one line per node (I8,3F16,2F8).

To take this idea a step further, adding a "-" or "+" to the end of the *INCLUDE keyword command signals to LS-DYNA that all the commands in the included file are standard format or long format, respectively.

I10 Format Input:

In some cases, the user may be satisfied in extending 8-character input fields where they exist in standard format input to 10-character fields. If that is all that is required, then invoking the so-called "I10 format" input would suffice.

I10 format input is invoked by appending "i10=**y**" to the execution line or else by adding "i10=**y**" to the *KEYWORD command in the input deck. Or you can invoke I10 format for specific keywords in an input deck by adding the percent sign "%" to the end of the keyword. For example, "*NODE %" in place of "*NODE" invokes a read format of (I10, 3F16,2I10) instead of the standard (I8,3F16,2I8).

To convert a standard format input deck to an I10 format input deck, run LS-DYNA with "newformat = i10" on the execution line. For example, if standard.k is a standard format input deck,

LS-DYNA i=**standard.k** newformat=**i10**

will create an I10 format input deck called standard.k.i10.

*AIRBAG

Purpose: Define an airbag or control volume.

The keyword *AIRBAG provides a way of defining thermodynamic behavior of the gas flow into the airbag as well as a reference configuration for the fully inflated bag. The keyword cards in this section are defined in alphabetical order:

AIRBAG_*OPTION1_{OPTION2}_{OPTION3}_{OPTION4}

*AIRBAG_ALE

*AIRBAG_INTERACTION

*AIRBAG_PARTICLE

*AIRBAG_REFERENCE_GEOMETRY

*AIRBAG_SHELL_REFERENCE_GEOMETRY

***AIRBAG**_*OPTION1_{OPTION2}_{OPTION3}_{OPTION4}*

OPTION1 specifies one of the following thermodynamic models for modeling airbags using a control volume (CV) approach:

SIMPLE_PRESSURE_VOLUME

SIMPLE_AIRBAG_MODEL

ADIABATIC_GAS_MODEL

WANG_NEFSKE

WANG_NEFSKE_JETTING

WANG_NEFSKE_MULTIPLE_JETTING

LOAD_CURVE

LINEAR_FLUID

HYBRID

HYBRID_JETTING

HYBRID_CHEMKIN

FLUID_AND_GAS

OPTION2 specifies that an additional line of data is read for the WANG_NEFSKE type thermodynamic relationships. The additional data controls the initiation of exit flow from the airbag. *OPTION2* takes the single option:

POP

OPTION3 specifies that a constant momentum formulation is used to calculate the jetting load on the airbag an additional line of data is read in. *OPTION3* takes the single option:

CM

OPTION4, given by:

ID

specifies that an airbag ID and heading information will be the first card of the airbag definition. This ID is a unique number that is necessary for the identification of the airbags in the definition of airbag interaction using *AIRBAG_INTERACTION keyword. The numeric IDs and heading are written into the abstat and d3hsp files.

Core Cards: Common to all airbags

ID Card. Additional card for the ID keyword option. To use the *AIRBAG_INTERACTION keyword ID Cards are required.

Card ID	1	2	3	4	5	6	7	8
Variable	ABID	HEADING						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF
Type	I	I	I	F	F	F	F	F
Default	none	0	0	1.	1.	0.	0.	0.
Remark			optional					

VARIABLE	DESCRIPTION
ABID	Airbag ID. This must be a unique number.
HEADING	Airbag descriptor. It is suggested that unique descriptions be used.
SID	Set ID
SIDTYP	Set type: EQ.0: segment NE.0: part set ID
RBID	Rigid body part ID for user defined activation subroutine: LT.0: -RBID is taken as the rigid body part ID. Built in sensor subroutine initiates the inflator. Load curves are offset by initiation time. EQ.0: the control volume is active from time zero.

VARIABLE	DESCRIPTION
	GT.0: RBID is taken as the rigid body part ID. User sensor subroutine initiates the inflator. Load curves are offset by initiation time. See Appendix D.
VSCA	Volume scale factor (default = 1.0)
PSCA	Pressure scale factor (default = 1.0)
VINI	Initial filled volume
MWD	Mass weighted damping factor, D
SPSF	Stagnation pressure scale factor, $0 \le \gamma \le 1$

Remarks:

Card 1 is necessary for all airbag options. The option dependent cards follow.

Lumped parameter control volumes are a mechanism for determining volumes of closed surfaces and applying a pressure based on some thermodynamic relation. The volume is specified by a list of polygons similar to the pressure boundary condition cards or by specifying a material subset which represents shell elements that form the closed boundary. All polygon normal vectors must be oriented to face *outwards* from the control volume; however for *AIRBAG_PARTICLE, which does not rely on control volumes, all polygon normal vectors must be oriented to face *inwards* to get proper volume (see *AIRBAG_PARTICLE). If holes are detected, they are assumed to be covered by planar surfaces.

There are two sets of volume and pressure variables used for each control volume model. First, the finite element model computes a volume V_{femodel} and applies a pressure P_{femodel}. The thermodynamics of a control volume may be computed in a different unit system with its own set of variables: V_{cvolume} and P_{cvolume} which are used for integrating the differential equations for the control volume. The conversion is as follows:

$$V_{\text{cvolume}} = (\text{VSCA} \times V_{\text{femodel}}) - \text{VINI}$$
$$P_{\text{femodel}} = \text{PSCA} \times P_{\text{cvolume}}$$

where VSCA, PSCA, and VINI are input parameters. Damping can be applied to the structure enclosing a control volume by using a mass weighted damping formula:

$$F_i^d = m_i D\left(v_i - v_{\text{cg}}\right) \ ,$$

where F_i^d is the damping force, m_i is the nodal mass, v_i is the velocity for a node, v_{cg} is the mass weighted average velocity of the structure enclosing the control volume, and D is the damping factor.

An alternative, separate damping is based on the stagnation pressure. The stagnation pressure is roughly the maximum pressure on a flat plate oriented normal to a steady state flow field. The stagnation pressure is defined as $p = \gamma\rho V^2$, where V is the normal velocity of the control volume relative to the ambient velocity, ρ is the ambient air density, and γ is a factor which varies from 0 to 1 that must be chosen by the user. Small values are recommended to avoid excessive damping.

Sensor Input:

The sensor is mounted on a rigid body which is attached to the structure. *The motion of the sensor is evaluated in the local coordinate system of the rigid body. See *MAT_RIGID.* This local system rotates and translates with the rigid material. The default local system for a rigid body is taken as the principal axes of the inertia tensor.

When the user defined criterion for airbag deployment is satisfied, a flag is set and deployment begins. All load curves relating to the mass flow rate as a function of time are then shifted by the initiation time.

RBID = 0: No Rigid Body

For this case there is no rigid body, and the control volume is active from time zero. There are no additional sensor cards.

RBID > 0: User Supplied Sensor Subroutine

The value of RBID is taken as a rigid body part ID, and a user supplied sensor subroutine will be called to determine the flag that initiates deployment. See Appendix D for details regarding the user supplied subroutine. For RBID > 0 the additional cards are specified below:

User Subroutine Control Card. This card is read in when RBID > 0.

Card 2a	1	2	3	4	5	6	7	8
Variable	N							
Type	I							
Default	none							

User Subroutine Constant Cards. Define N constants for the user subroutine. Include only the number of cards necessary, that is, for nine constants use 2 cards.

Card 2a.1	1	2	3	4	5	6	7	8
Variable	C1	C2	C3	C4	C5			
Type	F	F	F	F	F			
Default	0.	0.	0.	0.	0.			

VARIABLE	DESCRIPTION
N	Number of input parameters (not to exceed 25)
C1, …, CN	Up to 25 constants for the user subroutine

RBID < 0: User supplied sensor subroutine

The value of –RBID is taken as rigid body part ID and a built in sensor subroutine is called. For RBID < 0, there are three additional cards.

Acceleration Sensor Card.

Card 2b.1	1	2	3	4	5	6	7	8
Variable	AX	AY	AZ	AMAG	TDUR			
Type	F	F	F	F	F			
Default	0.	0.	0.	0.	0.			

Velocity Sensor Card.

Card 2b.2	1	2	3	4	5	6	7	8
Variable	DVX	DVY	DVZ	DVMAG				
Type	F	F	F	F				
Default	0.	0.	0.	0.				

Displacement Sensor Card.

Card 2b.3	1	2	3	4	5	6	7	8
Variable	UX	UY	UZ	UMAG				
Type	F	F	F	F				
Default	0.	0.	0.	0.				

VARIABLE	DESCRIPTION
AX	Acceleration level in the local *x*-direction to activate inflator. The absolute value of the *x*-acceleration is used. EQ.0: inactive
AY	Acceleration level in local the *y*-direction to activate inflator. The absolute value of the *y*-acceleration is used. EQ.0: inactive
AZ	Acceleration level in the local *z*-direction to activate inflator. The absolute value of the *z*-acceleration is used. EQ.0: inactive
AMAG	Acceleration magnitude required to activate inflator. EQ.0: inactive
TDUR	Time duration acceleration must be exceeded before the inflator activates. This is the cumulative time from the beginning of the calculation, meaning it is not continuous.

VARIABLE	DESCRIPTION
DVX	Velocity change in the local x-direction to activate the inflator. (The absolute value of the velocity change is used.) EQ.0: inactive
DVY	Velocity change in the local y-direction to activate the inflator. (The absolute value of the velocity change is used.) EQ.0: inactive
DVZ	Velocity change in the local z-direction to activate the inflator. (The absolute value of the velocity change is used.) EQ.0: inactive
DVMAG	Velocity change magnitude required to activate the inflator. EQ.0: inactive
UX	Displacement increment in the local x-direction to activate the inflator. (The absolute value of the x-displacement is used.) EQ.0: inactive
UY	Displacement increment in the local y-direction to activate the inflator. (The absolute value of the y-displacement is used.) EQ.0: inactive
UZ	Displacement increment in the local z-direction to activate the inflator. (The absolute value of the z-displacement is used.) EQ.0: inactive
UMAG	Displacement magnitude required to activate the inflator. EQ.0: inactive

*AIRBAG_SIMPLE_PRESSURE_VOLUME_{OPTION}

Card Summary:

The additional card required for the SIMPLE_PRESSURE_VOLUME keyword is Card 3. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if and only if the ID keyword option is used. To use the *AIRBAG_INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF

Card 2a. This card is read when RBID > 0.

N							

Card 2a.1. This card is read when RBID > 0. Define N constants for the user subroutine. Include only the number of cards necessary, that is, for nine constants use 2 cards.

C1	C2	C3	C4	C5			

Card 2b.1. This card is read when RBID < 0.

AX	AY	AZ	AMAG	TDUR			

Card 2b.2. This card is read when RBID < 0.

DVX	DVY	DVZ	DVMAG				

Card 2b.3. This card is read when RBID < 0.

UX	UY	UZ	UMAG				

Card 3. This card is required.

CN	BETA	LCID	LCIDDR				

Data Card Definitions:

Additional card for SIMPLE_PRESSURE_VOLUME option. (For card 1 see the "core cards" section of *AIRBAG.)

Card 3	1	2	3	4	5	6	7	8
Variable	CN	BETA	LCID	LCIDDR				
Type	F	F	I	I				
Default	none	none	none	0				

VARIABLE	DESCRIPTION
CN	Coefficient. Define if the load curve ID, LCID, is unspecified. LT.0.0: |CN| is the load curve ID, which defines the coefficient as a function of time.
BETA	Scale factor, β. Define if a load curve ID is not specified.
LCID	Optional load curve ID defining pressure as a function of relative volume.
LCIDDR	Optional load curve ID defining the coefficient, CN, as a function of time during the dynamic relaxation phase.

Remarks:

Pressure is calculated using the following:

$$\text{Pressure} = \frac{\beta \times \text{CN}}{\text{Relative Volume}}$$

$$\text{Relative Volume} = \frac{\text{Current Volume}}{\text{Initial Volume}}$$

The pressure, therefore, is a function of the ratio of current volume to the initial volume. The constant, CN, is used to establish a relationship known from the literature. The scale factor β is simply used to scale the given values. This simple model can be used when an initial pressure is given and no leakage, no temperature, and no input mass flow is assumed. A typical application is the modeling of air in automobile tires.

The load curve, LCIDDR, can be used to ramp up the pressure during the dynamic relaxation phase to avoid oscillations after the desired gas pressure is reached. In the DE-

FINE_CURVE section this load curve must be flagged for dynamic relaxation. After initialization either the constant or load curve ID, |CN|, is used to determine the pressure.

*AIRBAG_SIMPLE_AIRBAG_MODEL_{OPTION}

Card Summary:

The additional cards required for the SIMPLE_AIRBAG_MODEL option begin with Card 3. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if and only if the ID keyword option is used. To use the *AIRBAG_INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF

Card 2a. This card is read when RBID > 0.

N							

Card 2a.1. This card is read when RBID > 0. Define N constants for the user subroutine. Include only the number of cards necessary, that is, for nine constants use 2 cards.

C1	C2	C3	C4	C5			

Card 2b.1. This card is read when RBID < 0.

AX	AY	AZ	AMAG	TDUR			

Card 2b.2. This card is read when RBID < 0.

DVX	DVY	DVZ	DVMAG				

Card 2b.3. This card is read when RBID < 0.

UX	UY	UZ	UMAG				

Card 3. This card is required.

CV	CP	T	LCID	MU	AREA	PE	RO

Card 4a. This card is included if CV = 0.

LOU	T_EXT	A	B	MW	GASC		

Card 4b. This card is included if CV ≠ 0.

LOU							

Data Card Definitions:

Card 3	1	2	3	4	5	6	7	8
Variable	CV	CP	T	LCID	MU	AREA	PE	RO
Type	F	F	F	I	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
CV	Heat capacity at constant volume (e.g., Joules/kg/°K). See Remark 3.
CP	Heat capacity at constant pressure (e.g., Joules/kg/°K). See Remark 3.
T	Temperature of input gas
LCID	Load curve ID specifying input mass flow rate. See *DEFINE_CURVE. See Remark 2.
MU	Shape factor for exit hole, μ (see Remark 2): LT.0.0: $\lvert\mu\rvert$ is the load curve number defining the shape factor as a function of absolute pressure.
AREA	Exit area, A (see Remark 2): GE.0.0: A is the exit area and is constant in time. LT.0.0: $\lvert A\rvert$ is the load curve number defining the exit area as a function of absolute pressure.
PE	Ambient pressure, p_e
RO	Ambient density, ρ

Card 4a	1	2	3	4	5	6	7	8
Variable	LOU	T_EXT	A	B	MW	GASC		
Type	I	F	F	F	F	F		
Default	0	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
LOU	Optional load curve ID giving mass flow out as a function of gauge pressure in bag. See *DEFINE_CURVE. See Remark 2.
T_EXT	Ambient temperature
A	First heat capacity coefficient of inflator gas (e.g., Joules/mole/^oK)
B	Second heat capacity coefficient of inflator gas, (e.g., Joules/mole/$^oK^2$)
MW	Molecular weight of inflator gas (e.g., kg/mole)
GASC	Universal gas constant of inflator gas (e.g., 8.314 Joules/mole/^oK)

Card 4b	1	2	3	4	5	6	7	8
Variable	LOU							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
LOU	Optional load curve ID giving mass flow out as a function of gauge pressure in bag. See *DEFINE_CURVE. See Remark 2.

Remarks:

1. **Airbag Pressure.** The gamma law equation of state used to determine the pressure in the airbag is given by:

$$p = (\gamma - 1)\rho e \ ,$$

where p is the pressure, ρ is the density, e is the specific internal energy of the gas, and γ is the ratio of the specific heats, such that

$$\gamma = \frac{c_p}{c_v} \ .$$

2. **Leakage.** From conservation of mass, the time rate of change of mass flowing into the bag is given as:

$$\frac{dM}{dt} = \frac{dM_{\text{in}}}{dt} - \frac{dM_{\text{out}}}{dt} \ .$$

The inflow mass flow rate is given by the load curve ID, LCID. Leakage, the mass flow rate out of the bag, can be modeled in two alternative ways. One is to give an exit area with the corresponding shape factor, then the load curve ID, LOU, must be set to zero. The other is to define a mass flow out by a load curve, then μ and A must both be set to zero.

3. **Specific Heats.** If CV = 0. then the constant-pressure specific heat is given by:

$$c_p = \frac{(a + bT)}{\text{MW}} \ ,$$

and the constant-volume specific heat is then found from:

$$c_v = c_p - \frac{R}{\text{MW}} \ .$$

*AIRBAG_ADIABATIC_GAS_MODEL_{OPTION}

Card Summary:

The additional cards required for the ADIABATIC_GAS_MODEL option begin with Card 3. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if and only if the ID keyword option is used. To use the *AIRBAG_INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF

Card 2a. This card is read when RBID > 0.

N							

Card 2a.1. This card is read when RBID > 0. Define N constants for the user subroutine. Include only the number of cards necessary, that is, for nine constants use 2 cards.

C1	C2	C3	C4	C5			

Card 2b.1. This card is read when RBID < 0.

AX	AY	AZ	AMAG	TDUR			

Card 2b.2. This card is read when RBID < 0.

DVX	DVY	DVZ	DVMAG				

Card 2b.3. This card is read when RBID < 0.

UX	UY	UZ	UMAG				

Card 3. This card is required.

ATMOST	ATMOSP	ATMOSD	GC	CC	HCONV		

Card 3	1	2	3	4	5	6	7	8
Variable	PSF	LCID	GAMMA	P0	PE	R0		
Type	F	I	F	F	F	F		
Default	1.0	none	none	none	none	none		

VARIABLE	DESCRIPTION
PSF	Pressure scale factor
LCID	Optional load curve for preload flag. See *DEFINE_CURVE.
GAMMA	Ratio of specific heats
P0	Initial pressure (gauge)
PE	Ambient pressure
RO	Initial density of gas

Remarks:

The optional load curve ID, LCID, defines a preload flag. During the preload phase the function value of the load curve versus time is zero, and the pressure in the control volume is given as:

$$p = \text{PSF} \times p_0$$

When the *first nonzero* function value is encountered, the preload phase stops and the ideal gas law applies for the rest of the analysis. If LCID is zero, no preload is performed.

The gamma law equation of state for the adiabatic expansion of an ideal gas is used to determine the pressure after preload:

$$p = (\gamma - 1)\rho e \ ,$$

where p is the pressure, ρ is the density, e is the specific internal energy of the gas, and γ is the ratio of the specific heats:

$$\gamma = \frac{c_p}{c_v} \ .$$

The pressure above is the absolute pressure. The resultant pressure acting on the control volume is:

$$p_s = \text{PSF} \times (p - p_e)$$

where PSF is the pressure scale factor. Starting from the initial pressure p_0 an initial internal energy is calculated:

$$e_0 = \frac{p_0 + p_e}{\rho(\gamma - 1)} \ .$$

*AIRBAG_WANG_NEFSKE_{OPTIONS}

Card Summary:

The additional cards required for WANG_NEFSKE, WANG_NEFSKE_JETTING, and WANG_NEFSKE_MULTIPLE_JETTING option begin with Card 3. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if the ID keyword option is used. To use the *AIRBAG_-INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF

Card 11. The is card is included if the CM keyword option is used.

NREACT							

Data Card Definitions:

Card 3	1	2	3	4	5	6	7	8
Variable	CV	CP	T	LCT	LCMT	TVOL	LCDT	IABT
Type	F	F	F	I	I	F	I	F
Default	none	none	0.	0	none	0.	0.	not used

VARIABLE	DESCRIPTION
CV	Specific heat at constant volume, e.g., Joules/kg/°K
CP	Specific heat at constant pressure, e.g., Joules/kg/°K
T	Temperature of input gas. For temperature variations a load curve, LCT, may be defined.
LCT	Optional load curve ID defining temperature of input gas as a function of time. This overrides T.
LCMT	Load curve specifying input mass flow rate or tank pressure versus time. If the tank volume, TVOL, is nonzero the curve ID is assumed to be tank pressure as a function of time. If LCMT = 0, then the inflator must be modeled; see Card 6. During the dynamic relaxation phase the airbag is ignored unless the curve is flagged to act during dynamic relaxation.
TVOL	Tank volume which is required only for the tank pressure as a function of time curve, LCMT.
LCDT	Load curve for time rate of change of temperature (dT/dt) as a function of time.
IABT	Initial airbag temperature. (Optional, generally not defined.)

Card 4	1	2	3	4	5	6	7	8
Variable	C23	LCC23	A23	LCA23	CP23	LCCP23	AP23	LCAP23
Type	F	I	F	I	F	I	F	I
Default	none	0	none	0	none	0	0.0	0

VARIABLE	DESCRIPTION
C23	Vent orifice coefficient which applies to exit hole. Set to zero if LCC23 is defined below.
LCC23	The absolute value, |LCC23|, is a load curve ID. If the ID is positive, the load curve defines the vent orifice coefficient which applies to exit hole as a function of time. If the ID is negative, the vent orifice coefficient is defined as a function of relative pressure, P_{air}/P_{bag};

VARIABLE	DESCRIPTION
	see [Anagonye and Wang 1999]. In addition, LCC23 can be defined through *DEFINE_CURVE_FUNCTION. A nonzero value for C23 overrides LCC23.
A23	Vent orifice area: GT.0.0: Vent orifice area which applies to exit hole LT.0.0: The absolute value |A23| is a part ID, see [Anagonye and Wang, 1999]. With LCA23 = -1, |A23| is a part set representing venting holes. The venting leakage through each venting hole represented by a part in part set |A23| is output to abstat. The area of this part/set becomes the vent orifice area. With SIDTYP > 0, airbag pressure will not be applied to part/set |A23| representing venting holes if part/set |A23| is not included in SID, the part set representing the airbag. EQ.0.0: Set A23 to zero if LCA23 is ≠ 0.
LCA23	Load curve defining the vent orifice area which applies to exit hole as a function of *absolute* pressure, or LCA23 can be defined through *DEFINE_CURVE_FUNCTION. A nonzero value for A23 overrides LCA23.
CP23	Orifice coefficient for leakage (fabric porosity). Set to zero if LCCP23 is defined below.
LCCP23	Load curve defining the orifice coefficient for leakage (fabric porosity) as a function of time, or LCCP23 can be defined through *DEFINE_CURVE_FUNCTION. A nonzero value for CP23 overrides LCCP23.
AP23	Area for leakage (fabric porosity)
LCAP23	Load curve defining the area for leakage (fabric porosity) as a function of (absolute) pressure, or LCAP23 can be defined through *DEFINE_CURVE_FUNCTION. A nonzero value for AP23 overrides LCAP23.

Card 5	1	2	3	4	5	6	7	8
Variable	PE	RO	GC	LCEFR	POVER	PPOP	OPT	KNKDN
Type	F	F	F	I	F	F	F	I
Default	none	none	none	0	0.0	0.0	0.0	0

VARIABLE	DESCRIPTION
PE	Ambient pressure
RO	Ambient density
GC	Gravitational conversion constant (mandatory - no default). If consistent units are being used for all parameters in the airbag definition, then unity should be input.
LCEFR	Optional curve for exit flow rate (mass/time) as a function of (gauge) pressure
POVER	Initial relative overpressure (gauge), P_{over} in control volume
PPOP	Pop Pressure: relative pressure (gauge) for initiating exit flow, P_{pop}
OPT	Fabric venting option. If nonzero, CP23, LCCP23, AP23, and LCAP23 are set to zero. Porosity leakage of each material is output to abstat. EQ.1: Wang-Nefske formulas for venting through an orifice are used. Blockage is not considered. EQ.2: Wang-Nefske formulas for venting through an orifice are used. Blockage of venting area due to contact is considered. EQ.3: Leakage formulas of Graefe, Krummheuer, and Siejak [1990] are used. Blockage is not considered. EQ.4: Leakage formulas of Graefe, Krummheuer, and Siejak [1990] are used. Blockage of venting area due to contact is considered. EQ.5: Leakage formulas based on flow through a porous media are used. Blockage is not considered. EQ.6: Leakage formulas based on flow through a porous media

VARIABLE	DESCRIPTION
	are used. Blockage of venting area due to contact is considered. EQ.7: Leakage is based on gas volume outflow as a function of pressure load curve. Blockage of flow area due to contact is not considered. Absolute pressure is used in the porous-velocity-versus-pressure load curve, given as FAC(p) in the *MAT_FABRIC card. EQ.8: Leakage is based on gas volume outflow as a function of pressure load curve. Blockage of flow area due to contact is considered. Absolute pressure is used in the porous-velocity-versus-pressure load curve, given as FAC(p) in the *MAT_FABRIC card.
KNKDN	*Optional* load curve ID defining the knock down pressure scale factor as a function of time. This option only applies to jetting. The scale factor defined by this load curve scales the pressure applied to airbag segments which do not have a clear line-of-sight to the jet. Typically, at very early times this scale factor will be less than unity and equal to unity at later times. The full pressure is always applied to segments which can see the jets.

Inflator Card. If the inflator is modeled (LCMT = 0), fill in the following card. *If not, include but leave blank.*

Card 6	1	2	3	4	5	6	7	8
Variable	IOC	IOA	IVOL	IRO	IT	LCBF		
Type	F	F	F	F	F	I		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
IOC	Inflator orifice coefficient
IOA	Inflator orifice area
IVOL	Inflator volume
IRO	Inflator density

VARIABLE	DESCRIPTION
IT	Inflator temperature
LCBF	Load curve defining burn fraction as a function of time

Temperature Dependent Heat Capacities Card. Include this card when CV = 0.

Card 7	1	2	3	4	5	6	7	8
Variable	TEXT	A	B	MW	GASC	HCONV		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
TEXT	Ambient temperature
A	First molar heat capacity coefficient of inflator gas (e.g., Joules/mole/K)
B	Second molar heat capacity coefficient of inflator gas, (e.g., Joules/mole/K^2)
MW	Molecular weight of inflator gas (e.g., Kg/mole).
GASC	Universal gas constant of inflator gas (e.g., 8.314 Joules/mole/K)
HCONV	Effective heat transfer coefficient between the gas in the air bag and the environment at temperature TEXT. If HCONV < 0, then HCONV defines a load curve of data pairs (time, hconv).

Criteria for Initiating Exit Flow Card. Additional card for the POP option to the *AIRBAG_WANG_NEFSKE card.

Card 8	1	2	3	4	5	6	7	8
Variable	TDP	AXP	AYP	AZP	AMAGP	TDURP	TDA	RBIDP
Type	F	F	F	F	F	F	F	I
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	none

VARIABLE	DESCRIPTION
TDP	Time delay before initiating exit flow after pop pressure is reached
AXP	Pop acceleration magnitude in the local x-direction. EQ.0.0: Inactive
AYP	Pop acceleration magnitude in the local y-direction. EQ.0.0: Inactive.
AZP	Pop acceleration magnitude in the local z-direction. EQ.0.0: Inactive
AMAGP	Pop acceleration magnitude. EQ.0.0: Inactive
TDURP	Time duration pop acceleration must be exceeded to initiate exit flow. This is a cumulative time from the beginning of the calculation, that is, it is not continuous.
TDA	Time delay before initiating exit flow after pop acceleration is exceeded for the prescribed time duration.
RBIDP	Part ID of the rigid body for checking accelerations against pop accelerations

Remarks:

The gamma law equation of state for the adiabatic expansion of an ideal gas is used to determine the pressure after preload:

$$p = (\gamma - 1)\rho e$$

where p is the pressure, ρ is the density, e is the specific internal energy of the gas, and γ is the ratio of the specific heats:

$$\gamma = \frac{c_p}{c_v} \ .$$

Here c_v is the specific heat at constant volume, and c_p is the specific heat at constant pressure. A pressure relation is defined as:

$$Q = \frac{p_e}{p} \ ,$$

where p_e is the external pressure and p is the internal pressure in the bag. A critical pressure relationship is defined as:

$$Q_{\text{crit}} = \left(\frac{2}{\gamma + 1}\right)^{\frac{\gamma}{\gamma - 1}},$$

where γ is the ratio of specific heats as defined above and

$$Q \le Q_{\text{crit}} \Rightarrow Q = Q_{\text{crit}} \ .$$

Wang and Nefske define the mass flow through the vents and leakage by

$$\dot{m}_{23} = C_{23} A_{23} \frac{p}{R\sqrt{T_2}} Q^{\frac{1}{\gamma}} \sqrt{2 g_c \left(\frac{\gamma R}{\gamma - 1}\right)\left(1 - Q^{\frac{\gamma - 1}{\gamma}}\right)}$$

and

$$\dot{m}'_{23} = C'_{23} A'_{23} \frac{p}{R\sqrt{T_2}} Q^{\frac{1}{\gamma}} \sqrt{2 g_c \left(\frac{\gamma R}{\gamma - 1}\right)\left(1 - Q^{\frac{\gamma - 1}{\gamma}}\right)} \ .$$

It must be noted that the gravitational conversion constant must be given in consistent units. As an alternative to computing the mass flow out of the bag by the Wang-Nefske model, a curve for the exit flow rate depending on the internal pressure can be taken. Then, no definitions for C23, LCC23, A23, LCA23, CP23, LCCP23, AP23, and LCAP23 are necessary.

The airbag inflator assumes that the control volume of the inflator is constant and that the amount of propellant reacted can be defined by the user as a tabulated curve of fraction reacted versus time. A pressure relation is defined as:

$$Q_{\text{crit}} = \frac{p_c}{p_I} = \left(\frac{2}{\gamma + 1}\right)^{\frac{\gamma}{\gamma - 1}} \ ,$$

where p_c is a critical pressure at which sonic flow occurs, and p_I is the inflator pressure. The exhaust pressure is given by

$$p_e = \begin{cases} p_a & \text{if } p_a \ge p_c \\ p_c & \text{if } p_a < p_c \end{cases}$$

where p_a is the pressure in the control volume. The mass flow into the control volume is governed by the equation:

$$\dot{m}_{\text{in}} = C_0 A_0 \sqrt{2 p_I \rho_I} \sqrt{\frac{g_c \gamma \left(Q^{\frac{2}{\gamma}} - Q^{\frac{\gamma+1}{\gamma}} \right)}{\gamma - 1}}$$

where C_0, A_0, and ρ_I are the inflator orifice coefficient, area, and gas density, respectively.

If OPT is defined, then for OPT set to 1 or 2 the mass flow rate out of the bag, $\dot{m}_{out}$ is given by:

$$\dot{m}_{out} = \sqrt{g_c} \left\{ \sum_{n=1}^{\text{nairmats}} [\text{FLC}(t)_n \times \text{FAC}(p)_n \times \text{Area}_n] \right\} \sqrt{2p\rho} \sqrt{\frac{\gamma \left(Q^{\frac{2}{k}} - Q^{\frac{\gamma+1}{\gamma}} \right)}{\gamma - 1}}$$

where, ρ is the density of airbag gas, "nairmats" is the number of fabrics used in the airbag, and Area_n is the current unblocked area of fabric number n.

If OPT is set to 3 or 4 then:

$$\dot{m}_{\text{out}} = \left\{ \sum_{n=1}^{\text{nairmats}} [\text{FLC}(t)_n \times \text{FAC}(p)_n \times \text{Area}_n] \right\} \sqrt{2(p - p_{\text{ext}})\rho}$$

while for OPT set to 5 or 6:

$$\dot{m}_{\text{out}} = \left\{ \sum_{n=1}^{\text{nairmats}} [\text{FLC}(t)_n \times \text{FAC}(p)_n \times \text{Area}_n] \right\} (p - p_{\text{ext}}) \ .$$

For OPT set to 7 or 8 (may be comparable to an equivalent model ALE model):

$$\dot{m}_{\text{out}} = \sum_{n=1}^{\text{nairmats}} \text{FLC}(t)_n \times \text{FAC}(p)_n \times \text{Area}_n \times \rho_n \ .$$

Note that for different OPT settings, $\text{FAC}(p)_n$ has different meanings (all units shown just as demonstrations):

1. For OPT of 1, 2, 3 and 4, $\text{FAC}(p)$ is unit-less.
2. For OPT of 5 and 6, $\text{FAC}(p)$ has a unit of (s/m).
3. For OPT of 7 or 8, $\text{FAC}(p)$ is the gas volume outflow through a unit area per unit time thus has the unit of speed,

$$[\text{FAC}(p)] = \frac{[\text{volume}]}{[\text{area}][t]} = \frac{[\text{L}]^3}{[\text{L}]^2[t]} = \frac{[L]}{[t]} = [\text{velocity}].$$

Multiple airbags may share the same part ID since the area summation is over the airbag segments whose corresponding part IDs are known. Currently, we assume that no more

than ten materials are used per bag for purposes of the output. This constraint can be eliminated if necessary.

The total mass flow out will include the portion due to venting, that is, constants C23 and A23 or their load curves above.

If CV = 0. then the constant-pressure specific heat is given by:

$$c_p = \frac{(a + bT)}{MW}$$

and the constant-volume specific heat is then found from:

$$c_v = c_p - \frac{R}{MW}$$

Additional Cards required for JETTING models:

The following additional cards are defined for the WANG_NEFSKE_JETTING and WANG_NEFSKE_MULTIPLE_JETTING options, two further cards are defined for each option. The jet may be defined by specifying either the coordinates of the jet focal point, jet vector head and secondary jet focal point, or by specifying three nodes located at these positions. The nodal point option is recommended when the location of the airbag changes as a function of time.

WANG_NEFSKE_JETTING Card. Include this card if the WANG_NEFSKE_JETTING keyword option is used.

Card 9a	1	2	3	4	5	6	7	8
Variable	XJFP	YJFP	ZJFP	XJVH	YJVH	ZJVH	CA	BETA
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	1.0
Remark	1	1	1	1	1	1		

WANG_NEFSKE_MULTIPLE_JETTING Card. Include this card if the WANG_-NEFSKE_MULTIPLE_JETTING keyword option is used.

Card 9b	1	2	3	4	5	6	7	8
Variable	XJFP	YJFP	ZJFP	XJVH	YJVH	ZJVH	LCJRV	BETA
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	1.0
Remark	1	1	1	1	1	1		

VARIABLE	DESCRIPTION
XJFP	x-coordinate of jet focal point, meaning the virtual origin in Figures 3-1 and 3-2.
YJFP	y-coordinate of jet focal point, meaning the virtual origin in Figures 3-1 and 3-2.
ZJFP	z-coordinate of jet focal point, meaning the virtual origin in Figures 3-1 and 3-2.
XJVH	x-coordinate of jet vector head to defined code centerline
YJVH	y-coordinate of jet vector head to defined code centerline
ZJVH	z-coordinate of jet vector head to defined code centerline
CA	Cone angle, α, defined in radians. LT.0.0: $\lvert\alpha\rvert$ is the load curve ID defining cone angle as a function of time
LCJRV	Load curve ID giving the spatial jet relative velocity distribution; see Figures 3-1, 3-2, and 3-3. The jet velocity is determined from the inflow mass rate and scaled by the load curve function value corresponding to the value of the angle ψ. Typically, the values on the load curve vary between 0 and unity. See *DEFINE_CURVE.
BETA	Efficiency factor, β, which scales the final value of pressure obtained from Bernoulli's equation. LT.0.0: $\lvert\beta\rvert$ is the load curve ID defining the efficiency factor as a

VARIABLE	DESCRIPTION
	function of time

Jetting Card. This card is included if the either the WANG_NEFSKE_JETTING or WANG_NEFSKE_MULTIPLE_JETTING keyword option is used.

Card 10	1	2	3	4	5	6	7	8
Variable	XSJFP	YSJFP	ZSJFP	PSID	ANGLE	NODE1	NODE2	NODE3
Type	F	F	F	I	F	I	I	I
Default	none	none	none	none	none	0	0	0
Remark						1	1	1

VARIABLE	DESCRIPTION
XSJFP	x-coordinate of secondary jet focal point, passenger side bag. If the coordinates of the secondary point are (0,0,0) then a conical jet (driver's side airbag) is assumed.
YSJFP	y-coordinate of secondary jet focal point
ZSJFP	z-coordinate of secondary jet focal point
PSID	Optional part set ID; see *SET_PART. If zero, all elements are included in the airbag.
ANGLE	Cutoff angle in degrees. The relative jet velocity is set to zero for angles greater than the cutoff. See Figure 3-3. This option applies to the MULTIPLE jet only.
NODE1	Node ID located at the jet focal point, that is, the virtual origin in Figures 3-1 and 3-2
NODE2	Node ID for node along the axis of the jet
NODE3	Optional node ID located at secondary jet focal point

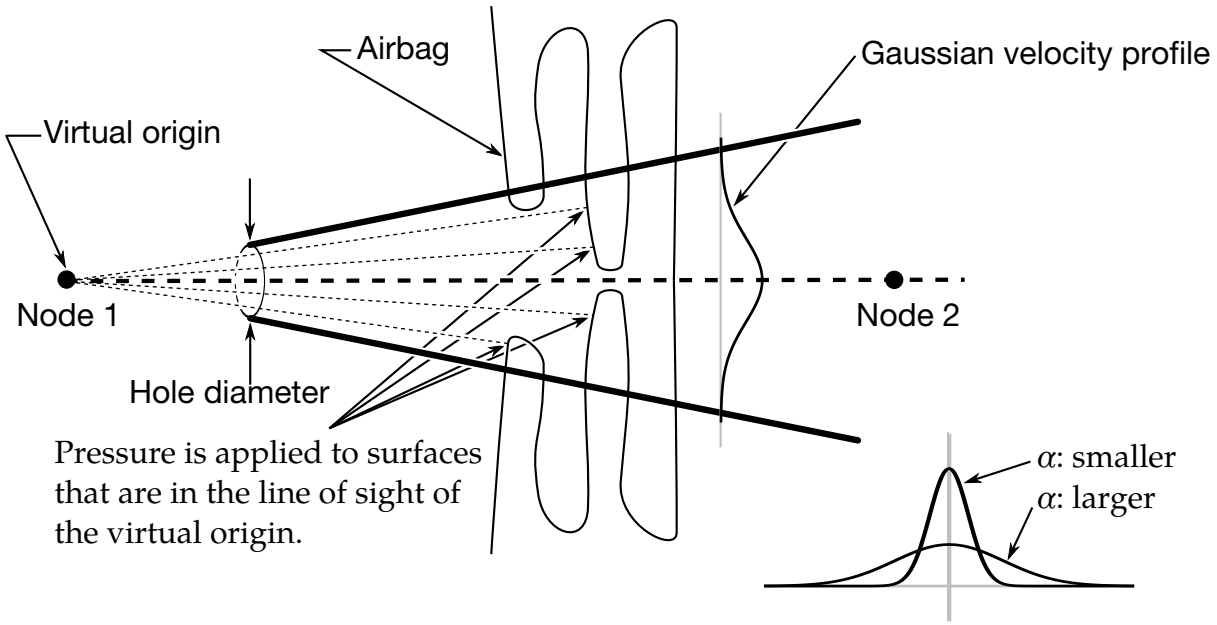

Figure 3-1. Jetting configuration for driver's side airbag (pressure applied only if centroid of surface is in line-of-sight)

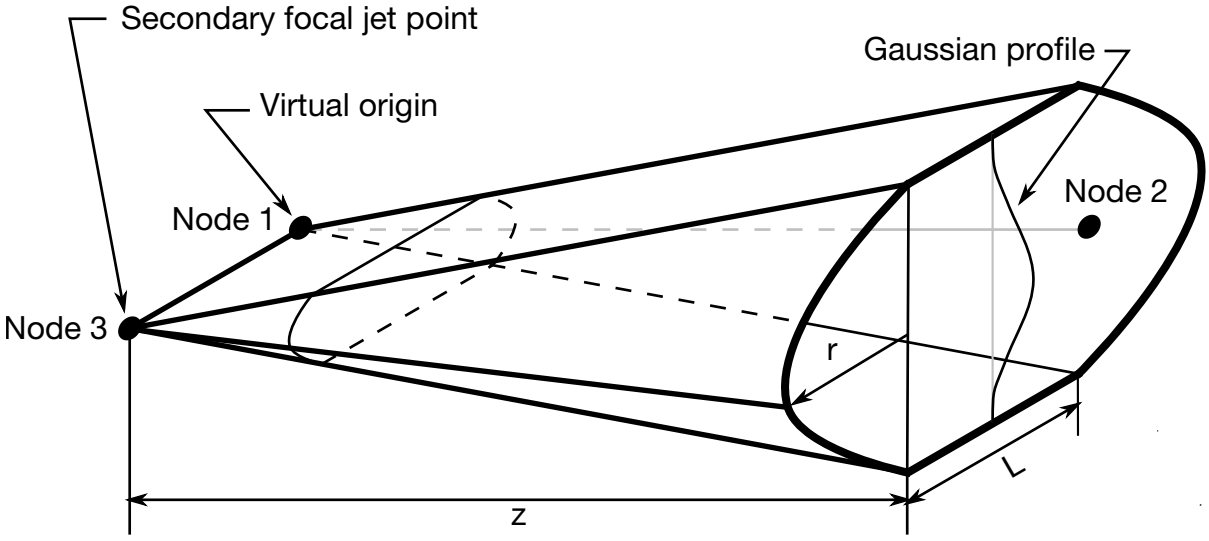

Figure 3-2. Jetting configuration for the passenger's side bag.

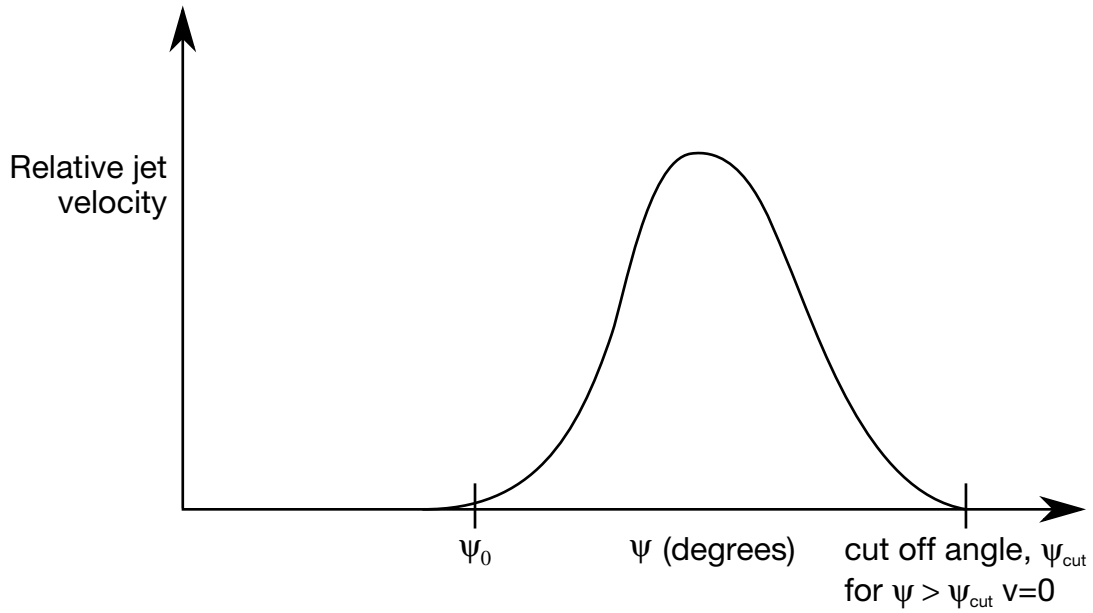

Figure 3-3. Normalized jet velocity versus angle for multiple jet driver's side airbag

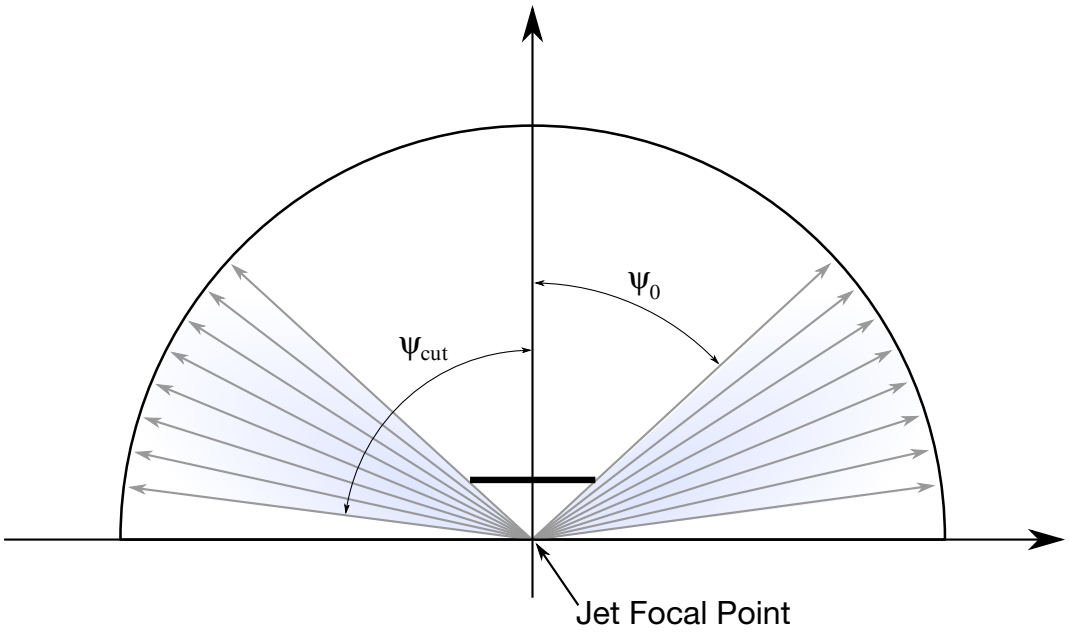

Figure 3-4. Multiple jet model for driver's side airbag. Typically, ψ_{cut} (see input ANGLE) is close to 90°. The angle ψ_0 is included to indicate that there is some angle below which the jet is negligible; see Figure 3-3.

Remarks:

1. **Jet Direction.** It is assumed that the jet direction is defined by the coordinate method (XJFP, YJFP, ZJFP) and (XJVH, YJVH, ZJVH) unless both NODE1 and NODE2 are defined. In which case the coordinates of the nodes give by NODE1, NODE2 and NODE3 will override (XJFP, YJFP, ZJFP) and (XJVH, YJVH, ZJVH). The use of nodes is recommended if the airbag system is undergoing rigid body motion. The nodes should be attached to the vehicle to allow for the coordinates of the jet to be continuously updated with the motion of the vehicle.

2. **Pressure Distribution.** The jetting option provides a simple model to simulate the real pressure distribution in the airbag during the breakout and early unfolding phase. Only the surfaces that are in the line of sight to the virtual origin have an increased pressure applied. With the optional load curve LCRJV, the pressure distribution with the code can be scaled according to the so-called relative jet velocity distribution.

3. **Jetting Configuration.** For passenger side airbags the cone is replaced by a wedge type shape. The first and secondary jet focal points define the corners of the wedge and the angle α then defines the wedge angle.

4. **Surfaces for Applying Pressure.** Instead of applying pressure to all surfaces in the line of sight of the virtual origin(s), a part set can be defined to which the pressure is applied.

5. **Jet Focal Point Placement.** Care must be used to place the jet focal point within the bag. If the focal point is outside the bag, inside surfaces will not be visible so jetting pressure will not be applied correctly.

Additional Card required for CM option:

The following additional card is defined for the WANG_NEFSKE_JETTING_CM and WANG_NEFSKE_MULTIPLE_JETTING_CM options.

CM Card. Additional card required for CM keyword option.

Card 11	1	2	3	4	5	6	7	8
Variable	NREACT							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
NREACT	Node for reacting jet force. If zero, the jet force will not be applied.

Remarks:

Compared with the standard LS-DYNA jetting formulation, the Constant Momentum option has several differences. Overall, the jetting usually has a more significant effect on airbag deployment than the standard LS-DYNA jetting: the total force is often greater and does not reduce with distance from the jet.

The velocity at the jet outlet is assumed to be a choked (sonic) adiabatic flow of a perfect gas. Therefore the velocity at the outlet is given by:

$$v_{\text{outlet}} = \sqrt{\gamma RT} = \sqrt{\frac{(c_p - c_v)Tc_p}{c_v}} \ .$$

The density in the nozzle is then calculated from conservation of mass flow.

$$\dot{m} = \rho_0 v_{\text{outlet}} A_{\text{outlet}}$$

This is different from the standard LS-DYNA jetting formulation, which assumes that the density of the gas in the jet is the same as atmospheric air, and then calculates the jet velocity from conservation of mass flow.

The velocity distribution at any radius, r, from the jet centerline and distance, z, from the focus, $v_{r,z}$, relates to the velocity of the jet centerline, $v_{r=0,z}$ in the same way as the standard LS-DYNA jetting options:

$$v_{r,z} = v_{r=0,z} e^{-\left(\frac{r}{\alpha z}\right)^2}$$

The velocity at the jet centerline, $v_r = 0$, at the distance, z, from the focus of the jet is calculated such that the momentum in the jet is conserved.

$$\begin{aligned} \text{momentum at nozzle} &= \text{momentum at z} \\ \rho_0 v_{\text{outlet}}^2 A_{\text{outlet}} &= \rho_0 \int v_{\text{jet}}^2 dA_{\text{jet}} \\ &= \rho_0 v_{r=0,Z}^2 \left\{ b + F\sqrt{b} \right\} \end{aligned}$$

where, $b = \frac{\pi(\alpha z)^2}{2}$, and F is the distance between the jet foci (for a passenger jet).

Finally, the pressure exerted on an airbag element in view of the jet is given as:

$$p_{r,z} = \beta \rho_0 v_{r,z}^2$$

By combining the equations above

$$p_{r,z} = \frac{\beta \dot{m} v_{\text{outlet}} \left[e^{-(r/\alpha z)^2} \right]^2}{\left\{ \frac{\pi(\alpha z)^2}{2} + F\sqrt{\frac{\pi(\alpha z)^2}{2}} \right\}}$$

The total force exerted by the jet is given by

$$F_{\text{jet}} = \dot{m} v_{\text{outlet}} \ ,$$

which is independent of the distance from the nozzle. Mass flow in the jet is not necessarily conserved, because gas is entrained into the jet from the surrounding volume. By contrast, the standard LS-DYNA jetting formulation conserves mass flow but not momentum. This has the effect of making the jet force reduce with distance from the nozzle.

The jetting forces can be reacted onto a node (NREACT), to allow the reaction force through the steering column or the support brackets to be modeled. The jetting force is written to the ASCII abstat file and the binary xtf file.

*AIRBAG_LOAD_CURVE_{OPTION}

Card Summary:

The additional card required for the LOAD_CURVE option is Card 3. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if and only if the ID keyword option is used. To use the *AIRBAG_INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF

Card 2a. This card is read when RBID > 0.

N							

Card 2a.1. This card is read when RBID > 0. Define N constants for the user subroutine. Include only the number of cards necessary, that is, for nine constants use 2 cards.

C1	C2	C3	C4	C5			

Card 2b.1. This card is read when RBID < 0.

AX	AY	AZ	AMAG	TDUR			

Card 2b.2. This card is read when RBID < 0.

DVX	DVY	DVZ	DVMAG				

Card 2b.3. This card is read when RBID < 0.

UX	UY	UZ	UMAG				

Card 3. This card is required.

STIME	LCID	RO	PE	PO	T	TO	

Data Card Definitions:

Card 3	1	2	3	4	5	6	7	8
Variable	STIME	LCID	RO	PE	P0	T	T0	
Type	F	I	F	F	F	F	F	
Default	0.0	none	none	none	none	none	none	

VARIABLE	DESCRIPTION
STIME	Time at which pressure is applied. LCID is offset by this amount.
LCID	Load curve ID defining pressure as a function of time; see *DEFINE_CURVE.
RO	Initial density of gas (ignored if LCID > 0)
PE	Ambient pressure (ignored if LCID > 0)
P0	Initial gauge pressure (ignored if LCID > 0)
T	Gas Temperature (ignored if LCID > 0)
T0	Absolute zero on temperature scale (ignored if LCID > 0)

Remarks:

Within this simple model the control volume is inflated with a pressure defined as a function of time or calculated using the following equation if LCID = 0.

$$P_{\text{total}} = C\rho(T - T_0)$$

$$P_{gauge} = P_{\text{total}} - P_{\text{ambient}}$$

The pressure is uniform throughout the control volume.

*AIRBAG_LINEAR_FLUID_{OPTION}

Card Summary:

The additional cards required for the LINEAR_FLUID option begin with Card 3. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if and only if the ID keyword option is used. To use the *AIRBAG_INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

Card 2b.3. This card is read when RBID < 0.

UX	UY	UZ	UMAG				

Card 3. This card is required.

BULK	RO	LCINT	LCOUTT	LCOUTP	LCFIT	LCBULK	LCID

Card 4. This card is optional.

P_LIMIT	P_LIMLC	NONULL					

Data Card Definitions:

Card 3	1	2	3	4	5	6	7	8
Variable	BULK	RO	LCINT	LCOUTT	LCOUTP	LCFIT	LCBULK	LCID
Type	F	F	I	I	I	I	I	I
Default	none	none	none	optional	optional	optional	optional	none

VARIABLE	DESCRIPTION
BULK	K, bulk modulus of the fluid in the control volume. Constant as a function of time. Define if LCBULK = 0.
RO	ρ, density of the fluid
LCINT	$F(t)$, input flow curve defining mass per unit time as a function of time; see *DEFINE_CURVE.
LCOUTT	$G(t)$, output flow curve defining mass per unit time as a function of time. This load curve is optional.
LCOUTP	$H(p)$, output flow curve defining mass per unit time as a function of pressure. This load curve is optional.
LFIT	$L(t)$, added pressure as a function of time. This load curve is optional.
LCBULK	Curve defining the bulk modulus as a function of time. This load curve is optional, but if defined, the constant, BULK, is not used.
LCID	Load curve ID defining pressure as a function of time; see *DEFINE_CURVE.

Card 4 is optional.

Card 4	1	2	3	4	5	6	7	8
Variable	P_LIMIT	P_LIMLC	NONULL					
Type	F	I	I					
Default	optional	optional	optional					

VARIABLE	DESCRIPTION
P_LIMIT	Limiting value on total pressure (optional)
P_LIMLC	Curve defining the limiting pressure value as a function of time. If nonzero, P_LIMIT is ignored.
NONULL	A flag determining whether pressure is applied on null material parts (see Remark 2): EQ.0: apply pressure everywhere inside the airbag. NE.0: do not apply pressure on null material part of the airbag.

Remarks:

1. **Pressure and Mass Flow Rate.** This model is intended for the simulation of hydroforming processes or similar problems. The pressure is controlled by the mass flowing into the volume and by the current volume. The pressure is uniformly applied to the control volume.

   If LCID = 0 then the pressure is determined from:

$$P(t) = K(t)\ln\left[\frac{V_0(t)}{V(t)}\right] + L(t) \ ,$$

   where

$$\begin{aligned} P(t) &= \text{Pressure,} \\ V(t) &= \text{Volume of fluid in compressed state,} \\ V_{0(t)} &= V_0(t) \\ &= \frac{M(t)}{\rho} \\ &= \text{Volume of fluid in uncompressed state,} \\ M(t) &= M(0) + \int F(t)dt - \int G(t)dt - \int H(p)dt \\ &= \text{Current fluid mass,} \end{aligned}$$

$$M(0) = V(0)\rho$$
$$= \text{Mass of fluid at time zero } P(0) = 0.$$

By setting LCID ≠ 0 a pressure time history may be specified for the control volume and the mass of fluid within the volume is then calculated from the volume and density.

Note the signs used in the equation for $M(t)$. The mass flow should always be defined as positive since the output flow is subtracted.

2. **NONULL.** The NONULL flag is useful for hydroforming simulations. In this type of simulation, the part set that makes up the airbag will usually include a part ID of null shells, defined by *MAT_NULL. The null shells together with a deformable sheet blank will form an airbag, which upon pressurization, will push the blank into a die cavity. This feature is available in SMP as of Dev 136254.

***AIRBAG_HYBRID**_{OPTIONS}

***AIRBAG_HYBRID_JETTING**_{OPTIONS}

Card Summary:

The additional cards required for HYBRID and HYBRID_JETTING options begin with Card 3. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if the ID keyword option is used. To use the *AIRBAG_-INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF

Card 7. This card is included for HYBRID_JETTING only.

XSJFP	YSJFP	ZSJFP	PSID	IDUM	NODE1	NODE2	NODE3

Card 8. This card is included if the CM keyword option is used with HYBRID_JETTING.

NREACT							

Data Card Definitions:

Card 3	1	2	3	4	5	6	7	8
Variable	ATMOST	ATMOSP	ATMOSD	GC	CC	HCONV		
Type	F	F	F	F	F	F		
Default	none	none	none	none	1.0	none		

VARIABLE	DESCRIPTION
ATMOST	Atmospheric temperature
ATMOSP	Atmospheric pressure
ATMOSD	Atmospheric density
GC	Universal molar gas constant

VARIABLE	DESCRIPTION
CC	Conversion constant EQ.0.0: Set to 1.0
HCONV	Effective heat transfer coefficient between the gas in the air bag and the environment at temperature at ATMOST. If HCONV < 0.0, then HCONV defines a load curve of data pairs (time, hconv).

Card 4	1	2	3	4	5	6	7	8
Variable	C23	LCC23	A23	LCA23	CP23	LCP23	AP23	LCAP23
Type	F	I	F	I	F	I	F	I
Default	none	0	none	0	none	0	none	0

VARIABLE	DESCRIPTION
C23	Vent orifice coefficient which applies to exit hole. Set to zero if LCC23 is defined below.
LCC23	The absolute value, |LCC23|, is a load curve ID. If the LCC23 is positive, the load curve defines the vent orifice coefficient which applies to the exit hole as a function of time. If the LCC23 is negative, the vent orifice coefficient is defined as a function of relative pressure, P_{air}/P_{bag}; see [Anagonye and Wang 1999]. In addition, LCC23 can be defined through *DEFINE_CURVE_FUNCTION. A nonzero value for C23 overrides LCC23.
A23	If defined as a positive number, A23 is the vent orifice area which applies to the exit hole. If defined as a negative number, with LCA23 ≠ -1, the absolute value |A23| is a part ID; see [Anagonye and Wang 1999]. With LCA23 = -1, a negative A23 represents venting holes by a part set |A23|. The venting leakage through each venting hole represented by a part in part set |A23| is output to abstat. The area of this part/set becomes the vent orifice area. With SIDTYP > 0, airbag pressure will not be applied to part/set |A23| representing venting holes if part/set |A23| is not included in SID, the part set representing the airbag. Set A23 to zero if a positive LCA23 is defined below.
LCA23	Load curve ID defining the vent orifice area which applies to exit

VARIABLE	DESCRIPTION
	hole as a function of *absolute* pressure, or LCA23 can be defined through *DEFINE_CURVE_FUNCTION. A nonzero value for A23 overrides LCA23.
CP23	Orifice coefficient for leakage (fabric porosity). Set to zero if LCCP23 is defined below.
LCCP23	Load curve ID defining the orifice coefficient for leakage (fabric porosity) as a function of time, or LCCP23 can be defined through *DEFINE_CURVE_FUNCTION. A nonzero value for CP23 overrides LCCP23.
AP23	Area for leakage (fabric porosity)
LCAP23	Load curve ID defining the area for leakage (fabric porosity) as a function of (absolute) pressure, or LCAP23 can be defined through *DEFINE_CURVE_FUNCTION. A nonzero value for AP23 overrides LCAP23.

Card 5	1	2	3	4	5	6	7	8
Variable	OPT	PVENT	NGAS	LCEFR	LCIDM0	VNTOPT		
Type	I	F	I	I	I	I		
Default	none	none	none	0	0	0		

VARIABLE	DESCRIPTION
OPT	Fabric venting option; if nonzero CP23, LCCP23, AP23, and LCAP23 are set to zero. Porosity leakage of each material is output to abstat. EQ.1: Wang-Nefske formulas for venting through an orifice are used. Blockage is not considered. EQ.2: Wang-Nefske formulas for venting through an orifice are used. Blockage of venting area due to contact is considered. EQ.3: Leakage formulas of Graefe, Krummheuer, and Siejak [1990] are used. Blockage is not considered. EQ.4: Leakage formulas of Graefe, Krummheuer, and Siejak

VARIABLE	DESCRIPTION
	[1990] are used. Blockage of venting area due to contact is considered. EQ.5: Leakage formulas based on flow through a porous media are used. Blockage due to contact is not considered. EQ.6: Leakage formulas based on flow through a porous media are used. Blockage due to contact is considered. EQ.7: Leakage is based on gas volume outflow versus pressure load curve. Blockage of flow area due to contact is not considered. Absolute pressure is used in the porous-velocity-versus-pressure load curve, given as FAC(P) in the *MAT_FABRIC card. EQ.8: Leakage is based on gas volume outflow versus pressure load curve. Blockage of flow area due to contact is considered.
PVENT	Gauge pressure when venting begins
NGAS	Number of gas inputs to be defined below (including initial air). The maximum number of gases is 17.
LCEFR	Optional curve for exit flow rate (mass/time) versus (gauge) pressure
LCIDM0	Optional curve representing inflator's total mass inflow rate. When defined, LCIDM in the following 2 × NGAS cards defines the molar fraction of each gas component as a function of time and INITM defines the initial molar ratio of each gas component.
VNTOPT	Additional options for venting area definition. For A23 ≥ 0 EQ.1: Vent area is equal to A23. EQ.2: Vent area is A23 plus the eroded surface area of the airbag parts. EQ.10: Same as VNTOPT = 2 For A23 < 0 EQ.1: Vent area is the increase in surface area of part |A23|. If there is no change in surface area of part |A23| over the initial surface area or if the surface area reduces from the initial area, there is no venting.

VARIABLE	DESCRIPTION
	EQ.2: Vent area is the total (not change in) surface area of part |A23| plus the eroded surface area of all other parts comprising the airbag.
	EQ.10: Vent area is the increase in surface area of part |A23| plus the eroded surface area of all other parts comprising the airbag.

Include NGAS pairs of Cards 5.1 and 5.2

Card 5.1	1	2	3	4	5	6	7	8
Variable	LCIDM	LCIDT		MW	INITM	A	B	C
Type	I	I		F	F	F	F	F
Default	none	none		none	none	none	none	none

Include NGAS pairs of Cards 5.1 and 5.2.

Card 5.2	1	2	3	4	5	6	7	8
Variable	FMASS							
Type	F							
Default	none							

VARIABLE	DESCRIPTION
LCIDM	Load curve ID for inflator mass flow rate (equal to 0 for gas in the bag at time = 0)
	GT.0: Piecewise linear interpolation
	LT.0: Cubic spline interpolation
LCIDT	Load curve ID for inflator gas temperature (equal to 0 for gas in the bag at time = 0)
	GT.0: Piecewise linear interpolation

VARIABLE	DESCRIPTION
	LT.0: Cubic spline interpolation
MW	Molecular weight
INITM	Initial mass fraction of gas component present in the airbag, prior to injection of gas by the inflator. INITM is used to calculate the averaged gas properties and the initial mass of all gas components, assuming that the airbag is initially at ambient temperature and under ambient pressure. The sum of INITM of all gas components should be 1.0.
A	Coefficient for molar heat capacity of inflator gas at constant pressure, (e.g., Joules/mole/^oK)
B	Coefficient for molar heat capacity of inflator gas at constant pressure, (e.g., Joules/mole/$^oK^2$)
C	Coefficient for molar heat capacity of inflator gas at constant pressure, (e.g., Joules/mole/$^oK^3$)
FMASS	Fraction of additional aspirated mass

Additional Cards required for HYBRID_JETTING and HYBRID_JETTING_CM:

The following two additional cards are defined for the HYBRID_JETTING options. The jet may be defined by specifying either the coordinates of the jet focal point, jet vector head and secondary jet focal point, or by specifying three nodes located at these positions. The nodal point option is recommended when the location of the airbag changes as a function of time.

Card 6	1	2	3	4	5	6	7	8
Variable	XJFP	YJFP	ZJFP	XJVH	YJVH	ZJVH	CA	BETA
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none
Remark	1	1	1	1	1	1		

VARIABLE	DESCRIPTION
XJFP	x-coordinate of jet focal point, that is., the virtual origin in Figures 3-1 and 3-2. See Remark 1 below.
YJFP	y-coordinate of jet focal point, that is, the virtual origin in Figures 3-1 and 3-2.
ZJFP	z-coordinate of jet focal point, that is, the virtual origin in Figures 3-1 and 3-2.
XJVH	x-coordinate of jet vector head to defined cone centerline
YJVH	y-coordinate of jet vector head to defined cone centerline
ZJVH	z-coordinate of jet vector head to defined cone centerline
CA	Cone angle, α, defined in radians. LT.0.0: $\lvert\alpha\rvert$ is the load curve ID defining cone angle as a function of time
BETA	Efficiency factor, β, which scales the final value of pressure obtained from Bernoulli's equation. LT.0.0: $\lvert\beta\rvert$ is the load curve ID defining the efficiency factor as a function of time

Card 7	1	2	3	4	5	6	7	8
Variable	XSJFP	YSJFP	ZSJFP	PSID	IDUM	NODE1	NODE2	NODE3
Type	F	F	F	I	F	I	I	I
Default	none	none	none	none	none	0	0	0
Remark					2	1	1	1

VARIABLE	DESCRIPTION
XSJFP	x-coordinate of secondary jet focal point, passenger side bag. If the coordinate of the secondary point is (0,0,0), then a conical jet (driver's side airbag) is assumed.

VARIABLE	DESCRIPTION
YSJFP	y-coordinate of secondary jet focal point
ZSJFP	z-coordinate of secondary jet focal point
PSID	Optional part set ID; see *SET_PART. If zero, all elements are included in the airbag.
IDUM	Dummy field (variable not used)
NODE1	Node ID located at the jet focal point, that is, the virtual origin in Figures 3-1 and 3-2 . See Remark 1 below.
NODE2	Node ID for node along the axis of the jet. See Figures 3-1 and 3-2.
NODE3	Optional node ID located at secondary jet focal point. See Figure 3-2.

Additional card required for HYBRID_JETTING_CM option.

Card 8	1	2	3	4	5	6	7	8
Variable	NREACT							
Type	I							
Default	none							
Remark	4							

VARIABLE	DESCRIPTION
NREACT	Node for reacting jet force. If zero the jet force will not be applied.

Remarks:

1. **Jetting.** It is assumed that the jet direction is defined by the coordinate method (XJFP, YJFP, ZJFP) and (XJVH, YJVH, ZJVH) unless both NODE1 and NODE2 are defined. In which case the coordinates of the nodes given by NODE1, NODE2 and NODE3 will override (XJFP, YJFP, ZJFP) and (XJVH, YJVH, ZJVH). The use of nodes is recommended if the airbag system is undergoing rigid body motion. The nodes should be attached to the vehicle to

allow for the coordinates of the jet to be continuously updated with the motion of the vehicle.

The jetting option provides a simple model to simulate the real pressure distribution in the airbag during the breakout and early unfolding phase. Only the surfaces that are in the line of sight to the virtual origin have an increased pressure applied. With the optional load curve LCRJV, the pressure distribution with the code can be scaled according to the so-called relative jet velocity distribution.

For passenger side airbags the cone is replaced by a wedge type shape. The first and secondary jet focal points define the corners of the wedge and the angle α then defines the wedge angle.

Instead of applying pressure to all surfaces in the line of sight of the virtual origin(s), a part set can be defined to which the pressure is applied.

2. **IDUM.** This variable is not used and has been included to maintain the same format as the WANG_NEFSKE_JETTING options.

3. **Focal Point Placement.** Care must be used to place the jet focal point within the bag. If the focal point is outside the bag, inside surfaces will not be visible so jetting pressure will not be applied correctly.

4. **NREACT.** See the description related to the WANG_NEFSKE_JETTING_CM option. For the hybrid inflator model the heat capacities are compute from the combination of gases which inflate the bag.

*AIRBAG_HYBRID_CHEMKIN_{OPTION}

Card Summary:

The HYBRID_CHEMKIN model includes 3 control cards (Cards 3 – 5). For each gas species an additional set of cards must follow consisting of a control card (Card 6) and several thermodynamic property data cards. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if and only if the ID keyword option is used. To use the *AIRBAG_INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF

Card 2a. This card is read when RBID > 0.

N							

Card 2a.1. This card is read when RBID > 0. Define N constants for the user subroutine. Include only the number of cards necessary, that is, for nine constants use 2 cards.

C1	C2	C3	C4	C5			

Card 2b.1. This card is read when RBID < 0.

AX	AY	AZ	AMAG	TDUR			

Card 2b.2. This card is read when RBID < 0.

LCIDM	LCIDT	NGAS	DATA	ATMT	ATMP	RG	

Card 4. This card is required.

HCONV							

Card 5. This card is required.

C23	A23						

Card 6. For each gas species (see NGAS on Card 3), include one of this card followed by several thermo-dynamic property data cards whose format depends on the DATA field on Card 3. The next keyword ("*") card terminates this input.

CHNAME	MW	LCIDN	FMOLE	FMOLET			

Card 7a.1. This card is included if and only if DATA = 1.

TLOW	TMID	THIGH					

Card 7a.2. This card is included if and only if DATA = 1.

ALOW	BLOW	CLOW	DLOW	ELOW	FLOW	HLOW	

Card 7a.3. This card is included if and only if DATA = 1.

AHIGH	BHIGH	CHIGH	DHIGH	EHIGH	FHIGH	HHIGH	

Card 7b. This card is included if and only if DATA = 3.

A	B	C	D	E			

Data Card Definitions:

Card 3	1	2	3	4	5	6	7	8
Variable	LCIDM	LCIDT	NGAS	DATA	ATMT	ATMP	RG	
Type	I	I	I	I	F	F	F	

VARIABLE	DESCRIPTION
LCIDM	Load curve specifying input mass flow rate as a function of time: GT.0: piece wise linear interpolation LT.0: cubic spline interpolation

VARIABLE	DESCRIPTION
LCIDT	Load curve specifying input gas temperature as a function of time: GT.0: piece wise linear interpolation LT.0: cubic spline interpolation
NGAS	Number of gas inputs to be defined below (including initial air)
DATA	Thermodynamic database (see remarks): EQ.1: NIST database (3 additional property cards are required below) EQ.2: CHEMKIN database (no additional property cards are required) EQ.3: Polynomial data (1 additional property card is required below)
ATMT	Atmospheric temperature
ATMP	Atmospheric pressure
RG	Universal gas constant

Card 4	1	2	3	4	5	6	7	8
Variable	HCONV							
Type	F							
Default	0.							

VARIABLE	DESCRIPTION
HCONV	Effective heat transfer coefficient between the gas in the air bag and the environment at temperature ATMT. If HCONV < 0, then HCONV defines a load curve of data pairs (time, hconv).

Card 5	1	2	3	4	5	6	7	8
Variable	C23	A23						
Type	F	F						
Default	0.	0.						

VARIABLE	DESCRIPTION
C23	Vent orifice coefficient
A23	Vent orifice area

Gas Species Control Card. For each gas species include a set of cards consisting of this card followed by several thermo-dynamic property data cards whose format depends on the DATA field on Card 3. The next keyword ("*") card terminates this input.

Card 6	1	2	3	4	5	6	7	8
Variable	CHNAME	MW	LCIDN	FMOLE	FMOLET			
Type	A	F	I	F	F			
Default	none	none	0	none	0.			

VARIABLE	DESCRIPTION
CHNAME	Chemical symbol for this gas species (e.g., N2 for nitrogen, AR for argon). Required for DATA = 2 (CHEMKIN), optional for DATA = 1 or DATA = 3.
MW	Molecular weight of this gas species.
LCIDN	Load curve specifying the input mole fraction versus time for this gas species. If > 0, FMOLE is not used.
FMOLE	Mole fraction of this gas species in the inlet stream.
FMOLET	Initial mole fraction of this gas species in the tank.

NIST Data Cards. Include this card if DATA = 1. The required data can be found on the NIST web site at http://webbook.nist.gov/chemistry/.

Card 7a.1	1	2	3	4	5	6	7	8
Variable	TLOW	TMID	THIGH					
Type	F	F	F					
Default	none	none	none					

NIST Data Cards. Include this card if DATA = 1. The required data can be found on the NIST web site at http://webbook.nist.gov/chemistry/.

Card 7a.2	1	2	3	4	5	6	7	8
Variable	ALOW	BLOW	CLOW	DLOW	ELOW	FLOW	HLOW

Default	none	none	none	none	none	none	none	

NIST Data Cards. Include this card if DATA = 1. The required data can be found on the NIST web site at http://webbook.nist.gov/chemistry/.

Card 7a.3	1	2	3	4	5	6	7	8
Variable	AHIGH	BHIGH	CHIGH	DHIGH	EHIGH	FHIGH	HHIGH	
Type	F	F	F	F	F	F	F	
Default	none	none	none	none	none	none	none	

VARIABLE	DESCRIPTION
TLOW	Curve fit low temperature limit
TMID	Curve fit low-to-high transition temperature
THIGH	Curve fit high temperature limit

VARIABLE	DESCRIPTION
ALOW, …, HLOW	Low temperature range NIST polynomial curve fit coefficients (see remarks)
AHIGH, …, HIGH	High temperature range NIST polynomial curve fit coefficients (see remarks)

Polynomial Fit Card. This card is included if DATA = 3.

Card 7b	1	2	3	4	5	6	7	8
Variable	A	B	C	D	E			
Type	F	F	F	F	F			
Default	none	0.	0.	0.	0.			

VARIABLE	DESCRIPTION
A	Coefficient; see remarks.
B	Coefficient; see remarks.
C	Coefficient; see remarks.
D	Coefficient; see remarks.
E	Coefficient; see remarks.

Remarks:

Specific heat curve fits:

$$\text{NIST:} \quad c_p = \frac{1}{M}\left(a + bT + cT^2 + dT^3 + \frac{e}{T^2}\right)$$

$$\text{CHEMKIN:} \quad c_p = \frac{\overline{R}}{M}\left(a + bT + cT^2 + dT^3 + eT^4\right)$$

$$\text{POLYNOMIAL:} \quad c_p = \frac{1}{M}\left(a + bT + cT^2 + dT^3 + eT^4\right)$$

where,

$\overline{R}$ = universal gas constant $8.314 \dfrac{\text{Nm}}{\text{mole} \times K}$

M = gas molecular weight

*AIRBAG_FLUID_AND_GAS_{OPTION}

Card Summary:

The additional cards required for the AIRBAG_FLUID_AND_GAS option begin with Card 3. See the "core cards" section of *AIRBAG for cards preceding Card 3.

Card ID. This card is included if and only if the ID keyword option is used. To use the *AIRBAG_INTERACTION keyword ID Cards are required.

ABID	HEADING

Card 1. This card is required.

SID	SIDTYP	RBID	VSCA	PSCA	VINI	MWD	SPSF

Card 2a. This card is read when RBID > 0.

N							

Card 2a.1. This card is read when RBID > 0. Define N constants for the user subroutine. Include only the number of cards necessary, that is, for nine constants use 2 cards.

C1	C2	C3	C4	C5			

Card 2b.1. This card is read when RBID < 0.

AX	AY	AZ	AMAG	TDUR			

Card 2b.2. This card is read when RBID < 0.

DVX	DVY	DVZ	DVMAG				

Card 2b.3. This card is read when RBID < 0.

UX	UY	UZ	UMAG				

Card 3. This card is required.

XWINI	XWADD	XW	P	TEND	RHO	LCXW	LCP

Card 4. This card is required.

GDIR	NPROJ	IDIR	IIDIR	KAPPA	KBM		

Data Card Definitions:

Additional cards required for FLUID_AND_GAS option. (For card 1 see the "core cards" section of *AIRBAG.) Currently this option only works in SMP and explicit analysis.

Card 3	1	2	3	4	5	6	7	8
Variable	XWINI	XWADD	XW	P	TEND	RHO	LCXW	LCP
Type	F	F	F	F	F	F	I	I
Default	none	none	none	none	none	none	none	none

Card 4	1	2	3	4	5	6	7	8
Variable	GDIR	NPROJ	IDIR	IIDIR	KAPPA	KBM		
Type	F	I	I	I	F	F		
Default	none	3	none	none	1.0	none		

VARIABLE	DESCRIPTION
XWINI	Fluid level at time $t = 0$ in |GDIR| direction
XWADD	Fluid level filling increment per time step
XW	Final fluid level in filling process
P	Gas pressure at time t = TEND
TEND	Time when gas pressure P is reached
RHO	Density of the fluid (for example, for water, RHO ≈ 1.0 kg/m^3)
LCXW	Load curve ID for fluid level as a function of time. XW, XWADD, and XWINI are ignored with this option.
LCP	Load curve ID for gas pressure as a function of time. P and TEND are ignored with this option.

VARIABLE	DESCRIPTION
GDIR	Global direction of gravity. Use negative numbers for the negative direction, such as -3.0 for the negative global z-axis. EQ.1.0: Global x-direction EQ.2.0: Global y-direction EQ.3.0: Global z-direction
NPROJ	Number of projection directions (only global axis) for volume calculation
IDIR	First direction of projection (if |NPROJ| ≠ 3), only global axis.
IIDIR	Second direction of projection (if |NPROJ| = 2), only global axis.
KAPPA	Adiabatic exponent
KBM	Bulk modulus of the fluid (e.g. for water, BKM ≈ 2080 N/mm^2)

Remarks:

The *AIRBAG_FLUID_AND_GAS option models a quasi-static multi chamber fluid/gas structure interaction in a simplified way including three possible load cases: (i) only gas, (ii) only incompressible fluid, or (iii) the combination of incompressible fluid with additional gas "above." See Figure 3-5.

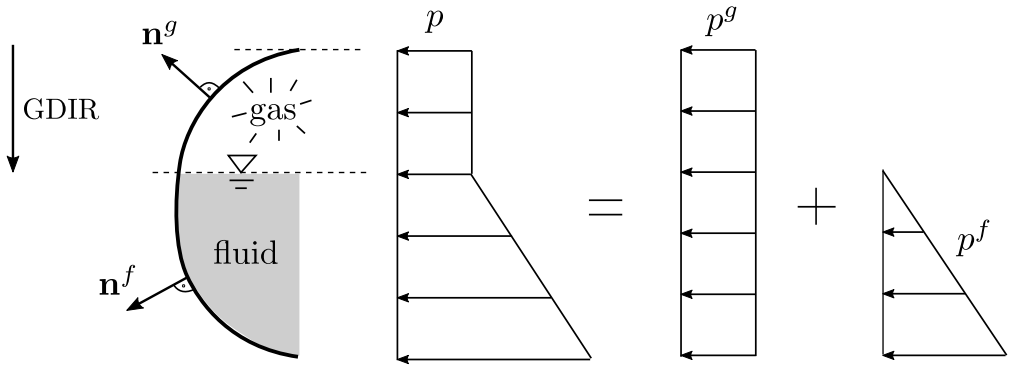

Figure 3-5. Hydrostatic pressure distribution in a chamber filled with gas and incompressible fluid

The theory is based on the description of gases and fluids as energetically equivalent pressure loads. The calculation of the fluid volume is carried out using the directions of projection and a non-normalized normal vector. This model, therefore, requires that the

normal of the shell elements belonging to a filled structure must point outwards. Holes are not detected, but can be taken into account as described below.

In case of a pure gas (no fluid), the *AIRBAG_SIMPLE_PRESSURE_VOLUME and *AIRBAG_FLUID_AND_GAS cards give identical results as they are based on the same theory. The update of the gas pressure due to volume change is calculated with the following simple gas law

$$p^g = \left(1 - \text{KAPPA} \times \frac{v^g - v^g_{\text{old}}}{v^g_{\text{old}}}\right) p^g_{\text{old}}$$

with adiabatic exponent KAPPA and gas volume v^g.

The theory of incompressible fluids is based on the variation of the potential energy and an update of the water level due to changes in the volume and the water surface, see Haßler and Schweizerhof [2007], Haßler and Schweizerhof [2008], Rumpel and Schweizerhof [2003], and Rumpel and Schweizerhof [2004].

In case of multiple fluid/gas filled chambers each chamber requires an additional *AIRBAG_FLUID_AND_GAS card. Some of the parameters which are called local parameters only belong to a single chamber (such as gas pressure). In contrast global, parameters belong to all chambers (such as the direction of gravitation).

Because the theory only applies to quasi-static fluid-structure interaction, the load must be applied slowly, so the kinetic energy is almost zero throughout the process.

All parameters input on Card 3 are local parameters describing the filling of the chamber. The water level and the gas pressure can be defined by curves using LCXW and LCP or by using the parameters XWINI, XW, XWADD, P and TEND. When describing the fluid and gas filling using the parameters, the gas pressure at time $t = 0$ is set to 0 and the initial water level is set to XWINI in |GDIR|-direction. At each timestep, XWADD is added to the water level, until XW is reached. The gas pressure will be raised until P is reached at time $t =$ TEND.

In general, global parameters belong to all chambers. To describe the global axis in GDIR, NPROJ, IDIR and IIDIR the following mapping applies: the x-axis is axis 1, the y-axis is axis 2, and the z-axis is axis 3.

The gas and fluid volume is calculated by using contour integrals in the global x-, y- and z-coordinates. If one of the boundaries is discontinuous in one or two global directions, these directions must be ignored in NPROJ, IDIR and IIDIR. At least one direction of projection must be set (NPROJ = 1, IDIR = value), but it is recommended to use as many directions of projection as possible.

In case of a structure filled exclusively with fluid, IDIR and IIDIR should not be set to |GDIR|. In case of holes in a structure (for example, take advantage of symmetry planes),

IDIR and IIDIR should not be set to the normal direction of the plane describing the hole or symmetry plane.

An example of a water filled tube structure illustrating how to use NPROJ, IDIR, IIDIR, and GDIR is shown in Figure 3-6. In this example gravity is acting opposite to the global z-axis. In this case, then, GDIR = -3. The structure is filled exclusively with water, so the projection direction cannot be set to |GDIR| = 3. To use the symmetry of the tube only half of the structure has been modeled. The normal of the symmetry plane is in the y-direction, so the projection direction cannot be set to 2. Because the symmetry axes (2 and 3) are not allowed, the only direction of projection is 1; therefore, NPROJ = 1 and IDIR = 1.

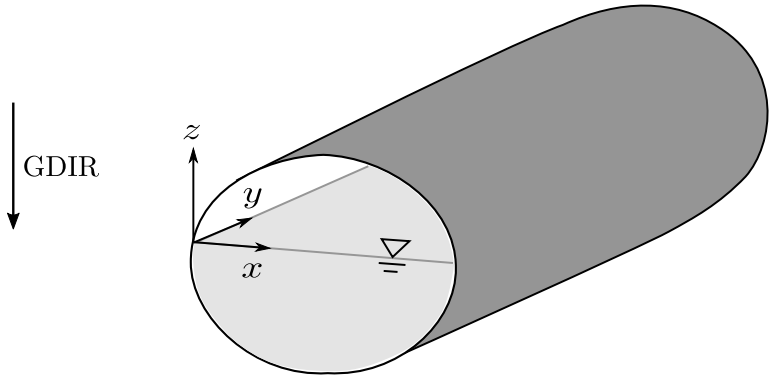

Figure 3-6. Example for water filled tube structure

For further explanations and examples see Haßler and Schweizerhof [2007], Haßler and Schweizerhof [2008], and Maurer, Gebhardt, and Schweizerhof [2010].

The possible entries for NPROJ, IDIR and IIDIR are:

NPROJ	IDIR	IIDIR
3		
2	1	2
2	1	3
2	2	3
1	1	
1	2	
1	3	

*AIRBAG_ALE

Purpose: Provide a simplified approach to defining the deployment of the airbag using the ALE capabilities with an option to switch from the initial ALE method to a control volume (CV) method similar to *AIRBAG_HYBRID at a chosen time. An enclosed airbag (and possibly the airbag canister/compartment and/or a simple representation of the inflator) shell structure interacts with the inflator gas(es). This definition provides a single fluid to structure coupling for the airbag-gas interaction during deployment in which the CV input data may be used directly.

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SID	SIDTYP					MWD	SPSF
Type	I	I					F	F
Default	none	none					0	0

VARIABLE	DESCRIPTION
SID	Set ID. This set ID contains the Lagrangian elements (segments) which make up the airbag and possibly the airbag canister/compartment and/or a simple representation of the inflator. See Remark 1.
SIDTYP	Set type: EQ.0: Segment set EQ.1: Part set
MWD	Mass weighted damping factor, D, used during the CV phase
SPSF	Stagnation pressure scale factor, $0 \leq \gamma \leq 1$. SPSF is needed during the CV phase.

Ambient Environment Card.

Card 2	1	2	3	4	5	6	7	8
Variable	ATMOST	ATMOSP		GC	CC	TNKVOL	TNKFINP	
Type	F	F		F	F	F	F	
Default	0.	0.		none	1.0	0.0	0.0	

VARIABLE	DESCRIPTION
ATMOST	Atmospheric ambient temperature. See Remark 2.
ATMOSP	Atmospheric ambient pressure. See Remark 2.
GC	Universal molar gas constant.
CC	Conversion constant. EQ.0: Set to 1.0.
TNKVOL	Tank volume from the inflator tank test or inflator canister volume. See Remark 9 and Card 6. **LCVEL = 0 and TNKFINP is defined:** TNKVOL is the defined tank. Inlet gas velocity is estimated by LS-DYNA method (testing). **LCVEL = 0 and TNKFINP is not defined:** TNKVOL is the estimated inflator canister volume inlet gas velocity is estimated automatically by the Lian-Bhalsod-Olovsson method. **LCVEL ≠ 0:** This must be left blank.
TNKFINP	Tank final pressure from the inflator tank test data. Only define this parameter for option 1 of TNKVOL definition above. See Remark 9.

Coupling Card. See keyword *CONSTRAINED_LAGRANGE_IN_SOLID.

Card 3	1	2	3	4	5	6	7	8
Variable	NQUAD	CTYPE	PFAC	FRIC	FRCMIN	NORMTYP	ILEAK	PLEAK
Type	I	I	F	F	F	I	I	F
Default	4	4	0.1	0.0	0.3	0	2	0.1

VARIABLE	DESCRIPTION
NQUAD	Number of (quadrature) coupling points for coupling Lagrangian parts to ALE solid parts. If NQUAD = n, then n × n coupling points will be parametrically distributed over the surface of each Lagrangian segment. See Remark 12.
CTYPE	Coupling type (see Remark 12): EQ.4: Penalty coupling with coupling in the normal direction under compression only (default). EQ.6: Penalty coupling in which coupling is under both tension and compression in the normal direction for the unfolded region and under only compression in the normal direction for folded region.
PFAC	Penalty factor. PFAC is a scale factor for scaling the estimated stiffness of the interacting (coupling) system. It is used to compute the coupling forces to be distributed on the Lagrangian and ALE parts. See Remark 13. GT.0: Fraction of estimated critical stiffness. LT.0: -PFAC is a load curve ID. The curve defines the relative coupling pressure (y-axis) as a function of the tolerable fluid penetration distance (x-axis).
FRIC	Coupling coefficient of friction
FRCMIN	Minimum fluid volume fraction in an ALE element to activate coupling.
NORMTYP	Penalty coupling spring direction: EQ.0: Normal vectors are interpolated from nodal normals.

VARIABLE	DESCRIPTION
	EQ.1: Normal vectors are interpolated from segment normals.
ILEAK	Leakage control flag. Default = 2 (with energy compensation).
PLEAK	Leakage control penalty factor (default = 0.1)

Venting Hole Card.

Card 4	1	2	3	4	5	6	7	8
Variable	IVSETID	IVTYPE	IBLOCK	VNTCOF				
Type	I	I	I	F				
Default	0	0	0	0.0				

VARIABLE	DESCRIPTION
IVSETID	Set ID defining the venting hole surface(s). See Remark 4.
IVTYPE	Set type of IVSETID: EQ.0: Part Set (default). EQ.1: Part ID. EQ.2: Segment Set.
IBLOCK	Flag for considering blockage effects for porosity and vents (see Remark 5): EQ.0: no (blockage is NOT considered, default). EQ.1: yes (blockage is considered).
VNTCOF	Vent Coefficient for scaling the flow. See Remark 6.

ALE Mesh from Part ID Card. Parameters for transformation of the ALE mesh specified with part IDs.

Card 5a	1	2	3	4	5	6	7	8
Variable	IDA	IDG	NZ	MOVERN	ZOOM			
Type	I	I	I	I	I			
Default	none	none	↓	0	0			

VARIABLE	DESCRIPTION
IDA	Part ID of the initial air mesh
IDG	Part ID of the initial gas mesh
NZ	Leave blank to activate.
MOVERN	ALE mesh automatic motion option. EQ.0: ALE mesh is fixed in space. GT.0: Node group ID. See *ALE_REFERENCE_SYSTEM_-NODE ALE mesh can be moved with PRTYP = 5, mesh motion follows a coordinate system defined by 3 reference nodes. See Remark 7.
ZOOM	ALE mesh automatic expansion option: EQ.0: Do not expand ALE mesh EQ.1: Expand/contract ALE mesh by keeping all airbag parts contained within the ALE mesh (equivalent to PRTYP = 9). See Remark 8.

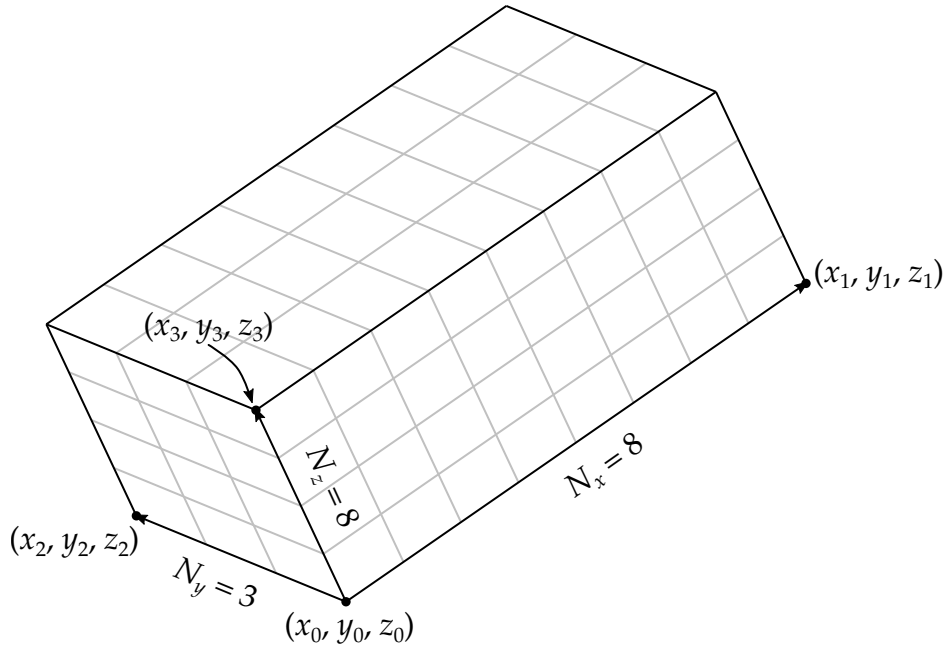

Figure 3-7. Illustration of automatic mesh generation for the ALE mesh in a hexahederal region

Automatic ALE Mesh Card. Parameters for ALE mesh automatic definition and its transformation. See Figure 3-7.

Card 5b	1	2	3	4	5	6	7	8
Variable	NX	NY	NZ	MOVERN	ZOOM			
Type	I	I	I	I	I			
Default	none	none	none	0	0			

VARIABLE	DESCRIPTION
NX	NX is the number of ALE elements to be generated in the x-direction.
NY	NY is the number of ALE elements to be generated in the y-direction.
NZ	NZ is the number of ALE elements to be generated in the z-direction.
MOVERN	ALE mesh automatic motion option.

VARIABLE	DESCRIPTION
	EQ.0: ALE mesh is fixed in space. GT.0: Node group ID. See *ALE_REFERENCE_SYSTEM_-NODE ALE mesh can be moved with PRTYP = 5, mesh motion follows a coordinate system defined by 3 reference nodes. See Remark 7.
ZOOM	ALE mesh automatic expansion option: EQ.0: Do not expand ALE mesh. EQ.1: Expand/contract ALE mesh by keeping all airbag parts contained within the ALE mesh (equivalent to PRTYP = 9). See Remark 8.

Origin for ALE Mesh Card. Include Cards 5b.1 and 5b.2 when NZ > 0.

Card 5b.1	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	X1	Y1	Z1		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

Card 5b.2	1	2	3	4	5	6	7	8
Variable	X2	Y2	Z2	Z3	Y3	Z3		
Type	F	F	F	F	F	F		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
X0, Y0, Z0	Coordinates of origin for ALE mesh generation (node0).
X1, Y1, Z1	Coordinates of point 1 for ALE mesh generation (node1). x-extent = node1 − node0

VARIABLE	DESCRIPTION
X2, Y2, Z2	Coordinates of point 2 for ALE mesh generation (node2). y-extent = node2 − node0
X3, Y3, Z3	Coordinates of point 3 for ALE mesh generation (node3). z-extent = node3 − node0

Miscellaneous Parameters Card.

Card 6	1	2	3	4	5	6	7	8
Variable	SWTIME		HG	NAIR	NGAS	NORIF	LCVEL	LCT
Type	F		F	I	I	I	I	I
Default	10^{16}		0.	0	0	0	0	0
Remarks	3						9	10

VARIABLE	DESCRIPTION
SWTIME	Time to switch from ALE method to control volume (CV) method. Once switched, a method similar to that used by the *AIRBAG_-HYBRID card is used.
HG	Hourglass control for ALE fluid mesh(es).
NAIR	Number of air components. For example, this equals 2 when air contains 80% of N_2 and 20% of O_2. If air is defined as a single gas, then NAIR = 1.
NGAS	Number of inflator gas components.
NORIF	Number of point sources or orifices. This determines the number of point source cards to be read.
LCVEL	Load curve ID for inlet velocity (see also TNKVOL & TNKFINP of Card 2 above). This is the same estimated velocity curve used in *SECTION_POINT_SOURCE_MIXTURE card.
LCT	Load curve ID for inlet gas temperature (see *AIRBAG_HYBRID).

Air Component Card. Include NAIR cards, one for each air component.

Card 7	1	2	3	4	5	6	7	8
Variable				MWAIR	INITM	AIRA	AIRB	AIRC
Type				F	F	F	F	F
Default				0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
MWAIR	Molecular weight of air component
INITA	Initial Mass Fraction of air component(s)
AIRA	First coefficient of molar heat capacity at constant pressure (e.g., J/mole/K). See Remark 11.
AIRB	Second coefficient of molar heat capacity at constant pressure (e.g., J/mole/K^2). See Remark 11.
AIRC	Third coefficient of molar heat capacity at constant pressure (e.g., J/mole/K^3). See Remark 11.

Gas Component Card. Include NGAS cards, one for each gas component.

Card 8	1	2	3	4	5	6	7	8
Variable	LCMF			MWGAS		GASA	GASB	GASC
Type	I			F		F	F	F
Default	none			0		0	0.	0.

VARIABLE	DESCRIPTION
LCMF	Load curve ID for mass flow rate (see *AIRBAG_HYBRID, e.g., kg/s). See Remark 11.
MWGAS	Molecular weight of inflator gas components.

VARIABLE	DESCRIPTION
GASA	First coefficient of molar heat capacity at constant pressure (e.g., J/mole/K). See Remark 11.
GASB	Second coefficient of molar heat capacity at constant pressure (e.g., J/mole/K^2). See Remark 11.
GASC	Third coefficient of molar heat capacity at constant pressure (e.g., J/mole/K^3). See Remark 11.

Point Source Cards. Include NORIF cards, one for each point source.

Card 9	1	2	3	4	5	6	7	8
Variable	NODEID	VECID	ORIFARE					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
NODEID	The node ID defining the point source.
VECID	The vector ID defining the direction of flow at the point source.
ORIFARE	The orifice area at the point source.

Remarks:

1. **Lagrangian Elements for Airbag Components.** This set ID typically contains the Lagrangian segments of the 3 parts that are coupled to the inflator gas: airbag, airbag canister (compartment), and inflator. As in all control-volume, orientation of elements representing bag and canister should point outward. During the ALE phase the segment normal will be reversed automatically for fluid-structure coupling. *However, the orientation of inflator element normal vectors should point to its center.* See Figure 3-8.

2. **Atmospheric Density.** Atmospheric density for the ambient gas (air) can be computed from

$$\rho_{\text{amb}} = \frac{P_{\text{amb}}}{RT_{\text{amb}}}$$

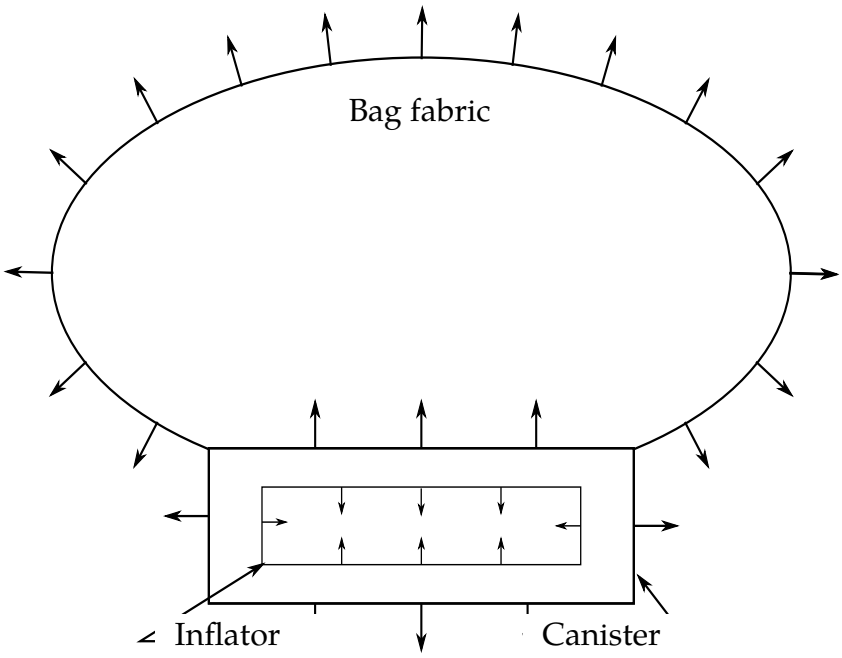

Figure 3-8. Arrows indicate "outward" normal

3. **ALE to Control Volume Switch.** Since *all* ALE related activities will be turned off after the switch from ALE method to control volume method, no other ALE coupling will exist beyond t = SWTIME.

4. **Venting.** Vent definition will be used for ALE venting. Upon switching, area of the segments will be used for venting as a23 in *AIRBAG_HYBRID.

5. **Fabric Porosity.** Fabric porosity for ALE and *AIRBAG_HYBRID can be defined on *MAT_FABRIC. Define FLC and FAC on *MAT_FABRIC. FVOPT 7 and 8 will be used for both ALE and *AIRBAG_HYBRID. IBLOCK = 0 will use FVOPT = 7 and IBLOCK = 1 will use FVOPT=8.

6. **Vent Coefficient.** VCOF will be used to scale the vent area for ALE venting and this coefficient will be used as vent coefficient c23 for *AIRBAG_HYBRID upon switching.

7. **ALE Mesh Motion.** If the airbag moves with the vehicle, set MOVERN = GROUPID; this GROUPID is defined using *ALE_REFERENCE_SYSTEM_NODE. The 3 nodes defined in *ALE_REFERENCE_SYSTEM_NODE will be used to transform the ALE mesh. The point sources will also follow this motion. This simulates PRTYP = 5 in the *ALE_REFERENCE_SYSTEM_GROUP card.

8. **Mesh Expansion.** Automatic expansion/contraction of the ALE mesh to follow the airbag expansion can be turned on by setting zoom = 1. This feature is particularly useful for fully folded airbags requiring very fine ale mesh initially. As

the airbag inflates the ale mesh will be automatically scaled such that the airbag will be contained within the ALE mesh. This simulates PRTYP = 9 in the *ALE_-REFERENCE_SYSTEM_GROUP card.

9. **Inlet Gas Velocity.** There are 3 methods for defining the inlet gas velocity:

   a) Inlet gas velocity is estimated by LS-DYNA method (testing), if

   $$\text{LCVEL} = 0 \Rightarrow \text{TNKVOL} = \text{Tank volume}$$

   and

   $$\text{TNKFINP} = \text{Tank final pressure from tank test data.}$$

   b) Inlet gas velocity is estimated automatically by Lian-Bhalsod-Olovsson method if,

   $$\text{LCVEL} = 0 \Rightarrow \text{TNKVOL} = \text{Tank volume.}$$

   and

   $$\text{TNKFINP} = \text{blank.}$$

   c) Inlet gas velocity is defined by user via a load curve LCVEL if,

   $$\begin{aligned}\text{LCVEL} &= \text{n,}\\ \text{TNKVOL} &= 0,\end{aligned}$$

   and

   $$\text{TNKFINP} = 0$$

10. **Sampling Points.** LCT and LCIDM should have the same number of sampling points.

11. **Heat Capacity at Constant Pressure.** The per-mass-unit, temperature-dependent, constant-pressure heat capacity is

$$C_p(T) = \frac{\left[A + BT + CT^2\right]}{MW}.$$

where,

$$A = \tilde{C}_{p_0}$$

these quantities often have units of,

$C_p(T)$	A	B	C
$\frac{\text{J}}{\text{kg} \times \text{K}}$	$\frac{\text{J}}{\text{mole} \times \text{K}}$	$\frac{\text{J}}{\text{mole} \times \text{K}^2}$	$\frac{\text{J}}{\text{mole} \times \text{K}^3}$

12. **Coupling.** Sometimes CTYPE = 6 may be used for a complex folded airbag. NQUAD = 2 may be used as a starting value and increased as necessary depending on the relative mesh resolutions of the Lagrangian and ALE meshes.

13. **PFAC.** Use a load curve for PFAC whenever possible. It tends to be more robust.

In this example, LS-DYNA automatically creates the background ALE mesh with:

NX = 11 ⇒ 11 elements in the *x*-direction
NY = 11 ⇒ 11 Elements in the *y*-direction
NZ = 9 ⇒ 9 Elements in the *z*-direction

*AIRBAG_INTERACTION

Purpose: To define two connected airbags which vent into each other.

Card 1	1	2	3	4	5	6	7	8
Variable	AB1	AB2	AREA	SF	PID	LCID	IFLOW	EXCP
Type	I	I	F	F	I	I	I	I
Default	none	none	none	none	0	0	0	0

VARIABLE	DESCRIPTION
AB1	First airbag ID, as defined on *AIRBAG card.
AB2	Second airbag ID, as defined on *AIRBAG card.
AREA	Orifice area between connected bags. LT.0.0: |AREA| is the load curve ID defining the orifice area as a function of absolute pressure. EQ.0.0: AREA is taken as the surface area of the part ID defined below.
SF	Shape factor. LT.0.0: |SF| is the load curve ID defining vent orifice coefficient as a function of relative time.
PID	Optional part ID of the partition between the interacting control volumes. AREA is based on this part ID. If PID is negative, the blockage of the orifice part due to contact is considered,
LCID	Load curve ID defining mass flow rate as a function of pressure difference, see *DEFINE_CURVE. If LCID is defined, AREA, SF and PID are ignored.
IFLOW	Flow direction LT.0: One way flow from AB1 to AB2 only. EQ.0: Two way flow between AB1 and AB2. GT.0: One way flow from AB2 to AB1 only.

VARIABLE	DESCRIPTION
EXCP	Excluding partition part, PID, from bag pressure application. This option applies to *AIRBAG_WANG_NEFSKE and *AIRBAG_HYBRID only. EQ.0: bag pressure will be applied to PID. EQ.1: PID is excluded from bag pressure application.

Remarks:

Mass flow rate and temperature load curves for the secondary chambers must be defined as null curves, for example, in the DEFINE_CURVE definitions give two points (0.0,0.0) and (10000.,0.0).

All input options are valid for the following airbag types:

*AIRBAG_SIMPLE_AIRBAG_MODEL

*AIRBAG_WANG_NEFSKE

*AIRBAG_WANG_NEFSKE_JETTING

*AIRBAG_WANG_NEFSKE_MULTIPLE_JETTING

*AIRBAG_HYBRID

*AIRBAG_HYBRID_JETTING

The LCID defining mass flow rate as a function of pressure difference may additionally be used with:

*AIRBAG_LOAD_CURVE

*AIRBAG_LINEAR_FLUID

If the AREA, SF, and PID are used to define the interaction, then the airbags must contain the same gas, that is, C_p, C_V and g must be the same. The flow between bags is governed by formulae which are similar to those of Wang-Nefske.

***AIRBAG_PARTICLE**_{OPTION1}_..._{OPTION6}

Available options include:

OPTION1 applies to the MPP implementation only.

MPP

OPTION2 also applies to the MPP implementation only. When the DECOMPOSITON option is present, LS-DYNA will automatically insert *CONTROL_MPP_DECOMPOSITION_BAGREF and *CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS keywords if they are not already present in the input.

DECOMPOSITION

With *OPTION3* you can specify an airbag ID and a heading for the airbag.

ID

TITLE

OPTION4:

MOLEFRACTION (see Remark 10)

INFLATION (see Remark 17)

JET (see Remark 18)

Include *OPTION5* to specify the airbag volume with a segment set:

SEGMENT

OPTION6 allows you to give the birth and death times for the current CPM airbag.

TIME

Purpose: To define an airbag using the particle method. This method is also sometimes referred to as CPM (Corpuscular Particle Method)

> **NOTE:** This model requires that surface normal vectors be oriented *inward*, unlike the traditional Control Volume or CV method (also known as Uniform Pressure or UP method) for which they must point *outward*. To check bag and chamber integrity, see the CPMERR option on the *CONTROL_CPM card.

Card Summary:

Card MPP. This card is included if the MPP keyword option is used.

SX	SY	SZ					

Card ID. This card is included if the ID or TITLE keyword options are used.

BAGID	HEADING	

Card T. This card is included if the TIME keyword option is used.

BIRTH	DEATH						

Card 1. This card is required.

SID1	STYPE1	SID2	STYPE2	BLOCK	NPDATA	FRIC	IRPD

Card 2. This card is included if the SEGMENT keyword option is used.

SEGSID							

Card 3. This card is required.

NP	UNIT	VISFLG	TATM	PATM	NVENT	TEND	TSW

Card 4. This card is included if the JET keyword option is used.

JNODE							

Card 5. When the card after Card 3 or 4 depending on if the JET keyword option is used begins with a "+" character, the input reader processes it as this card; otherwise this card is skipped.

TSTOP	TSMTH	OCCUP	REBL	SIDSV	PSID1	TSPLIT	SFFDC

Card 5.1. When Card 5 is included and the card after Card 5 begins with a "+" character, the input reader processes it as this card; otherwise, this card is skipped.

SFIAIR4	IDFRIC						

Card 6. This card is included if UNIT = 3. See Card 3.

	MASS		TIME		LENGTH		

Card 7. This card is required.

IAIR	NGAS	NORIF	NID1	NID2	NID3	CHM	CD_EXT

Card 8. This card is included when STYPE2 = 2 (see Card 1). Define SID2 cards, one for each internal part or part set.

SIDUP	STYUP	PFRAC	LINKING				

Card 9. Additional cards for NPDATA > 0 (see Card 1). Define NPDATA cards, one for each heat convection part or part set.

SIDH	STYPEH	HCONV	PFRIC	SDFBLK	KP	INIP	CP

Card 10. Define NVENT of this card (see Card 3).

SID3	STYPE3	C23	LCTC23	LCPC23	ENH_V	PPOP	

Card 11. This card is included when IAIR ≠ 0. See Card 7.

PAIR	TAIR	XMAIR	AAIR	BAIR	CAIR	NPAIR	NPRLX

Card 12. This card is included if the MOLEFRACTION keyword option is used.

LCMASS							

Card 13. Included NGAS of this card. See Card 7.

LCM*i*	LCT*i*	XM*i*	A*i*	B*i*	C*i*	INFG*i*	

Card 14. Include NORIF of this card. See Card 7.

NID*i*	AN*i*	VD*i*	CA*i*	INFO*i*	IMOM	IANG	CHM_ID

Data Card Definitions:

MPP Card. Additional card for MPP keyword option.

Card MPP	1	2	3	4	5	6	7	8
Variable	SX	SY	SZ					
Type	F	F	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
SX, SY, SZ	Scale factor for each direction used during the MPP decomposition. For instance, increasing SX from 1 to 10 increases the probability that the model is divided along the *x*-direction.

Title Card. Additional card for ID or TITLE keyword options.

Card ID	1	2	3	4	5	6	7	8
Variable	BAGID	HEADING						
Type	I	A60						

VARIABLE	DESCRIPTION
BAGID	Airbag ID. This must be a unique number. The BAGID is referenced in, for example, *INITIAL_AIRBAG_PARTICLE_POSITION.
HEADING	Airbag descriptor. It is suggested that unique descriptions be used.

TIME Card. Additional card for TIME keyword option.

Card T	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH						
Type	F	F						
Default	none	10^{20}						

VARIABLE	DESCRIPTION
BIRTH, DEATH	Time to activate/deactivate CPM algorithm. CPM particles will be generated after the birth time.

Card 1	1	2	3	4	5	6	7	8
Variable	SID1	STYPE1	SID2	STYPE2	BLOCK	NPDATA	FRIC	IRPD
Type	I	I	I	I	I	I	F	I
Default	none	0	0	0	0	0.0	0.0	0

VARIABLE	DESCRIPTION
SID1	Part or part set ID defining the complete airbag.
STYPE1	Set type: EQ.0: Part EQ.1: Part set
SID2	Part or part set ID defining the internal parts of the airbag
STYPE2	Set type: EQ.0: Part EQ.1: Part set EQ.2: Number of parts to read (not recommended for general use)
BLOCK	Blocking. Block must be set to a two-digit number $$\text{BLOCK} = \text{M} \times 10 + \text{N},$$ The 10's digit controls the treatment of particles that escape due to deleted elements (particles are always tracked and marked). M.EQ.0: Active particle method which causes particles to be put back into the bag. M.EQ.1: Particles are leaked through unmeshed vents. See Remark 3. M.EQ.2: Blockage logic is turned on when the contact pressure is greater than the bag/chamber pressure for the external vents. The 1's digit controls the treatment of leakage. N.EQ.0: Always consider porosity leakage without considering blockage due to contact.

VARIABLE	DESCRIPTION
	N.EQ.1: Check if airbag node is in contact or not. If yes, 1/4 (quad) or 1/3 (tri) of the segment surface will not have porosity leakage due to contact. N.EQ.2: Same as 1 but no blockage for external vents N.EQ.3: Same as 1 but no blockage for internal vents N.EQ.4: Same as 1 but no blockage for all vents.
NPDATA	Number of parts or part sets data
FRIC	Friction factor F_r if -1.0 < FRIC ≤ 1.0. Otherwise, LE.-1.0: |FRIC| is the curve ID which defines F_r as a function of the part pressure. GT.1.0: FRIC is the *DEFINE_FUNCTION ID that defines F_r. See Remark 2.
IRPD	Dynamic scaling of particle radius flag: EQ.0: Off EQ.1: On

SEGMENT Card. This card is included if the SEGMENT keyword option is used.

Card 2	1	2	3	4	5	6	7	8
Variable	SEGSID							
Type	I							

VARIABLE	DESCRIPTION
SEGSID	ID for a segment set. The segments define the volume and should belong to the parts from SID1.

Card 3	1	2	3	4	5	6	7	8
Variable	NP	UNIT	VISFLG	TATM	PATM	NVENT	TEND	TSW
Type	I	I	I	F	F	I	F	F
Default	200,000	0	0	293 K	1 atm	0	10^{10}	10^{10}

VARIABLE	DESCRIPTION
NP	Number of particles
UNIT	Unit system: EQ.0: kg-mm-ms-K EQ.1: SI EQ.2: tonne-mm-s-K EQ.3: User defined units (see Remark 11)
VISFLG	Visible particles. This field affects only the CPM database. See Remark 5. EQ.0: Default to 1 EQ.1: Output particle's coordinates, velocities, mass, radius, spin energy, translational energy EQ.2: Output reduced data set with coordinates only EQ.3: Suppress CPM database
TATM	Atmospheric temperature
PATM	Atmospheric pressure
NVENT	Number of vent hole parts or part sets
TEND	Time when all (NP) particles have entered bag. See Remark 14.
TSW	Time at which algorithm switches to control volumes.

Jet Card. This card is included if the JET keyword option is used.

Card 4	1	2	3	4	5	6	7	8
Variable	JNODE							
Type	I							

VARIABLE	DESCRIPTION
JNODE	Node ID on which to apply the reaction force from the thrust (see Remark 18)

Optional Control Cards. When the card after Card 3 or 4 depending on if the JET keyword option is used begins with a "+" character, the input reader processes it as this card; otherwise this card is skipped.

Card 5	1	2	3	4	5	6	7	8
Variable	TSTOP	TSMTH	OCCUP	REBL	SIDSV	PSID1	TSPLIT	SFFDC
Type	F	F	F	I	I	I	F	F
Default	10^{10}	1.0 ms	0.1	0	none	none	none	1.0

VARIABLE	DESCRIPTION
TSTOP	Time at which front tracking switches from IAIR = 4 to IAIR = 2. See Card 7.
TSMTH	To avoid sudden jumps in the pressure signal during switching, the front tracking is tapered during a transition period. If set to zero, the default time of 1.0 millisecond will be applied.
OCCUP	Particles occupy OCCUP percent of the airbag's volume (default = 10%). This field can be used to balance computational cost and signal quality. OCCUP ranges from 0.001 to 0.1.
REBL	If the option is ON, all energy stored from damping will be evenly distributed as vibrational energy to all particles. This improves the pressure calculation in certain applications. EQ.0: Off (Default)

VARIABLE	DESCRIPTION
	EQ.1: On
SIDSV	Part set ID for internal shell part. The volume occupied by this part is excluded from the bag volume. These internal parts must be consistently orientated for the excluded volume to be correctly calculated.
PSID1	Part set ID for external parts which have normals pointed outward. This option is usually used with an airbag integrity check when there are two CPM bags connected with bag interaction. Therefore, one of the bags can have the correct shell orientation but the shared parts for the second bag will have wrong orientation. This option will automatically flip the parts defined in this set in the second bag during integrity checking.
TSPLIT	Start time to activate particle splitting algorithm. See Remark 15.
SFFDC	Scale factor for the force decay constant. SFFDC has a range of [0.01,100.0]. The default value is 1.0. The value given here will replaced the values from *CONTROL_CPM.

Optional Control Cards. When Card 5 is included and the card after Card 5 begins with a "+" character, the input reader processes it as this card; otherwise this card is skipped.

Card 5.1	1	2	3	4	5	6	7	8
Variable	SFIAIR4	IDFRIC						
Type	F	I						
Default	1.0	0						

VARIABLE	DESCRIPTION
SFIAIR4	Scale factor for the ratio of initial air particles to inflator gas particles for IAIR = 4. Smaller values weaken the effect of gas front tracking.
IDFRIC	Direction of P2F impact force: EQ.0: No change (default) EQ.1: The force is applied in the segment normal direction.

Optional unit card. Additional card when UNIT = 3.

Card 6	1	2	3	4	5	6	7	8
Variable		MASS		TIME		LENGTH		
Type		F		F		F		
Default		none		none		none		

VARIABLE	DESCRIPTION
MASS, TIME, LENGTH	Conversion factor from current unit to MKS unit. For example, if the current unit is using kg-mm-ms, the input should be 1.0, 0.001, 0.001.

Card 7	1	2	3	4	5	6	7	8
Variable	IAIR	NGAS	NORIF	NID1	NID2	NID3	CHM	CD_EXT
Type	I	I	I	I	I	I	I	F
Default	0	none	none	0	0	0	None	0.

VARIABLE	DESCRIPTION
IAIR	Initial gas inside bag considered: EQ.0: No EQ.1: Yes, using control volume method. EQ.-1: Yes, using control volume method. In this case ambient air enters the bag when PATM is greater than bag pressure. EQ.2: Yes, using the particle method.

VARIABLE	DESCRIPTION
	EQ.4: Yes, using the particle method. Initial air particles are used for the gas front tracking algorithm, but they do not apply forces when they collide with a segment. Instead, a uniform pressure is applied to the airbag based on the ratio of air and inflator particles. In this case NPRLX must be negative so that forces are not applied by the initial air.
NGAS	Number of gas components
NORIF	Number of orifices
NID1 - NID3	Three nodes defining a moving coordinate system for the direction of flow through the gas inlet nozzles (Default = fixed system)
CHM	Chamber ID used in *DEFINE_CPM_CHAMBER. See Remark 7.
CD_EXT	Drag coefficient of the external air. If the value is not zero, the inertial effect from external air will be considered and forces will be applied in the normal direction on the exterior airbag surface. GT.0: Drag coefficient LT.0: Curve ID for time dependent drag coefficient Note: To model drag, ambient air properties must be defined via IAIR.

Internal Part Set Cards. Additional Cards for STYPE2 = 2. Define SID2 cards, one for each internal part or part set.

Card 8	1	2	3	4	5	6	7	8
Variable	SIDUP	STYUP	PFRAC	LINKING				
Type	I	I	F	I				
Default	none	none	0.	none				

VARIABLE	DESCRIPTION
SIDUP	Part or part set ID defining the internal parts that pressure will be applied to. This internal structure acts as a valve to control the external vent hole area. Pressure will be applied only after switch to UP (uniform pressure) using TSW.
STYUP	Set type: EQ.0: Part EQ.1: Part set
PFRAC	Fraction of pressure to be applied to the set (0.0 to 1.0). If PFRAC = 0.0, no pressure is applied to internal parts.
LINKING	Part ID of an internal part that is coupled to the external vent definition. The minimum area of this part or the vent hole will be used for actual venting area.

Heat Convection Part Set Cards. Additional cards for NPDATA > 0. Define NPDATA cards, one for each heat convection part or part set.

Card 9	1	2	3	4	5	6	7	8
Variable	SIDH	STYPEH	HCONV	PFRIC	SDFBLK	KP	INIP	CP
Type	I	I	F	F	F	F	I	F
Default	none	none	none	FRIC	1.0	0.	0	none

VARIABLE	DESCRIPTION
SIDH	Part or part set ID defining part data.
STYPEH	Set type: EQ.0: Part EQ.1: Part set EQ.2: Part. HCONV is the *DEFINE_CPM_NPDATA ID. EQ.3: Part set. HCONV is the *DEFINE_CPM_NPDATA ID.

VARIABLE	DESCRIPTION
HCONV	Convective heat transfer coefficient used to calculate heat loss from the airbag external surface to ambient. See *AIRBAG_HYBRID developments (Resp. P.O. Marklund). LT.0: |HCONV| is a load curve ID defines heat convection coefficient as a function of time. When STYPEH is greater than 1, HCONV is a *DEFINE_CPM_-NPDATA ID.
PFRIC	Friction factor F_r if -1.0 < PFRIC ≤ 1.0. Defaults to FRIC from Card 1 if undefined. Otherwise, LE.-1.0: |PFRIC| is the curve ID which defines F_r as a function of the part pressure. GT.1.0: PFRIC is the *DEFINE_FUNCTION ID that defines F_r. See Remark 2.
SDFBLK	Scaling down factor for blockage factor (Default = 1.0, no scaling down). The valid factor will be (0.0,1.0]. If 0.0, it will set to 1.0.
KP	Thermal conductivity of the part. See Remark 9.
INIP	Place initial air particles on surface. EQ.0: Yes (default) EQ.1: No This feature excludes surfaces from initial particle placement. This option is useful for preventing particles from being trapped between adjacent fabric layers.
CP	Specific heat (see Remark 16).

Vent Hole Card. Additional cards for NVENT > 0. Define NVENT cards, one for vent hole.

Card 10	1	2	3	4	5	6	7	8
Variable	SID3	STYPE3	C23	LCTC23	LCPC23	ENH_V	PPOP	
Type	I	I	F	I	I	I	F	
Default	0	none	1.0	0	0	0	0.0	

VARIABLE	DESCRIPTION
SID3	Part or part set ID defining vent holes.
STYPE3	Set type: EQ.0: Part EQ.1: Part set which each part being treated separately EQ.2: Part set and all parts are treated as one vent. See Remark 13.
C23	GE.0: Vent hole coefficient, a parameter of Wang-Nefske leakage. A value between 0.0 and 1.0 can be input. See Remark 1. LT.0: ID for *DEFINE_CPM_VENT. Some extended options can only be defined through *DEFINE_CPM_VENT. Please check this keyword for more information.
LCTC23	Load curve defining vent hole coefficient as a function of time. LCTC23 can be defined through *DEFINE_CURVE_FUNCTION. If omitted, a curve equal to 1.0 used. See Remark 1.
LCPC23	Load curve defining vent hole coefficient as a function of pressure. If omitted a curve equal to 1.0 is used. See Remark 1.
ENH_V	Enhanced venting option. See Remark 8. EQ.0: Off (default) EQ.1: On EQ.2: Two way flow for internal vent; treated as hole for external vent (see Remark 8)
PPOP	Pressure difference between interior and ambient pressure (PATM) to open the vent holes. Once the vents are open, they will stay open.

Air Card. Additional card for IAIR ≠ 0.

Card 11	1	2	3	4	5	6	7	8
Variable	PAIR	TAIR	XMAIR	AAIR	BAIR	CAIR	NPAIR	NPRLX
Type	F	F	F	F	F	F	I	I/F
Default	PATM	TATM	none	none	0.0	0.0	0	0

VARIABLE	DESCRIPTION
PAIR	Initial pressure inside bag
TAIR	Initial temperature inside bag
XMAIR	Molar mass of gas initially inside bag: LT.0: -XMAIR references the ID of a *DEFINE_CPM_GAS_PROPERTIES keyword that defines the gas thermodynamic properties. Note that AAIR, BAIR, and CAIR are ignored.
AAIR - CAIR	Constant, linear, and quadratic heat capacity parameters
NPAIR	Number of air particles. See Remark 6.
NPRLX	Number of cycles to reach thermal equilibrium. See Remark 6. LT.0: If more than 50% of the collision to fabric is from initial air particles, the contact force will not apply to the fabric segment in order to keep its original shape. If the number contains ".", "e" or "E", NPRLX will treated as an end *time* rather than as a cycle count. When the keyword option INFLATION is used, NPRLX is also the number of cycles for maintaining the initial pressure given by PAIR.

MOLEFRACTION Card. Additional card for the MOLEFRACTION option.

Card 12	1	2	3	4	5	6	7	8
Variable	LCMASS							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
LCMASS	Total mass flow rate curve for the MOLEFRACTION option

Gas Cards. NGAS additional cards, one for each gas (card format for i^{th} gas).

Card 13	1	2	3	4	5	6	7	8
Variable	LCM*i*	LCT*i*	XM*i*	A*i*	B*i*	C*i*	INFG*i*	
Type	I	I	F	F	F	F	I	
Default	none	none	none	none	0.0	0.0	1	

VARIABLE	DESCRIPTION
LCM*i*	Mass flow rate curve for gas component *i*, unless the MOLEFRACTION option is used. If the MOLEFRACTION option is used, then it is the time dependent molar fraction of the total flow for gas component *i*.
LCT*i*	Temperature load curve/DEFINE_FUNCTION for gas component *i*
XM*i*	Molar mass of gas component *i*. LT.0: The absolute value of XM*i* references the ID of a *DEFINE_CPM_GAS_PROPERTIES keyword that defines the gas thermodynamic properties. Note that A*i*, B*i*, and C*i* are ignored.

VARIABLE	DESCRIPTION
A*i* - C*i*	Constant, linear, and quadratic heat capacity parameters for gas component *i*
INFG*i*	Inflator ID for this gas component (defaults to 1). The user inflator routine can only be defined using *DEFINE_CPM_GAS_PROPERTIES. Please check this extra card for the interface I/O.

Orifice Cards. NORIF additional cards, one for each orifice (card format for i^{th} orifice).

Card 14	1	2	3	4	5	6	7	8
Variable	NID*i*	AN*i*	VD*i*	CA*i*	INFO*i*	IMOM	IANG	CHM_ID
Type	I	F	I	F	I	I	I	I
Default	none	↓	none	30°	1	0	0	0

VARIABLE	DESCRIPTION
NID*i*	Node ID/Shell ID defining the location of nozzle *i*. See Remark 12.
AN*i*	GT.0: Area of nozzle *i* (default: all nozzles are assigned the same area). LT.0: Load curve ID. Time dependent area of nozzle *i*.
VD*i*	GT.0: Vector ID. Initial direction of gas inflow at nozzle *i*. LT.0: Values in the NID*i* fields are interpreted as shell IDs. See Remark 12. EQ.-1: Direction of gas inflow is using shell normal EQ.-2: Direction of gas inflow is in reversed shell normal
CA*i*	Cone angle in degrees (defaults to 30°). This option is used only when IANG is equal to 1.
INFO*i*	Inflator ID for this orifice. (default = 1)
IMOM	Inflator reaction force (R5.1.1 release and later): EQ.0: Off EQ.1: On

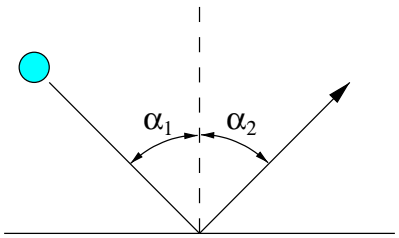

Figure 3-9. Particle Deflection

VARIABLE	DESCRIPTION
IANG	Activation for cone angle to use for friction calibration (not normally used; eliminates thermal energy of particles from inflator). EQ.0: Off (default) EQ.1: On
CHM_ID	Chamber ID where the inflator node resides. Chambers are defined using the *DEFINE_CPM_CHAMBER keyword.

Remarks:

1. **Formula for Total Vent Hole Coefficient.** The value must be between 0.0 and 1.0.

   Total vent hole coefficient = $\min(\max(\text{C23} \times \text{LCTC23} \times \text{LCPC23}, 0.0), 1.0)$

2. **Surface Roughness.** Friction factor to simulate the surface roughness. If the surface is frictionless the particle incoming angle α_1 is equal to the deflection angle α_2 (see Figure 3-9).

   The surface roughness F_r and the total angle α will have the following relationships:

   $$0.0 \le F_r \le 1.0$$
   $$\alpha = \alpha_1 + \alpha_2$$

   For the special case when

   $$F_r = 1.0 \ ,$$

   the incoming particle will bounce back from its incoming direction, so

   $$\alpha = 0.0 \ .$$

   For $-1.0 < F_r < 0.0$, particles will bounce towards the surface by the following relationship

   $$\alpha = 2\left[\alpha_1 - F_r\left(\frac{\pi}{4} - \frac{\alpha_1}{2}\right)\right] \ .$$

If $F_r \leq -1.0$, the absolute value is the curve ID which defines the F_r as a function of the part pressure.

If $F_r > 1.0$, the value is the *DEFINE_FUNCTION ID. Currently, the code will pass the following 3 values in this function: airbag pressure, airbag volume, and current time. The function will return the value of F_r. A simple example of user provide function with ID 900 is shown below.

```
*DEFINE_FUNCTION
       900
float pfric100(float pressure_bag, float volume_bag, float current_t)
/* function using bag volume to set Fr  */
{
float x = 0., vol1 = 0.5, vol2 = 1.1, vol3 = 1.2;
  if(volume_bag>=0 && volume_bag < vol1 ) {
    x = 1.2;
  } elseif (volume_bag>=vol1 && volume_bag < vol2 ) {
    x = 1;
  } elseif (volume_bag>=vol2 && volume_bag < vol3) {
    x = 1-(volume_bag-vol2)/vol3;
  } elseif (volume_bag>=vol3 ) {
    x = 0.;
  }
  return -0.06*x;
}
```

3. **Blocking and BLOCK Field.** Setting the 10's digit to 1 allows for physical holes in an airbag. In this case, particles that are far away from the airbag are disabled. In most cases, these are particles that have escaped through unclosed surfaces due to physical holes, failed elements, etc. This reduces the bucket sort search distance.

4. **Convection Energy Balance.** The change in energy due to convection is given by

$$\frac{\mathrm{d}E}{\mathrm{d}t} = A \times \mathrm{HCONV} \times \left(T_{\mathrm{bag}} - T_{\mathrm{atm}}\right) \ ,$$

where

A = is part area.
HCONV = user defined heat convection coefficient.
T_{bag} = the weighted average temperature impacting particles.
T_{atm} = aambient temperature.

5. **Output Files.** Particle time history data is output to the d3plot database. LS-PrePost can display and fringe this data. To reduce runtime memory requirements, VISFLG controls the data output. Note that VISFLG only affects version

4 of the CPM output. Version 3 is the default, so you need to change the value of CPMOUT on *CONTROL_CPM for VISFLG to have any effect.

6. **Spatial Distribution Equilibration for Airbag Particles.** Total number of particles initialized is NP + NPAIR. Since the initial air particles are placed at the surface of the airbag segments with correct velocity distribution initially, particles are not randomly distributed in space. It requires a finite number of relaxation cycles, NPRLX, to allow particles to move and produce better spatial distribution.

   Since the momentum and energy transfer between particles are based on perfect elastic collisions, the CPM solver would like to keep a similar mole per particle between the inflator and initial air particles. The CPM solver will check the following factor:

$$\text{factor} = \left| 1 - \frac{\text{mole per particle of initial air}}{\text{mole per particle of inflator gas}} \right| .$$

   If the factor is more than 10% apart, the code will issue the warning message with the tag, (SOL+1232), and provide the suggested NPAIR value. The NPAIR value should be adjusted based on the application. For example, this message should be ignored if for certain impact analyses the simulation is setup with only initial air, that is, no inflator gas.

7. **Remark Concerning *DEFINE_CPM_CHAMBER.** By default, initial air particles will be evenly placed on airbag segments which cannot sense the local volume. This will create an incorrect pressure field if the bag has several distinct pockets. *DEFINE_CPM_CHAMBER allows the user to initialize air particles by volume ratios of regions of the airbag. The particles will be distributed proportional to the defined chamber volume to achieve better pressure distribution.

   When looking at the airbag statistics in abstat_cpm, plotting the output for the chambers is more meaningful than for the whole bag. The lumped bag data could possibly give wrong pressure and temperature outputs, which can be misleading.

8. **Enhanced Venting.** When enhanced venting is on, the vent hole's equivalent radius R_{eq} will be calculated. Particles within R_{eq} on the high pressure side of the vent hole geometry center will be moved toward the hole. This will increase the collision frequency near the vent for particles to detect small structural features and produce better flow through the vent hole.

   When ENH_V equals 1, particles flow from high to low pressure only. When EHN_V equals 2, particles can flow in both directions for internal vent.

   Particles encountering external vents are released. The ambient pressure is not taken into account, and the particle will be released regardless of the value of

the pressure in the bag/chamber. Therefore, the vent rate will be sensitive to the vent location.

9. **Effective Convection Heat Transfer Coefficient.** If the thermal conductivity, KP, is given, then the effective convection heat transfer coefficient is given by

$$H_{\text{eff}} = \left(\frac{1.0}{\text{HCONV}} + \frac{\text{shell thickness}}{\text{KP}} \right)^{-1} ,$$

where the part thickness comes from the SECTION database. If KP is not given, H_{eff} defaults to HCONV.

10. **MOLEFRACTION Option.** Without the MOLEFRACTION option, a flow rate is specified for each species on the LCM*i* fields of Card 13. With the MOLEFRACTION option the total mass flow rate is specified in the LCMASS field on Card 12 and the molar fractions are specified in the LCM*i* fields of Card 13.

11. **User Defined Units.** If UNIT = 3 is used, there is no default value for TATM and PATM, and proper values must be provided. Unit conversion factors must also be provided so that the code sets the correct universal gas constant as well as some other variables.

12. **Shell Based Nozzle.** Node ID and shell ID based nozzle should not be used in the same airbag definition. The nozzle location is taken to be at the center of the shell and the initial nozzle direction can be defined by the shell's normal vector or by its reversed normal vector. The shell must include in the airbag definition. This vector transforms with the moving coordinate system defined by NID1 - NID3. The nozzle area is set on the AN*i* fields and shell area is not taken into account; therefore, the mass flowrate distribution with shells is determined in the same way as it is with nozzles defined by nodes.

13. **Merge Part Set for Vent.** When STYPE3 = 2, the first part in the set is designated as the master. All remaining parts are merged into the master so that enhanced venting is treated correctly. ABSTAT_CPM output will be associated with the master part. This option has the same effect as manually merging elements into the master part.

14. **TEND.** If TEND is not defined, particle mass and release rate will be calculated using the whole of the mass-flow curves LCM*i*, regardless of termination time. TEND can be used to limit the curve data but must be equal to or greater than the analysis termination time.

15. **TSPLIT.** Particles that exit by porosity leakage or a vent are removed from the system. If TSPLIT is set, the code keeps track of the number of removed particles (A) and active particles (B) every 200 cycles after time TSPLIT. Once A is greater than B, each active particle will be split into A/B + 1 particles for a better particle density in the volume.

16. **CP.** If the specific heat of the structure part is given, the initial temperature of this part has the initial air temperature, and the part mass (M) is automatically calculated. Heat transfer between gas and structure is based on the convection equation. The time history of the part temperature is stored in the abstat_cpm database under the field of *part_temp*

$$E = \text{AREA} \times H_{\text{eff}} \times \left(T_{\text{gas}} - T_{\text{part}}(t-1)\right)$$
$$T_{\text{part}}(t) = T_{\text{part}}(t-1) + E/(M \times CP)$$

17. **INFLATION Keyword Option.** The pressure in the closed volume may gradually deviate from the initial value due to volume changes caused by the pressure difference, such as during the process of tire inflation. INFLATION is designed to maintain this initial pressure by adding mass to the initial gas in the closed volume during the NPRLX time steps.

18. **JET Keyword Option.** For CPM vent, the flow equation is used to construct probability density function to release or reflect the particle. The algorithm does not create the thrusting effect. To get correct thrust force created from the discharge, the thrust force is evaluated from the following equation and the reaction force is applied to the JNODE input from user.

$$F_{\text{thrust}} = \dot{m}(v_{\text{sound}} - v_{\text{exit}}) + A_{\text{vent}}\left(P_{\text{bag}} - P_{\text{ambient}}\right)$$
$$F_{\text{JNODE}} = -F_{\text{thrust}}$$

***AIRBAG_REFERENCE_GEOMETRY**_*{OPTION}*_*{OPTION}*_*{OPTION}*

Available options include:

<BLANK>

BIRTH

RDT

ID

Purpose: If the reference configuration of the airbag is taken as the folded configuration, the geometrical accuracy of the deployed bag will be affected by both the stretching and the compression of elements during the folding process. Such element distortions are very difficult to avoid in a folded bag. By reading in a reference configuration such as the final unstretched configuration of a deployed bag, any distortions in the initial geometry of the folded bag will have no effect on the final geometry of the inflated bag. This is because the stresses depend only on the deformation gradient matrix:

$$F_{ij} = \frac{\partial x_i}{\partial X_j}$$

where the choice of X_j may coincide with the folded or unfold configurations. It is this unfolded configuration which may be specified here.

When the BIRTH option is specified an additional card setting the BIRTH parameter is activated. The BIRTH parameter specifies a critical time value before which the reference geometry is *not used*. Until the BIRTH time is reached the input geometry is used for (1) inflating the airbag and for (2) determining the time step size, even when the RDT option is set.

NOTE: This card does not support multiple birth times. The last BIRTH value read will be used for *all* preceding *AIRBAG_REFERENCE_GEOMETRY_BIRTH definitions. RGBRTH in *MAT_FABRIC supports a material dependent birth time.

When the RDT option is active the time step size will be based on the reference geometry once the solution time exceeds the birth time. This option is useful for shrunken bags where the bag does not carry compressive loads and the elements can freely expand before stresses develop. If this option is not specified, the time step size will be based on the current configuration and will increase as the area of the elements increase. The default may be much more expensive but possibly more stable.

ID card. Additional card for keyword option ID.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	SX	SY	SZ	NIDO			
Type	I	F	F	F	I			
Default	none	1.0	1.0	1.0	1st NID			

Birth Card. Additional card for keyword option BIRTH.

Card 1	1	2	3	4	5	6	7	8
Variable	BIRTH							
Type	F							
Default	0.0							

Node Cards. For each node ID having an associated reference position include an additional card in format 2. The next keyword ("*") card terminates this input.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	NID	X		Y		Z				
Type	I	F		F		F				
Default	none	0.		0.		0.				

VARIABLE	DESCRIPTION
ID	Card ID
SX, SY, SZ	Scale factor in each direction
NIDO	Node ID for origin. Default is the first node ID defined in this keyword.

VARIABLE	DESCRIPTION
BIRTH	Time at which the reference geometry activates
NID	Node ID for which a reference configuration is defined. Nodes defined in this section must also appear under the *NODE input. It is only necessary to define the reference coordinates of nodal points, if their coordinates are different than those defined in the *NODE section.
X	x coordinate
Y	y coordinate
Z	z coordinate

Remarks:

1. **Smaller Reference Geometry.** Note that a reference geometry which is smaller than the initial airbag geometry will not induce initial tensile stresses.

2. **Liner.** If a liner is included and the parameter LNRC is set to 1 in *MAT_FABRIC, compression is disabled in the liner until the reference geometry is reached, i.e., the fabric element becomes tensile.

3. **Nodes Shared by Foam and Fabric.** Some shell and solid elements modeling the fabric and foam, respectively, share nodes. The reference geometry specified by either *INITIAL_FOAM_REFERENCE_GEOMETRY or *AIRBAG_REFERENCE_GEOMETRY will be applied to both the shell and solid elements that share these nodes. However, having different reference geometry for shell and solid elements sharing common nodes can be achieved by using *INITIAL_FOAM_REFERENCE_GEOMETRY for solid elements and *AIRBAG_SHELL_REFERENCE_GEOMETRY for shell elements.

*AIRBAG_SHELL_REFERENCE_GEOMETRY_{OPTION}_{OPTION}

Available options include:

<BLANK>

RDT

ID

Purpose: Usually, the input in this section is not needed; however, sometimes it is convenient to use disjoint pre-cut airbag parts to define the reference geometries. If the reference geometry is based only on nodal input, this is not possible since in the assembled airbag the boundary nodes are merged between parts. By including the shell connectivity with the reference geometry, the reference geometry can be based on the pre-cut airbag parts instead of the assembled airbag. The elements, which are defined in this section, must have identical element ID's as those defined in the *ELEMENT_SHELL input, but the nodal ID's, which may be unique, are only used for the reference geometry. These nodes are defined in the *NODE section but can be additionlly defined in *AIRBAG_REFERENCE_GEOMETRY. The element orientation and n1-n4 ordering must be identical to the *ELEMENT_SHELL input.

When the RDT option is active the time step size will be based on the reference geometry once the solution time exceeds the birth time which can be defined by RGBRTH of *MAT_FABRIC.

ID card. Additional card for keyword option ID.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	SX	SY	SZ	NID			
Type	I	F	F	F	I			
Default	none	1.0	1.0	1.0	See List			

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	EID	PID	N1	N2	N3	N4				
Type	I	I	I	I	I	I				
Default	none	none	none	none	none	none				

VARIABLE	DESCRIPTION
ID	Card ID
SX, SY, SZ	Scale factor in each direction
NID	Node ID for origin. Default is the first node ID defined in this keyword.
EID	Element ID
PID	Optional part ID, see *PART, the part ID is not used in this section.
N1	Nodal point 1
N2	Nodal point 2
N3	Nodal point 3
N4	Nodal point 4

*ALE

The Arbitrary-Lagrangian-Eulerian, or ALE, method is an explicit Finite Element hydrocode. It handles multiple materials (multi-materials) in a single ALE mesh. ALE meshes are neither fixed in space nor attached to a material. The ALE mesh(es) may transform (translate, rotate, and expand) as needed. These transformations can reduce the number of elements required, potentially improving computational efficiency.

A model can contain more than one ALE mesh. Within each ALE mesh multiple ALE materials may move around, deform, and impact each other. If some Lagrangian structures (meshes) overlap with the ALE domain, the ALE materials can interact with these structures. These structures may be constructed as any combination of Lagrangian, SPH, SPG and DEM parts. This fluid-structure interaction (FSI) capability enables analyzing very complex FSI problems. The ALE solver does not have turbulence or boundary layer features, so it is not intended for modeling the traditional CFD problems which require those features.

Generally, the ALE mesh is unstructured to accommodate complex geometries. For simple rectilinear geometries, a structured, logically regular, mesh can be used with the Structure ALE (S-ALE) solver. This solver has algorithmic simplifications, memory reductions, and performance enhancements due to the type of mesh.

ALE *does not* support implicit time integration, nor does it support dynamic relaxation. Furthermore, except for ALE formulation 5, which *does* support contact, ALE *does not*, in general, support contact.

In three dimensions, ALE supports *only* one-point solid elements. These solid elements can either be hexahedral, pentahedral, or tetrahedral. Pentahedrons and tetrahedrons are treated as degenerate hexahedron elements. For each ALE multi-material, strain and stress is evaluated in each solid element at a single integration point. In this sense, the ALE element formulation is equivalent to ELEFORM 1 solid formulation.

Input required for LS-DYNA's ALE capability is specified using *ALE cards. The keyword cards in this section, excluding those specifically for the S-ALE solver, are listed in alphabetical order:

*ALE_AMBIENT_HYDROSTATIC

*ALE_BURN_SWITCH_MMG

*ALE_COUPLING_NODAL_CONSTRAINT

*ALE_COUPLING_NODAL_DRAG

*ALE_COUPLING_NODAL_PENALTY

*ALE_COUPLING_RIGID_BODY

*ALE_ESSENTIAL_BOUNDARY

*ALE_FAIL_SWITCH_MMG

*ALE_FRAGMENTATION

*ALE_FSI_PROJECTION

ALE_FSI_SWITCH_MMG_*{OPTION}

*ALE_FSI_TO_LOAD_NODE

*ALE_INJECTION

*ALE_MAPPING

*ALE_MAPPING_FROM_LAGRANGIAN

*ALE_MESH_INTERFACE

*ALE_MULTI-MATERIAL_GROUP

*ALE_PRESCRIBED_MOTION

*ALE_REFERENCE_SYSTEM_CURVE

*ALE_REFERENCE_SYSTEM_GROUP

*ALE_REFERENCE_SYSTEM_NODE

*ALE_REFERENCE_SYSTEM_SWITCH

*ALE_REFINE

*ALE_SMOOTHING

*ALE_SWITCH_MMG

*ALE_TANK_TEST

*ALE_UP_SWITCH

Keywords specifically for the S-ALE solver are:

*ALE_STRUCTURED_FSI

*ALE_STRUCTURED_MESH

*ALE_STRUCTURED_MESH_CONTROL_POINTS

*ALE_STRUCTURED_MESH_MOTION

*ALE_STRUCTURED_MESH_REFINE

*ALE_STRUCTURED_MESH_TRIM

*ALE_STRUCTURED_MESH_VOLUME_FILLING

*ALE_STRUCTURED_MULTI-MATERIAL_GROUP

For simplifying applying boundary conditions to S-ALE meshes, see:

*BOUNDARY_SALE_MESH_FACE

For other input information related to the ALE capability, see keywords:

*BOUNDARY_AMBIENT_EOS

*CONSTRAINED_EULER_IN_EULER

*CONSTRAINED_LAGRANGE_IN_SOLID

*CONTROL_ALE

*DATABASE_FSI

*INITIAL_VOID

*INITIAL_VOLUME_FRACTION

*INITIAL_VOLUME_FRACTION_GEOMETRY

*SECTION_SOLID

*SECTION_POINT_SOURCE_FOR_GAS_ONLY

*SECTION_POINT_SOURCE_MIXTURE

*SET_MULTIMATERIAL_GROUP_LIST

For a single gaseous material:

*EOS_LINEAR_POLYNOMIAL

*EOS_IDEAL_GAS

*MAT_NULL

For multiple gaseous materials:

*MAT_GAS_MIXTURE

*INTIAL_GAS_MIXTURE

*ALE_AMBIENT_HYDROSTATIC

Purpose: When an ALE model contains one or more ambient (or reservoir-type) ALE parts (ELFORM = 11 and AET = 4), this command may be used to initialize the hydrostatic pressure field in the ambient ALE domain due to gravity. The *LOAD_BODY_*OPTION* keyword must be defined. The associated *INITIAL_HYDROSTATIC_ALE keyword may be used to define a similar initial hydrostatic pressure field for the regular ALE domain (not reservoir-type region).

Card 1	1	2	3	4	5	6	7	8
Variable	ALESID	STYPE	VECID	GRAV	PBASE	RAMPTLC		
Type	I	I	I	F	F	I		
Default	none	0	none	0.0	0.0	0		

Card 2	1	2	3	4	5	6	7	8
Variable	NID	MMGBL						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
ALESID	ALESID defines the reservoir-type. ALE domain/mesh whose hydrostatic pressure field due to gravity is being initialized by this keyword. See Remark 4.
STYPE	ALESID set type. See Remark 4. EQ.0: Part set ID (PSID), EQ.1: Part ID (PID), EQ.2: Solid set ID (SSID).
VECID	Vector ID of a vector defining the direction of gravity.

VARIABLE	DESCRIPTION
GRAV	Magnitude of the Gravitational acceleration. For example, in metric units the value is usually set to 9.80665 m/s^2.
PBASE	Nominal or reference pressure at the top surface of all fluid layers. By convention, the gravity direction points from the top layer to the bottom layer. Each fluid layer must be represented by an ALE multi-material group ID (AMMGID or MMG). See Remark 1.
RAMPTLC	A ramping time function load curve ID. This curve (via *DEFINE_CURVE) defines how gravity is ramped up as a function of time. Given GRAV value above, the curve's ordinate varies from 0.0 to 1.0, and its abscissa is the (ramping) time. See Remark 2.
NID	Node ID defining the top of an ALE fluid (AMMG) layer.
MMGBL	AMMG ID of the fluid layer immediately below this NID. Each node is defined in association with one AMMG layer below it. See Remark 3. In case of S-ALE, AMMG name (AMMGNM) could be also used in place of AMMGID. See Remark 5.

Remarks:

1. **Pressure in Multi-Layer Fluids.** For models using multi-layer ALE Fluids the pressure at the top surface of the top fluid layer is set to PBASE and the hydrostatic pressure is computed as following

$$P = P_{\text{base}} + \sum_{i=1}^{N_{\text{layers}}} \rho_i g h_i \, .$$

2. **Hydrostatic Pressure Ramp Up.** If RAMPTLC is activated (i.e. not equal to "0"), then the hydrostatic pressure is effectively ramped up over a user-defined duration and kept steady. When this load curve is defined, do not define the associated *INITIAL_HYDROSTATIC_ALE card to initialize the hydrostatic pressure for the non-reservoir ALE domain. The hydrostatic pressure in the regular ALE region will be initialized indirectly because of the hydrostatic pressure generated in the reservoir-type ALE domain. The same load curve should be used to ramp up gravity in a corresponding *LOAD_BODY card. With this approach, any submerged Lagrangian structure coupled to the ALE fluids will have time to equilibrate to the proper hydrostatic condition.

3. **Limitation on EOS Model.** This keyword only supports *EOS_GRUNEISEN and *EOS_LINEAR_POLYNOMIAL, but only in the following two cases:

$$c_3 = c_4 = c_5 = c_6 = 0, \qquad E_0 = 0$$
$$c_4 = c_5 > 0, \qquad c_1 = c_2 = c_3 = c_6 = 0, \qquad V_0 = 0.$$

4. **Structured ALE usage.** When used with structured ALE, the PART and PART set options might not make too much sense. This is because all elements inside a structured ALE mesh are assigned to one single PART ID. In the Structured ALE case, we should generate a solid set which contains those ALE boundary elements we want to prescribe hydrostatic pressures on. To do this, define the solid set using *SET_SOLID_GENERAL keyword with the SALECPT option and set STYPE = 2 (Solid element set ID) for this keyword.

5. **AMMG NAME for S-ALE.** For the general ALE solver, you define each AMMG with *ALE_MULTI-MATERIAL_GROUP. In this case, each AMMG can only be referred to by their AMMGID. The AMMGID for each AMMG is based on the order of appearance of the AMMG in the input deck. For the S-ALE solver, you can define the AMMG using *ALE_STRUCTURED_MULTI-MATERIAL_-GROUP instead of *ALE_MULTI-MATERIAL_GROUP. With *ALE_STRUC-TURED_MULTI-MATERIAL_GROUP, you give each AMMG a name with the field AMMGNM. Each AMMG defined with that keyword can then be referred with either its name or its AMMGID (which is again based on order of appear-ance). We recommend using the name as it leads to fewer errors. For instance, if you add or delete AMMGs, then the AMMGIDs may change. Then, you must find all those references and change them accordingly. With the name, you do not need to modify the input deck for unchanged AMMGs.

Example:

Model Summary: Consider a model consisting of 2 ALE parts, air on top of water.

H3 = AMMG1 = Air part above

H4 = AMMG2 = Water part below

```

*ALE_BURN_SWITCH_MMG

Purpose: Change a volume fraction of an explosive modeled by an ALE multi-material group (AMMGID) into the explosion product (another ALE group). The reaction starts if some ignition conditions are met. These conditions and the reaction rate computing the explosive fraction to be switched are specified by *DEFINE_FUNCTION functions. The functions take as many arguments as there are fields specified on Card 4.

Card Summary:

Card 1. This card is required.

MMGFR	MMGTO	NVARLINE					

Card 2. This card is required.

REACT							

Card 3. This card is required.

IGNI	IGNIV	IGNIVF					

Card 4. Include NVARLINES of this card.

VAR	VAR	VAR	VAR	VAR	VAR	VAR	VAR

Card 5. Include as many of this card as desired. The next keyword ("*") card terminates this input.

PAR	PAR	PAR	PAR	PAR	PAR	PAR	PAR

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	MMGFR	MMGTO	NVARLINE					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
MMGFR	ALE multi-material-group (explosive) before the switch
MMGTO	ALE multi-material-group (explosion product) after the switch
NVARLINE	Number of lines with arguments in the functions REACT, IGNI and IGNIV

Card 2	1	2	3	4	5	6	7	8
Variable	REACT							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
REACT	ID of the *DEFINE_FUNCTION function controlling the reaction rate. This function determines the explosive volume fraction to be switched.

Card 3	1	2	3	4	5	6	7	8
Variable	IGNI	IGNIV	IGNIVF					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
IGNI	ID of the *DEFINE_FUNCTION function controlling the conditions of ignition
IGNIV	ID of the *DEFINE_FUNCTION function computing the ignition front speed. See Remark 1.

VARIABLE	DESCRIPTION
IGNIVF	Flag that activates computing the ignition front as a material interface between MMGFR and MMGTO. This flag will automatically turn on if *both* IGNI and IGNIVF are undefined (see Remark 2). EQ.0: Not activated EQ.1: Activated

Variable Cards. Cards defining the function arguments. Include NVARLINES of this card.

Card 4	1	2	3	4	5	6	7	8
Variable	VAR1	VAR2	VAR3	VAR4	VAR5	VAR6	VAR7	VAR8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
VAR*i*	Variables that provide the arguments for REACT, IGNI, and IGNIV (see Remark 3): EQ.1: *xx*-stress for MMGFR EQ.2: *yy*-stress for MMGFR EQ.3: *zz*-stress for MMGFR EQ.4: *xy*-stress for MMGFR EQ.5: *yz*-stress for MMGFR EQ.6: *zx*-stress for MMGFR EQ.7: Plastic strain for MMGFR EQ.8: Internal energy for MMGFR EQ.9: Bulk viscosity for MMGFR EQ.10: Volume from the previous cycle for MMGFR GE.11 and LE.20: Other auxiliary variables for MMGFR GE.21 and LE.40: Auxiliary variables for MMGTO (*xx*-stress, …)

VARIABLE	DESCRIPTION
EQ.41:	Mass for MMGFR
EQ.42:	Mass for MMGTO
EQ.43:	Volume fraction for MMGFR
EQ.44:	Volume fraction for MMGTO
EQ.45:	Material volume for MMGFR
EQ.46:	Material volume for MMGTO
EQ.47:	Time step
EQ.48:	Time
EQ.49:	Cycle
GE.50 and LE.57:	x-positions of the ALE nodes
GE.58 and LE.65:	y-positions of the ALE nodes
GE.66 and LE.73:	z-positions of the ALE nodes
GE.74 and LE.81:	x-velocities of the ALE nodes
GE.82 and LE.89:	y-velocities of the ALE nodes
GE.90 and LE.97:	z-velocities of the ALE nodes
GE.98 and LE.105:	x-accelerations of the ALE nodes
GE.106 and LE.113:	y-accelerations of the ALE nodes
GE.114 and LE.121:	z-accelerations of the ALE nodes
GE.122 and LE.129:	Masses of the ALE nodes

Parameter Cards. Cards defining parameters to control user-defined routines in the user-subroutine Fortran files:

- `alebrnswmg_ignitioncondition`
- `alebrnswmg_ignitionspeed`
- `alebrnswmg_reactionrate`

They can be used along with or instead of the functions IGNI, IGNIV, and REACT. The usermat version of LS-DYNA is required to access these routines. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 5	1	2	3	4	5	6	7	8
Variable	PAR1	PAR2	PAR3	PAR4	PAR5	PAR6	PAR7	PAR8
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
PAR*i*	User-defined routines parameters

Remarks:

1. **Nodal Lighting Times.** Each ALE node has a lighting time. When reached for a given node *i*, the reaction in the elements connected to this node can begin. The lighting time of another node (*j*) of an element connected to node *i* is computed by dividing the distance from *j* to *i* by the ignition speed provided by IGNIV. The first nodes to be ignited can be selected with *INITIAL_DETONATION. If the detonation point (located by (X, Y, Z) in *INITIAL_DETONATION) is close to a node, this node becomes the first node to be ignited. If the detonation point is close to an element center, the nodes of this element are first ignited.

2. **Ignition Front.** If IGNIVF = 1, the ignition front is a material interface between MMGFR and MMGTO. Every node behind the front is ignited; if a node in an element with MMGFR and MMGTO is on the MMGTO side, its lighting time is set to the current time to activate the reaction in the elements connected to this node.

3. **Variable Specification.** The variables are presented to the function IDFUNC as floating point data. The order of the arguments appearing in the *DEFINE_-FUNCTION should match the order of VAR*i* specified on Card 4 (for this

keyword). For example, when there is one card in format 4 containing "48, 49, 41, 42", then the time (48), the cycle (49), and the masses (41 & 42) should be the first, second, third, and fourth arguments to the function defined on the *DEFINE_FUNCTION keyword.

If there is a blank column between 2 VAR*i* fields, the list between the values in these two fields is specified. For example, if the card contains "1, ,6", then the six stresses (1 through 6) are selected as arguments.

*ALE_COUPLING_NODAL_CONSTRAINT_{OPTION}

Available options include:

<BLANK>

ID

TITLE

Purpose: This keyword activates constraint coupling between ALE materials and non-ALE (structure) nodes. The structure nodes may belong to Lagrangian solid, shell, beam, thick shell, or discrete sphere (see *ELEMENT_DISCRETE_SPHERE) elements. In contrast to *ALE_COUPLING_NODAL_PENALTY, caution should be exercised when using EFG, SPG or SPH nodes, as meshless methods generally do not satisfy essential boundary conditions, leading to energy dissipation.

> This keyword requires a 3D ALE formulation. It is, therefore, incompatible with parts defined using *SECTION_ALE2D or *SECTION_ALE1D.

If a title is not defined, LS-DYNA will automatically create an internal title for this coupling definition.

Title Card. Additional card for TITLE and ID keyword options.

Card ID	1	2	3	4	5	6	7	8
Variable	COUPID	TITLE						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	STRSID	ALESID	STRSTYP	ALESTYP	CTYPE	MCOUP		
Type	I	I	I	I	I	I		
Default	none	none	0	0	1	0		

Card 2	1	2	3	4	5	6	7	8
Variable	START	END				FRCMIN		
Type	F	F				F		
Default	0	10^{10}				0.5		

VARIABLE	DESCRIPTION
COUPID	Coupling (card) ID number (I10). If not defined, LSDYNA will assign an internal coupling ID based on the order of appearance in the input deck.
TITLE	A description of this coupling definition (A70)
STRSID	ID for a part, part set, segment set, or node set giving the structure. The structure may include Lagrangian solid, shell, beam, thick shell, or discrete sphere elements. EFG, SPH, or EFG nodes may be used, but the boundary conditions may not be satisfied.
ALESID	ID for a part or part set specifying the ALE solid elements
STRSTYP	Set type for STRSID: EQ.0: Part set ID (see *SET_PART) EQ.1: Part ID (see *PART) EQ.2: Segment set ID (see *SET_SEGMENT) EQ.3: Node set ID (see *SET_NODE)
ALESTYP	Set type for ALESID: EQ.0: Part set ID (see *SET_PART) EQ.1: Part ID (see *PART)
CTYPE	Coupling type: EQ.1: Constrained velocity only EQ.2: Constrained acceleration and velocity
MCOUP	Multi-material option (see Remarks). EQ.0: Couple with all multi-material groups

VARIABLE	DESCRIPTION
	LT.0: MCOUP must be an integer. –MCOUP refers to a set ID of an ALE multi-material groups defined in *SET_MULTI-MATERIAL_GROUP.
START	Start time for coupling
END	End time for coupling
FRCMIN	Only to be used with nonzero MCOUP. Minimum volume fraction of the fluid materials included in the list of AMMGs to activate coupling. Default value is 0.5.

Remarks:

When MCOUP is a negative integer, say for example MCOUP = -123, then an ALE multi-material set-ID (AMMSID) of 123 must exist. This is an ID defined by a *SET_MULTI-MATERIAL_GROUP_LIST card.

*ALE_COUPLING_NODAL_DRAG

Available options include:

<BLANK>

ID

TITLE

Purpose: This command provides a coupling mechanism to model the drag interaction between ALE fluids and discrete element forms (particles). The particles are assumed to be of spherical shape being either SPH elements or discrete elements (*ELEMENT_DISCRETE_SPHERE). The coupling forces are proportional to the relative speed between the fluid and particles plus the buoyancy force due to gravitational loading.

> This keyword requires a 3D ALE formulation. It is, therefore, incompatible with parts defined using *SECTION_ALE2D or *SECTION_ALE1D.

If the title is not defined, LS-DYNA will automatically generate an internal title for this coupling definition.

Title Card. Additional card for TITLE and ID keyword options.

Card ID	1	2	3	4	5	6	7	8
Variable	COUPID	TITLE						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	STRSID	ALESID	STRSTYP	ALESTYP				
Type	I	I	I	I				
Default	none	none	0	0				

Card 2	1	2	3	4	5	6	7	8
Variable	START	END		FCOEF			DIRECG	GRAV
Type	F	F		F			I	F
Default	0	10^{10}		1.0			none	0.0

VARIABLE	DESCRIPTION
COUPID	Coupling (card) ID number (I10). If not defined, LS-DYNA will assign an internal coupling ID based on the order of appearance in the input deck.
TITLE	A description of this coupling definition (A70).
STRSID	ID for a part, part set, segment set, or node set specifying the particles. The particles can be SPH or discrete elements.
ALESID	ID for a part or part set ID giving the ALE solid elements. See Remark 1.
STRSTYP	Particle set type: EQ.0: Part set ID (see *SET_PART) EQ.1: Part ID (see *PART) EQ.2: Segment set ID (see *SET_SEGMENT) EQ.3: Node set ID (see *SET_NODE)
ALESTYP	ALE set type: EQ.0: Part set ID (see *SET_PART) EQ.1: Part ID (see *PART)
START	Start time for coupling
END	End time for coupling
FCOEF	Drag coefficient scale factor or function ID to calculate drag coefficient GT.0: Drag coefficient scale factor.

VARIABLE	DESCRIPTION
	LT.0: The absolute value of FCOEF is the Function ID of the user provided function to calculate drag coefficient; See Remark 1.
DIRECG	Gravity force direction. EQ.1: Global x direction EQ.2: Global y direction EQ.3: Global z direction
GRAV	Gravity value. This value is used to calculate buoyance force.

Remarks:

1. **Drag Coupling Force.** The drag coupling force between the particles and ALE fluids takes the following form:

$$F_{\text{drag}} = c_{\text{drag}} \times \frac{1}{2}\rho v^2 \times \frac{1}{4}\pi d^2 \ ,$$

where c_{drag} is the drag coefficient, ρ is the density of the fluid in which the particle is submerged, v is the relative velocity between the particle and the fluid, and d is the diameter of the particle.

The default drag coefficient is a function of Reynolds's number and calculated by using the following formula:

$$c_{\text{drag}} = \left(0.63 + \frac{4.8}{\sqrt{\text{Re}}}\right)^2.$$

You can define your own function of drag coefficient. To do that, you need to define a function using *DEFINE_FUNCTION and assign the negative function ID to FCOEF flag.

An example is provided below to illustrate the setup. It is equivalent to the default drag coefficient calculation.

```
*ALE_COUPLING_NODAL_DRAG
     10001         1         3         1
                                    -10                                 3      9.81
*DEFINE_FUNCTION
        10
float cd(float re)
{
  float cd;
  cd=(0.63+4.8/sqrt(re))*(0.63+4.8/sqrt(re));
  if (cd > 2.0) cd = 2.0;
  return cd;
}
```

*ALE_COUPLING_NODAL_PENALTY

Available options include:

<BLANK>

ID

TITLE

Purpose: This command provides a penalty coupling mechanism between ALE materials and non-ALE (structure) nodes. The structure nodes may belong to Lagrangian solid, shell, beam, thick shell, or discrete (*ELEMENT_DISCRETE_SPHERE) elements. In contrast to *ALE_COUPLING_NODAL_CONSTRAINT, EFG, SPG, and SPH nodes *are* supported.

> This keyword is incompatible with parts that use *SECTION_ALE2D or *SECTION_ALE1D, meaning it requires a 3D ALE formulation.

If a title is not defined, LS-DYNA will automatically create an internal title for this coupling definition.

Title Card. Additional card for TITLE and ID keyword options.

Card ID	1	2	3	4	5	6	7	8
Variable	COUPID	TITLE						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	STRSID	ALESID	STRSTYP	ALESTYP		MCOUP		
Type	I	I	I	I		I		
Default	none	none	0	0		0		

Card 2	1	2	3	4	5	6	7	8
Variable	START	END	PFORM	PFAC		FRCMIN		
Type	F	F	I	F		F		
Default	0	10^{10}	0	0.1		0.5		

VARIABLE	DESCRIPTION
COUPID	Coupling (card) ID number (I10). If not defined, LSDYNA will assign an internal coupling ID based on the order of appearance in the input deck.
TITLE	A description of this coupling definition (A70)
STRSID	ID of a part, part set, segment set, or node set giving the structure. The structure may include Lagrangian elements, EFG, SPG, or SPH.
ALESID	ID of a part or part set specifying the ALE solid elements
STRSTYP	Set type for STRSID: EQ.0: Part set ID (see *SET_PART) EQ.1: Part ID (see *PART) EQ.2: Segment set ID (see *SET_SEGMENT) EQ.3: Node set ID (see *SET_NODE)
ALESTYP	Set type of ALESID: EQ.0: Part set ID (see *SET_PART) EQ.1: Part ID (see *PART)
MCOUP	Multi-material option (see Remarks): EQ.0: Couple with all multi-material groups LT.0: MCOUP must be an integer. –MCOUP refers to a set ID of an ALE multi-material groups defined in *SET_MULTI-MATERIAL_GROUP.
START	Start time for coupling

VARIABLE	DESCRIPTION
END	End time for coupling
PFORM	Penalty stiffness formulations: EQ.0: Mass based penalty stiffness EQ.1: Bulk modulus based penalty stiffness EQ.2: Penalty stiffness is determined by the user-provided load curve between penetration and penalty pressure.
PFAC	Penalty stiffness factor (PFORM = 0 or 1) for scaling the estimated stiffness of the interacting (coupling) system or load curve ID (PFORM = 2).
FRCMIN	Only to be used with nonzero MCOUP. Minimum volume fraction of the fluid materials included in the list of AMMGs to activate coupling. Default value is 0.5.

Remarks:

When MCOUP is a negative integer, say for example MCOUP = -123, then an ALE multi-material set-ID (AMMSID) of 123 must exist. This is an ID defined by a *SET_MULTI-MATERIAL_GROUP_LIST card.

*ALE_COUPLING_RIGID_BODY

Purpose: This command serves as a simplified constraint type coupling method between ALE fluids and a Lagrange rigid body.

In certain FSI simulations structure deformation is either small or not of the interest. Often these structures are modeled as rigid bodies to shorten the simulation time and reduce the complexity. For such kind of problems, a full scale ALE/FSI simulation is costly in both simulation time and memory. This keyword provides a light-weight alternative FSI method for systems with minimal structural response.

It has a similar input format to *ALE_ESSENTIAL_BOUNDARY and maybe regarded as being an extension of the essential boundary feature. The documentation for *ALE_ESSENTIAL_BOUNDARY_BODY applies, in large part, to this card also.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	NSID						
Type	I	I						
Default	none	none						

ALE Coupling Interfaces Cards. Include one card for each part, part set or segment to define ALE coupling interface. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	ID	IDTYPE	ICTYPE	IEXCL				
Type	I	I	I	I				
Default	none	none	1	none				

VARIABLE	DESCRIPTION
PID	Rigid body part ID
NSID	Node set ID defining ALE boundary nodes to follow rigid body motion

VARIABLE	DESCRIPTION
ID	Set ID defining a part, part set or segment set ID of the ALE coupling interface
IDTYPE	Type of set ID: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID) EQ.2: Segment set ID (SGSID)
ICTYPE	Constraint type: EQ.1: No flow through all directions EQ.2: No flow through normal direction (slip condition)
IEXCL	Segment Set ID to be excluded from applying ALE essential boundary condition. For example, inlet/outlet segments.

Remarks:

For ICTYPE = 2, the constrained direction(s) at each surface node comes in part from knowing whether the node is a surface node, an edge node, or a corner node. If the ALE mesh boundary is identified by part(s) (IDTYPE = 0/1), edge and corner nodes are automatically detected during the segment generation process. However, this automatic detection is not foolproof for complicated geometries. Identifying the ALE mesh boundary using segment sets (IDTYPE = 2) is generally preferred for complicated geometries in order to avoid misidentification of edge and corner nodes. When segment sets are used, the edge and corner nodes are identified by their presence in multiple segment sets where each segment set describes a more or less smooth, continuous surface. The intersections of these surfaces are used to identify edge/corner nodes.

*ALE_ESSENTIAL_BOUNDARY

Purpose: This command applies and updates essential boundary conditions on ALE or S-ALE boundary surface nodes. Updating the boundary conditions is important if the ALE mesh moves according to *ALE_REFERENCE_SYSTEM_GROUP. If the mesh does not move, it's more correct to call it an Eulerian mesh rather than an ALE mesh, but *ALE_ESSENTIAL_BOUNDARY can be applied nonetheless.

Certain engineering problems need to constrain the flow along the ALE mesh boundary. A simple example would be water flowing in a curved tube. Using the *ALE_ESSENTIAL_BOUNDARY approach, the tube material is not modeled and there is no force coupling between the fluid and the tube, rather the interior volume of the tube is represented by the location of the ALE mesh. Defining SPC boundary conditions with a local coordinate system at each ALE boundary node would be extremely inconvenient in such a situation. The *ALE_ESSENTIAL_BOUNDARY command applies the desired constraints along the ALE surface mesh automatically. You only need to specify the part(s) or segment set(s) corresponding to the ALE boundary surfaces and the type of constraint desired.

Boundary Condition Cards. Include one card for each part, part set or segment on which essential boundary conditions are applied. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	IDTYPE	ICTYPE	IEXCL				
Type	I	I	I	I				
Default	none	none	1	none				

VARIABLE	DESCRIPTION
ID	Set ID defining a part, part set or segment set ID of the ALE or S-ALE mesh boundary
IDTYPE	Type of set ID: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID) EQ.2: Segment set ID (SGSID)

VARIABLE	DESCRIPTION
ICTYPE	Constraint type: EQ.1: No flow through all directions. EQ.2: No flow through normal direction (slip condition)
IEXCL	Segment set ID to be excluded from applying ALE or S-ALE essential boundary condition. For example, inlet/outlet segments.

Remarks:

For ICTYPE = 2, the constrained direction(s) at each surface node comes in part from knowing whether the node is a surface node, an edge node, or a corner node. If the ALE mesh boundary is identified by part(s) (IDTYPE = 0 or 1), edge/corner nodes are automatically detected during the segment generation process. However, this automatic detection is not foolproof for complicated geometries. Identifying the ALE mesh boundary using segment sets (IDTYPE = 2) is generally preferred for complicated geometries in order to avoid misidentification of edge/corner nodes. When segment sets are used, the edge/corner nodes are identified by their presence in multiple segment sets where each segment set describes a more or less smooth, continuous surface. In short, the junctures or intersections of these surfaces identify edge/corner nodes.

*ALE_FAIL_SWITCH_MMG_{OPTION}

Purpose: This card is used to allow the switching of an ALE multi-material-group ID (AMMGID) if a failure criteria is reached. If this card is not used and *MAT_VACUUM has a multi-material group in the input deck, failed ALE groups are replaced by the group for *MAT_VACUUM.

Available options include:

<BLANK>

ID

TITLE

A title for the card may be input between the 11th and 80th character on the title-ID line. The optional title line precedes all other cards for this command.

The user can explicitly define a title for this coupling.

Title Card. Additional card for the ID or TITLE options to keyword.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	TITLE						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	FR_MMG	TO_MMG						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
FR_MMG	This is the AMMG-SID before the switch. The AMMG-SID corresponds to the SID defined under the *SET_MULTI-MATERIAL_GROUP_LIST (SMMGL) card. This SID points to one or more AMMGs. See Remark 1.

VARIABLE	DESCRIPTION
TO_MMG	This is the AMMG-SID after the switch. The AMMG-SID corresponds to the SID defined under the *SET_MULTI-MATERIAL_GROUP_LIST card. This SID points to one or more AMMGs. See Remark 1.

Remarks:

1. **AMMG Switch.** There is a correspondence between the FR_MMG and TO_MMG. Consider an example where:

   a) The FR_MMG SID points to a SID = 12 (the SID of its SMMGL card is 12, and this SID contains AMMG 1 and AMMG 2)

   b) The TO_MMG points to a SID = 34 (the SID of the SMMGL card is 34, and this SID contains AMMG 3 and AMMG 4)

   Then, AMMG 1, if switched, will become AMMG 3, and AMMG 2, if switched, will become AMMG 4.

2. **History Variables.** In the switch example above, if AMMG 1 in FR_MMG has n_1 history variables and its corresponding ALE group AMMG 3 in TO_MMG has n_3 history variables, the number of history variables copied from AMMG 1 to AMMG 3 is $\min(n_1, n_3)$.

*ALE_FRAGMENTATION

Purpose: When a material fails, this card is used to switch the failed material to vacuum. When used with FRAGTYP = 2, it can be used to model material fragmentation.

Card 1	1	2	3	4	5	6	7	8
Variable	FR_MMG	TO_MMG	FRAGTYP					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
FR_MMG	This is the AMMGID of the failed material.
TO_MMG	This is the AMMGID of the vacuum to which the failed material is being switched.
FRAGTYP	Flag defining whether the failed material is completely or partially switched to vacuum. EQ.1: Fully switch; all failed material is switched to vacuum (see Remark 1). EQ.2: Partially switch; only the volume expansion from the last time step is switched to vacuum (see Remark 2).

Remarks:

The Lagrange element contains only one material. Once the failure criterion is met in a Lagrange element, the whole element is marked as "failed" and either deleted or kept from further element force calculation.

However, for multi-material ALE elements, such an approach is not practical as these elements are occupied by multiple materials. Failure, therefore, cannot be adequately modeled at the element level. Instead we convert the failed material inside an ALE element to vacuum. The effect is similar to element deletion in Lagrange simulations. The failed material, once switched to vacuum, is excluded from any future element force calculation.

1. **Switch to Vacuum, (FRAGTYPE = 1).** By default, multi-material elements switch failed materials to vacuum. This switch involves assigning the full

volume fraction of the failed material, say AMMG 1, in an element to vacuum, say AMMG 2.

FRAGTYP = 1 is equivalent to the default treatment. However, with this card the vacuum AMMG can be explicitly specified. In the case that more than one vacuum AMMG exist, it is strongly recommended to use the FRAGTYP = 1 approach to eliminate ambiguity. It is also helpful during post-processing since it is possible to see the material interface of the switched material by assigning a dedicated vacuum AMMG to the switched material.

2. **Fragmentation, (FRAGTYPE = 2).** FRAGYP = 2 models material fragmentation. Note that the FRAGTYP = 1 approach leads to loss of mass and, consequently, dissipates both momentum and energy. With FRAGTYP = 2, instead of converting the full volume of the failed material to vacuum, LS-DYNA only converts the material expansion to vacuum. This approach conserves mass and, therefore, momentum and energy.

   To illustrate how this fragmentation model works, consider a tension failure example. At the time step when the material fails, LS-DYNA calculates the material expansion in the current step and converts this volume to vacuum. The stresses and other history variables are left unchanged, so that in the next time step it will again fail. The expansion in the next time step will be also converted to vacuum. This process continues until maybe at a later time the gap stops growing or even starts to close due to compression.

Example:

Consider a simple bar extension example:

FR_MMG: H5 = AMMG1 = Metal bar
H6 = AMMG2 = Ambient air
TO_MMG: H7 = AMMG3 = Dummy vacuum part

```
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
*ALE_FRAGMENTATION
$    FR_MMG    TO_MMG   FRAGTYP
         1         3         2
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
```

*ALE_FSI_PROJECTION

Purpose: This card provides a coupling method for simulating the interaction between a Lagrangian material set (structure) and ALE material set (fluid). The nearest ALE nodes are projected onto the Lagrangian structure surface at each time step. This method does not conserve energy, as mass and momentum are transferred using the constraint based approach.

Card 1	1	2	3	4	5	6	7	8
Variable	LAGSID	ALESID	LSIDTYP	ASIDTYP	SMMGID	ICORREC	INORM	
Type	I	I	I	I	I	I	I	
Default	0	0	0	0	0	0	0	

Card 2	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH						
Type	F	F						
Default	0.0	10^{10}						

VARIABLE	DESCRIPTION
LAGSID	A set ID defining the Lagrangian part(s) for this coupling (structures).
ALESID	A set ID defining the ALE part(s) for this coupling (fluids).
LSIDTYP	Lagrangian set ID type: EQ.0: Part set ID (PSID), EQ.1: Part ID (PID).
ASIDTYP	ALE set ID type: EQ.0: Part set ID (PSID), EQ.1: Part ID (PID).

VARIABLE	DESCRIPTION
SMMGID	A set ID referring to a group of one or more ALE-Multi-Material-Group (AMMG) IDs which represents the ALE materials interacting with the Lagrangian structure. This SMMGID is a set ID defined by *SET_MULTI-MATERIAL_GROUP_LIST.
ICORREC	Advection error correction method (see Remark 1): EQ.1: ALE mass is conserved. Leaked mass is moved, EQ.2: ALE mass is almost conserved, EQ.3: No correction performed (default). ALE mass is conserved. Some leakage may occur. This may be the best solution.
INORM	Type of coupling: EQ.0: Couple in all directions, EQ.1: Couple in compression and tension (free sliding), EQ.2: Couple in compression only (free sliding). This choice requires ICORREC = 3.
BIRTH	Start time for coupling.
DEATH	End time for coupling.

Remarks:

1. **Advection Errors.** As the ALE nodes are projected onto the closest Lagrangian surface, there may be some advection errors introduced. These errors may result in a small element mass fraction being present on the "wrong" side of the coupled Lagrangian surface. There are 3 possible scenarios:

   a) Mass on the wrong side of the Lagrangian structure may be moved to the right side. This may cause P oscillations. No leakage will occur.

   b) Mass on the wrong side is deleted. Mass on the right side is scaled up to compensate for the lost mass. No leakage will occur.

   c) Mass on the wrong side is allowed (no correction performed). Some leakage may occur. This may be the most robust and simplest approach.

Example:

Model Summary:

H1 = AMMG1 = background air mesh
H2 = AMMG1 = background air mesh
S3 = cylinder containing AMMG2
S4 = dummy target cylinder for impact

The gas inside S3 is AMMG2. S3 is given an initial velocity and it will impact S4.

*ALE_FSI_SWITCH_MMG_{OPTION}

Purpose: This card is used to allow the switching of an ALE multi-material-group ID (AMMGID) of a fluid as that fluid passes across a monitoring surface. This monitoring surface may be a Lagrangian shell structure or a segment set. It does not have to be included in the Lagrangian structure set of the coupling card: *CONSTRAINED_LAGRANGE_IN_SOLID. However, at least one coupling card must be present in the model.

Available options include:

<BLANK>

ID

TITLE

An ID number (up to 8 digits) may be defined for this switch command in the first 10-character space. A title for the card may be input between the 11th and 80th character on the title-ID line. The optional title line precedes all other cards for this command.

The user can explicitly define a title for this coupling.

ID Card. Additional card for the Title or ID keyword options.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	TITLE						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	SID	STYPE	NQUAD	XOFF	BTIME	DTIME	NFREQ	NFOLD
Type	I	I	I	F	F	F	I	I
Default	none	0	1	0.0	0.0	1.0E20	1	0

Card 2	1	2	3	4	5	6	7	8
Variable	FR_MMG	TO_MMG	XLEN					
Type	I	I	F					
Default	none	none	0.0					

VARIABLE	DESCRIPTION
SID	A set ID defining a monitoring surface over which an ALE fluid flows across, and its ALE multi-material-group-ID (AMMGID) is switched. The monitoring surface may be a Lagrangian shell structure or a segment set. This surface, if Lagrangian, does not have to be included in the coupling definition (see Remark 4).
STYPE	Set ID type of the above SID: EQ.0: Part set ID (PSID) (default). EQ.1: Part ID (PID). EQ.2: Segment set ID (SGSID).
NQUAD	The number of flow-sensor points to be distributed over each monitoring surface/segment. There should be enough sensor points distributed to monitor the flow in each ALE element intersected by this monitoring surface (default = 1; see Remark 3).
XOFF	An offset distance away from the monitoring surface, beyond which the AMMGID switching occurs. The direction of XOFF is defined by the normal vector of the monitoring segment. This offset distance, in general, should be at least 2 ALE element widths away from, and beyond, the monitoring interface (default = 0.0).
BTIME	Start time for the AMMGID switch to be activated (default = 0.0).
DTIME	Ending time for the AMMGID switch (default = 1.0E20).
NFREQ	Number of computational cycles between ALE switch check (default = 1).

VARIABLE	DESCRIPTION
NFOLD	Flag for checking folding logic: EQ.0: Off EQ.1: On. LS-DYNA will check if the monitoring segment is in the fold which is applicable to airbags. If the monitoring segment is still located within a folded (shell) region, then no switching is allowed yet until it has unfolded.
FR_MMG	This is the AMMG SID before the switch. The AMMG SID corresponds to the SID defined under the *SET_MULTI-MATERIAL_GROUP_LIST (SMMGL) card. This SID points to one or more AMMGs. See Remark 1.
TO_MMG	This is the AMMG SID after the switch. The AMMG SID corresponds to the SID defined under the *SET_MULTI-MATERIAL_GROUP_LIST card. This SID points to one or more AMMGs. See Remark 1.
XLEN	This is an absolute distance for distributing the flow sensor points over the ALE elements. To make sure that at least 1 sensor point, defined on each Lagrangian segment, is present in each ALE element to track the flow of an AMMG, XLEN may be estimated as roughly half the length of the smallest ALE element in the mesh. See Remark 3.

Remarks:

1. **AMMG SIDs.** There is a correspondence between the FR_MMG and TO_MMG. Consider an example where:

   a) The FR_MMG SID points to a SID = 12 (the SID of its SMMGL card is 12, and this SID contains AMMG 1 and AMMG 2)

   b) The TO_MMG points to a SID = 34 (the SID of the SMMGL card is 34, and this SID contains AMMG 3 and AMMG 4)

   Then, AMMG 1, if switched, will become AMMG 3, and AMMG 2, if switched, will become AMMG 4.

2. **Database Files.** The ID option must be activated if the parameter SWID is used in the *DATABAS_FSI card. Then the accumulated mass of an AMMG that goes through a tracking surface, and being switched, will be reported via the

parameter "mout" in the dbfsi ASCII output file (or equivalently the "POROSITY" parameter inside LS-PrePost ASCII plotting option).

3. **Sensor Point Interval.** When both NQUAD and XLEN are defined, whichever gives smaller sensor-point interval distance will be used. XLEN may give better control as in the case of a null shell acting as the monitoring surface. As this null shell is stretched, NQUAD distribution of sensor-points may not be adequate, but XLEN would be.

4. **Coupling Cards.** The monitoring surface does not have to be included in the Lagrangian structure set of the coupling card. However, at least one coupling card must be present in the model. The monitoring segment set can be made up of Lagrangian or ALE nodes.

Example:

Consider a simple airbag model with 3 part IDs:

H25 (AMMG1) = Inflator gas injected into the airbag.
H24 (AMMG2) = Air outside the airbag (background mesh).
H26 (AMMG3) = Dummy AMMG of inflator gas after it passes through a vent hole.
S9 = A Lagrangian shell part representing a vent hole.
S1 = A Lagrangian shell part representing the top half of an airbag.
S2 = A Lagrangian shell part representing the bottom half of an airbag.

The inflator gas inside the airbag is distinguished from the inflator gas that has passed through the monitoring surface (vent hole) to the outside of the airbag by assigning different ALE multi-material group set ID to each. The dummy fluid part (H26) should have the same material and EOS model IDs as the before-switched fluid (H25).

TO_MMG = 125
⇒ AMMGID (before switch) = *SET_MULTI-MATERIAL_GROUP_LIST(125) = 1
⇒ PART = PART(AMMGID1) = H25

FR_MMG = 126
⇒ AMMGID (before switch) = *SET_MULTI-MATERIAL_GROUP_LIST(126) = 3
⇒ PART = PART(AMMGID3) = H26

```

$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
```

Note:

1. The *DATABASE_FSI card tracks 3 surface entities: (a) top half of an airbag, (b) bottom half of an airbag, and (c) the vent hole monitoring surface where the AMMGID of the inflator gas is switched.

2. The amount of mass passing through the vent hole during the switch is output to a parameter called “pleak” in a dbfsi ASCII file. See *DATABASE_FSI.

3. The *ALE_FSI_SWITCH_MMG_ID card track any flow across S9 and switch the AMMGSID from 125 (AMMG 1) to 126 (AMMG 3).

*ALE_FSI_TO_LOAD_NODE

Purpose: Output the ALE coupling forces from *CONSTRAINED_LAGRANGE_IN_-SOLID for CTYPE = 4 in keyword format, so they may be applied directly in another run.

Card 1	1	2	3	4	5	6	7	8
Variable	DT	NSID	IOPT

Default	none	none	0					

Remaining card is optional.†

Path Card. Optional card for the directory path (see Remark 4).

Card 2	1	2	3	4	5	6	7	8
Variable	PATH							
Type	A80							
Default	optional							

VARIABLE	DESCRIPTION
DT	Output intervals
NSID	Node Set ID. See *SET_NODE.
IOPT	Options to map the coupling data between 2 runs: EQ.0: The keyword alefsiloadnode.k (see Remark 1) is created at the end of the run by LS-DYNA. EQ.1: A database of coupling forces is dumped without the conversion to a keyword file at the end of the run (see Remark 2). The database can be treated by a program (alefsiloadnode.exe) to write alefsiloadnode.k.

VARIABLE	DESCRIPTION
	EQ.2: The database of coupling forces created by IOPT = 1 (see Remark 2) is read back. The structure meshes should be identical. The forces are directly applied the nodes without using *LOAD_NODE. The parameters DT and NSID are not read.
	EQ.3: A database of coupling accelerations is dumped at the end of the run (see Remark 3).
	EQ.4: The database of coupling accelerations created by IOPT = 3 (see Remark 3) is read back. The structure meshes can be different. The accelerations are interpolated at the nodes provided by NSID. The parameters DT and NSID are read.
PATH	Path to the directory where the databases are created.

Remarks:

1. **Keyword Output File.** The name of the output keyword file is alefsiloadnode.k. For each node, this file contains three *LOAD_NODE for each global direction and three *DEFINE_CURVE for the coupling force histories.

2. **Database for IOPT = 1 and 2.** The name of the database is alefsi2ldnd.tmp (or alefsi2ldnd.tmp00… in MPP). It should be in the directory of the 2nd run for IOPT = 2. The database lists the coupling forces by node. The structure meshes (and their MPP decomposition) for the IOPT=1 and IOPT=2 runs should be the same.

3. **Databases for IOPT = 3 and 4.** The names of the databases are alefsi2ldnd.tmp (or alefsi2ldnd.tmp00… in MPP) and alefsi2lndndx.tmp. They should be in the directory of the 2nd run for IOPT = 4. The file alefsi2ldnd.tmp lists the coupling accelerations by node (coupling acceleration = coupling force / nodal mass). The file alefsi2lndndx.tmp lists the initial nodal coordinates and coupling segment connectivities (see *CONSTRAINED_LAGRANGE_IN_SOLID for coupling segment). The structure meshes for the IOPT = 3 and IOPT = 4 runs can be different. The IOPT = 3 initial geometry stored in alefsi2lndndx.tmp is used to interpolate the coupling accelerations (saved in alefsi2ldnd.tmp) at the nodes provided by NSID. For the interpolation to work, these nodes should be within the IOPT = 3 coupling segment initial locations.

4. **Directory Path.** The filenames of the databases can be prefixed by the variable PATH to control in which directory the databases should be created. Since the

directory path and filename are concatenated, PATH should end with "/" (or "\" in windows).

*ALE_INJECTION

Purpose: Select nodes and elements in a user defined volume to prescribe the velocities of the selected nodes and set the materials in the selected elements with material(s) from a multi-material group set.

Card 1	1	2	3	4	5	6	7	8
Variable	MMGSET	SEGSET	GLOBAL	LCE	LCRVL			
Type	I	I	I	I	I			
Default	none	none	0	0	0			

Remaining cards are optional.†

Velocity Card. Optional card for the nodal motion (see Remark 1).

Card 2	1	2	3	4	5	6	7	8
Variable	LCVT	VECT	LCVR	VECR	BOXV	XG	YG	ZG
Type	I	I	I	I	I	F	F	F
Default	0	0	0	0	0	0.0	0.0	0.0

Surface Card. Optional card for defining the geometry to be filled by MMGSET (see Remark 1)

Card 3	1	2	3	4	5	6	7	8
Variable	SURFCT	NDIV	XL	YL	ZD	ZU	XC	YC
Type	I	I	F	F	F	F	F	F
Default	0	3	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
MMGSET	Multi-Material Set ID (see *SET_MULTI-MATERIAL_GROUP_-LIST).
SEGSET	Segment set ID (see *SET_SEGMENT). A local coordinate system is created for each segment. See Remark 2.
GLOBAL	Three digit flag to control how to select the elements, how to prescribe the velocities, and how to define the geometrical parameters of Cards 2 and 3 (including BOXV): EQ.__0: Geometrical parameters are local to the segments of SEGSET EQ.__1: Geometrical parameters are natural to SEGSET segments (see Remark 3 and Figure 4-1) EQ._0_: Velocities are applied in local coordinate systems attached to each segment of SEGSET EQ._1_: Velocities are applied in the global coordinate system EQ.0__: Select the elements and nodes in the local volume around each segment of SEGSET EQ.1__: Select the elements in the global volume formed by all the segments of SEGSET. The nodes are selected in the local volume around each segment of SEGSET. EQ.2__: Select the elements and nodes in the global volume formed by all the segments of SEGSET. Velocities are applied in the global coordinate system.
LCE	Curve ID for the internal energy (see Remark 6): GT.0: Load curve ID; see *DEFINE_CURVE. See Remark 2. LT.0: -LCE is the function ID for the internal energy which depends on 26 arguments: time, number of cycles, and nodal coordinates of the 8 nodes for the ALE element. See *DEFINE_FUNCTION. See Remark 5.
LCRVL	Curve ID for the relative volume (see Remark 6): GT.0: Load curve ID; see *DEFINE_CURVE. See Remark 2. LT.0: -LCRVL is the function ID for the relative volume which depends on 26 arguments: time, number of cycles, and nodal coordinates of the 8 nodes for the ALE element. See *DEFINE_FUNCTION. See Remark 5.

VARIABLE	DESCRIPTION
LCVT	Curve ID for the translational velocity: GT.0: Load curve ID; see *DEFINE_CURVE. LT.0: -LCVT is the function ID for the translational velocity which depends on 5 arguments: time, number of cycles, and nodal coordinates. See *DEFINE_FUNCTION. See Remark 5.
VECT	Vector to orient the translation. See *DEFINE_VECTOR.
LCVR	Curve ID for the rotational velocity: GT.0: Load curve ID; see *DEFINE_CURVE. LT.0: -LCVR is the function ID for the rotational velocity which depends on 5 arguments: time, number of cycles, and nodal coordinates. See *DEFINE_FUNCTION. See Remark 5.
VECR	Vector to orient the rotational axis (see *DEFINE_VECTOR).
BOXV	Box (see *DEFINE_BOX) defining the region where the velocities are applied (see Remark 7).
XG, YG, ZG	Position of the rotation center (see Remark 8).
SURFCT	Flag to define the surface, inside which the nodes and elements are selected: LT.0: -SURFCT is the function ID (see *DEFINE_FUNCTION) for the rotational velocity with 17 arguments: time, number of cycles, ALE element center coordinates, segment nodal coordinates. EQ.0: Ellipsoid: $\frac{x^2}{XL^2}+\frac{y^2}{YL^2}+\frac{z^2}{ZL^2}=1$ where ZL = −ZD if $z<0$ and ZL = ZU if $z>0$ (see Remark 9 and Figure 4-3) EQ.1: Ellipse-based cylinder: $\frac{x^2}{XL^2}+\frac{y^2}{YL^2}=1$ where −ZD < z < ZU (see Remark 10 and Figure 4-4)

VARIABLE	DESCRIPTION
	EQ.2: Truncated ellipse-based cone: $$\frac{x^2}{X^2}+\frac{y^2}{Y^2}=1$$ where $0<z<\text{ZD}$, $X=(1-z/\text{ZU})\text{XL}$, and $Y=(1-z/\text{ZU})\text{YL}$. Also, ZD < ZU, so ZU is the apex z-coordinate of the cone (see Figure 4-5).
	EQ.3: Drop geometry meaning a cone for $-\text{ZD}<z<0$ and half an ellipsoid for $0<z<\text{ZU}$ (see Remark 11 and Figure 4-6)
	EQ.4: Box with side lengths $-\text{XL}<x<\text{XL}$, $-\text{YL}<y<\text{YL}$, and $-\text{ZD}<z<\text{ZU}$ (see Figure 4-7)
	EQ.5: Segment based cylinder (see Remark 12 and Figure 4-8)
NDIV	Number of divisions of an element cut by the surface SURFCT to compute the volume fractions (see Remark 13 and Figure 4-2).
XL	Length of the geometry SURFCT in the local x-direction
YL	Length of the geometry SURFCT in the local y-direction
ZD	Length for the geometry SURFCT in the local z-direction for $z<0$, except for SURFCT = 2 where $z>0$. ZD can be input as a negative or positive value.
ZU	Length for the geometry SURFCT in the local z-direction for $z>0$
XC	x-coordinate in the segment of the local coordinate center (see Remark 14).
YC	y-coordinate in the segment of the local coordinate center (see Remark 14).

Remarks:

1. **Card 1 Definition Only.** If only Card 1 is defined, the velocities are not prescribed. The surface to select the elements to apply the MMGSET is a sphere inscribed in the segment.

2. **Segment Local Coordinate System.** A local coordinate system is created at the center of each segment (see Figure 4-1). The normal is the local z-axis. The local x-axis is parallel to the vector that is the average of 2 vectors: the vector from Node 1 to Node 2 and the vector from Node 4 to Node 3 for a quadrangle. For a triangle, the local x-axis is parallel to the vector from Node 1 to Node 2.

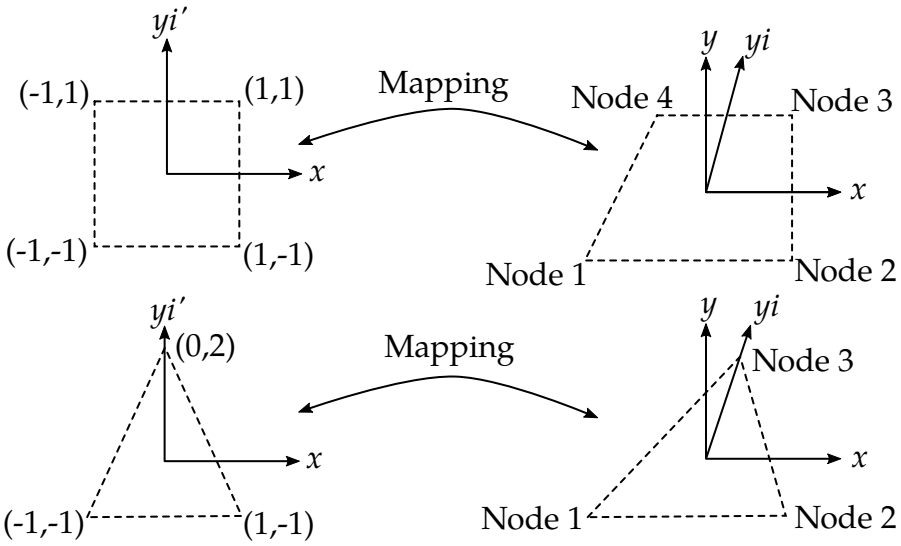

Figure 4-1. Isoparametric mapping if GLOBAL = 1

The local y-axis is the cross product of the local z- and x-axis. A 4th local axis called yi-axis can be considered for the isoparametric mapping (see Remark 3) if the segment is asymmetrical with the y-axis. For a quadrangle, the yi-axis is parallel to the vector that is an average of the 2 other sides: the vector from Node 1 to Node 4 and the vector from Node 2 to Node 3. For a triangle, the local yi-axis is parallel to the vector that points from the midpoint of the edge between Nodes 1 and 2 to Node 3.

3. **Isoparametric Mapping.** If GLOBAL = 1, the geometrical parameters, namely BOXV, XG, YG, ZG, XL, YL, ZD, ZU, XC, and YC, are natural to each segment in SEGSET. Therefore, inside the quadrangle segment, the coordinates XG, YG, ZG, XC, and YC are isoparametric, so they vary from -1 to 1, with 0 at the center. For the triangle, Node 1 is at $(-1,-1)$, Node 2 is at $(1,-1)$, and Node 3 is at $(0,2)$. The matching coordinates in the segment are in the segment-centered coordinate system (x,yi,z) (see Remarks 2 and 14). The coordinates in BOXV and lengths XL, YL, ZD, ZU are multiples of the characteristic lengths in each direction of the segment-centered orthonormal coordinate system (x,y,z) (see Remarks 2 and 14). For quadrangles, the characteristic length in the x-direction is an average of the lengths of the side from Node 1 to Node 2 and the side from Node 3 to Node 4. Similarly, the characteristic length in the y-direction is an average of the of the lengths of the side from Node 1 to Node 4 and the side from Node 2 to Node 3. For triangles, the characteristic length in the x-direction is the length of the side between Nodes 1 and 2; the characteristic length in the y-direction is the length of the median that joins the side length of Nodes 1 and 2 to the vertex of Node 3. For the z-direction, the characteristic length is an average of the characteristic x- and y-lengths.

4. **Load Curve Birth and Death Times.** The smallest and largest times in the curves are the birth and death times. If these time frames are equal to (or slightly

larger than) the time step, the related velocities can be initialized during the first cycle. If the first abscissa is a negative time with no ordinate, the curve is considered periodic and the negative time is the period.

5. **Function Birth and Death Times.** Birth and death times for functions can be considered. The functions are called twice:

   a) the first time with a negative time to determine if the function will be applied. The returned value is positive if the function is to be applied. If the returned value is negative, then the function is not applied.

   b) the second time to evaluate the function if the value returned from the first function call is positive.

6. **Internal Energy and Relative Volume Curves.** The internal energy and relative volume curves are equivalent to the ambient curves in *BOUNDARY_AMBIENT_EOS. So the materials in MMGSET should have *EOS to use these curves. If these curves are not defined, the initial values for the internal energies and relative volumes are applied (like for the ambients).

7. **Prescribed Velocity.** If BOXV is undefined, the velocities are applied to all the nodes inside the surface defined by SURFCT and the nodes of elements cut by this surface. If BOXV is defined, all the nodes inside the box have their velocities being prescribed including nodes outside the surface SURFCT.

8. **Rotation Center.** If the rotation center, namely XG, YG, and ZG, is undefined, the rotation is applied around an axis defined by VECR passing through the center of mass of the groups defined by MMGSET. In an ALE 2D model, this center is shifted to the y-axis.

9. **Ellipsoid Geometry.** The ellipsoid can have different lengths above ($z > 0$) and below ($z < 0$) the segment (see Figure 4-3). If only XL is defined, YL = ZD = ZU = XL, so the surface geometry is the surface of a sphere.

10. **Axisymmetric Cylinder Geometry.** If only XL is defined, YL = XL, so the surface is defined as an axisymmetric cylinder (see Figure 4-4).

11. **Drop Geometry.** For SURFCT = 3, the geometry is an ellipsoid-based cone is below the segment ($z < 0$) and half of an ellipsoid above the segment ($z > 0$). The geometry looks like a drop (or an ice cream cone. See Figure 4-6).

12. **Segment Projection Geometry.** For SURFCT = 5, a node or element center is inside this geometry if $-ZD < z < ZU$ and if the node or element center projection on the segment plane is inside this segment (see Figure 4-8).

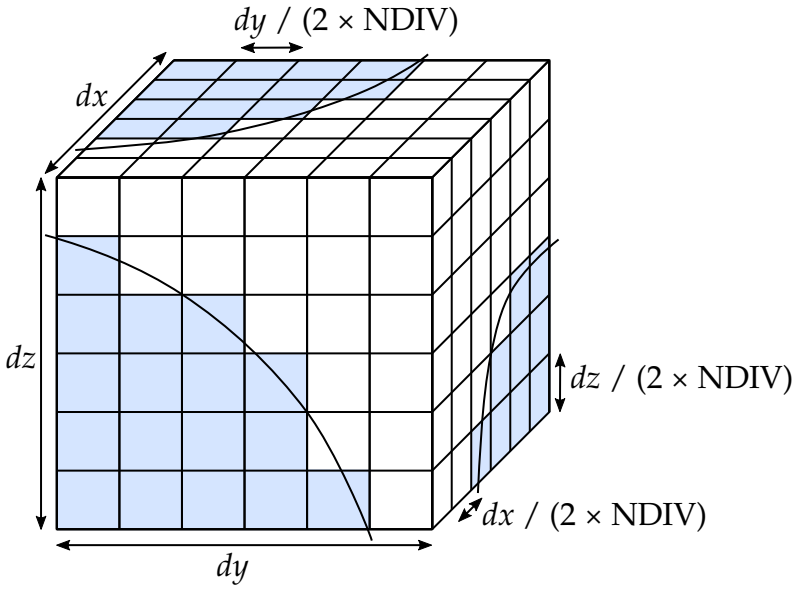

Figure 4-2. Division of an ALE element into $8 \times \text{NDIV}^3$ sub-cells to compute the volume fractions of elements cut by the surface defined by SURFCT

13. **Sub-Volumes.** Like NTRACE in *INITIAL_VOLUME_FRACTION_GEOMETRY, the division of an element into sub-volumes allows the computation of volume fractions of an element cut by the surface SURFCT. The definition of division differs from that for NTRACE in *INITIAL_VOLUME_FRACTION_GEOMETRY. For the initialization of *s*the volume fractions, the number of sub-volumes along an element edge is 2 × NTRACE + 1 for *INITIAL_VOLUME_FRACTION_GEOMETRY while it's 2 × NDIV for this keyword (see Figure 4-2).

14. **Segment Center.** The segment center is the average position of the segment nodes. By default, the local coordinate system is centered at this point. XC and YC can shift this center in the segment plane.

*ALE_MAPPING

Purpose: This card maps ALE data from a previous run to a region of elements at a given time. Data are read from or written to a mapping file specified with "map=" on the command line (see Remark 1). This keyword is *not* supported for S-ALE. To map data at the initial time to all the ALE domain (not just a region of elements) see *INITIAL_ALE_-MAPPING.

The following transitions are allowed:

1D → 2D	2D → 2D	3D → 3D
1D → 3D	2D → 3D	

Card Summary:

Card 1. This card is required.

AMMSID	RW						

Card 2. This card and all subsequent cards are optional.

NTIM	TBEG	TEND					

Card 3. This card is optional. It defines the location of the mapping for RW > 0. For RW = -1, if the subsequent cards are included, this card must be included as a blank line (all entries will be ignored).

VECID	ANGLE	XP	YP	ZP			

Card 4. This card is optional.

ID	TYPE	NVOL					

Card 4.1. Include NVOL of this card.

VOLTYP	VECID1	DW1	XL	YL	ZL	DW2	DV2

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	AMMSID	RW						
Type	I	I						
Default	none	-1						

VARIABLE	DESCRIPTION
AMMSID	Set ID of ALE multi-material groups defined in *SET_MULTI-MATERIAL_GROUP. See Remark 2.
RW	Flag defining if the keyword reads or writes in the mapping (see Remarks 3 and 4): EQ.-1: Write to the mapping file. See Remark 4. GT.0: Read from the mapping file. The magnitude of RW defines which part of the output to the mapping file is to be read in if more than one *ALE_MAPPING keywords was used to write the mapping file in the previous run. For example, if there was only one keyword used for writing the mapping file (most of the cases), set RW = 1 during the read.

"When" Card. Optional card to define the times of the mapping (see Remark 4).

Card 2	1	2	3	4	5	6	7	8
Variable	NTIM	TBEG	TEND					
Type	I	F	F					
Default	1	↓	ENDTIM					

VARIABLE	DESCRIPTION
NTIM	Number of times to write to the mapping file or data entry for the time selected to be read from the mapping file (see Remark 4):

VARIABLE	DESCRIPTION
	RW.EQ.-1: Number of times to write to the mapping file between the times TBEG and TEND. RW.GT.0: Data entry to be read if, during the previous run, a keyword *ALE_MAPPING with RW = -1 wrote several times to the mapping file. In most cases, only one time was output in which case NTIM = 1.
TBEG	RW.EQ.-1: Time to start writing to the mapping (TBEG = ENDTIM by default). See Remark 4. RW.GT.0: Time to which the read data entry indicated by NTIM will be mapped (TBEG = 0.0 by default).
TEND	For RW = -1 only, time to stop writing to the mapping file. See Remark 4.

"Where" Card. Optional card to define the location of the mapping for RW > 0 (see Remarks 5 and 6). For RW = -1, if the subsequent cards are included, this card must be included as a blank line (all entries will be ignored).

Card 3	1	2	3	4	5	6	7	8
Variable	VECID	ANGLE	XP	YP	ZP			
Type	I	F	F	F	F			
Default	0	0.0	0.0	0.0	0.0			

VARIABLE	DESCRIPTION
VECID	ID of the symmetric axis defined using *DEFINE_VECTOR. The fields XT, YT, and ZT in *DEFINE_VECTOR define the location of the origin in the previous run. See Remarks 5 and 6.
ANGLE	Angle of rotation in degrees around an axis defined by *DEFINE_VECTOR for the 3D to 3D mapping. See Remark 6.
XP	x-position of a point on a plane used by specific mappings (only for 2D plain strain to 3D mappings). See Remark 6.
YP	y-position of a point on a plane used by specific mappings (only for 2D plain strain to 3D mappings). See Remark 6.

VARIABLE	DESCRIPTION
ZP	z-position of a point on a plane used by specific mappings (only for 2D plain strain to 3D mappings). See Remark 6.

Region Card. Optional card to define which elements are targeted by the mapping (see Remark 7).

Card 4	1	2	3	4	5	6	7	8
Variable	ID	TYPE	NVOL					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
ID	Part ID, part set ID, or element set ID. See Remark 7.
TYPE	Type of "ID" (see Remark 7): EQ.0: Part set ID EQ.1: Part ID EQ.2: Element set ID
NVOL	Number of volumes in which the elements are selected for the mapping. See Remark 7.

Volume Card. Include NVOL of this card to define the volumes selecting the elements targeted by the mapping. See Remarks 7, 8, and 9.

Card 4.1	1	2	3	4	5	6	7	8
Variable	VOLTYP	VECID1	DW1	XL	YL	ZL	DW2	DV2
Type	I	I	F	F	F	F	F	F
Default	none	0	0.0	0.0	0.0	0.0	DW1	DV1

VARIABLE	DESCRIPTION
VOLTYP	Type of volume containing the selected elements for the mapping. The magnitude of VOLTYP indicates the type of volume. VOLTYP > 0 flags that the elements *inside* the volume are selected while VOLTYP < 0 indicates that the elements *outside* the volume are selected. The volume depends on geometrical lengths in a local coordinate system defined by orthonormal axis called **u**, **v** and **w** (see Remarks 7, 8, and 9). |VOLTYP|.EQ.1: Trapezoidal prism (see Figure 4-10) |VOLTYP|.EQ.2: Elliptic truncated cone (see Figure 4-11) |VOLTYP|.EQ.3: Ellipsoid (see Figure 4-12)
VECID1	ID of the local **u**-axis defined using *DEFINE_VECTOR. See Remark 8. LE.0: axis used to define special case volumes. See Remark 9.
DW1	Length in the local **w**-axis direction. See Remarks 8 and 9.
XL	Global *x*-position of a point used to define the local **v**-axis; the point cannot be on VECID1. See Remarks 8 and 9.
YL	Global *y*-position of a point used to define the local **v**-axis; the point cannot be on VECID1. See Remarks 8 and 9.
ZL	Global *z*-position of a point used to define the local **v**-axis; the point cannot be on VECID1. See Remarks 8 and 9.
DW2	Length in the local **w**-axis direction (DW2 = DW1 by default). See Remark 8.
DV2	Length in the local **v**-axis direction (DV2 = DV1 by default). See Remark 8.

Remarks:

1. **Mapping File.** To make one mapping, only the command-line argument "map=" is necessary. If RW = -1, the mapping file will be created and ALE data histories will be written to this file. If RW > 0, the mapping file will be read and ALE data histories will be used to interpolate the ALE variables of the selected elements.

   To include several successive mappings in the file, the prompt "map1=" is necessary. If RW = -1 and the prompt "map1=" is in the command line, the ALE

data are written to the mapping file given by "map1=." However, reading the map file is the same procedure as the single mapping case using "mapping=" on the command line.

The mapping file contains the following nodal and element data:

- nodal coordinates
- nodal velocities
- part IDs
- element connectivities
- element centers
- densities
- volume fractions
- stresses
- plastic strains
- internal energies
- bulk viscosities
- relative volumes

2. **Mapping of Multi-Material Groups.** The routines initiated by this keyword require knowing which mesh will be initialized with the mapping data and more specifically which multi-material groups will be mapped (if RW > 0) or output (for a next run if RW = -1). The field AMMSID refers to the *SET_MULTI-MATERIAL_GROUP_LIST card. That keyword defines a list of material groups in the current run. The number of entries in this list should match the number of entries from the previous run (as a reminder the data entries of multi-material groups are defined in *ALE_MULTI-MATERIAL_GROUP). For instance, if the previous model has 3 groups and the current one has 5 groups, the following is a possible mapping:

   The 1st group (previous) ⇒ the 3rd group (current),
   The 2nd group (previous) ⇒ the 5th group (current) and,
   The 3rd group (previous) ⇒ the 4th group (current).

   In this case, the *SET_MULTI-MATERIAL_GROUP_LIST card should be as follows:

```
*SET_MULTI-MATERIAL_GROUP_LIST
300
3,5,4
```

3. **Several Keywords Writing to the Mapping File.** Several instantiations of *ALE_MAPPING in a single run with RW = -1 can write to the mapping file. The

order with which the instantiations write to the file is important for retrieving the correct data. The first definition of *ALE_MAPPING with RW = -1 in the input deck will have the first position, the second *ALE_MAPPING with RW = -1 will have the second position, and so on. For instance, if 3 *ALE_MAPPING keywords output data to the mapping file during a previous run, then setting RW = 2 in the current run will cause LS-DYNA to read the data written in the previous run from the second instantiation.

4. **Writing Several Times to the Mapping File with a Single Keyword.** If NTIM > 1, *ALE_MAPPING with RW = -1 can write several times in the mapping file. When the time reaches TBEG, the data for TBEG are written to the mapping file. Then, data are output to the file NTIM-1 at $(\mathrm{TBEG} - \mathrm{TEND})/(\mathrm{NTIM} - 1)$ time intervals. If NTIM < 2, the data are only output for TBEG. The order of writing is in time order which is important for reading the data later. For instance, if the first run outputs data 4 times (NTIM = 4), then using RW = 1 and NTIM = 3 in a later run causes LS_DYNA to read the third time that data were written by the first run.

5. **Previous Origin.** Several *ALE_MAPPING with RW > 0 can map the same set of data to different parts of the current mesh by changing the origin of the previous run. The location of the origin is set by the fields XT, YT, and ZT in the *DEFINE_VECTOR referenced with VECID.

6. **Orientation Vector.** For a mapping file created by a previous asymmetric model, the symmetric axis orientation in the current model is specified by VECID. For a mapping file created by a 3D or 1D spherical model, the orientation of the vector VECID is computed but ignored. When 2D plain strain data are mapped in a 3D calculation, the point (XP,YP,ZP) together with the vector, VECID, define the plane in the 3D mesh where the mapping occurs.

7. **Elements for Mapping.** It's possible to select which elements should be the target of a mapping (if RW > 0) or have their data output in a mapping file (if RW = -1). The elements can be selected by part or element sets. Along with this first selection, volumes can defined (if NVOL > 0) to adjust the selection. The intersection of these volumes and sets provides the final selection.

   If NVOL > 0, NVOL extra lines at the end of the keyword should be added to define volumes for the element selection. Each line defines a volume. If VOLTYP > 0, the elements inside the intersection of these volumes are selected. If VOLTYP < 0, the elements outside the intersection of these volumes are selected.

8. **Defining Volumes.** Defining the three different kinds of volumes from the input fields requires a set of very similar steps. Defining VOLTYP = 1, the trapezoidal prism, will be discussed in detail to illustrate these steps. Then the differences

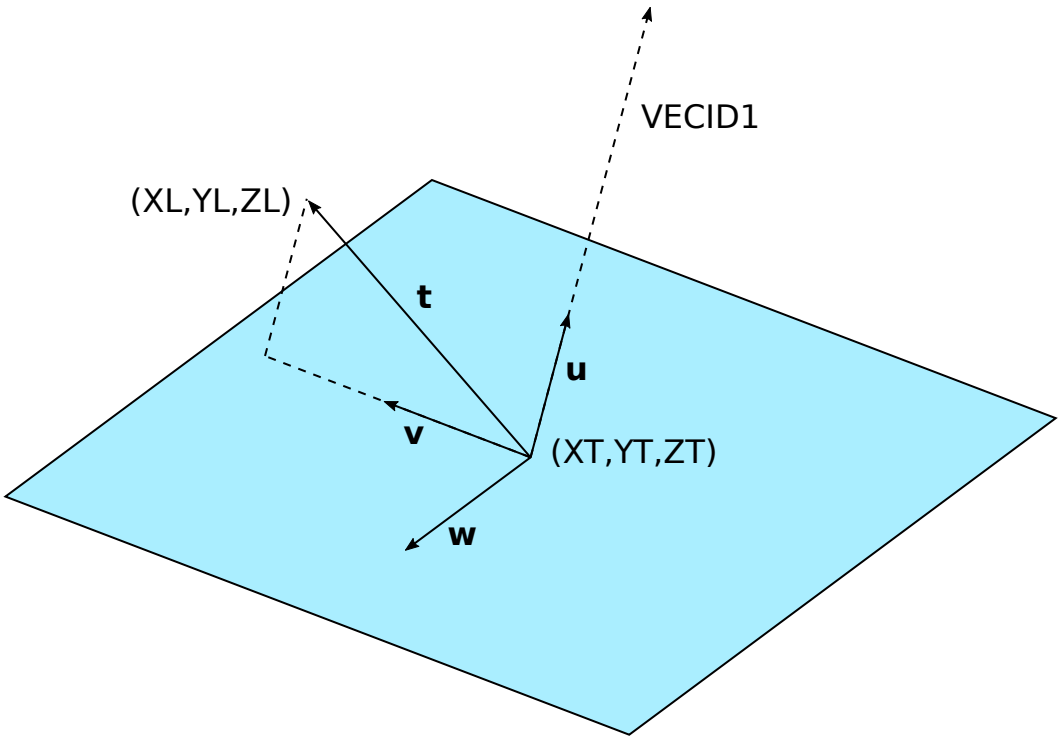

Figure 4-9. Local Coordinate System for the Defined Volumes

in how the fields are used for the other two volumes are highlighted following this discussion.

The first step required to construct the trapezoidal prism from the input fields is to define a local coordinate $(\mathbf{u}, \mathbf{v}, \mathbf{w})$.

a) *Defining the Local Coordinate System.* The local coordinate system is defined using a vector and a point, namely VECID1 and (XL,YL,ZL). The origin of the coordinate system is the tail of VECID1 which is the point (XT,YT,ZT) set in the *DEFINE_VECTOR input. See Figure 4-9.

   i) **u**-*axis.* The vector **u** is the unit direction of VECID1.

   ii) **v**-*axis.* From here the other two vectors can be constructed on the plane perpendicular to **u** using the point (XL,YL,ZL). Note that for this construction to work, (XL,YL,ZL) *cannot* be along the **u** vector. Let $\mathbf{t}$ = (XL,YL,ZL) − (XT,YT,ZT). Then, **v** is the unit vector along the projection of **t** onto the plane perpendicular to **u**.

   iii) **w**-*axis.* **w** is then the unit vector that completes the right-hand coordinate system.

The trapezoidal prism is constructed by connecting two faces defined with the local coordinate system. The two faces are both perpendicular to **u**. See Figure 4-10.

b) *First Face of the Trapezoidal Prism.* The first face is a rectangle on a plane that includes the point (XT,YT,ZT) and is perpendicular to **u**. The rectangle is centered at the point (XT,YT,ZT), and it has its sides oriented such that they align with the **v** and **w** vectors. The length of the side oriented along the **v**-axis is 2 × DV1. DV1 is the length of the projection of **t** onto the plane. The length of the side oriented along the **w**-axis is 2 × DW1, where DW1 is an input field.

c) *Second Face of the Trapezoidal Prism*. The second face of the trapezoidal is defined very similarly to the first. It is also a rectangle on a plane perpendicular to **u**, but the rectangle is centered on the point (XH,YH,ZH). This point is set in *DEFINE_VECTOR for VECID1. The sides are oriented the same way as in the first face definition. In this case the length of the side oriented along the **v**-axis is 2 × DV2 which is an input field. The length of the side oriented along the **w**-axis is 2 × DW2, where DW1 is an input field.

VOLTYP = 2, the elliptic truncated cone, is basically the same as the trapezoidal prism, except that it has two elliptic faces instead of two rectangular faces centered at the same locations as the rectangular faces. The ellipse semi-axes are aligned along **v** and **w** with lengths of DV1 and DW1 on the first face and lengths of DV2 and DW2 on the second face. DV1 is defined the same way as for the trapezoidal prism. See Figure 4-11.

VOLTYP = 3, the ellipsoid, is defined using an ellipse that is the same as the first face of the VOLTYP = 2. That ellipse is one of the symmetry planes of the ellipsoid. The ellipsoid is centered at the point (XT,YT,ZT). It has semi-axes that are the length of VECID1, DV1, and DW1 along **u**, **v**, and **w**, respectively. Both DV2 and DW2 are not used in this case. See Figure 4-12.

9. **Shortcuts for Defining Common Types of Volumes.** The keyword reader allows for certain shortcuts to define cylinders, ellipsoids with circular cross-sections, and spheres. All of these volumes can be constructed through the process described in Remark 8.

a) *Shortcut for Cylinder.* With VOLTYP = 2, a cylinder can be defined more simply with a vector and radius. To do this, let VECID1 be the axis of the cylinder, but to indicate to LS-DYNA that a shortcut is being used input the ID as a negative number. Set DW1 as the radius of the cylinder. No other input is required. The length of the cylinder is the length of VECID1. Its faces will be centered on the (XT,YT,ZT) and (XH,YH,ZH), just like an arbitrary truncated cone with ellipsoid faces.

b) *Shortcut for Ellipsoid with Circular Cross-Section.* To obtain an ellipsoid with a circular cross-section, set VOLTYP = 3 and pick a radius and the axis perpendicular to the cross-section. Set VECID1 to a the negative of the *DEFINE_VECTOR ID for the axis. Set the field DW1 as the radius. This input

will create an ellipsoid with a circular cross-section centered at the point (XT,YT,ZT). Like the normal ellipsoid definition, the remaining semi-axis will have the same length as VECID1.

c) *Shortcut for Sphere.* To obtain a sphere, set VOLTYP = 3 and VECID = 0. The only other required input are a radius which will be set in the field DW1 and a center point which will be set using (XL,YL,ZL).

10. **Comparison to *BOUNDARY_ALE_MAPPING.** Both *ALE_MAPPING and *BOUNDARY_ALE_MAPPING, can write multiple sets of data to a file at a given frequency between certain times. The big difference between these two keywords is reading the data. With *ALE_MAPPING, you select only one set of data to map from the previous run to the current run which is mapped at a time you select. With *BOUNDARY_ALE_MAPPING, all data output between t = BIRTH and t = DEATH from the previous run is mapped to the elements in the current run. The discrete histories from the previous run are interpolated.

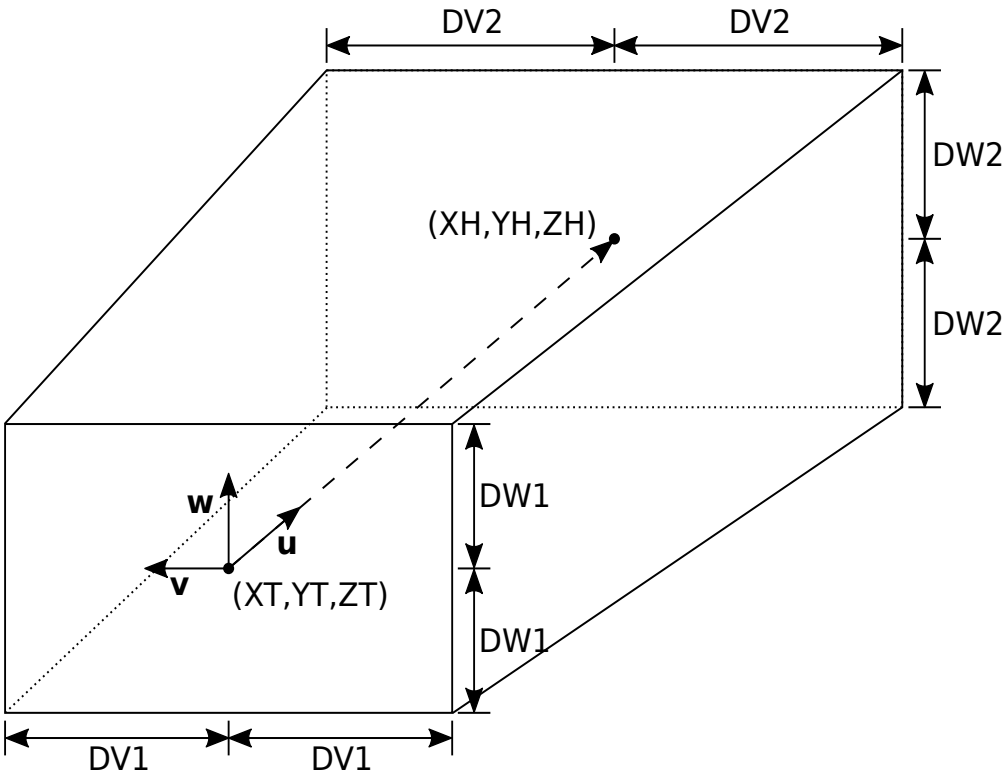

Figure 4-10. Trapezoidal Prism (VOLTYP = 1)

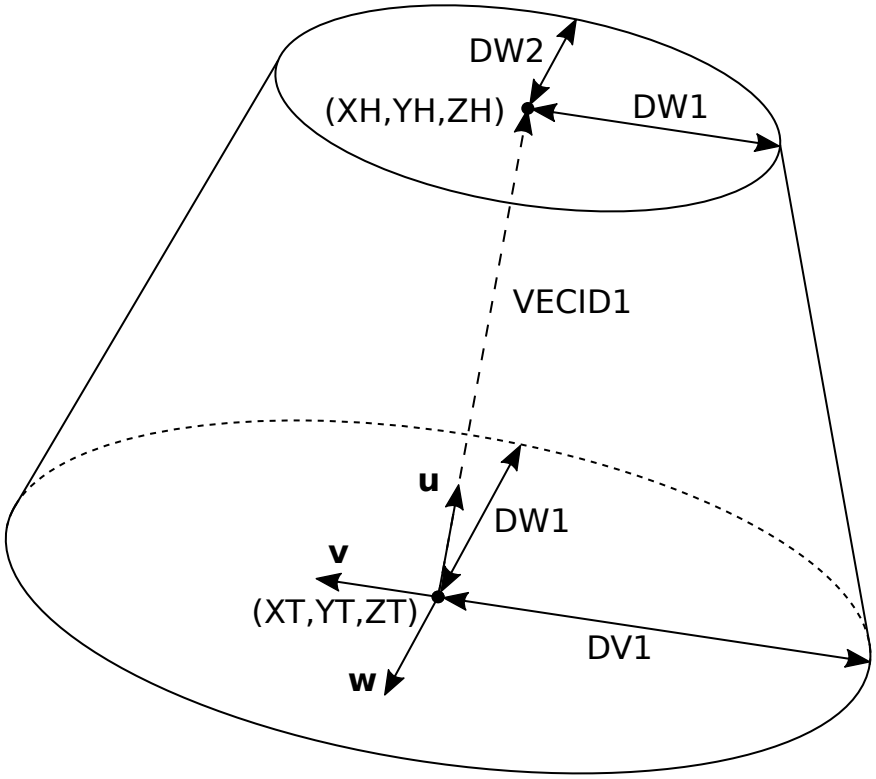

Figure 4-11. Elliptic Truncated Cone (VOLTYP = 2)

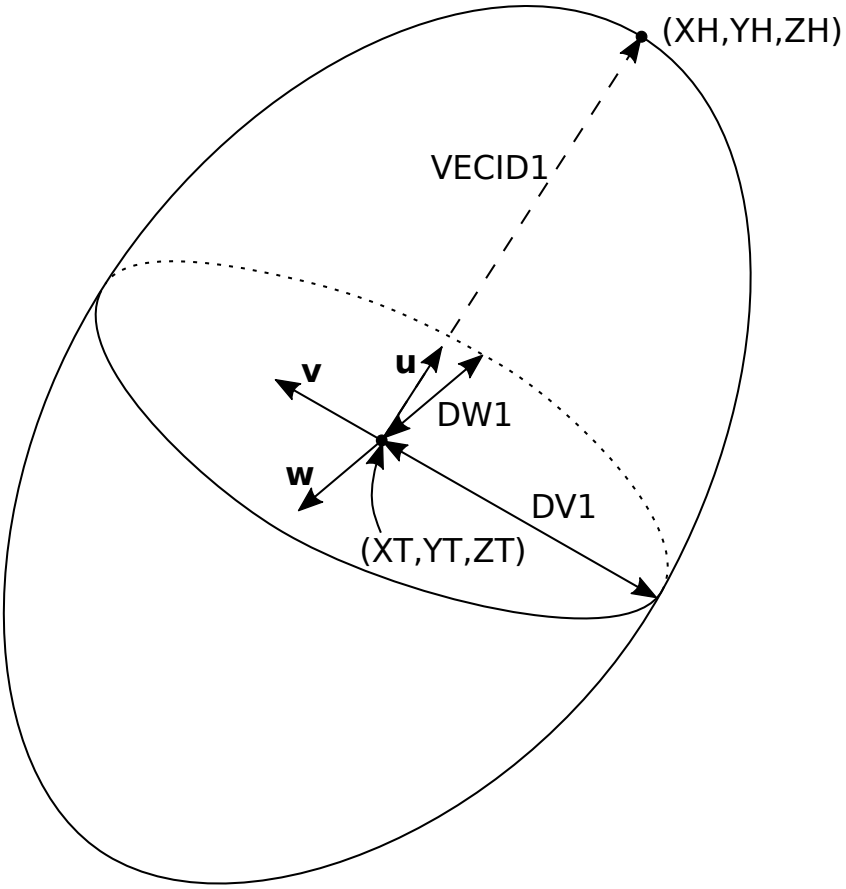

Figure 4-12. Ellipsoid (VOLTYP = 3)

*ALE_MAPPING_FROM_LAGRANGIAN

Purpose: Map data from a Lagrangian run (that is, non-ALE solid model) to ALE solids. Data are written to a mapping file called lag2ale_map (see Remark 1) that can be read back to initialize a 3D ALE mesh (see *INITIAL_ALE_MAPPING). To generate the mapping file, this keyword should be included in the input deck for the Lagrangian simulation.

Card Summary:

Card 1. This card is required to select which Lagrangian parts are mapped.

LAGPID	LAGPTYP						

Card 2. This card is required to generate the ALE mesh which Lagrangian data are mapped to.

NX	NY	NZ	NPX	NPY	NPZ	ALEPID	

Card 3. This card is optional. It controls how the volumes shared by the Lagrangian and ALE elements are computed.

METHOD	DIV						

Data Card Definitions:

Lagrangian Card. Card to select which Lagrangian parts are mapped.

Card 1	1	2	3	4	5	6	7	8
Variable	LAGPID	LAGPTYP						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
LAGPID	Part or part set ID for Lagrangian parts involved in the mapping
LAGPTYP	Type of LAGPID: EQ.0: ID is a part set ID (see *SET_PART) EQ.1: ID is a part ID (see *PART)

ALE Mesh Card. Card to create the ALE mesh which Lagrangian data are mapped to.

Card 2	1	2	3	4	5	6	7	8
Variable	NX	NY	NZ	NPX	NPY	NPZ	ALEPID	
Type	I	I	I	I	I	I	I	
Default	none	none	none	0	0	0	none	

VARIABLE	DESCRIPTION
NX, NY, NZ	Number of ALE elements in each direction of the global coordinate system. These parameters create a structured box mesh. See Remark 2.
NPX, NPY, NPZ	Number of extra elements to pad the box mesh beyond its lower and upper limits in each direction of the global coordinate system. See Remark 2.
ALEPID	Part ID of the ALE mesh

Intersection Computation Card. Optional card to control how the volumes shared by the Lagrangian and ALE elements are computed (see Remark 3).

Card 3	1	2	3	4	5	6	7	8
Variable	METHOD	DIV						
Type	I	I						
Default	0	10						

VARIABLE	DESCRIPTION
METHOD	Method to compute volumes at the intersection of Lagrangian and ALE elements: EQ.0: Both METHOD = 1 and METHOD = 2 are applied by default. See Remark 3. EQ.1: The intersection volumes are exactly computed.

VARIABLE	DESCRIPTION
	EQ.2: The intersection volumes are evaluated with DIV. See Remark 3.
DIV	Division of ALE element edges to create subcells, which volumes inside Lagrangian elements are added up by METHOD = 2 to approximate the intersection volumes at the intersection between ALE and Lagrangian elements. See Remark 3.

Remarks:

1. **Output Files.** When the Lagrangian run normally terminates with this keyword in the input deck, the following files are generated:

File Name	Description
lag2ale_lagmesh.k	Lagrangian mesh selected by this keyword
lag2ale_alemesh.k	ALE mesh generated by this keyword
lag2ale_volfrac.k	Fractions of the ALE element volumes occupied by Lagrangian elements. These volume fractions are listed in this file using *INITIAL_VOLUME_FRACTION.
lag2ale_mass	Lagrangian element masses distributed across the ALE mesh
lag2ale_stress.k	Lagrangian element stresses distributed across the ALE mesh. These stresses are listed in this file with *INITIAL_STRESS_SOLID.
lag2ale_velo.k	Lagrangian velocities interpolated at ALE nodes. These velocities are listed in this file with *INITIAL_VELOCITY_NODE.
lag2ale_map	Mapping file that can be read back with the command-line argument "map = " and *INITIAL_ALE_MAPPING to initialize the run of an ALE model with a mesh similar to the one in lag2ale_alemesh.k (that is, you can opt for a different ALE mesh, but its size, position and element size should be close to lag2ale_alemesh.k for the mapping to work properly)

2. **ALE Mesh.** The ALE mesh, which Lagrangian data are mapped to, is made of identical parallelepiped hexahedral solids. The nodal connectivities and nodal coordinates are listed under *ELEMENT_SOLID and *NODE, respectively, in a file called lag2ale_alemesh.k. The structured mesh has 2 zones:

a) A core mesh is a box of NX × NY × NZ elements. The box exactly embeds the Lagrangian parts selected by LAGPID. In other words, the dimensions of all these Lagrangian parts in each direction gives the box size.

b) The core mesh can be padded with extra layers of elements. NPX, NPY, and NPZ are the number of extra elements in each global direction.

3. **Mesh Intersection.** If a Lagrangian element is superimposed with an ALE element from the mesh created by this keyword, the volume that they share can be evaluated by 2 methods:

a) *METHOD = 1.* The computation of the intersections between edges and faces yields a volume that can be calculated in most of the cases.

b) *METHOD = 2.* The intersection volume is approximated by summing the volumes of smaller DIV × DIV × DIV subcells that:

i) divide the ALE element volumes and

ii) are inside the Lagrangian element

For the default (METHOD = 0), both methods are applied. In this case, if METHOD = 1 fails, METHOD = 2 will provide the intersection volume.

*ALE_MESH_INTERFACE

Purpose: Mesh with triangular shells the material interfaces (isosurfaces of the volume fraction 0.5) of ALE groups selected by a multi-material group set. The keyword also meshes the volume of these materials with tetrahedra. The meshes are output in keyword format when the run reaches termination time or if the user applies a sense switch (Ctrl-C and then enter a SW code when prompted. See "Sense Switch Controls" in "Getting Started").

Card 1	1	2	3	4	5	6	7	8
Variable	MMGSET	NOWRT	VOLRAT	INTERP				
Type	I	I	F	I				
Default	none	0	0.0	0				

Remeshing Card. Optional card controlling remeshing of the interface (see Remark 2).

Card 2	1	2	3	4	5	6	7	8
Variable	EDGMIN	EDGMAX						
Type	F	F						
Default	0.0	0.0						

VARIABLE	DESCRIPTION
MMGSET	Multi-Material Set ID (see *SET_MULTI-MATERIAL_GROUP_-LIST). The materials (or ALE groups) in this set are selected to be meshed.
NOWRT	File output flag. NOWRT is interpreted digit-wise, NOWRT = [*PNML*]: $$\text{NOWRT} = L + M \times 10 + N \times 100 + P \times 1000$$ The 1's digit controls the output of the initial triangular mesh on the material interfaces:

VARIABLE	DESCRIPTION
	L.EQ.0: Write the initial triangular meshes for the material interfaces (see Remark 1). The mesh is output to a keyword file called alemeshmatint.k. L.EQ.1: Do not output alemeshmatint.k. The 10's digit controls the output of the remesh for the triangular mesh on the material interface: M.EQ.0: Write triangular mesh on the material interfaces after remeshing (see Remark 2) to a keyword file called aleremeshmatint.k. M.EQ.1: Do not output aleremeshmatint.k. The 100's digit controls the output of the mesh in the material volumes: N.EQ.0: Write tetrahedral mesh of the material volumes to a keyword file called alemeshmatvol.k. N.EQ.1: Do not output alemeshmatvol.k. The 1000's digit controls the output of a mapping file that can be read back with *INITIAL_LAG_MAPPING to initialize the tetrahedral mesh in alemeshvolmatvol.k: P.EQ.0: Write the Lagrangian mapping file called alemeshmap.k. P.EQ.1: Do not output alemeshmap.k.
VOLRAT	Mesh volume ratio beyond which the mesh is output (see Remark 3)
INTERP	Interpolation method: EQ.0: The ALE hexahedron data are interpolated at the Lagrangian tetrahedron centers. EQ.1: The intersection volumes between ALE hexahedra and Lagrangian tetrahedra are computed, and the ALE data are mapped to the Lagrangian elements with a volume-averaged method.
EDGMIN	Minimum triangle edge applied during remeshing (see Remark 2)
EDGMAX	Maximum triangle edge applied during remeshing (see Remark 2)

Remarks:

1. **Initial material interface mesh.** The isosurfaces of the volume fraction 0.5 (material interfaces) for the selected ALE groups (materials) are first meshed with triangles, whose areas depend on the ALE element face sizes and how the material interface cuts these elements. For instance, if a material interface in an ALE element is parallel to one of its faces, the area of the 2 triangles meshing the interface will be half the face area. If the material interface only cuts one corner of an ALE element, the resulting triangular surface will be one shell. In this case, if the material volume is small, the triangle meshing the material interface will be small as well. Thus, the interface mesh can have triangles of very different sizes. If the material volume needs to be meshed, a remeshing of its surface is required. If a material is in contact with the ALE mesh boundary, this contact surface will be meshed to ensure a closed volume.

2. **Remeshing of the material interface.** The material interface is remeshed based on the coordinates of the first try to mesh it. The remeshing code is the same as the one controlled by *CONTROL_REMESHING. Similar to RMIN and RMAX for that keyword, each triangle edge of the new mesh should be between a minimum EDGMIN and maximum EDGMAX. If these parameters are not provided, EDGMIN and EDGMAX are the minimum and maximum edge size of the initial mesh, respectively.

3. **Mesh volume ratio threshold.** A material can be divided into several volumes. Some of them could be so small that they would be useless or difficult to mesh. If one of these fragments has a ratio of its volume over the total material volume smaller than VOLRAT, the fragment will not be meshed.

4. **Part IDs in alemeshmatint.k.** If a material is fragmented into N volumes, each of these fragments will have a specific part ID in alemeshmatint.k. The ID for fragment i with $1 \leq i \leq N$ of the j^{th} ALE group is $\times\, 1000 + j$.

5. **File names.** If there are several *ALE_MESH_INTERFACE, files are output for each of these keywords. The base names for a given instance of this keyword are appended with a number that refers to the order in which that instance is included, meaning the output for the second instance, for example, would have a 2 appended.

*ALE_MULTI-MATERIAL_GROUP

Purpose: This command defines the appropriate ALE material groupings for interface reconstruction when two or more ALE Multi-Material Groups (AMMG) are present in a model. This card is required when ELFORM = 11 in the *SECTION_SOLID card or when ALEFORM = 11 in *SECTION_ALE1D or *SECTION_ALE2D. Each data line represents one ALE multi-material group (AMMG), with the first line referring to AMMGID 1, second line AMMGID 2, etc. Each AMMG represents one unique "fluid" which may undergo interaction with any Lagrangian structure in the model.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	IDTYPE						
Type	I	I						
Default	none	0						
Remarks	1							

VARIABLE	DESCRIPTION
SID	Set ID
IDTYPE	Set type: EQ.0: Part set, EQ.1: Part.

Remarks:

1. **ELFORM.** When ELFORM = 12 in the *SECTION_SOLID card (single material and void), this card should not be used. In one model, ELFORM = 12 cannot be used together with ELFORM = 11. If possible, it is recommended that ELFORM = 11 be used as it is the most robust and versatile formulation for treating multi-material ALE parts.

2. **AMMGID Assignment.** Each AMMG is automatically assigned an ID (AMMGID) and consists of one or more PART IDs. The interface of each AMMGID is reconstructed as it evolves dynamically. Each AMMGID is represented by one material contour color in LS-PrePost.

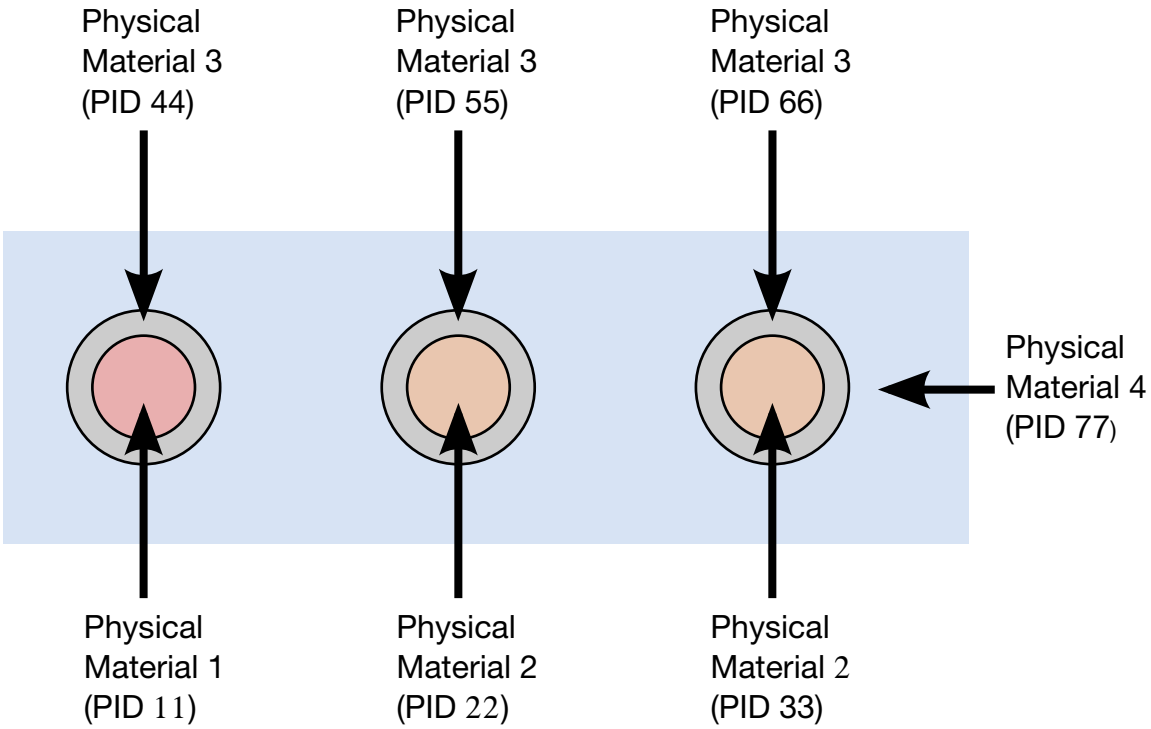

Figure 4-13. Schematic illustration of Example 1.

3. **ALE Elements and AMMGs.** The maximum number of AMMGIDs allowed has been increased to 20. However, there may be 2, at most 3, AMMGs inside an ALE element at any time. If there are more than 3 AMMGs inside any 1 ALE element, the ALE mesh needs refinement. Better accuracy is obtained with 2 AMMGs in mixed elements.

4. **Plotting AMMGIDs.** To plot these AMMGIDs in LS-PrePost:

   [FCOMP] ⇒ [MISC] ⇒ [VOLUME FRACTION OF AMMGID #] ⇒ [APPLY]

   (Note: Contour definitions maybe different for gas mixture application)

5. **Model Description.** It is very important to distinguish among the

   a) Physical materials,

   b) PART IDs, and

   c) AMMGIDs.

   A *PART may be any mesh component. In ALE formulation, it is simply a geometric entity and a time = 0.0 concept. This means a *PART may be a mesh region that can be filled with one or more AMMGIDs at time zero, via a volume filling command (*INITIAL_VOLUME_FRACTION_GEOMETRY). An AM-

MGID represents a physical material group which is treated as one material entity (represented by 1 material color contour in LS-PrePost plotting). AMMGID is used in dealing with multiple ALE or Eulerian materials. For example, it can be used to specify an ALE group in a coupling card.

Example 1:

Consider a purely Eulerian model containing 3 containers containing 2 different physical materials (fluids 1 and 2). All surrounded by the background material (maybe air). The containers are made of the same material, say, metal. Assume that these containers explode and spill the fluids. We want to track the flow and possibly mixing of the various materials. Note that all 7 parts have ELFORM = 11 in their *SECTION_SOLID cards. So we have total of 7 PIDs, but only 4 different physical materials. See Figure 4-13.

Approach 1: If we want to track only the interfaces of the **physical** materials.

```
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
*SET_PART
         1
        11
*SET_PART
         2
        22        33
*SET_PART
         3
        44        55        66
*SET_PART
         4
        77
*ALE_MULTI-MATERIAL_GROUP
         1         0   ← 1st line = 1st AMMG ⇒ AMMGID = 1
         2         0   ← 2nd line = 2nd AMMG ⇒ AMMGID = 2
         3         0   ← 3rd line = 3rd AMMG ⇒ AMMGID = 3
         4         0   ← 4th line = 4th AMMG ⇒ AMMGID = 4
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
```

With this approach, we define only 4 AMMGs (NALEGP = 4). So in LS-PrePost, when plotting the material-group (history variable) contours, we will see 4 colors, one for each material group. One implication is that when the fluids from part 22 and part 33 flow into the same element, they will coalesce and no boundary distinction between them is maintained subsequently. While this may be acceptable for fluids at similar thermodynamic states, this may not be intuitive for solids. For example, if the solid container materials from parts 44, 55 and 66 flow into one element, they will coalesce "like a single fluid", and no interfaces among them are tracked. If this is undesirable, an alternate approach may be taken. It is presented next.

Approach 2: If we want to reconstruct as many interfaces as necessary, in this case, we follow the interface of each part.

```
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
*ALE_MULTI-MATERIAL_GROUP
         1         1   ← 1st line = 1st AMMG ⇒ AMMGID = 1
         2         1   ← 2nd line = 2nd AMMG ⇒ AMMGID = 2
         3         1   ← 3rd line = 3rd AMMG ⇒ AMMGID = 3
         4         1   ← 4th line = 4th AMMG ⇒ AMMGID = 4
         5         1   ← 4th line = 5th AMMG ⇒ AMMGID = 5
         6         1   ← 4th line = 6th AMMG ⇒ AMMGID = 6
         7         1   ← 4th line = 7th AMMG ⇒ AMMGID = 7
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|....8
```

There are 7 AMMGs in this case (NALEGP = 7). This will involve more computational cost for the additional tracking. Realistically, accuracy will be significantly reduced if there are more than 3 or 4 materials in any one element. In that case, higher mesh resolution may be required.

Example 2:

Oil	Water	Air
Group 1	Group 2	Group 3
Part IDs 1 and 2	Part ID 3	Part IDs 5, 6, and 7

The above example defines a mixture of three groups of materials (or "fluids"), oil, water and air, that is, the number of ALE multi-material groups (AMMGs) NALEGP = 3.

The first group contains two parts (materials), part IDs 1 and 2.

The second group contains one part (material), part ID 3.

The third group contains three parts (materials), part IDs 5, 6 and 7.

*ALE_PRESCRIBED_MOTION

Purpose: Define an imposed nodal motion on a set of multi-material ALE groups for a given time span (if this time frame is short enough, velocity initialization by group can be considered).

Card 1	1	2	3	4	5	6	7	8
Variable	MMSID	INSIDE	SIDR					
Type	I	I	I					
Default	none	0	0					

Remaining cards are optional.†

Translational Velocity Card. Optional card for the translational velocity (see Remark 1).

Card 2	1	2	3	4	5	6	7	8
Variable	LCVTX	LCVTY	LCVTZ					
Type	I	I	I					
Default	Rem 1	Rem 1	Rem 1					

Rotational Velocity Card. Optional card for the rotational velocity (see Remark 1).

Card 3	1	2	3	4	5	6	7	8
Variable	LCVRX	LCVRY	LCVRZ					
Type	I	I	I					
Default	Rem 1	Rem 1	Rem 1					

Center of Rotation Card. Optional card for defining a center of rotation.

Card 4	1	2	3	4	5	6	7	8
Variable	XG	YG	ZG					
Type	F	F	F					
Default	Rem 4	Rem 4	Rem 4					

VARIABLE	DESCRIPTION
MMSID	Multi-Material Set ID (see *SET_MULTI-MATERIAL_GROUP_-LIST).
INSIDE	Flag to define which nodes the motion is prescribed for (see Remark 2): EQ.0: Nodes connected to at least one ALE element that is at the minimum partially filled by a group of MMSID EQ.1: Nodes connected to at least one ALE element that is fully filled by a group of MMSID EQ.2: Nodes only connected to ALE elements that are fully filled by a group of MMSID.
SIDR	Flag controlling the use of this keyword during dynamic relaxation: EQ.0: the keyword is applied during the normal analysis phase only. EQ.1: the keyword is applied during the dynamic relaxation phase but not the normal analysis phase. EQ.2: the keyword is applied during both the dynamic relaxation and the normal analysis phases.
LCVTX LCVTY LCVTZ	Curve IDs for the translation in each global direction; see *DEFINE_CURVE. See Remark 3.
LCVRX LCVRY LCVRZ	Curve IDs for the rotation around each global direction; see *DEFINE_CURVE. See Remark 3.
XG, YG, ZG	Position of the rotation center. See Remark 4.

Remarks:

1. **Zero Velocity.** If only the 1st card is defined, the velocities of the nodes inside ALE groups defined by MMSID are set to zero.

2. **INSIDE.** Depending on the flag INSIDE, the motion is applied to nodes connected to elements partially or fully filled by ALE groups of the set MMSID. For INSIDE = 0, when an element is partially filled by one of these groups, the motion of all its nodes will be prescribed. INSIDE = 1 is more restrictive and only selects nodes connected to at least one element fully filled by a group in MMSID. INSIDE = 2 is even more selective: nodes connected to only fully filled elements are considered. So INSIDE = 1 can apply velocities to nodes at the boundary between fully filled and "empty" elements while INSIDE = 2 only selects nodes inside the ALE group surrounded by fully filled elements.

3. **Birth and Death Times.** The smallest and largest times in the curves are the birth and death times of the related motions. If these time frames are equal to (or slightly larger than) the time step, the related velocities can be initialized during the first cycle.

4. **Rotation Center.** If the rotation center (XG, YG, ZG) is undefined (no 4th card), the rotation is applied around an axis (defined by LCVRX, LCVRY, LCVRZ) passing through the center of mass of the groups defined by MMSID. In an ALE 2D model, this center is shifted to the Y-axis. If the card is included, but has blank fields, then the blank field values default 0.0.

*ALE_REFERENCE_SYSTEM_CURVE

Purpose: This command defines a motion and/or a deformation prescribed for a geometric entity, where a geometric entity may be any part, part set, node set, or segment set. The motion or deformation is completely defined by the 12 parameters shown in the equation below. These 12 parameters are defined in terms of 12 load curves. This command is required only when PRTYPE = 3 in the *ALE_REFERENCE_SYSTEM_GROUP command.

Card 1	1	2	3	4	5	6	7	8
Variable	ID							
Type	I							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	LCID1	LCID2	LCID3	LCID4	LCID5	LCID6	LCID7	LCID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

Card 3	1	2	3	4	5	6	7	8
Variable	LCID9	LCID10	LCID11	LCID12				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
ID	Curve group ID.
LCID1, …, LCID12	Load curve IDs.

Remarks:

1. The velocity of a node at coordinate (x, y, z) is defined as:

$$\begin{Bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \end{Bmatrix} = \begin{Bmatrix} f_1 \\ f_5 \\ f_9 \end{Bmatrix} + \begin{bmatrix} f_2 & f_3 & f_4 \\ f_6 & f_7 & f_8 \\ f_{10} & f_{11} & f_{12} \end{bmatrix} \begin{Bmatrix} x - \mathrm{XC} \\ y - \mathrm{YC} \\ z - \mathrm{ZC} \end{Bmatrix}$$

where $f_1(t)$ is the value of load curve LCID1 at time t, $f_2(t)$ is the value of load curve LCID2 at time t and so on. The functions $f_1(t), f_5(t)$, and $f_9(t)$ respectively correspond to the translation components in global x, y, and z direction, while the functions $f_2(t), f_7(t)$, and $f_{12}(t)$ correspond to and expansion or contraction along the x, y, and z axes.

The parameters XC, YC and ZC from the second data card of *ALE_REFERENCE_SYSTEM_GROUP define the center of rotation and expansion of the mesh. If the mesh translates, the center position is updated with $f_1(t), f_5(t)$, and $f_9(t)$.

If LCID8, LCID10, LCID3 are equal to -1, their corresponding values $f_8(t), f_{10}(t)$, and $f_3(t)$ will be equal to $-f_{11}(t)$, $-f_4(t)$, and $-f_6(t)$ so as to make a skew symmetric matrix thereby inducing a rigid rotation of the mesh about the axis **v** defined by the triple,

$$\mathbf{v} = \left(f_{11}(t), f_4(t), f_6(t)\right)$$

Example:

Consider a motion that consists of translation in the x and y direction only. Thus only $f_1(t)$ and $f_5(t)$ are required. Hence only 2 load curve ID's need be defined:

*ALE_REFERENCE_SYSTEM_GROUP

Purpose: Associate a geometric entity to a reference system type. A geometric entity may be any part, part set, node set, or segment set of a model (or a collection of meshes). A reference system type refers to the possible transformation allowed for a geometric entity (or mesh). This command defines the type of reference system or transformation that a geometric entity undergoes. In other words, it prescribes how a specified mesh can translate, rotate, expand, contract, be fixed in space, etc.

Card 1	1	2	3	4	5	6	7	8

Card 3	1	2	3	4	5	6	7	8
Variable	IPIDXCL	IPIDTYP						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
SID	Set ID
STYPE	Set type: EQ.0: part set EQ.1: part EQ.2: node set EQ.3: segment set
PRTYPE	Reference system type (see Remark 1): EQ.0: Eulerian EQ.1: Lagrangian EQ.2: Normal ALE mesh smoothing EQ.3: Prescribed motion following load curves; see *ALE_REFERENCE_SYSTEM_CURVE. EQ.4: Automatic mesh motion following mass weighted average velocity in ALE mesh EQ.5: Automatic mesh motion following a local coordinate system defined by three user defined nodes; see *ALE_REFERENCE_SYSTEM_NODE. EQ.6: Switching in time between different reference system types; see *ALE_REFERENCE_SYSTEM_SWITCH. EQ.7: Automatic mesh expansion in order to enclose up to twelve user defined nodes; see *ALE_REFERENCE_SYSTEM_NODE. EQ.8: Mesh smoothing option for shock waves, where the element grid contracts in the vicinity of the shock front: this may be referred to as the Delayed-ALE option. It controls how much the mesh is to be moved during the remap step. This option requires the definition of the 5th parameter Card 2, EFAC; see below for definition. EQ.9: Allowing the ALE mesh(es) to: 1. Translate and/or rotate to follow a local Lagrangian reference coordinate system (whose *ALE_REFERENCE_SYSTEM_NODE card ID is defined by the BCTRAN parameter)

VARIABLE	DESCRIPTION
	2. Expand or contract to enclose a Lagrangian part set ID defined by the PRID parameter. 3. Has a Lagrangian node ID be defined by the ICR/NID parameter to be the center of the ALE mesh expansion.
PRID	A parameter giving additional information depending on the reference system (PRTYPE) choice: PRTYPE.EQ.3: PRID defines a load curve group ID specifying an *ALE_REFERENCE_SYSTEM_CURVE card for mesh translation. This defines up to 12 curves which prescribe the motion of the system. PRTYPE.EQ.4: PRID defines a node set ID (*SET_NODE), for which a mass average velocity is computed. This velocity controls the mesh motion. PRTYPE.EQ.5: PRID defines a node group ID specifying an *ALE_REFERENCE_SYSTEM_NODE card, via which, three nodes forming a local coordinate system are defined. PRTYPE.EQ.6: PRID defines a switch list ID specifying an *ALE_REFERENCE_SYSTEM_SWITCH card. This defines the switch times and the reference system choices for each time interval between the switches. PRTYPE.EQ.7: PRID defines a node group ID specifying an *ALE_REFERENCE_SYSTEM_NODE card. Up to 12 nodes in space forming a region to be enveloped by the ALE mesh are defined. PRTYPE.EQ.9: PRID defines a Lagrangian part set ID (PSID) defining the Lagrangian part(s) whose range of motion is to be enveloped by the ALE mesh(es). This is useful for airbag modeling.
If PRTYPE = 4 or PRTYPE = 5, then	
BCTRAN	BCTRAN is a translational constraint (Remark 3). EQ.0: no constraints EQ.1: constrained x translation

VARIABLE	DESCRIPTION
	EQ.2: constrained y translation
	EQ.3: constrained z translation
	EQ.4: constrained x and y translation
	EQ.5: constrained y and z translation
	EQ.6: constrained z and x translation
	EQ.7: constrained x, y, and z translation
Else If PRTYPE = 9, then	
BCTRAN	BCTRAN is a node group ID from a *ALE_REFERENCE_SYSTEM_NODE card prescribing a local coordinate system (3 node IDs) whose motion is to be followed by the ALE mesh(es).
Else	
BCTRAN	Ignored
End if	
BCEXP	For PRTYPE = 4 and 7, BCEXP is an expansion constraint; otherwise it is ignored (Remark 3).
	EQ.0: no constraints
	EQ.1: constrained x expansion
	EQ.2: constrained y expansion
	EQ.3: constrained z expansion
	EQ.4: constrained x and y expansion
	EQ.5: constrained y and z expansion
	EQ.6: constrained z and x expansion
	EQ.7: constrained x, y, and z expansion
BCROT	BCROT is a rotational constraint (Remark 3). It is ignored unless PRTYPE = 4.
	EQ.0: no constraints
	EQ.1: constrained x rotation
	EQ.2: constrained y rotation

VARIABLE	DESCRIPTION
	EQ.3: constrained z rotation
	EQ.4: constrained x and y rotation
	EQ.5: constrained y and z rotation
	EQ.6: constrained z and x rotation
	EQ.7: constrained x, y, and z rotation
If PRTYPE = 4	
ICR/(NID)	ICR is a flag the specifies the method LS-DYNA uses for determining the center point for expansion and rotation (Remark 3).
	EQ.0: The center is at center of gravity of the ALE mesh.
	EQ.1: The center is at (XC,YC,ZC), just a point in space (it does not have to be a defined node)
Else if PRTYPE = 9	
(ICR)/NID	NID sets the Lagrangian node ID for the node that anchors the center of ALE mesh expansion (Remark 2).
End if	
XC, YC, ZC	Center of mesh expansion and rotation for PRTYPE = 4; otherwise ignored. See ICR above.
EXPLIM	Limit ratio for mesh expansion and contraction. Each cartesian direction is treated separately. The distance between the nodes is not allowed to increase by more than a factor EXPLIM or decrease to less than a factor 1/EXPLIM. This flag applies only for PRTYPE = 4, otherwise it is ignored.
EFAC	Mesh remapping factor for PRTYPE = 8 only, otherwise it is ignored. EFAC ranges between 0.0 and 1.0. When EFAC approaches 1.0, the remapping approaches the Eulerian behavior. The smaller the value of EFAC, the closer the mesh will follow the material flow in the vicinity of a shock front, that is, approaching Lagrangian behavior.

VARIABLE	DESCRIPTION
	Note that excessively small values for EFAC can result in severe mesh distortions as the mesh follows the material flow. As time evolves, the mesh smoothing behavior will approach that of an Eulerian system.
FRCPAD	For PRTYPE = 9 this is an ALE mesh padding fraction, otherwise it is ignored. FRCPAD ranges from 0.01 to 0.2. If the characteristic Lagrange mesh dimension, dL_1, exceeds $$(1 - 2 \times \text{FRCPAD}) \times dL_A,$$ where dL_A is the characteristic length of the ALE mesh, then the ALE mesh is expanded so that $$dL_A = \frac{dL_1}{1 - 2 \times \text{FRCPAD}}.$$ This provides an extra few layers of ALE elements beyond the maximum Lagrangian range of motion. EQ.0.01: $dL_A = {dL_L}/{0.98} = dL_L \times 1.020408$ EQ.0.20: $dL_A = {dL_L}/{0.60} = dL_L \times 1.666667$
IEXPND	For PRTYPE = 9, this is an ALE mesh expansion control flag, otherwise it is ignored. EQ.0: Both mesh expansion and contraction are allowed. EQ.1: Only mesh expansion is allowed.
IPIDXCL	An ALE set ID to be excluded from the expansion and/or contraction only. Translation and rotation are allowed. For example, this may be used to prevent the ALE mesh (or part) at the inflator gas inlet region from expanding too much. High ALE mesh resolution is usually required to resolve the high speed flow of the gas into the airbag via point sources. See Remark 2.
IPIDTYPE	Set ID type of IPIDXCL: EQ.0: PSID EQ.1: PID

Remarks:

1. **Required Associated Cards.** Some PRTYP values may require a supplemental definition defined using the corresponding PRID. For example, PRTYP = 3 requires a *ALE_REFERENCE_SYSTEM_CURVE card. If PRID = *n*, then in the corresponding *ALE_REFERENCE_SYSTEM_CURVE card, ID = *n*. Similar association applies for any PRTYP (i.e. 3, 5, 6, or 7) which requires a definition for its corresponding PRID parameter.

2. **Mesh Centering.** For PRTYPE = 9, ICR/NID can be used to keep a high density ALE mesh centered on the region of greatest interest, such as the inflator orifices region in an airbag model. For example, in the case of nonsymmetrical airbag deployment, assuming that the ALE mesh is initially finer near the inlet orifices and gradually coarsened away from it, defining an "anchor node" at the center of the orifice location will keep the fine ALE mesh region centered on the orifice region. Then this fine ALE mesh region will not be shifted away (from the point sources) during expansion and translation. The ALE mesh can move and expand outward to envelop the Lagrangian airbag in such a way that the inlet is well resolved throughout the deployment.

3. **Additional Constraints.** The table below shows the applicability of the various choices of PRTYPE. Simple deductions from the functional definitions of the PRTYPE choices will clarify the applications of the various constraints. For example, when PRTYP = 3, nodal motion of the ALE mesh is completely controlled by the 12 curves. Therefore, no constraints are needed.

PRTYPE	ICR/NID	BCTRAN	BCROT	BCEXP
3	NO	NO	NO	NO
4	YES (ICR)	YES	YES	YES
5	NO	YES	NO	NO
6	NO	NO	NO	NO
7	NO	NO	NO	YES
8	NO	NO	NO	NO
9	YES (NID)	YES (NGID)	NO	NO

Example 1:

Consider a bird-strike model containing 2 ALE parts: a bird surrounded by air (or void). Part set ID 1 is defined containing both parts. To allow for the meshes of these 2 parts to

move with their combined mass-weighted-average velocity, PRTYPE = 4 is used. Note that BCEXP = 7 indicating mesh expansion is constrained in all global directions.

```

$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|...8
```

Example 2:

Consider a bouncing ball model containing 2 ALE parts: a solid ball (PID 1) surrounded by air or void (PID 2). Part set ID 1 is defined containing both parts. To allow for the meshes of these 2 parts to move with 2 reference system types: (a) first, they move with their combined mass-weighted-average velocity between 0.0 and 0.01 second; and subsequently (between 0.01 and 10.0 seconds) their reference system is switched to (b) an Eulerian system (thus the mesh is fixed in space), a reference system "SWITCH" is required. This is done by setting PRTYPE = 6. This PRTYPE requires a corresponding *ALE_REFERENCE_SYSTEM_SWITCH card. Note that PRID = 11 in the *ALE_REFERENCE_SYSTEM_GROUP card corresponds to the SWITCHID = 11 in *ALE_REFERENCE_SYSTEM_SWITCH card.

*ALE_REFERENCE_SYSTEM_NODE

Purpose: Define a group of nodes that control the motion of an ALE mesh. This keyword is used *only* when PRTYPE = 5 or 7 in a corresponding *ALE_REFERENCE_SYSTEM_-GROUP card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID							
Type	I							
Default	none							

Card 2	1	2	3	4	5	6	7	8
Variable	NID1	NID2	NID3	NID4	NID5	NID6	NID7	NID8
Type	I	I	I	I	I	I	I	I

Enclosing Nodes Card. This card is only included if PRTYPE = 7.

Card 3	1	2	3	4	5	6	7	8
Variable	NID9	NID10	NID11	NID12				
Type	I	I	I	I				

VARIABLE	DESCRIPTION
ID	Node group ID for PRTYPE 5 or 7; see PRID on *ALE_REFERENCE_SYSTEM_GROUP.
NID1, …, NID12	User specified nodes. See Remarks 1 and 2.

Remarks:

1. **ALE Motion from Local Coordinate System.** For PRTYPE = 5, the ALE mesh is forced to follow the motion of a coordinate system, which is defined by three

nodes (NID1,NID2,NID3). These nodes are located at x_1, x_2, and x_3, respectively. The axes of the coordinate system, x', y', and z', are defined as:

$$x' = \frac{x_2 - x_1}{|x_2 - x_1|}$$
$$y' = z' \times x'$$
$$z' = x' \times \frac{x_3 - x_1}{|x' \times (x_3 - x_1)|}$$

Note that $x_1 \rightarrow x_2$ is the local x'axis, $x_1 \rightarrow x_3$ is the local y' axis and x' crosses y' gives the local z' axis. These 3 nodes are used to locate the reference system at any time. Therefore, their positions relative to each other should be as close to an orthogonal system as possible for better transformation accuracy of the ALE mesh.

2. **ALE Motion from Enclosing Nodes.** For PRTYPE = 7, the ALE mesh is forced to move and expand, so as to enclose up to twelve user defined nodes (NID1, …, NID12). This is a rarely used option.

Example 1:

Consider modeling the sloshing of water inside a rigid tank. Assuming there are 2 ALE parts, the water (PID 1) and air or void (PID 2) contained inside a rigid (Lagrangian) tank (PID 3). The outer boundary nodes of both ALE parts are merged with the inner tank nodes. Part set ID 1 is defined containing both ALE parts (PIDs 1 and 2). To allow for the meshes of the 2 ALE parts to move with the rigid Lagrangian tank, PRTYPE = 5 is used. The motion of the ALE parts then follows 3 reference nodes on the rigid tank. These 3 reference nodes must be defined by a corresponding *ALE_REFERENCE_SYSTEM_NODE card. In this case the reference nodes have the nodal IDs of 5, 6 and 7. Note that PRID = 12 in the *ALE_REFERENCE_SYSTEM_GROUP card corresponds to the SID = 12 in the *ALE_REFERENCE_SYSTEM_NODE card.

```

          5         6          7
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|...8
```

*ALE_REFERENCE_SYSTEM_SWITCH

Purpose: Time-dependent switching between the reference system types for ALE geometric entities. Multiple switches can occur during the simulation. See PRTYPE in *ALE_REFERENCE_SYSTEM_GROUP. This command is required only when PRTYPE = 6 in *ALE_REFERENCE_SYSTEM_GROUP. See Example 2 in the *ALE_REFERENCE_SYSTEM_GROUP.

Card 1	1	2	3	4	5	6	7	8
Variable	ID							
Type	I

Variable	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
ID	Switch list ID; see *ALE_REFERENCE_SYSTEM_GROUP.
T1, …, T7	Times for switching reference system type. By default, the reference system TYPE1 occurs between time = 0.0 and time = T1, and TYPE2 occurs between time = T1 and time = T2, etc.
TYPE1, …, TYPE8	Reference system types (also see PRTYPE under *ALE_REFERENCE_SYSTEM_GROUP): EQ.0: Eulerian EQ.1: Lagrangian EQ.2: Normal ALE mesh smoothing EQ.3: Prescribed motion following load curves; see *ALE_REFERENCE_SYSTEM_CURVE. EQ.4: Automatic mesh motion following mass weighted average velocity in ALE mesh EQ.5: Automatic mesh motion following a local coordinate system defined by three user defined nodes; see *ALE_REFERENCE_SYSEM_NODE.
ID1, …, ID8	The corresponding PRID parameters supporting each PRTYPE used during the simulation.

Remarks:

1. **Switching Time.** The beginning time is assumed to be t = 0.0, and the starting PRTYPE is TYPE1. So at T1, the 1st switching time, PRTYPE is switched from TYPE1 to TYPE2, and so forth. This option can be complex in nature, so it is seldom applied.

*ALE_REFINE

See *CONTROL_REFINE_ALE.

*ALE_SMOOTHING

Purpose: This smoothing constraint either keeps a dependent ALE node at its initial parametric location along a line between two other ALE nodes (see Figure 4-14) or causes a dependent ALE node to follow the motion of two non-ALE nodes (see Remark 1). This constraint is active during each mesh smoothing operation. This keyword can be used with ALE solids, ALE shells, and ALE beams.

Card 1	1	2	3	4	5	6	7	8
Variable	DNID	NID1	NID2	IPRE	XCO	YCO	ZCO	
Type	I	I	I	I	F	F	F	
Default	none	none	none	0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
DNID	Dependent node or node set ID: GT.0: DNID is an ALE node. EQ.0: The dependent nodes are the nodes of an ALE mesh connected to the nodes in INID1. See Remark 2. LT.0: -DNID is the ID of an ALE node set. See Remark 2.
NID1	ID of first node or set for constraining the dependent nodes: GT.0: NID1 is a node. LT.0: -NID1 is a segment set ID if XCO = YCO = ZCO = 0.0. Otherwise, -NID1 is a node set ID. See Remark 2.
NID2	ID of second node or node set for constraining the dependent nodes: GT.0: NID2 is a node. EQ.0: The dependent node motion is solely controlled by NID1. See Remarks 2 and 3. LT.0: -NID2 is a node set ID. See Remark 2.
IPRE	EQ.0: Smoothing constraints are performed after mesh relaxation.

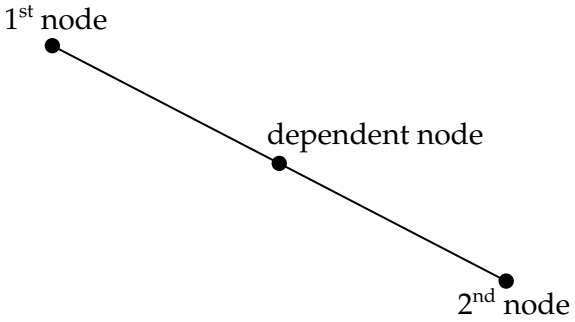

Figure 4-14. This simple constraint, which ensures that a constrained node remains on a straight line between two controlling nodes, is sometimes necessary during ALE smoothing.

VARIABLE	DESCRIPTION
	EQ.1: Smoothing constraints are performed before mesh relaxation.
XCO	x-coordinate of constraint vector
YCO	y-coordinate of constraint vector
ZCO	z-coordinate of constraint vector

Remarks:

1. **When NID1 and NID2 Nodes are not ALE Nodes.** If DNID, NID1 and NID2 are ALE nodes, the positions of NID1 and NID2 are interpolated to position DNID. If NID1 and NID2 are *not* ALE nodes, the motions of NID1 and NID2 are interpolated to move DNID.

2. **Constraint Generation.** If NID1 is a set ID, DNID and NID2 should be node set IDs or zeros. In this case, the constraints are created during initialization and printed out to a file called alesmoothingenerated.k.

   If NID1 is a node set, the constraints associated with a given node in NID1 are generated by finding the closest dependent nodes to an axis passing through the NID1 node and oriented by the constraint vector (XCO,YCO,ZCO). If NID1 is a segment set, each node in the given segments can constrain dependent nodes. The axis direction for a node is found by averaging all the normals of the segments connected to the node.

   If DNID = 0, NID1 should be a set of nodes or segments along the boundary of an ALE mesh. For a given node in NID1 or in a segment of NID1, constraints are created for all the nodes of the mesh found the closest to the axis described previously. The search for dependent nodes starts with nodes of elements

connected to the node in NID1 and stops when a boundary node with an element connectivity similar to that of the node in NID1 is reached or when a node in the set NID2 (if defined) is found.

3. **NID2 = 0 and DNID ≠ 0.** If NID2 = 0 and DNID is nonzero, NID1 should *not* be an ALE node or set. Otherwise, the positions of DNID and INID1 would match and the element volumes between them could be zero or negative. Only DNID and INID1 motion should match in such a case.

***ALE_STRUCTURED_FSI**_*{OPTION}*

Purpose: Perform Fluid-Structure Interaction (FSI) between Lagrangian structures modeled by shell/solids and ALE multi-material fluids using a structured ALE mesh (*ALE_STRUCTURED_MESH).

Available options for *OPTION* include:

<BLANK>

TITLE

With the keyword option TITLE, you can set a coupling (card) ID number and title for each coupling card. If a title is not defined, LS-DYNA will automatically create an internal title for this coupling definition.

Comparison to *CONSTRAINED_LAGRANGE_IN_SOLID:

*ALE_STRUCTURED_FSI, as its name suggests, only works with the structured ALE solver. It mostly follows the format of *CONSTRAINED_LAGRANGE_IN_SOLID, but with a few exceptions:

- **Coupling Type.** Unlike *CONSTRAINED_LAGRANGE_IN_SOLID, *ALE_STRUCTURED_FSI only has one penalty formulation coupling method which is similar to a combination of CTYPE = 4 and 5 in *CONSTRAINED_LAGRANGE_IN_SOLID.
- **Number of Coupling Points.** For each Lagrangian segment, there are a certain number of coupling points, evenly distributed at the segment surface. Penalty springs are attached to those coupling points. When using *CONSTRAINED_LAGRANGE_IN_SOLID, you need to specify the number while with this keyword, you do not need to since LS-DYNA automatically determines the number of coupling points during the initialization phase.
- **Leakage Control.** Leakage control is automated when using *ALE_STRUCTURED_FSI. Fluid leakage is detected and cured automatically with no user intervention needed.
- **Normal Type.** Normal type selection is automated, based on the local geometry. Users do not need to choose between nodal/segment normal.
- **Edge Coupling.** Edge coupling is automatic. Shell segments are picked out and the exposed edges are coupled. *CONSTRAINED_LAGRANGE_IN_SOLID_EDGE is not needed.
- **Erosion Coupling.** Eroded solid elements will change the coupling segments. Segments belonging to eroded elements need to be deleted, and newly exposed segments need to be added. With *CONSTRAINED_LAGRANGE_IN_SOLID,

CTYPE = 5 needs to be specified in order to activate this segments modification algorithm. In the new *ALE_STRUCTURED_FSI, this process is always on and no flag is needed.

Title Card. Additional card for the TITLE keyword option.

Card ID	1	2	3	4	5	6	7	8

Default	0.0	10^{10}	0.1	0.0		0		

VARIABLE	DESCRIPTION
COUPID	Coupling (card) ID. If not defined, LS-DYNA will assign an internal coupling ID based on the order of appearance in the input deck.
TITLE	Description of this coupling definition (A70)
LSTRSID	Set ID defining a part, part set, or segment set ID of the Lagrangian structure (see *PART, *SET_PART or *SET_SEGMENT)

VARIABLE	DESCRIPTION
ALESID	Set ID defining a part or part set ID of the Structured ALE mesh (see *PART)
LSTRSTYP	Set type of LSTRSID: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID) EQ.2: Segment set ID (SGSID)
ALESTYP	Set type of ALESID: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID)
MCOUP	Multi-material(s) to be coupled (see Remark 1): EQ.0: Couple with all multi-material groups. EQ.-N: -N is the ID of *SET_MULTI-MATERIAL_GROUP.
START	Start time for coupling
END	End time for coupling
PFAC	Penalty factor. PFAC is a scale factor for scaling the estimated stiffness of the interacting (coupling) system. It is used to compute the coupling forces to be distributed on the Lagrangian and ALE parts. GT.0: Fraction of estimated critical stiffness LT.0: PFAC must be an integer, and -PFAC is a load curve ID. The curve defines the coupling pressure on the y-axis as a function of the penetration along the x-axis.
FRIC	Friction coefficient. The friction force is evaluated as the normal force multiplied by the friction coefficient. GT.0: Constant friction coefficient EQ.-N: Variable friction coefficient defined by a table with ID N. The friction coefficient is a function of coupling pressure and relative velocity. The table uses the coupling pressure as the parameter values. See Examples.
FLIP	A Lagrangian segment will couple to fluid on only one side of the segment. The segment normal is assumed to point toward the fluids to which it is coupled. If that is not the case, set FLIP to 1.

VARIABLE	DESCRIPTION
	EQ.0: No action
	EQ.1: Flip the segment normal, so it points toward the fluids to which it is to be coupled.

Remarks:

1. **Multi-Material Coupling Option.** MCOUP is used to specify which ALE multi-materials are to be coupled. In a typical simulation we want to prevent some fluid(s) on one side of structure from penetrating through to the other side. In this case, we would pick the AMMGs on one side and list them under * SET_-MULTI-MATERIAL_GROUP card.

   Coupling to all materials as activated by MCOUP = 0 is generally not recommended. LS-DYNA calculates the fluid coupling interface as the surface where the sum of coupled ALE materials occupies a volume fraction equal to 50%. Since MCOUP = 0 couples to all materials, the sum of all coupled ALE materials is, in this case, trivially 100%. Consequently, when MCOUP = 0, there will not be a fluid interface with which to track leakage.

Examples:

The following is a partial input deck that illustrates defining a variable friction table. Table 2 gives three coupling pressures that correspond to the three *DEFINE_CURVEs specified under the table definition (see *DEFINE_TABLE for details). Each curve specifies the relationship between relative velocity and friction coefficient for a given coupling pressure. For example, if the coupling pressure is 100, curve 4 is used. If coupling pressure = 50, both curves 3 and 4 are used. The friction coefficient is interpolated from the values given by the curves.

*ALE_STRUCTURED_MESH

Purpose: Generate a structured 2D or 3D mesh and invoke the Structured ALE (S-ALE) solver. Spacing parameters are input through one or more of the *ALE_STRUCTURED_-MESH_CONTROL_POINTS cards. The local coordinate system is defined using the *ALE_STRUCTURED_MESH card.

In certain contexts, it is advantageous to use structured meshes. With structured meshes the element and node connectivity are straightforward and the searching algorithm used for ALE coupling is greatly simplified. Also, numerous checks are avoided because these meshes include only hex elements.

The S-ALE solver supports SMP, MPP and MPP hybrid configurations. All three implementations require less simulation time and memory usage than the regular ALE solver. We, therefore, encourage using the S-ALE solver when the ALE mesh is structured.

Once an ALE mesh is generated using *ALE_STRUCTURED_MESH card, this card invokes the S-ALE solver and performs the ALE advection time step. For fluid-structure interaction, *ALE_STRUCTURED_FSI is recommended over *CONSTRAINED_LAGRANGE_IN_SOLID. *ALE_STRUCTURED_FSI has a better, automated leakage detection and control, has a much cleaner and easier input, and is designed for the S-ALE solver.

This keyword can be used multiple times. In each occurrence an independent, separate mesh is constructed. These meshes can occupy different spatial domains or the same spatial domain. Simulations are executed in those meshes independently.

There are two related keywords: *ALE_STRUCTURED_MESH_TRIM to trim/untrim the generated mesh and *ALE_STRUCTURED_MESH_MOTION to control the mesh motion during the simulation.

Card 1	1	2	3	4	5	6	7	8
Variable	MSHID	DPID	NBID	EBID				TDEATH
Type	I	I	I	I				F
Default	0	none	0	0				10^{16}

Card 2	1	2	3	4	5	6	7	8
Variable	CPIDX	CPIDY	CPIDZ	NID0	LCSID			
Type	I	I	I	I	I			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
MSHID	S-ALE Mesh ID. A unique number must be specified.
DPID	Default Part ID. The elements generated are assigned to DPID. This part definition is automatically generated during the input phase and contains neither material nor element formulation information. Please see Remark 1. This ID also serves as an indicator for mesh merging, that is, if the same part ID is used for several adjacent generated meshes, they will be merged together to form a single mesh consisting of these sub-meshes. Please see Remark 5.
NBID	Nodes are generated and assigned with node IDs starting from NBID. This field is optional. If unset or 0, LS-DYNA uses the maximum node ID + 1 for NBID.
EBID	Elements are generated and assigned with element IDs starting from EBID. This field is optional. If unset or 0, LS-DYNA uses the maximum element ID + 1 for EBID.
TDEATH	Death time for this mesh. Please see Remark 3.
CPIDX, CPIDY, CPIDZ	Control point IDs defining node ID/value pairs along each local axis. See *ALE_STRUCTURED_MESH_CONTROL_POINTS. Setting CPIDX to 0 or -1 invokes the ALE to S-ALE converter. Please see Remark 4. Note that for 2D problems CPIDZ is ignored.
NID0	NID0 sets the mesh's origin node. During the simulation, prescribed motion applied to this node applies to the entire structure S-ALE mesh.
LCSID	Local coordinate system ID. Please see Remark 2.

Remarks:

1. **DPID.** DPID only consists of elements and nodes. It does not include material properties or integration rules. The requirement that a part ID be specified for these automatically generated S-ALE solid elements exists only to satisfy the legacy rule that every element must be associated with a part. Users do not need to set up the *PART card for DPID. All PART definitions used in this card only refer to the mesh, not material.

2. **LCSID.** The local coordinate system is defined on the data cards associated with the *DEFINE_COORDINATE keyword. This local coordinate system specifies the three cardinal directions used for generating the structured ALE mesh. The structured mesh can be made to rotate by specifying a rotating local coordinate system. To define a rotating local coordinate system, use the *DEFINE_COORDINATE_NODES keyword with FLAG = 1 and then apply prescribed motion to the three coordinate nodes.

3. **TDEATH.** This option provides a way to terminate an ALE calculation while Lagrangian parts still evolve. Once this death time is reached, all elements belonging to this mesh are deleted. In addition to that, ALE FSI cards, including *ALE_STRUCTURED_FSI, *CONSTRAINED_LAGRANGE_IN_SOLID and *ALE_COUPLING_NODAL_*OPTION*, are checked to see if related ALE elements were deleted. If no ALE elements are left on the fluid side for certain coupling cards, this coupling card is disabled from further calculation as well.

   For example, consider a 2-stage simulation. In the first stage Lagrange structures are under certain loadings from ALE fluids through ALE/FSI. Later in the second stage we continue simulating the Lagrange structure behavior while stopping all ALE related calculations by setting TDEATH to the start time of the 2nd stage.

4. **ALE to S-ALE Converter.** For existing ALE models with rectilinear meshes, *ALE_STRUCTURED_MESH can invoke the conversion of the ALE mesh into an S-ALE mesh. To use this feature, add a *ALE_STRUCTURED_MESH card in the model input with CPIDX = -1 or 0 leaving all other fields blank. LS-DYNA will then convert all ALE keywords to the S-ALE format and write the modified input to a file named saleconvrt.inc. The solver used to perform the analysis depends on the value of CPIDX. If -1, the S-ALE solver is used; if 0, the ALE solver is used.

5. **Merging Meshes.** Two or more separated, but adjacent sub-meshes can be merged to form a mesh of complex shape. To do that, first set up the two or more sub-meshes; make sure their mesh spacing are the same at their interfaces so that these interface nodes collides with each other (a tolerance of 1/100 element size is allowed); and finally use the SAME DPID in those *ALE_STRUC-

TURED_MESH cards. The code automatically checks and merges sub-meshes with the same DPID.

Example:

The following example generates a regular evenly distributed 0.2 by 0.2 by 0.2 box mesh that has 22 nodes along each direction. The generated mesh is aligned to the local coordinate system specified by nodes 2, 3, and 4 with an origin at node 1.

All the elements inside the mesh are assigned to part 1. Note that part 1 is not explicitly defined in the input. The necessary part definition is automatically generated and contains neither material definitions nor integration rules.

*ALE_STRUCTURED_MESH_CONTROL_POINTS

Purpose: Provide spacing information used by the *ALE_STRUCTURED_MESH keyword to generate a 2D or 3D structured ALE mesh.

Each instance of the *ALE_STRUCTURED_MESH_CONTROL_POINTS card defines a one-dimensional mesh using control points. Each control point consists of a node number (see N in Card 2a/b) and a coordinate (see X in Card 2a/b). The first control point *must* be node 1, and the node number of the last point defines the total number of nodes. Between any two control points the mesh is uniform or progressive depending on the input. The *ALE_STRUCTURED_MESH card, in turn, defines a simple three-dimensional mesh from the triple product of three *ALE_STRUCTURED_MESH_CONTROL_POINT one-dimensional meshes.

Card Summary:

Card 1. This card is required.

CPID		ICASE	SFO		OFFO		

Card 2a. For ICASE = 0, include at least two instantiations of this card to give the control points. A minimum of two cards is required to give the end points and the number of nodes. Input is terminated with the next keyword ("*") card.

N	X	RATIO	

Card 2b. For ICASE = 1 or 2, include at least two instantiations of this card to give the control points. A minimum of two cards is required to give the end points and the number of nodes. Input is terminated with the next keyword ("*") card.

N	X	XL	

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	CPID		ICASE	SFO		OFFO		
Type	I		I	F		F		
Default	none		0	1.		0.		

VARIABLE	DESCRIPTION
CPID	Control Points ID. A unique number must be specified. This ID is to be referred in the three fields marked up CPIDX, CPIDY, CPIDZ in *ALE_STRUCTURED_MESH.
ICASE	A flag to trigger special algorithms for a more user-friendly input format for creating progressive mesh spacing. See Remarks 4 and 5 to see how ICASE = 1 and 2 work.
SFO	Scale factor for ordinate value. This is useful for simple modifications. EQ.0.0: default set to 1.0.
OFFO	Offset for ordinate values. See Remark 1.

Point Cards for ICASE = 0. Include this card for ICASE = 0. Put one control point per card. Input is terminated at the next keyword ("*") card. *At least two cards are required with one having N = 1.*

Card 2a	1	2	3	4	5	6	7	8
Variable	N		X		RATIO			
Type	I		F		F			
Default	none		none		0.0			

VARIABLE	DESCRIPTION
N	Control point node number
X	Control point position
RATIO	Ratio for progressive mesh spacing. A progressively larger or smaller mesh will be generated between the control point that has a nonzero ratio specified and the control point following it. If a control point and the one following it both have RATIO as zero, the mesh is uniform between them. See Remarks 2 and 3. GT.0.0: Mesh size increases $dl_{n+1} = dl_n \times (1 + \text{RATIO})$ LT.0.0: Mesh size decreases

VARIABLE	DESCRIPTION
	$dl_{n+1} = dl_n/(1 - \text{RATIO})$

Point Cards for ICASE = 1 or 2. Include this card for ICASE = 1 or 2. Put one control point per card. Input is terminated at the next keyword ("*") card. *At least two cards are required with one having N = 1.* See Remarks 4 and 5 for details about how to use these cards to obtain uniform and progressive meshes. See Remark 3.

Card 2b	1	2	3	4	5	6	7	8
Variable	N		X		XL			
Type	I		F		F			
Default	none		none/optional		0.0/none			

VARIABLE	DESCRIPTION
N	Control point node number
X	Control point position. This is required for ICASE = 1. For ICASE = 2, see Remark 5 for details about when to include this input.
XL	Length of element at the control. For ICASE = 1, see Remark 4 for details about when to enter this value. This input is required for ICASE = 2.

Remarks:

1. **Coordinates Scaling.** The ordinate values are scaled after the offsets are applied, that is:

$$\text{Ordinate value} = \text{SFO} \times (\text{Defined value} + \text{OFFO}) .$$

2. **Progressive Mesh Spacing.** The formula used to calculate element length is as follows:

$$dl_{base} = |x_{end} - x_{start}| \times (\text{factor} - 1)/(\text{factor}^n - 1)$$

in which dl_{base} is the smallest base length; x_{start} and x_{end} are the coordinates of the start and end points, respectively; factor = 1 + RATIO if RATIO > 0 or 1/(1 − RATIO) if RATIO < 0; and n is number of elements. Please note that element size either increases by RATIO if RATIO > 0 or decreases by

$-\text{RATIO}/(1-\text{RATIO})$ if RATIO < 0 each time. The overall effect is the same; that is, starting from the smallest element, each time the element size is increased by |RATIO|.

3. **Transition Meshes.** If the mesh has different mesh sizes and transition zones between them (where the mesh size progressively increases or decreases), then the ratios and number of elements for these zones are reported in the messag file (look for messages KEY+1174). Updated lists of control points are output in the messag file for each *ALE_STRUCTURED_MESH_CONTROL_POINTS with more than 3 control points.

4. **ICASE = 1.** Assume we want to use progressive mesh spacing for a certain region. We know the number of elements and the overall length. And we have a "base" element size in mind. However, the generic setup requires a "ratio", which needs an iterative solution of a n^{th} order polynomial equation based on the "base" element size. ICASE = 1 aims to simplify the setup. When it is activated, we can input the "base" element size. The value of the "ratio" is internally calculated and used to generate the S-ALE mesh. We will use examples to illustrate this option.

   For this discussion, a region is defined by 2 point cards (2 instantiations of Card 2b). In the example below, *ALE_STRUCTURED_MESH_CONTROL_-POINTS with CPID 1001 has three regions. The first region spans $[0, 0.0755]$; the second one $[0.0755, 0.1245]$; and the third one $[0.1245, 0.2]$.

   The RATIO field in the generic setup is now marked as XL. In this case, it specifies the element size at that location. The rule is simple: a region can have a total of 0, 1, or 2 nonzero XL values specified at its two ends. 1 occurrence causes progressive mesh spacing. 0 or 2 occurrences cause an evenly spaced mesh. Please note that when 2 values of XL are given, they must have the same value since the mesh is evenly spaced. Otherwise, the input is not logically correct.

   In the example below:

   a) Region 1 has progressive spacing, and the preferred element size at the 8^{th} node is 0.0070.

   b) In region 2, the mesh is evenly distributed.

   c) Region 3 has progressive spacing, and the preferred element size at the 15^{th} node is 0.0070.

```
*ALE_STRUCTURED_MESH_CONTROL_POINTS
$     CPID               ICASE
      1001                   1
$                x1                  x2                  xl
                  1                  .0
                  8              0.0755              0.0070
```

```
                  15              0.1245              0.0070
                  22                 0.2
```

The above setup will produce a progressive mesh for regions 1 and 3 (indicated by 1 XL value for each region's two end points) and a uniform mesh for region 2 (indicated by 2 XL values for the region's two end points). The element size is 0.0155 at the 1st node; gradually reduces to 0.007 at the 8th node; remains unchanged until the 15th node; then gradually increased to 0.0155 at the 22nd node.

We include two other examples to illustrate the versatility of the setup. For CPID 1002, regions 1 and 3 have progressive meshes and region 2 has a uniform mesh. For CPID 1003, regions 1 and 2 both have progressive meshes.

```
*ALE_STRUCTURED_MESH_CONTROL_POINTS
      1002                    1
$                 x1                  x2                  xl
                   1                  .0              0.0155
                   8              0.0755
                  15              0.1245
                  22                 0.2              0.0155
*ALE_STRUCTURED_MESH_CONTROL_POINTS
      1003                    1
$                 x1                  x2                  xl
                   1                  .0
                  11                 0.1              0.0070
                  21                 0.2
```

5. **ICASE = 2.** For ICASE = 2, the idea is to build the progressive spaced mesh starting from a point and extend the mesh to the left and the right. To use this option, we need to first pick a "base node" and put it at a location by specifying its coordinate. The "base node" in the example below is the 8th node with a coordinate of 0.0755. Next, we specify the element size at all the nodes listed. In the example below, we want the element size to be 0.0155 at the 1st node, 0.007 at the 8th node, 0.007 at the 15th node and 0.0155 at the 22nd node.

   Internally, the mesh is divided into 3 regions as discussed for ICASE = 1 in Remark 4. Progressive meshes are used between two control points with different element lengths while uniform meshes are used between two control points with the same element length. In the example below, regions 1 and 3 have progressive mesh spacing while region 2 has an evenly distributed mesh.

```
*ALE_STRUCTURED_MESH_CONTROL_POINTS
$     CPID                ICASE
      1001                    1
$                 x1                  x2                  xl
                   1                                      0.0155
                   8              0.0755              0.0070
                  15                                      0.0070
                  22                                      0.0155
```

   We include two other examples to illustrate the versatility of the setup. For CPID 1002, regions 1 and 3 have progressive meshes and region 2 has a uniform mesh. For CPID 1003, regions 1 and 2 both have progressive meshes.

```
*ALE_STRUCTURED_MESH_CONTROL_POINTS
      1002                    1
$                 x1                   x2                   xl
                   1                                     0.0155
                   8                                     0.0070
                  15                                     0.0070
                  22                   0.2               0.0155

```

Examples:

1. The example below generates a regular box mesh. Its size is 0.2 × 0.2 × 0.2. It is generated in a local coordinate system defined by nodes 2, 3, and 4 that originates from node 1.

   The local *x*-axis mesh spacing is defined by control points ID 1001. It has 21 nodes evenly distributed from 0.0 to 0.2. The local *y*-axis is defined by ID 1002 and has twice the number of elements of 1001. It has 41 nodes evenly distributed from 0.0 to 0.2. The local *z*-axis is defined by ID 1003. It has 31 nodes and covers from 0.0 to 0.2. The mesh is two times finer in the region between node 6 and node 26.

```

2. This example shows how to generate a progressively larger/smaller mesh spacing. The mesh geometry is the same as the example above. In the x-direction the mesh becomes progressively smaller between nodes 1 and 8. For these 7 elements, each element is 0.1/1.1 = 9.09% smaller than its left neighbor. Between nodes 15 and node 22, the elements become progressively larger by 10% in comparison to each element's left neighbor. The 7 elements in the middle between node 8 and 15 are of equal length.

*ALE_STRUCTURED_MESH_MOTION

Purpose: This keyword controls the motion of a structured 3D ALE mesh generated by *ALE_STRUCTURED_MESH. Two motions are implemented. With the first the mesh follows the center of mass of certain fluids and expands/contracts at the same rate as the specified fluids. With the second, the mesh follows the motion of a Lagrangian structure and expands/contracts so that the structure is covered by the mesh.

Card Summary:

Include as many of the following card types as needed. For example, you can include 1b, 1a, 1a, 1a, and 1b in a single input. This input ends at the next keyword ("*") card.

Each card represents a mesh motion operation. You can choose from two options (specified in the field OPTION) to control S-ALE mesh motion:

1. FOLLOW_GC makes the mesh follow the mass center of certain fluid(s) in the mesh and expand/contract at the same rate as those fluid(s). This mesh motion is useful, for instance, when modeling a moving projectile hitting a target.

2. COVER_LAG makes the mesh follow the motion of a Lagrangian structure and expand/contract so that the Lagrangian structure is fully covered by the S-ALE mesh. This motion is useful for modeling airbag deployment.

Card 1a. This card is included when OPTION = FOLLOW_GC.

MSHID	OPTION	AMMGSID	EXPLIM				ISYM

Card 1b. This card is included when OPTION = COVER_LAG.

MSHID	OPTION	SID	STYPE	NODCEN		FRCPAD	

Data Card Definitions:

Fluid-Controlled Motion Card. This card is used when OPTION = FOLLOW_GC.

Card 1a	1	2	3	4	5	6	7	8
Variable	MSHID	OPTION	AMMGSID	EXPLIM				ISYM
Type	I	A	I	F				I
Default	none	none	0	1.0				0

VARIABLE	DESCRIPTION
MSHID	S-ALE Mesh ID defined in *ALE_STRUCTURED_MESH
OPTION	FOLLOW_GC
AMMGSID	Set of ALE multi-material group list IDs which the mesh follows. Please refer to *SET_MULTI-MATERIAL_-GROUP_LIST card for details.
EXPLIM	Limit ratio for mesh expansion and contraction. The distance between the nodes is not allowed to increase by more than a factor EXPLIM or decrease to less than a factor 1/EXPLIM. Default value of 1.0 means no expansion/contraction.
ISYM	A three digit number, [XYZ], to define symmetry: $$\text{ISYM} = 100 \times X + 10 \times Y + Z$$ Each digit specifies one direction, X for the local x, Y for local y, and Z for local z (local x, y, and z are defined in *ALE_STRUCTURED_MESH). Each digit can have the following values: EQ.0: No symmetry EQ.1: Symmetry plane along the face with a normal vector in the negative direction EQ.2: Symmetry plane along the face with a normal vector in the positive direction For example, ISYM = 201 means quarter symmetry with symmetry planes at the faces with normal vectors $+x$ and $-z$. 111 means 1/8 symmetry with symmetry planes at the faces with normal vectors $-x$, $-y$ and $-z$.

Structure-Controlled Motion Card. This card is included if OPTION = COVER_LAG.

Card 1b	1	2	3	4	5	6	7	8
Variable	MSHID	OPTION	SID	STYPE	NODCEN		FRCPAD	
Type	I	A	I	I	I		F	
Default	none	none	none	0	none		0.1	

VARIABLE	DESCRIPTION
MSHID	S-ALE Mesh ID. Defined in *ALE_STRUCTURED_MESH.
OPTION	COVER_LAG
SID	Set ID to identify the Lagrange structure
STYPE	Set type for SID: EQ.0: Part set EQ.1: Part EQ.2: Segment set EQ.3: Node set
NODCEN	Optional node ID used as the center of mesh expansion
FRCPAD	Multiplier that causes the S-ALE mesh to extend beyond the Lagrangian structure in each of the local directions of the S-ALE mesh (see *ALE_STRUCTURED_MESH). In each direction, the length of the S-ALE is calculated as: $l_i^S = (1 + 2 \times \text{FRCPAD}) \times l_i^L$ where l_i^S is the length of the S-ALE mesh in the i^{th} direction ($i = 1, 2, 3$) and l_i^L is the longest length of the Lagrangian structure in the i^{th} direction. The padding beyond the structure is applied evenly to each side. FRCPAD prevents the fluid-structure interaction (FSI) from occurring on the edge of the S-ALE mesh.

*ALE_STRUCTURED_MESH_REFINE

Purpose: This keyword provides a convenient utility to refine existing structured ALE (S-ALE) meshes generated by the *ALE_STRUCTURED_MESH keyword. This keyword automatically updates sets defined using the values SALECPT and SALEFAC in the OPTION field for the keywords SET_SOLID_GENERAL, SET_SEGMENT_GENERAL, and SET_NODE_GENERAL. As a result, this card is the only modification needed in the input deck for users to refine an S-ALE mesh.

Card 1	1	2	3	4	5	6	7	8
Variable	MSHID	IFX	IFY	IFZ				
Type	I	I	I	I				
Default	none	1	1	1				

VARIABLE	DESCRIPTION
MSHID	S-ALE Mesh ID. The ID of the S-ALE mesh to be refined.
IFX, IFY, IFZ	Refinement factor for each local direction. The number of elements in each direction of the new mesh is the refinement factor for that direction multiplied by the current number of elements in that direction. They must be integers.

Remarks:

1. **Multi-Material Problems.** This keyword provides a new modeling technique to handle multi-material ALE problems. In comparison to pure Lagrange problems, models containing multi-material ALE fluids are often time consuming and memory demanding. Therefore, constructing a concept model with a coarse mesh to estimate the computational resources required and refining the concept model mesh gradually until convergence is achieved is a recommended approach to these problems. This keyword minimizes the user's effort to follow such a procedure.

Example:

The example below generates a regular evenly distributed box mesh with mesh ID 1. The S-ALE mesh has 22 nodes along each direction, and the overall size is 0.2 by 0.2 by 0.2. S-

ALE mesh 1 is generated using the local coordinate system defined by nodes 2, 3, and 4 with the origin located at node 1.

```

$   OPTION     MSHID       XMN       XMX       YMN       YMX       ZMN       ZMX
   SALECPT         1         1        22         1        22        11        22
*ALE_STRUCTURED_MESH_CONTROL_POINTS
      1001
$                x1                  x2
                  1                  .0
                 22                  .2
*NODE
       1   0.0000000e+00   0.0000000e+00   0.0000000e+00
       2   0.0000000e+00   0.0000000e+00   0.0000000e+00
       3   0.1000000e+00   0.0000000e+00   0.0000000e+00
       4   0.0000000e+00   0.1000000e+00   0.0000000e+00
       5   0.0000000e+00   0.0000000e+00   0.0000000e+00
*END
```

If at a later time we decided to make the mesh finer, we can simply add the following card to the input deck:

```
*ALE_STRUCTURED_MESH_REFINE
$    mshid       ifx       ify       ifz
         1         3         3         3
```

The mesh now contains 63 elements (64 nodes) in each direction. The solid element set 100 now contains elements ranging between nodes (1,1,31) and (64,64,64), instead of the original (1,1,11) and (22,22,22).

*ALE_STRUCTURED_MESH_TRIM

Purpose: Perform trim/un-trim operations on a structured ALE mesh generated by the *ALE_STRUCTURED_MESH keyword card. This keyword is supported for 2D and 3D S-ALE meshes.

As many cards as needed can be input with each card representing one mesh trim/un-trim operation. This input ends at the next keyword ("*") card. These operations are completed one by one, in the order of their cards' appearance. Please see the examples below.

Card 1	1	2	3	4	5	6	7	8
Variable	MSHID	OPTION	OPER	IOUTIN	E1	E2	E3	E4
Type	I	A	I	I	I or F	I or F	I or F	I or F
Default	0	none	0	0	none	none	none	None

VARIABLE	DESCRIPTION
MSHID	S-ALE Mesh ID.
OPTION	There are six available options. They are trim by: PART-SET, SEGSET, PLANE, CYLINDER, BOXCOR, BOXCPT and SPHERE. See the table below for more details.
OPER	To trim or un-trim, that is, to delete the picked elements or keep them. EQ.0: trim (default) EQ.1: keep
IOUTIN	Flag to select which elements to trim, that is, "outside" or "inside" the specified object defined with the OPTION and E*n*. For PARTSET and SEGSET options, "outside" is defined as the region to which the segment normal points. EQ.0: Outside (default) EQ.1: Inside
E1, E2, E3, E4	These values have different definitions for different options. See the table below for details.

The "OPTION" column in the table below enumerates the allowed values for the OPTION variable as well as describing E1, …, E4 for each OPTION. Each of the following operations accepts up to 4 arguments but may take fewer. Values of E*n* left unspecified are ignored.

OPTION	DESCRIPTION
PARTSET	Trim by PARTSET. E1 is the shell part set ID. E2 is the distance. Elements farther away than the distance in the direction of the shell normal vectors (depending on the value of IOUTIN) are deleted/kept. Please note, only elements on one side will be deleted. To delete the elements on both sides, repeat the card with the IOUTIN value reversed.
SEGSET	Trim by SEGMENT SET. E1 is the segment set ID. E2 is the distance. Elements farther away than the distance in the direction of the segment normal vectors (depending on the value of IOUTIN) are deleted/kept. To delete both sides, repeat the card with the IOUTIN value reversed.
PLANE	Trim by PLANE. E1 is the node ID of a node on the plane. E2 is another node ID off the plane. And vector E2 – E1 is normal to the plane.
CYLINDER	Trim by CYLINDER. E1, E2 are node IDs of the center nodes at two ends. E3, E4 are the radius at those two ends.
BOXCOR	Trim by BOX. E1 is the BOX ID. Please refer to *DEFINE_BOX for details on setting up a box in global coordinate system or *DEFINE_BOX_LOCAL in local coordinate system.
BOXCPT	Trim by BOX. The box is defined using S-ALE control points (CPT). E1 is BOX ID. Please refer to *DEFINE_BOX for details on setting up a box.
SPHERE	Trim by SPHERE. E1 is the node ID of the sphere center node. E2 is the radius of the sphere.

Examples:

This example shows how to trim a mesh generated by *ALE_STRUCTURED_MESH card. We use the same mesh as the example in the *ALE_STRUCTURED_MESH card manual

page, but now we trim the mesh so any elements outside of a sphere centered at (0.0,0.0,0.0) with a radius of 0.1 are deleted.

```
*ALE_STRUCTURED_MESH
$    mshid       pid      nbid      ebid
         1         1    200001    200001
$     nptx      npty      nptz      nid0     lcsid
      1001      1001      1001         1       234
*ALE_STRUCTURED_MESH_TRIM
$    mshid    option      oper    ioutin       nid    radius
         1    SPHERE                            1      0.10
*NODE
       1   0.0000000e+00   0.0000000e+00   0.0000000e+00
       2   0.0000000e+00   0.0000000e+00   0.0000000e+00
       3   0.1000000e+00   0.0000000e+00   0.0000000e+00
       4   0.0000000e+00   0.1000000e+00   0.0000000e+00
*END
```

If instead we want to trim the elements inside the sphere, we simply change flip to 1 as follows.

```
*ALE_STRUCTURED_MESH
$    mshid       pid      nbid      ebid
         1         1    200001    200001
$     nptx      npty      nptz      nid0     lcsid
      1001      1001      1001         1       234
*ALE_STRUCTURED_MESH_TRIM
$    mshid    option      oper    ioutin       nid    radius
         1    SPHERE                 1         1      0.10
*END
```

If we want to trim the elements between two spheres both centered at (0.0,0.0,0.0) with radii of 0.05 and 0.1, respectively, multiple methods requiring two cards can achieve this. In one method, first delete all the elements inside the large sphere (0.1 radius). Then un-delete, the elements inside the small sphere (0.05 radius).

```
*ALE_STRUCTURED_MESH
$    mshid       pid      nbid      ebid
         1         1    200001    200001
$     nptx      npty      nptz      nid0     lcsid
      1001      1001      1001         1       234
*ALE_STRUCTURED_MESH_TRIM
$    mshid    option      oper    ioutin       nid    radius
         1    SPHERE                 1         1      0.10
         1    SPHERE         1       1         1      0.00
*END
```

Another method is to first delete all the elements outside the small sphere (0.05 radius) and then un-delete the elements outside the large sphere (0.1 radius).

```
*ALE_STRUCTURED_MESH
$    mshid       pid      nbid      ebid
         1         1    200001    200001
$     nptx      npty      nptz      nid0     lcsid
```

```
      1001      1001      1001         1       234
*ALE_STRUCTURED_MESH_TRIM
$    mshid    option      oper    ioutin       nid    radius
         1    SPHERE                 0         1      0.05
         1    SPHERE          1      0         1      0.10
*END
```

To use BOXCPT, we define a box using S-ALE control point numbers. The example below deletes all elements outside of a box with two endpoints at (8.0,8.0,8.0) and (15.0,15.0,15.0) in S-ALE control points.

```
*ALE_STRUCTURED_MESH
$    mshid       pid      nbid      ebid
         1         1    200001    200001
$     nptx      npty      nptz      nid0     lcsid
      1001      1001      1001         1       234
*ALE_STRUCTURED_MESH_TRIM
$    mshid    option      oper    ioutin     boxid
         1    BOXCPT                 0         1
*DEFINE_BOX
$    boxid       xmn       xmx       ymn       ymx       zmn       zmx
         1         8        15         8        15         8        15
*END
```

*ALE_STRUCTURED_MESH_VOLUME_FILLING

Purpose: Perform volume filling operations on a structured ALE mesh generated by the *ALE_STRUCTURED_MESH keyword card.

In a typical Structured ALE (S-ALE) simulation, *ALE_STRUCTURED_MESH constructs the S-ALE mesh. The mesh includes a set of hex solid elements and their nodes. *ALE_-STRUCTURED_MULTI-MATERIAL_GROUP is used to specify the multi-materials flow in that mesh and their material properties.

With the above defined, we have the S-ALE mesh which defines our domain for the ALE simulation, and the materials flowing inside, but we have no idea of how those materials occupy the domain. We have two methods for identifying how the materials occupy the domain:

1. The first is to use *INITIAL_VOLUME_FRACTION. With this keyword, we list elements one by one and then for each AMMG in each element, its volume fraction. This approach is tedious and impractical, so it is rarely used.

2. The second way is to fill the volume automatically based on instructions given with *ALE_STRUCTURED_MESH_VOLUME_FILLING. Each instance of *ALE_STRUCTURED_MESH_VOLUME_FILLING with its data cards represents an instruction. Those instructions are executed consecutively, based on the order of appearance in the input file. Each instruction fills the volume either inside or outside of a geometry type (field GEOM in Card 2) with a certain AMMG.

Each *ALE_STRUCTURED_MESH_VOLUME_FILLING keyword has two data cards. Multiple *ALE_STRUCTURED_MESH_VOLUME_FILLING keywords can be defined and are executed in the order of appearance. Please see the examples below.

Card 1	1	2	3	4	5	6	7	8
Variable	MSHID		AMMGTO		NSAMPLE			VID
Type	I		A		I			I
Default	0		0		3			none

Card 2	1	2	3	4	5	6	7	8
Variable	GEOM	IN/OUT	E1	E2	E3	E4	E5	
Type	A	I	I or F	I or F	I or F	I or F	I or F	
Default	none	0	none	none	none	none	none	

VARIABLE	DESCRIPTION
MSHID	S-ALE Mesh ID. A unique number must be specified.
AMMGTO	AMMG name (AMMGNM on *ALE_STRUCTURED_MULTI-MATERIAL_GROUP) of the ALE multi-material group filling the geometry. See *ALE_STRUCTURED_MULTI-MATERIAL_GROUP for reference.
NSAMPLE	Number of sampling points. In case an element is partially filled, in each direction, 2 × NSAMPLE + 1 points are generated. These $(2 \times \text{NSAMPLE} + 1)^3$ points, each representing a volume, are used to determine if its volume is in or out.
VID	ID of *DEFINE_VECTOR card. This flag is used to assign initial velocity to material filling the domain. Fields 2 to 5 (XT, YT, ZT) of the *DEFINE_VECTOR card are used to define the initial translational velocities. Please refer to Example 1 below for usage.
GEOM	Geometry types. They are: PARTSET, PART, SEGSET, PLANE, CYLINDER, BOXCOR, BOXCPT and SPHERE. See the table below for more details.
IN/OUT	To fill inside or outside of the geometry. For PARTSET / PART / SEGSET options, inside is taken as in the normal direction of the container's segments (see Remark 1). EQ.0: Inside (default) EQ.1: Outside
E*i*	These values have different definitions for different options. See the table below for details.

The "GEOM" column in the table below enumerates the allowed values for the geometry variable as well as describing E1, …, E5 for each geometry type. Each of the following

operations accepts up to 5 arguments but may take fewer. Values of E*n* left unspecified are ignored.

GEOM	DESCRIPTION
ALL	Fill all volume inside the mesh. No additional variables are needed.
PARTSET	Geometry defined by PARTSET. E1 is a shell, thick shell, or solid element part set ID. E2 is the offset from the geometry (see Remark 2).
PART	Geometry defined by PART. E1 is a shell, thick shell, or solid element part ID. E2 is the offset from the geometry (see Remark 2).
SEGSET	Geometry defined by SEGSET. E1 is the segment set ID. E2 is the offset from the geometry (see Remark 2).
PLANE	Geometry defined by PLANE. E1 is the node ID of a node on the plane. E2 is another node ID off the plane. The vector going from node E1 to node E2 is the normal vector of the plane.
CYLINDER	Geometry defined by CYLINDER. E1 and E2 are node IDs of the center nodes at the two ends. E3 and E4 are the radii at those two ends.
BOXCOR	Geometry defined by BOX. E1 is the BOX ID. See *DEFINE_BOX for details on setting up a box in global coordinate system or *DEFINE_BOX_LOCAL in local coordinate system.
BOXCPT	Geometry defined by BOX. The box is defined using S-ALE control points (CPT). E1 is BOX ID. See *DEFINE_BOX.
ELLIPSOID	Geometry defined by ELLIPSOID. E1 is the node ID of the ellipsoid center node. E2, E3, and E4 are the radii along x, y, and z directions, respectively. E5 is the local coordinate system ID if a local coordinate system is used; see *DEFINE_COOR-DINATE_SYSTEM.

Remarks:

1. **Geometry specified with Solid Element Parts.** When solid element parts specify the geometry for GEOM = PARTSET and PART, then their boundaries define the container geometry. The inside/outside direction depends on the normal vectors of the segments on the boundaries of the container.

2. **Offset Direction for PART / PARTSET /SEGSET.** For GEOM = PART, PARTSET, and SEGSET, you can specify an offset distance for the fluid interface from the container's mesh. The direction of the offset depends on the normal vectors associated with the mesh of the container (see Remark 1). If the offset specified with E2 is greater than 0, then the offset is along the normal vectors from the boundary of the container. If it is less than 0, then it is offset in the negative normal direction from the boundary of the container.

3. **Files Output for Subsequent Analyses.** This keyword causes file alevfrc.inc and salevfrc.lsda to be output at the end of the simulation. salevfrc.lsda is an lsda version of alefrc.inc. alefrc.inc can be included with *INCLUDE for subsequent analyses while salevfrc.lsda can be included with *INITIAL_VOLUME_FRACTION_LSDA. These files pre-fill the volume fractions and store the trimmed mesh which can save time for subsequent analyses.

Examples:

1. This example uses two *ALE_STRUCTURE_VOLUME_FILLING cards. The first fills all volume in a mesh with AMMG 1, outside air, with an AMMGNM "airout". The second fills AMMG 2, inside air, with an AMMGNM "airin" in a spherical domain. We use the same mesh as the example in the *ALE_STRUCTURED_MESH card manual page.

```
*ALE_STRUCTURED_MESH
$    mshid       pid      nbid      ebid
         1         1    200001    200001
$     nptx      npty      nptz
      1001      1001      1001
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto             nsample                          vid
         1             airout
$     geom
       ALL
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto             nsample                          vid
         1              airin
$     geom    in/out      node        rx        ry        rz     lcsid
 ELLIPSOID                          0.03                           234
*DEFINE_COORDINATE_NODES
$      cid      nid1      nid2      nid3      flag
       234         2         3         4         1
*NODE
       1   0.0000000e+00   0.0000000e+00   0.0000000e+00
       2   0.0000000e+00   0.0000000e+00   0.0000000e+00
       3   0.1000000e+00   0.0000000e+00   0.0000000e+00
       4   0.0000000e+00   0.1000000e+00   0.0000000e+00
       5   0.1000000e+00   0.1000000e+00   0.1000000e+00
*END
```

Or we could fill every element with AMMG 2 and then switch the domain outside of the sphere to AMMG 1 as follows:

```
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto             nsample                          vid
```

```
         1             airin
$     geom
       ALL
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto            nsample                          vid
         1             airout
$     geom    in/out      node        rx        ry        rz     lcsid
 ELLIPSOID         1               0.03                           234
```

If we want to give the sphere filled in by AMMG 2 an initial velocity, simply define a *DEFINE_VECTOR card as below and assign its ID to field VID.

```
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto            nsample                          vid
         1             airin
$     geom    in/out      node        rx        ry        rz     lcsid
 ELLIPSOID                           0.03                           234
*DEFINE_VECTOR
$      vid        xt        yt        zt
         1      100.      -20.       0.0
```

2. In this model, we fill the whole mesh with AMMG 4 (“vacuum”) first. And then fill AMMG 1 (“water1”), AMMG 2 (“water2”) and AMMG 3 (“air”) into 3 containers, each defined by a Lagrangian shell part. 4 cards are required to do that.

```
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto            nsample                          vid
         1             vacuum
$     geom
       ALL
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto            nsample                          vid
         1            water1
$     geom    in/out       pid    offset
      PART                2001
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto            nsample                          vid
         1            water2
$     geom    in/out       pid    offset
      PART                2002
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto            nsample                          vid
         1              air
$     geom    in/out       pid    offset
      PART                2003
```

The above filling by PART cards assume the shell normal vectors point inward to the container. If the shell normal vectors point outwards, we need to assign the in/out value to 1. Assuming shell part 2003’s normal is pointing outwards, the card will need to be set as:

```
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto            nsample                          vid
         1              air
$     geom    in/out       pid    offset
      PART          1     2003
```

3. To use BOXCPT, we define a box using S-ALE control point indices.

```
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto             nsample                          vid
         1            water1
$     geom
       ALL
*ALE_STRUCTURED_MESH_VOLUME_FILLING
$    mshid              ammgto             nsample                          vid
         1            water2
$     geom    in/out     boxid
    BOXCPT                   1
*DEFINE_BOX
$    boxid       xmn       xmx       ymn       ymx       zmn       zmx
         1         8        15         8        15         8        15
```

*ALE_STRUCTURED_MULTI-MATERIAL_GROUP_{OPTION}

Purpose: Specify the material properties of each ALE multi-material group (AMMG) used by the S-ALE solver. Each AMMG represents one unique "fluid" which flows in the S-ALE mesh.

To set up a typical Structured ALE (S-ALE) simulation, you construct the S-ALE mesh with*ALE_STRUCTURED_MESH. The mesh includes a set of hex solid (quad for 2D) elements and their nodes. You specify the ALE material properties with *ALE_STRUCTURED_MULTI-MATERIAL_GROUP. *ALE_STRUCTURED_MESH_VOLUME_FILLING fills the domain with these AMMGs.

> **NOTE:** You can use *ALE_MULTI-MATERIAL_GROUP to specify the AMMGs. However, this keyword provides a simpler interface since you specify the material and EOS here instead of needing a separate part ID. Because of this, you do not need a section definition. This keyword uses ELFORM = 11 on *SECTION_SOLID for 3D, ELFORM = 13 on *SECTION_ALE2D for 2D plane strain, and ELFORM = 14 on *SECTION_ALE2D for 2D axisymmetric. This keyword also allows you to give each AMMG a name and reference pressure (see Remarks 2 and 3).

Available options include:

<BLANK>

PLNEPS

AXISYM

No keyword option (<BLANK>) is for 3D S-ALE simulations. The element formulation is equivalent to ELFORM = 11 on *SECTION_SOLID. The PLNEPS and AXISYM options are for 2D S-ALE simulations to set up plane strain and axisymmetric element formulations. They correspond to ELFORM = 13 and 14 in *SECTION_ALE2D, respectively.

Card 1	1	2	3	4	5	6	7	8
Variable	AMMGNM	MID	EOSID					PREF
Type	A	I	I					F
Default	none	none	none					0.

VARIABLE	DESCRIPTION
AMMGNM	AMMG name. This name is required to identify the AMMG (S-ALE fluid). It is not case sensitive, but it needs to be unique. See Remark 2.
MID	Material ID
EOSID	Equation-of-state ID
PREF	Reference pressure of this AMMG. See Remark 3.

Remarks:

1. **AMMGID.** Each AMMG is automatically assigned an ID (AMMGID) according to its order of appearance in the input deck. The AMMG defined in the first line has an AMMGID = 1, the second line AMMGID = 2, so on and so forth. This ID later could be used in other keyword cards, such as *SET_MULTI-MATERIAL_-GROUP. The general ALE solver uses this convention which is inherited by the S-ALE solver.

2. **AMMG NAME.** Traditionally keywords refer to ALE multi-materials with their AMMGIDs. This ID is automatically assigned based on the order of appearance of each AMMG as discussed in Remark 1. This arrangement works in most cases but has its problems. For example, if you want to switch the order of the AMMGs or want to add or remove certain AMMGs, all references to those AMMGs are affected and need to be modified/corrected. Fixing those references is often forgotten, leading to errors.

   The name specified with AMMGNM on this keyword provides an alternative way to refer to AMMGs. Other ALE keyword cards, such as *SET_MULTI-MATERIAL_GROUP, accept it in place of AMMGID for S-ALE simulations. For example, suppose the third AMMG defined with *ALE_STRUCTURED_MULTI-MATERIAL_GROUP has AMMGNM = air. In the other keywords, we could either input 3 or air where it asks for AMMGID.

   We recommend using AMMGNM over AMMGID as it is more user-friendly and less error prone.

3. **PREF.** PREF allows you to provide different reference pressures for each AMMG. With this, we can handle mismatched reference pressures among different AMMGs.

   Each ALE material definition (*MAT +*EOS) has an implicit reference pressure. Different AMMGs in the same model are generally required to have the same reference pressure. For example, assume we have two AMMGs, air and water.

For the *EOS, we need to carefully choose E0 and V0 values so that their initial pressure matches this reference pressure, most likely atmospheric pressure.

Sometimes mismatch could happen. For example, air and high explosive may have different reference pressures. Air may have a reference pressure of 1 bar, but the high explosive defined with *EOS_JWL may have a reference pressure of 0 bar. Before PREF, this discrepancy was considered small and ignored. PREF resolves this discrepancy by allowing us to input 101325.0 as PREF for air and 0.0 as PREF for high explosive. Then, when force is evaluated for an element, this PREF pressure will be subtracted off from that of the corresponding material.

*ALE_SWITCH_MMG

Purpose: This card changes a fraction of an ALE multi-material-group (AMMGID) into another group. The fraction is to be specified by a *DEFINE_FUNCTION function. The function take as many arguments as there are fields specified on the cards in format 2.

Card 1	1	2	3	4	5	6	7	8
Variable	FR_MMG	TO_MMG	IDFUNC	IDSEGSET	IDSLDSET	NCYCSEG	NCYCSLD	
Type	I	I	I	I	I	I	I	
Default	none	none	none	0	0	50	50	

Variable Cards. Cards defining the function arguments. Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	VAR1	VAR2	VAR3	VAR4	VAR5	VAR6	VAR7	VAR8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

VARIABLE	DESCRIPTION
FR_MMG	This is the AMMG-SID before the switch. The AMMG-SID corresponds to the SID defined on a *SET_MULTI-MATERIAL_GROUP_LIST (SMMGL) card. This SID refers to one or more AMMGs. See Remark 1.
TO_MMG	This is the AMMG-SID after the switch. The AMMG-SID corresponds to the SID defined on a *SET_MULTI-MATERIAL_GROUP_LIST card. This SID refers to one or more AMMGs. See Remark 1.
IDFUNC	ID of a *DEFINE_FUNCTION function. This function determines the material fraction to be switched. See Example 1.

VARIABLE	DESCRIPTION
IDSEGSET	ID of *SEGMENT_SET that is used to pass geometric properties to the function specified by IDFUNC. *This field is optional*. LS-DYNA computes the segment center positions and normal vectors. For each ALE element, this data can be passed to the function IDFUNC for the segment that is closest to the element center. See Example 2.
IDSLDSET	The ID of a *SOLID_SET specifying which elements are affected by this particular instance of the *ALE_SWITCH_MMG keyword. *This field is optional*. If undefined, *ALE_SWITCH_MMG affects all ALE elements. The element centers are computed and can be used as variables in the function IDFUNC.
NCYCSEG	Number of cycles between each update of the segment centers and normal vectors (if a segment set is defined). For each update, a bucket sort is applied to find the closest segment to each ALE element. If the segment nodes are fully constrained, the segment centers and normal vectors are computed only one time.
NCYCSLD	Number of cycles between each update of the ALE element centers. For each update, a bucket sort is applied to find the closest segment to each ALE element. If the element nodes do not move (as with AFAC = -1 in *CONTROL_ALE), the element centers are computed exactly once.
VAR*i*	Variables used by IDFUNC which must be in the argument order (See Remark 2): EQ.0: See Remark 3. EQ.1: *xx*-stress for FR_MMG EQ.2: *yy*-stress for FR_MMG EQ.3: *zz*-stress for FR_MMG EQ.4: *xy*-stress for FR_MMG EQ.5: *yz*-stress for FR_MMG EQ.6: *zx*-stress for FR_MMG EQ.7: Plastic strain for FR_MMG EQ.8: Internal energy for FR_MMG EQ.9: Bulk viscosity for FR_MMG

VARIABLE	DESCRIPTION	
	EQ.10:	Volume from previous cycle for FR_MMG
	GE.11.and.LE.20:	Other auxiliary variables for FR_MMG
	GE.21.and.LE.40:	Auxiliary variables for TO_MMG (*xx*-stress, …)
	EQ.41:	Mass for FR_MMG
	EQ.42:	Mass for TO_MMG
	EQ.43:	Volume fraction for FR_MMG
	EQ.44:	Volume fraction for TO_MMG
	EQ.45:	Material volume for FR_MMG
	EQ.46:	Material volume for TO_MMG
	EQ.47:	Time
	EQ.48:	Cycle
	EQ.49:	*x*-position of the ALE element center
	EQ.50:	*y*-position of the ALE element center
	EQ.51:	*z*-position of the ALE element center
	EQ.52:	*x*-position of the segment center
	EQ.53:	*y*-position of the segment center
	EQ.54:	*z*-position of the segment center
	EQ.55:	*x*-component of the segment normal
	EQ.56:	*y*-component of the segment normal
	EQ.57:	*z*-component of the segment normal
	GE.58.and.LE.65:	*x*-positions of the ALE nodes
	GE.66.and.LE.69:	*x*-positions of the segment nodes
	GE.70.and.LE.77:	*y*-positions of the ALE nodes
	GE.79.and.LE.81:	*y*-positions of the segment nodes
	GE.83.and.LE.89:	*z*-positions of the ALE nodes
	GE.90.and.LE.93:	*z*-positions of the segment nodes
	GE.94.and.LE.101:	*x*-velocities of the ALE nodes
	GE.102.and.LE.105:	*x*-velocities of the segment nodes
	GE.106.and.LE.113:	*y*-velocities of the ALE nodes
	GE.114.and.LE.117:	*y*-velocities of the segment nodes

VARIABLE	DESCRIPTION
	GE.118.and.LE.125: z-velocities of the ALE nodes
	GE.126.and.LE.129: z-velocities of the segment nodes
	GE.130.and.LE.137: x-accelerations of the ALE nodes
	GE.138.and.LE.141: x-accelerations of the segment nodes
	GE.142.and.LE.149: y-accelerations of the ALE nodes
	GE.150.and.LE.153: y-accelerations of the segment nodes
	GE.154.and.LE.161: z-accelerations of the ALE nodes
	GE.162.and.LE.165: z-accelerations of the segment nodes
	GE.166.and.LE.173: Masses of the ALE nodes
	GE.174.and.LE.177: Masses of the segment nodes
	EQ.178: Position of the variable updated by the function (See Remark 4)
	EQ.179: Index of the multi-material group in the set
	EQ.180: Time step

Remarks:

1. **Mapping.** The multi-material group sets that are specified by the fields FR_-MMG and TO_MMG must be of the same length. Multi-material groups are switched so that, for instance, the fourth multi-material group in the set FR_-MMG is mapped to the fourth multi-material group in the set TO_MMG. (see Example 1).

2. **Variable Specification.** The variables are presented to the function IDFUNC as floating point data. The order of the arguments appearing in the *DEFINE_-FUNCTION should match the order of the variables, VAR*i*, specified on Card 2 (for this keyword). For example, when there is one card in format 2 containing "47, 48, 41, 42", then the time (47), the cycle (48), and the masses (41 & 42) should be the first, second, third, and fourth arguments to the function defined on the *DEFINE_FUNCTION keyword.

   If there is a blank column between 2 variables, the list between these 2 ranks is specified. For example, if the card contains "1, ,6", then the 6 stresses (1 through 6) are selected as arguments (see Example 2). In the case that there are several groups in the sets, if a variable is repeated, the corresponding variable will be defined in the function for the same number of groups as variable instances. For instance, if the sets have 3 groups and the volume fractions of the 2 first groups

in the set TO_MMG are required as arguments of the function, a card in format 2 should have "44,44".

3. **Variable Update for Several Groups.** If there is more than one group in the set, the function is called for each group. For a given group that has an index in the set > 1 (VAR*i* = 179), some variables, including the volume fraction, mass, and internal energy, may have been updated during the previous switches. If their original values are required, they can be obtained by setting the first field (VAR1) to 0.

4. **Variable Update by the User.** The variables can be updated by the user. If VAR*i* < 0 for some variables, the function is called again (after the switch) for each of these variables. VAR*i* = 178 gives the position of the variable for which the function is called. The function's return value is taken as the new value for this variable (instead of the fraction of material to switch). If the position given by VAR*i* = 178 is zero, it means that the function is called for the switch. Only the 46 first variables 1 < VAR*i* < 46, 58 < VAR*i* < 165 and VAR*i* = 180 can be modified.

Example 1:

The first example switches the material if the pressure is lower than a given value.

```
*comment
units: mks

Switch from the 3rd group to the 5th one if the pressure of the 3rd group
is lower than pc : pres < pc
Do the same for the switch from 4th to 7th
If the switch occurs, the function frac returns 1.0. So the whole
material is permuted.

xxsig : xx-stress of the groups in the 1st *set_multi-material_group_list
yysig : yy-stress of the groups in the 1st *set_multi-material_group_list
zzsig : zz-stress of the groups in the 1st *set_multi-material_group_list
pres  : pressure
pc    : pressure cutoff

*ALE_TANK_TEST

Purpose: Control volume airbags (*AIRBAG_) only require two engineering curves to define the gas inflator, i.e. $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$; those two curves can be experimentally measured. However, the ALE inflator needs one additional state variable - the inlet gas velocity which is impractical to obtain. This keyword provides such a curve through an engineering approximation.

It takes two curves from the accompanying *SECTION_POINT_SOURCE as input. It assumes inflator gas under choking condition to generate the velocity curve. During this process, the original curves, $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$, are modified accordingly.

This keyword complements and must be used together with the*SECTION_POINT_-SOURCE command. Please see *SECTION_POINT_SOURCE for additional information.

Card 1	1	2	3	4	5	6	7	8
Variable	MDOTLC	TANKV	PAMB	PFINAL	MACHL	VELMAX	AORIF	
Type	I	I	I	I	F	F	F	
Default	0	0.0	0.0	0.0	0.0	0.0	0.0	

Card 2	1	2	3	4	5	6	7	8
Variable	AMGIDG	AMGIDA	NUMPNT					
Type	I	I	I					
Default	0	0	50					

VARIABLE	DESCRIPTION
MDOTLC	LCID for mass flow rate as a function of time. This may be obtained directly from the control-volume type input data.
TANKV	Volume of the tank used in a tank test from which the tank pressure is measured; $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$ are computed from this tank pressure data.

VARIABLE	DESCRIPTION
PAMB	The pressure inside the tank before jetting (usually 1 bar).
PFINAL	The final equilibrated pressure inside the tank from the tank test.
MACHL	A limiting MACH number for the gas at the throat (MACH = 1 preferred).
VELMAX	Maximum allowable gas velocity across the inflator orifice (not preferred).
AORIF	Total inflator orifice area (optional, only needed if the *SECTION_POINT_SOURCE card is not used).
AMGIDG	The ALE multi-material group ID (AMMGID) of the gas.
AMGIDA	The ALE multi-material group ID (AMMGID) of the air.
NUMPNT	The number of points in $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$ curves. If NUMPNT = 0, defaults to 50 points.

Remarks:

In an airbag inflator tank test, the tank pressure data is measured. This pressure is used to derive $\dot{m}(t)$ and to estimate $\overline{T}_{\text{gas}}(t)$, the stagnation temperature of the inflator gas. This is done by applying a lumped-parameter method to the system of conservation equations using an equation of state.

Together $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$ provide enough information to model an airbag with the control volume method (see *AIRBAG cards). However, for an ALE or Eulerian fluid-structure interaction analysis, the gas velocity, $v(t)$, and density, $\rho(t)$, at the inlet must be computed. But, since only $\dot{m}(t)$ is known, additional assumptions must be made about the inlet conditions. If $v(t)$ and $\rho(t)$ are calculated outside of LS-DYNA, then LS-DYNA combines them with $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$ to obtain $\overline{T}_{\text{gas corrected}}(t)$, $v(t)$ and $\rho(t)$ which are sufficient input for an ALE calculation.

The curves $v(t)$ and $\rho(t)$ need not be calculated outside of LS-DYNA as LS-DYNA features a method for calculating them itself. This card, *ALE_TANK_TEST, activates this capability. Thus, with the combination of this card and the *SECTION_POINT_SOURCE card, LS-DYNA can proceed directly from the control volume method input, $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$, to an ALE or Eulerian fluid-structure interaction analysis. The user does not have to do the conversion himself.

If the *ALE_TANK_TEST card is present:

1. The definitions of the relative volume, $V(t)$, and the velocity, $v(t)$, curves in the *SECTION_POINT_SOURCE card will be ignored in favor of those computed by LS-DYNA.

2. The $\dot{m}(t)$curve is read in on *ALE_TANK_TEST card.

3. The $\overline{T}_{\text{gas}}(t)$ curve (stagnation temperature), as opposed to $\overline{T}_{\text{gas corrected}}(t)$, is read in on *SECTION_POINT_SOURCE card.

   There is a subtle, but important, distinction between the two temperatures. $\overline{T}_{\text{gas}}(t)$ is derived directly from the tank pressure data based on a lump-parameter approach, whereas $\overline{T}_{\text{gas corrected}}(t)$ is computed from $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$ with additional isentropic and sonic flow assumptions for the maximum velocity at an orifice. $\overline{T}_{\text{gas corrected}}(t)$ is most appropriately interpreted as the static temperature. These assumptions provide a necessary and physically reasonable supplement to the governing equation,

   $$\dot{m}(t) = \rho(t)v(t)A$$

   in which only $\dot{m}(t)$ and A are known, leaving two parameters, $\rho(t)$ and $v(t)$, as unkown.

4. The inflator area is computed from the *SECTION_POINT_SOURCE card that has the AMMGID of the inflator gas in the *ALE_TANK_TEST card. If the *BOUNDARY_AMBIENT_EOS card is used instead of the *SECTION_POINT_-SOURCE card, then the area may be input in this *ALE_TANK_TEST card.

5. The reference density of the propellant "gas," ρ_0, is computed internally and automatically used for the calculation. The ρ_0 value from the *MAT_NULL card is ignored.

Example:

Consider a tank test model that consists of the inflator gas (PID 1) and the air inside the tank (PID 2). The following information from the control volume model is available:

- $\dot{m}(t)$ (LCID 1 is from control volume model input).
- $\overline{T}_{\text{gas}}(t)$ (LCID 2 is from control volume model input).
- Volume of the tank used in the inflator tank test.
- Final equilibrated pressure inside the tank.
- Ambient pressure in the air.

Also available are:

- The nodal IDs of the nodes defining the orifice holes through which the gas flows into the tank.
- The area associated with each hole (the node is assumed to be at the center of this area).
- The vector associated with each hole defining the direction of flow.

In the input below LCID 1 and 2 are $\dot{m}(t)$ and $\overline{T}_{\text{gas}}(t)$, respectively. LCID 4 and 5 will be ignored when the *ALE_TANK_TEST card is present. If it is not present, all 3 curves in the *SECTION_POINT_SOURCE card will be used. When the *SECTION_POINT_-SOURCE card is present, the element formulation is equivalent to an ELFORM = 11.

*ALE_UP_SWITCH

Purpose: For the simulation of airbag inflation process, this card allows the switching from an ALE computation to a control volume (CV) or uniform pressure (UP) method at a user-defined switch time.

Card 1	1	2	3	4	5	6	7	8
Variable	UPID	SWTIME						
Type	I	F						
Default	0	10^{16}						

Card 2	1	2	3	4	5	6	7	8
Variable	FSI_ID1	FSI_ID2	FSI_ID3	FSI_ID4	FSI_ID5	FSI_ID6	FSI_ID7	FSI_ID8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

Hybrid Card. This card is included if and only if UPID = 0.

Card 3	1	2	3	4	5	6	7	8
Variable	SID	SIDTYPE	MMGAIR	MMGGAS				
Type	I	I	I	I				
Default	0	0	0	0				

VARIABLE	DESCRIPTION
UPID	An ID defines a corresponding *AIRBAG_HYBRID_ID card for use in an ALE-method-switching-to-CV-method simulation. The simulation starts with ALE computational method, then switches to a CV (or UP) method at some given time.

VARIABLE	DESCRIPTION
	EQ.0: The code will construct an equivalent *AIRBAG_HYBRID_ID card automatically internally (default). Card 3 is then a required input. NE.0: An ID points to a corresponding *AIRBAG_HYBRID_ID card which must be defined for use after the switch. If UPID is defined, do not define Card 3.
SWTIME	The time at which the computation does a switch from an ALE-method-to-CV-method.
FSI_ID1, …, FSI_ID8	Coupling IDs for one or more ALE fluid-structure-interaction (FSI) *CONSTRAINED_LAGRANGE_IN_SOLID_ID cards. These couplings are deleted during the 2nd, CV computational phase.
SID	A set ID that defines the Lagrangian parts which make up the airbag
SIDTYPE	Set ID type for the above SETID (following the conventions in *AIRBAG_HYBRID card). EQ.0: SID is a segment set ID (SGSID). NE.0: SID is a part set ID (PSID).
MMGAIR	The AMMG (ALE multi-material group) ID of surrounding air.
MMGGAS	The AMMG ID of inflator gas injected into the airbag.

Example 1:

Consider an airbag model with a 2-phase simulation: an ALE calculation being switched to a CV method. During the CV phase, the simulation is defined by an *AIRBAG_HYBRID_ID card.

*BOUNDARY_USA_SURFACE

*BOUNDARY_ACOUSTIC_COUPLING_{OPTION}

Purpose: This keyword provides fluid-structure coupling when the fluid is modeled with *MAT_ACOUSTIC and solid formulation 8 or 14, *and* the nodes of the fluid at the fluid-structure interface are not merged/shared with nodes of the structure.

If acoustic fluid exists on one side of a structural surface *and* the nodes of the fluid and structure are merged/shared at the interface, this keyword is not required. Coupling between an acoustic fluid and a structural surface occurs automatically when nodes are shared at the interface.

Available options for the keyword are:

<BLANK>

MISMATCH

If the nodes of the fluid are not coincident with the nodes of the structure at the fluid-structure interface, the MISMATCH option must be used. If the nodes are coincident, the <BLANK> option is sufficient. The input for this keyword is a segment set that defines the structural surface(s) to be coupled to the acoustic fluid.

If acoustic fluid exists on both sides of a structural surface comprised of shells, that is, the shell surface constitutes a physical break between the two fluid masses (call these fluid A and fluid B), fluid A should not share nodes with fluid B. In this case, coupling may be defined (1) wholly through use of this keyword if the structural shells do not share nodes with either fluid, or (2) by fluid A sharing nodes with the structural shells and by using this keyword to couple fluid B to the structural shells. Note that this concept of coupling two fluid masses to a structural surface does not apply to structural solids because a solid face can have direct contact with only one fluid.

If no keyword option is used (<BLANK>), then the nodes of the structural element segments must be coincident with, but not merged to, the nodes of the acoustic element faces. Each structural element face to be coupled, regardless of whether there is fluid on one or both sides of that face, requires only one corresponding segment to be included in the segment set, and the orientation of the segment normal is unimportant.

The MISMATCH option permits the coupling of acoustic fluid elements to a structural surface when the meshes of the fluid and structural elements are moderately mismatched, meaning the nodes of the fluid and structure at the interface are not necessarily coincident. The segments in the segment set should define the structural surface and, following the right-hand rule, the normal vector for the segments should point toward the fluid volume elements with which coupling is intended. If fluid-structure coupling is required on both sides of structural shell elements, duplicate segments with opposite normal vectors should be defined. Every segment in the segment set must couple with the fluid volume at some integration point, but not all integration points on the segment need to

couple with the fluid. The meshes do not have to be mismatched to use the MISMATCH option, as long as the fluid and structural nodes are not merged.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT. This set defines the structural segments being coupled to the acoustic elements.

Remarks:

1. **Stability Condition.** For the stability of the acoustic-structure coupling, the following condition must be satisfied:

$$\frac{2\rho_a D}{\rho_s t_s} < 5 \ ,$$

where ρ_a is the density of the acoustic medium, D is the total thickness of the acoustic elements adjacent to the structural element, ρ_s is the density, and t_s is the thickness of the structural shell element. If the structural element is a solid or thick shell element, then t_s should be half the thickness of the element. If coupling is on both sides of the structural elements, then t_s should also be half the thickness of the structural element.

2. **Mismatched Coupling and Orientation.** In mismatched coupling, free fluid faces are considered for coupling with the structural segments if they are near one another and if they face each other. Faces and segments that differ in orientation by more than 45 degrees are excluded. In regions of high curvature, the surfaces, therefore, need to be more similar than when the surfaces are flat. If a fluid face couples with any structural segment, then all four integration points on the fluid face must couple with some structural segment. Fluid faces may not be partially coupled. Structural segments are allowed to be partially coupled.

3. **Mismatched Coupling Output Files.** The mismatched coupling process dumps two LS-DYNA files that can be imported into LS-PrePost for review of the results of the coupling process. The file bac_str_coupling.dyn contains shell

elements where structural segments have coupled with the fluid and mass elements at structural integration points with coupling. When the messag file indicates that some structural segments have partial coupling, this file can be used to check the unconnected segment integration points. The file bac_flu_coupling.dyn contains shell elements where free fluid faces have coupled with the structural segments and mass elements at free fluid face integration points with coupling. These files are only for visualization of the coupling and serve no other purpose.

4. **Mismatched Coupling Excludes *MAT_ACOUSTIC.** The free surface given on *MAT_090 is excluded from the mismatched coupling logic. If there are multiple fluid regions with different free surfaces, then those regions should be given different material IDs.

*BOUNDARY_ACOUSTIC_COUPLING_SPECTRAL

Purpose: Specify the acoustic and structural surfaces that are to participate in fluid-structure coupling. This keyword is only for coupling the structure with spectral acoustic elements. *CONTROL_ACOUSTIC_SPECTRAL must also be in the input deck.

Card 1	1	2	3	4	5	6	7	8
Variable	SSIDS	SSIDF						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
SSIDS	Segment set ID for the structural faces
SSIDF	Segment set ID for the fluid faces

Remarks:

1. **Segment Orientation.** The normal vectors of the segments in SSIDS and SSIDF should point toward each other.

*BOUNDARY_ACOUSTIC_FREE_SURFACE

Purpose: Assign properties to an acoustic free surface in an SSD or spectral analysis (see *CONTROL_IMPLICIT_SSD_DIRECT and CONTROL_ACOUSTIC_SPECTRAL). The surface may exhibit a zero pressure condition, or for very low frequency response, a small amplitude (linear) wave surface.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	GRAV						
Type	I	F						
Default	none	0.0						

VARIABLE	DESCRIPTION
SSID	Segment set ID of an acoustic surface
GRAV	Acceleration of gravity

Remarks:

1. **Zero Pressure Surface.** If GRAV = 0.0, then the acoustic surface (SSID) exhibits a zero pressure boundary condition.

2. **Small Amplitude Waves.** If GRAV ≠ 0.0, then the acoustic surface exhibits the small amplitude, linear wave condition of sloshing.

*BOUNDARY_ACOUSTIC_IMPEDANCE

Purpose: Define a segment set to prescribe the acoustic impedance of acoustic volume element (type 8 and type 14 solid elements) faces.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	ZEE						
Type	I	F						
Default	none	none						

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT
ZEE	Value of the acoustic impedance ρc

Remarks:

1. **Stability of Solutions.** The effect of the boundary impedance on the acoustic cavity response is incorporated in the forcing vector. Solutions are conditionally stable; low values of impedance relative to the impedance of the *MAT_ACOUSTIC elements cause instabilities. Reducing the factor of safety on the time step extends the range of applicability; however, it is recommended that pressure release conditions be handled by leaving the boundary free rather than by providing a relatively low boundary acoustic impedance value. If the boundary impedance value is less than 25 percent of the *MAT_ACOUSTIC impedance, LS-DYNA displays a warning. A value less than 1 percent of the *MAT_ACOUSTIC impedance is considered to be an error.

2. **Non-Reflecting Entrant Boundary Condition.** A non-reflecting entrant boundary condition is assumed when on the same segments both *LOAD_SEGMENT sets pressures and *BOUNDARY_ACOUSTIC_IMPEDANCE is defined. The pressures in the LOAD_SEGMENT_SET definition are treated as incoming incident pressure. Pressure waves within the *MAT_ACOUSTIC domain striking this boundary will exit the model. In contrast, a *LOAD_SEGMENT_SET on *MAT_ACOUSTIC volume faces in the absence of *BOUNDARY_ACOUSTIC_IMPEDANCE acts as a time-dependent, total pressure constraint. Pressure waves within the *MAT_ACOUSTIC domain striking this boundary will be reflected back into the model.

*BOUNDARY_ACOUSTIC_IMPEDANCE_COMPLEX

Purpose: Assign complex impedance properties to an acoustic surface in an SSD analysis invoked with *CONTROL_IMPLICIT_SSD_DIRECT.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	ZR	ZI	LCIDR	LCIDI			
Type	I	F	F	I	I			
Default	none	0.0	0.0	0	0			

VARIABLE	DESCRIPTION
SSID	Segment set ID of an acoustic surface
ZR	Real part of the boundary impedance Z_R
ZI	Imaginary part of the boundary impedance Z_I
LCIDR	Frequency dependence of Z_R
LCIDI	Frequency dependence of Z_I

Remarks:

1. **Impedance**. On the boundary, the contribution to the damping matrix is:

$$[\bar{W}_f] = \frac{-Z_r}{(Z_r^2 + Z_i^2)} \int_S N_f^T N_f \, dS + \frac{iZ_i}{(Z_r^2 + Z_i^2)} \int_S N_f^T N_f \, dS \ .$$

2. **Frequency Dependence**. If the frequency dependence is not specified by a load curve, then the impedance is assumed to be constant.

*BOUNDARY_ACOUSTIC_IMPEDANCE_MECHANICAL

Purpose: Assign mechanical impedance properties to an acoustic surface in an SSD analysis invoked with *CONTROL_IMPLICIT_SSD_DIRECT.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	MPAREA	CPAREA	KPAREA				
Type	I	F	F	F				
Default	none	0.0	0.0	0.0				

VARIABLE	DESCRIPTION
SSID	Segment set ID of an acoustic surface
MPAREA	Mass per unit area m
CPAREA	Damping per unit area c
KPAREA	Stiffness per unit area k

Remarks:

1. **Impedance**. On the boundary, the impedance is given by

$$[\bar{W}_f] = \frac{-Z_r}{(Z_r^2 + Z_i^2)} \int_S N_f^T N_f \, dS + \frac{iZ_i}{(Z_r^2 + Z_i^2)} \int_S N_f^T N_f \, dS$$

where

$$Z_r = c, \quad Z_i = \frac{k}{\omega} - \omega m \ .$$

*BOUNDARY_ACOUSTIC_INTERFACE

Purpose: Read the interface file generated by *INTERFACE_ACOUSTIC from a prior analysis to load an acoustic fluid model in a second SSD analysis (see *CONTROL_IMPLICIT_SSD_DIRECT).

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	IFID						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT. This set defines the structural segments being coupled to the acoustic elements.
IFID	Interface ID from the file baifac.db created by *INTERFACE_ACOUSTIC. It will be used to drive the acoustic fluid boundary.

Remarks:

1. **Coupling.** The faces of the acoustic boundary defined by SSID do not need to identically match up with the structural segments of IFID from the interface file. The fluid faces are projected on the structural faces, so the acoustic volume may be meshed with tetrahedra and the structure with hexahedra or shells.

2. **Interpolation.** The displacements that drive the acoustic fluid boundary are linearly interpolated from the bracketing displacement states in the interface file.

*BOUNDARY_ACOUSTIC_MAPPING

Purpose: Define a set of elements or segments on a structure for mapping structural nodal velocity to acoustic volume boundary.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	STYP						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
SSID	Set or part ID
STYP	Set type: EQ.0: part set ID, see *SET_PART, EQ.1: part ID, see *PART, EQ.2: segment set ID, see *SET_SEGMENT.

Remarks:

If acoustic elements are not overlapping the structural elements, this keyword passes structural velocity to acoustic volume boundary, for subsequent frequency domain acoustic computation.

*BOUNDARY_ACOUSTIC_NON_REFLECTING

Purpose: Specify an absorbing acoustic boundary condition. This keyword differs from *BOUNDARY_NON_REFLECTING in the sense that higher order conditions are supported (see Remark 2).

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	NRBTYP	CRVOPT	DATA1	DATA2	DATA3		
Type	I	I	I	F	F	F		
Default	none	none	none	none	none	none		

VARIABLE	DESCRIPTION
SSID	Segment set ID of an acoustic surface
NRBTYP	Absorbing boundary type: EQ.1: Plane wave absorbing boundary EQ.2: Curved wave absorbing boundary (see CRVOPT)
CRVOPT	Curvature specification option for NRBTYP = 2: EQ.1: Provide average curvature, $1/R$ EQ.2: Provide coordinates of the center of curvature, (X_c, Y_c, Z_c)
DATA1	CRVOPT.EQ.1: Average curvature, $1/R$ CRVOPT.EQ.2: Coordinate X_c
DATA2	Coordinate Y_c for CRVOPT = 2
DATA3	Coordinate Z_c for CRVOPT = 2

Remarks:

1. **Orientation.** The boundaries are most effective if the incident wave is roughly normal to the boundary. Sharp corners with three faces coming together at a point should be avoided.

2. **Equivalence.** NRBTYP = 1 is the same as *BOUNDARY_NON_REFLECTING and the 0^{th} order condition of Kallivokas, Bielak and McCamy. NRBTYP = 2 is equivalent to the 1^{st} order condition of Kallivokas, Bielak and McCamy.

*BOUNDARY_ACOUSTIC_PRESCRIBED_MOTION

Purpose: Impose a prescribed motion on the boundary of an acoustic volume.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	VAD	LCID	SF				
Type	I	I	I	F				
Default	none	none	none	1.0				

VARIABLE	DESCRIPTION
SSID	Segment set ID for the fluid boundary faces
VAD	Velocity/acceleration/displacement flag (see Remark 2): EQ.0: Velocity EQ.1: Acceleration EQ.2: Displacement
LCID	Load curve ID to describe motion as a function of time or frequency (see Remarks 1 and 2)
SF	Load curve scale factor

Remarks:

1. **SSD Analyses.** Fluid boundary velocities, accelerations, or displacements may be prescribed in SSD analyses (see *CONTROL_IMPLICIT_SSD_DIRECT). The abscissa of the load curve should then be in Hertz.

2. **Explicit Spectral Element Analyses.** Explicit simulations with *CONTROL_ACOUSTIC_SPECTRAL require the boundary motions be accelerations, VAD = 1. The abscissa of the load curve is in units of time.

*BOUNDARY_ACOUSTIC_PRESSURE_SPECTRAL

Purpose: Impose a varying pressure condition on the boundary of an acoustic volume.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	LCID	SF	TDEATH				
Type	I	I	F	F				
Default	none	none	1.0	10^{10}				

VARIABLE	DESCRIPTION
SSID	Segment set ID for the fluid boundary faces
LCID	Load curve ID to specify pressure as a function of time
SF	Load curve scale factor
TDEATH	Time when the pressure boundary condition should no longer be applied

*BOUNDARY_ALE_MAPPING

Purpose: This card maps ALE data histories from a previous run to a region of elements. Data are read or written in a mapping file called by the prompt "map=" on the command line (see Remarks 4 and 5). To map data at the initial time (not the histories) to all the ALE domain (not just a region of elements) see *INITIAL_ALE_MAPPING.

The following transitions are allowed:

1D → 2D	2D → 2D	3D → 3D
1D → 3D	2D → 3D	

Card Summary:

Card 1. This card is required.

ID	TYP	AMMSID	IVOLTYP	BIRTH	DEATH	DTOUT	INI

Card 2a. This card is included for |IVOLTYP| = 1.

THICK	RADIUS	X1	Y1	Z1			

Card 2b. This card is included for |IVOLTYP| = 2.

		X1	Y1	Z1	X2	Y2	Z2

Card 2c. This card is included for |IVOLTYP| = 3.

THICK	RADIUS	X1	Y1	Z1	X2	Y2	Z2

Card 2d. This blank card is included for |IVOLTYP| = 4.

Card 3. This card is required.

XO	YO	ZO	VECID				

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TYP	AMMSID	IVOLTYP	BIRTH	DEATH	DTOUT	INI
Type	I	I	I	I	F	F	F	I
Default	none	none	none	none	0.0	10^{20}	time step	0

VARIABLE	DESCRIPTION
ID	Part ID, part set ID, or element set ID
TYP	Type of "ID" (see Remark 1): EQ.0: Part set ID EQ.1: Part ID EQ.2: Shell set ID EQ.3: Solid set ID
AMMSID	Set ID of ALE multi-material groups defined in *SET_MULTI-MATERIAL_GROUP. See Remark 1.
IVOLTYP	Type of volume containing the selected elements for the mapping. The absolute value of IVOLTYPE indicates the type of volume and the sign indicates whether the data is being read of written. **Volume Type** |IVOLTYP|.EQ.1: Spherical surface with thickness (THICK) |IVOLTYP|.EQ.2: Box |IVOLTYP|.EQ.3: Cylindrical surface with thickness (THICK) |IVOLTYP|.EQ.4: All the elements defined by ID **Read/Write** IVOLTYP.LT.0: Data from the mapping file are read for the elements of this volume. IVOLTYP.GT.0: Data from the elements of this volume are written in the mapping file.

VARIABLE	DESCRIPTION
BIRTH	Birth time to write or read the mapping file. If a mapping file is written, the next run reading this file will begin at time BIRTH if this parameter for this next run is not larger.
DEATH	Death time to write or read the mapping file. If a mapping file is written, the next run will stop to read this file at time DEATH if this parameter for this next run is not smaller.
DTOUT	Time interval between outputs in the mapping file. This parameter is only used to write in the mapping file.
INI	Flag to initialize all the ALE domain of the next run: EQ.0: No initialization EQ.1: Initialization. *INITIAL_ALE_MAPPING will have to be in the input deck of the next run to read the data from the mapping file. The initial time of the next run will be BIRTH.

Spherical Surface with Thickness Card. This card is included for |IVOLTYP| = 1.

Card 2a	1	2	3	4	5	6	7	8
Variable	THICK	RADIUS	X1	Y1	Z1			
Type	F	F	F	F	F			
Default	0.0	0.0	0.0	0.0	0.0			

VARIABLE	DESCRIPTION
THICK	Thickness for the element selection using surfaces
RADIUS	Radius
X1	*x*-coordinate of the sphere center
Y1	*y*-coordinate of the sphere center
Z1	*z*-coordinate of the sphere center

Box Card. This card is included for |IVOLTYP| = 2.

Card 2b	1	2	3	4	5	6	7	8
Variable			X1	Y1	Z1	X2	Y2	Z2
Type			F	F	F	F	F	F
Default			0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
X1	*x*-coordinate of the box's minimum point
Y1	*y*-coordinate of the box's minimum point
Z1	*z*-coordinate of the box's minimum point
X2	*x*-coordinate of the box's maximum point
Y2	*y*-coordinate of the box's maximum point
Z2	*z*-coordinate of the box's maximum point

Cylindrical Surface with Thickness Card. This card is included for |IVOLTYP| = 3.

Card 2c	1	2	3	4	5	6	7	8
Variable	THICK	RADIUS	X1	Y1	Z1	X2	Y2	Z2
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
THICK	Thickness for the element selection using surfaces
RADIUS	Radius
X1	*x*-coordinate of a point on the cylinder's axis
Y1	*y*-coordinate of a point on the cylinder's axis

VARIABLE	DESCRIPTION
Z1	z-coordinate of a point on the cylinder's axis
X2	x-coordinate of a vector parallel to the cylinder's axis
Y2	y-coordinate of a vector parallel to the cylinder's axis
Z2	z-coordinate of a vector parallel to the cylinder's axis

All Elements in Set Card. This blank card is included for |IVOLTYP| = 4.

Card 2d	1	2	3	4	5	6	7	8
Variable								
Type								

Card 3	1	2	3	4	5	6	7	8
Variable	X0	Y0	Z0	VECID				
Type	F	F	F	I				
Default	0.0	0.0	0.0	none				

VARIABLE	DESCRIPTION
X0	Origin position in global x-direction. See Remark 2.
Y0	Origin position in global y-direction. See Remark 2.
Z0	Origin position in global z-direction. See Remark 2.
VECID	ID of the symmetric axis defined by *DEFINE_VECTOR. See Remark 3.

Remarks:

1. **Mapping of Multi-Material Groups.** The routines of this card need to know which mesh will be initialized with the mapping data and more specifically which multi-material groups. The first 2 parameters (ID and TYP) defines the

mesh and the third one (AMMSID) refer to the *SET_MULTI-MATERIAL_-GROUP_LIST card. This card will define a list of material groups in the current run. The rank in this list should match the rank of the multi-material groups from the previous run (as a reminder the ranks of multi-material groups are defined by *ALE_MULTI-MATERIAL_GROUP). For instance, if the previous model has 3 groups, the current one has 5 groups, and the following mapping is wanted:

The 1st group (previous) ⇒ the 3rd group (current),
The 2nd group (previous) ⇒ the 5th group (current) and,
The 3rd group (previous) ⇒ the 4th group (current).

Then, the *SET_MULTI-MATERIAL_GROUP_LIST card should be as follows:

```
*SET_MULTI-MATERIAL_GROUP_LIST
300
3,5,4
```

2. **Origin.** The data can be mapped to different parts of the mesh by defining the origin of the coordinate system (X0, Y0, Z0).

3. **Orientation Vector: VECID.** For a mapping file created by a previous axisymmetric model, the symmetric axis orientation in the current model is specified by VECID. For a mapping file created by a 3D or 1D spherical model, the vector VECID is read but ignored. The definitions of X0, Y0, Z0 and VECID change in the case of the following mappings:

   a) plane strain 2D (ELFORM = 13 in *SECTION_ALE2D) to plane strain 2D

   b) plane strain 2D to 3D

   While VECID still defines the *y*-axis in the 2D domain, the 3 first parameters in *DEFINE_VECTOR, additionally, define the location of the origin. The 3 last parameters define a position along the y-axis. For this case when 2D data is used in a 3D calculation the point X0, Y0, Z0 together with the vector, VECID, define the plane.

4. **Mapping File.** To make one mapping: only the command-line argument "map=" is necessary. If IVOLTYP is positive, the mapping file will be created, and ALE data histories will be written in this file. If IVOLTYP is negative the mapping file will be read, and ALE data histories will be used to interpolate the ALE variables of the selected elements. This file contains the following nodal and element data:

   - nodal coordinates
   - nodal velocities
   - part ids

- element connectivities
- element centers
- densities
- volume fractions
- stresses
- plastic strains
- internal energies
- bulk viscosities
- relative volumes

5. **Successive Mappings.** To make several successive mappings: the prompt "map1=" is necessary. If IVOLTYP is positive and the prompt "map1=" is in the command line, the ALE data are written to the mapping file given by "map1=". If IVOLTYP is negative and the prompt "map=" is in the command line, ALE data are read from the mapping file given by "map=".

6. **Comparison to *ALE_MAPPING.** Both *ALE_MAPPING and *BOUNDARY_-ALE_MAPPING, can write multiple sets of data to a file at a given frequency between certain times. The big difference between these two keywords is reading the data. With *ALE_MAPPING, you select only one set of data to map from the previous run to the current run which is mapped at a time you select. With *BOUNDARY_ALE_MAPPING, all data output between t = BIRTH and t = DEATH from the previous run is mapped to the elements in the current run. The discrete histories from the previous run are interpolated.

*BOUNDARY_AMBIENT

Purpose: This command defines ALE "ambient" type element formulations (see Remarks 1, 2, and 5).

Card 1	1	2	3	4	5	6	7	8
Variable	SETID	MMG	AMBTYP	SIDR				
Type	I	I/A	I	I				
Default	none	none	none	0				

Optional Card. Additional optional card for AMBTYP = 4 with curves.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID1	LCID2						
Type	I	I						
Default	Rem 1	Rem 1						

VARIABLE	DESCRIPTION
SETID	The ambient element set ID for which the thermodynamic state is being defined. The element set can be *SET_SOLID for a 3D ALE model, *SET_SHELL for a 2D ALE model, or *SET_BEAM for a 1D ALE model.
MMG	ALE multi-material group ID. In the case of S-ALE, the AMMG name (AMMGNM) can be used in place of the AMMGID. See Remark 6.
AMBTYP	Ambient element type: EQ.4: Pressure inflow/outflow (see Remarks 1 and 2) EQ.5: Receptor for blast load (See *LOAD_BLAST_ENHANCED)

VARIABLE	DESCRIPTION
SIDR	Flag controlling the use of this keyword during dynamic relaxation: EQ.0: LS-DYNA applies this keyword only during the normal analysis phase. EQ.1: LS-DYNA applies this keyword during the dynamic relaxation phase but not the normal analysis phase. EQ.2: LS-DYNA applies this keyword during the dynamic relaxation and the normal analysis phases.
LCID1	A load curve ID for internal energy per unit reference volume (see Remark 4 and the *EOS section for details). If using *EOS_IDEAL_GAS, this ID refers to a temperature load curve ID.
LCID2	Load curve ID for relative volume, $v_r = (v/v_0 = \rho_0/\rho)$. See Remark 3 and the *EOS section for details.

Remarks:

1. **Ambient Elements.** The term "ambient" refers to a medium with a predetermined thermodynamic state throughout the simulation. LS-DYNA resets the thermodynamic state of all "ambient" elements to this predetermined state every cycle. If using a *EOS card to determine this state, this predetermined thermodynamic state is constant throughout the simulation. For AMTYP = 4, if specifying the state with the load curves of Card 2, the thermodynamic state varies according to these defined load curves. The first and last abscissa values in these curves are this keyword's birth and death times. The literature sometimes refers to "ambient" elements as "reservoir" elements as they may be used to simulate a semi-infinite region.

2. **Thermodynamic State.** In general, two thermodynamic variables define a thermodynamic state of a non-reacting and no-phase-change material. By defining (a) an internal energy per unit reference volume load curve (or a temperature load curve if using *EOS_IDEAL_GAS) and (b) a relative volume load curve, LS-DYNA can computer the pressure as a function of time for this ambient part ID using the equation of state (*EOS_…).

3. **Reference Specific Volume.** A reference specific volume, $v_0 = 1/\rho_0$, is the inverse of a reference density, ρ_0. The reference density is the density at which the material is under a reference or nominal state. Refer to the *EOS section for a more complete explanation.

4. **Internal Energy.** The internal energy per unit reference volume may be defined as

$$e_{\text{ipv0}} = \frac{C_v T}{v_0} \ .$$

The specific internal energy (or internal energy per unit mass) is defined as $C_v T$.

5. **Related Cards.** This card does not require AET to be defined under *SECTION_SOLID or SECTION_ALE2D or SECTION_ALE1D card.

6. **AMMG NAME for S-ALE.** For the general ALE solver, you define each AMMG with *ALE_MULTI-MATERIAL_GROUP. In this case, you can only refer to each AMMG with their AMMGID. The order of appearance of the AMMGs in the input deck dictates the AMMGID for each AMMG. For the S-ALE solver, you can define the AMMG using *ALE_STRUCTURED_MULTI-MATERIAL_GROUP instead of *ALE_MULTI-MATERIAL_GROUP. With *ALE_STRUCTURED_MULTI-MATERIAL_GROUP, you give each AMMG a name with the field AMMGNM. You can then refer to each AMMG defined with that keyword with either its name or its AMMGID (which is again based on order of appearance). We recommend using the name as it leads to fewer errors. For instance, if you add or delete AMMGs, the AMMGIDs may change. Then, you must find all those references and alter them accordingly. With the name, you do not need to modify the input deck for unchanged AMMGs.

*BOUNDARY_AMBIENT_EOS

Purpose: This command defines the IDs of 2 load curves: (1) internal energy per unit reference volume (or temperature if using *EOS_IDEAL_GAS) and (2) relative volume. These 2 curves completely prescribe the thermodynamic state as a function of time for any ALE or Eulerian part with an "ambient" type element formulation (please see Remark 5). For a more specific form of this keyword that allows specification of ambient boundary conditions by element set, see *BOUNDARY_AMBIENT.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	LCID1	LCID2					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
PID	The ambient part ID for which the thermodynamic state is being defined
LCID1	Load curve ID (see *DEFINE_CURVE or *DEFINE_CURVE_FUNCTION) for internal energy per unit reference volume (please read the beginning of the EOS section for details). If *EOS_IDEAL_GAS is being used, then this ID refers to a temperature load curve ID.
LCID2	Load curve ID (see *DEFINE_CURVE or *DEFINE_CURVE_FUNCTION) for relative volume, $$v_r = \left(\frac{v}{v_0} = \frac{\rho_0}{\rho}\right) .$$ (Please read the beginning of the EOS section for details.)

Remarks:

1. **Ambient Parts.** The term "ambient" refers to a medium that has predetermined thermodynamic state throughout the simulation. All "ambient" parts/elements will have their thermodynamic state reset back to this predetermined state every cycle. If this state is defined via the *EOS card, then this predetermined thermodynamic state is constant throughout the simulation. If it is defined via this card, *BOUNDARY_AMBIENT_EOS, then its thermodynamic state will vary

according to these defined load curves. "Ambient" part is sometimes also referred to as "reservoir" part as it may be used to simulate semi-infinite region.

2. **Thermodynamic Variables.** In general, a thermodynamic state of a non-reacting and no-phase-change material may be defined by 2 thermodynamic variables. By defining (a) an internal energy per unit reference volume load curve (or a temperature load curve if using *EOS_IDEAL_GAS) and (b) a relative volume load curve, the pressure as a function of time for this ambient part ID can be computed directly via the equation of state (*EOS_…).

3. **Reference Specific Volume.** A reference specific volume, $v_0 = 1/\rho_0$, is the inverse of a reference density, ρ_0. The reference density is defined as the density at which the material is under a reference or nominal state. Please refer to the *EOS section for additional explanation on this.

4. **Internal Energy.** The internal energy per unit reference volume may be defined as

$$e_{\text{ipv0}} = \frac{C_v T}{v_0}.$$

The specific internal energy (or internal energy per unit mass) is defined as $C_v T$.

5. **"Ambient" Elements.** This card is only to be used with an "ambient" element type as defined by the parameters under the *SECTION_SOLID card:

   a) ELFORM = 7,

   b) ELFORM = 11 and AET = 4, or

   c) ELFORM = 12 and AET = 4.

Example:

Consider an ambient ALE part ID 1 which has its internal energy per unit reference volume in a load curve ID 2 and relative volume load curve ID 3:

```
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|...8
*BOUNDARY_AMBIENT_EOS
$      PID  e/T_LCID rvol_LCID
         1         2         3
$...|....1....|....2....|....3....|....4....|....5....|....6....|....7....|...8
```

***BOUNDARY_CONVECTION**_*OPTION*

Available options include:

SEGMENT

SET

Purpose: Apply a convection boundary condition on a SEGMENT or SEGMENT_SET for a thermal analysis. Two cards are defined for each option.

Card 1 for SET keyword option.

Card 1a	1	2	3	4	5	6	7	8
Variable	SSID	PSEROD						
Type	I	I						
Default	none	none						

Card 1 for SEGMENT keyword option.

Card 1b	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4				
Type	I	I	I	I				
Default	none	none	none	none				

Card 2	1	2	3	4	5	6	7	8
Variable	HLCID	HMULT	TLCID	TMULT	LOC			
Type	I	F	I	F	I			
Default	none	0.	none	0.	0			

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT.
PSEROD	Part set ID for updating boundary segments exposed to the environment as solid elements erode; see Remark 4.
N1, N2, ….	Node ID's defining segment.
HLCID	Convection heat transfer coefficient, h. This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 2). When the reference is to a curve, HLCID has the following interpretation: GT.0: h is given as a function of time, t. The curve consists of $(t, h(t))$ data pairs. EQ.0: h is a constant defined by the value HMULT. LT.0: h is given as a function of temperature, T_{film}. The curve consists of (T_{film}, h) data pairs. |HLCID| references the *DEFINE_CURVE load curve ID. See Remark 1.
HMULT	Convection heat transfer coefficient, h, curve multiplier.
TLCID	Environment temperature, T_∞. This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 3). When the reference is to a curve, TLCID has the following interpretation: GT.0: T_∞ is defined by a curve indexed by time consisting of $(t, T_\infty(t))$ data pairs. EQ.0: T_∞ is a constant defined by the value TMULT.
TMULT	Environment temperature, T_∞, curve multiplier.
LOC	For a thick thermal shell, the convection will be applied to the surface identified by LOC. See parameter, THSHEL, on the *CONTROL_SHELL keyword. EQ.-1: lower surface of thermal shell element EQ.0: middle surface of thermal shell element EQ.1: upper surface of thermal shell element

Remarks:

1. **Film Temperature.** A convection boundary condition is calculated using $\dot{q}'' = h(T_{\text{surface}} - T_\infty)$ where h is the heat transfer coefficient, and $T_{\text{surface}} - T_\infty$ is a temperature potential. If h is a function of temperature, h is evaluated at the average or "film" temperature defined by

$$T_{film} = \frac{(T_{\text{surface}} + T_\infty)}{2}.$$

2. **Function Arguments for HLCID.** If HLCID references a *DEFINE_FUNCTION, the convective heat transfer coefficient can be a function of the segment centroid coordinates, the segment centroid velocity components, the segment centroid temperature, the environment temperature (T_∞), and the solution time, that is, "f(x, y, z, vx, vy, vz, temp, tinf, time)."

3. **Function Arguments for Environment Temperature.** If TLCID references a DEFINE_FUNCTION, the environment temperature can be a function of the segment centroid coordinates, the segment centroid velocity components, and the solution time, that is, "f(x, y, z, vx, vy, vz, time)."

4. **Erosion.** When convection is applied to a segment set associated with solid elements that erode, the convection condition on a deleted segment will not by default be transferred to newly exposed segments. It will instead cease to exist. By specifying a part set through the parameter PSEROD, any such new segment, *that is attached to an element in this part set*, will inherit this boundary condition, using the same data as prescribed for all original segments.

*BOUNDARY_COUPLED

Purpose: Define a boundary that is coupled with an external program. Two cards are required for each coupled boundary.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	TITLE						
Type	I	A70						

Card 2	1	2	3	4	5	6	7	8
Variable	SET	TYPE	PROG					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
ID	ID for this coupled boundary
TITLE	Descriptive name for this boundary
SET	Node set ID
TYPE	Coupling type: EQ.1: node set with force feedback EQ.2: node set for multiscale spotwelds
PROG	Program to couple to EQ.1: MPP-DYNA

Remarks:

This option is only available in the MPP version and allows for loose coupling with other MPI programs using a "multiple program" execution method. Currently it is only useful when linking with MPP-DYNA for the modeling of multiscale spotwelds (TYPE = 2,

PROG = 1). See *INCLUDE_MULTISCALE_SPOTWELD for information about using this capability.

*BOUNDARY_CYCLIC_{OPTION}

The *OPTION* allows an optional ID to be given that applies to each cyclic definition

ID

Purpose: Define nodes in boundary planes for cyclic symmetry.

These boundary conditions can be used to model a segment of an object that has rotational symmetry such as an impeller (see Figure 5-1). The segment boundary, denoted as a side 1 and side 2, may be curved or planar. In this section, a paired list of points is defined on the sides that are to be joined.

ID Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	XC	YC	ZC	NSID1	NSID2	IGLOBAL	ISORT	
Type	F	F	F	I	I	I	I	
Default	none	none	none	none	none	0	0	

VARIABLE	DESCRIPTION
ID	ID for boundary definition
HEADING	Description of cyclic boundary
XC	*x*-component axis vector of axis of rotation
YC	*y*-component axis vector of axis of rotation
ZC	*z*-component axis vector of axis of rotation
NSID1	Node set ID for first boundary (side 1, see Figure 5-1).

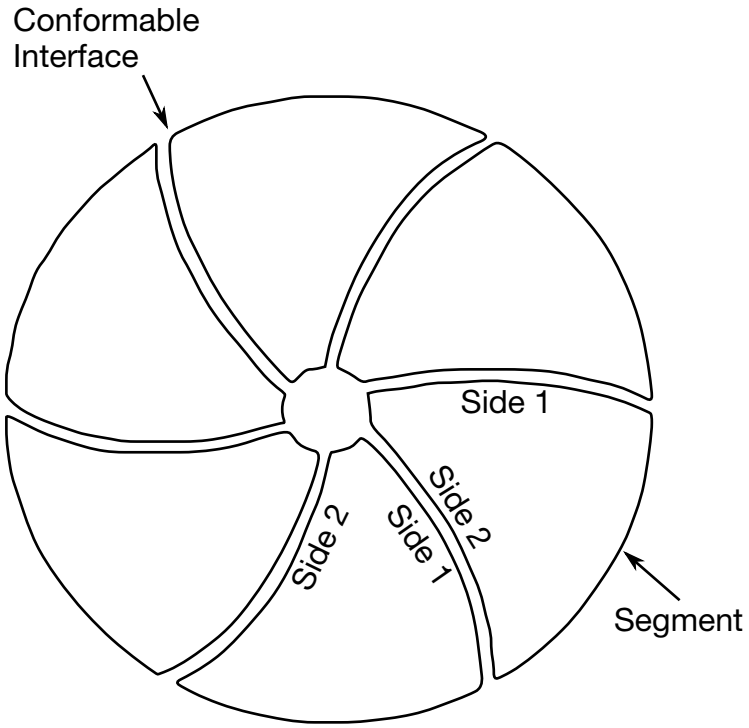

Figure 5-1. With axisymmetric cyclic symmetry, only one segment is modeled.

VARIABLE	DESCRIPTION
NSID2	Node set ID for second boundary (side 2, see Figure 5-1). Each node in this set is constrained to its corresponding node in the first node set. Node sets NSID1 and NSID2 must contain the same number of nodal points. The shape of the two surfaces formed by the two node sets need not be planar, but the shapes should match.
IGLOBAL	Flag for repeating symmetry: EQ.0: Axisymmetric cyclic symmetry (default) EQ.1: Repeating symmetry in planes normal to global X EQ.2: Repeating symmetry in planes normal to global Y EQ.3: Repeating symmetry in planes normal to global Z
ISORT	Set to 1 for automatic sorting of nodes in node sets. See Remark 2.

Remarks:

1. **Node Sets.** Each node set should generally be boundaries of the model.

2. **Node Sorting.** Prior to version 970, it was assumed that the nodes are correctly ordered within each set, that is, the n^{th} node in NSID1 is equivalent to the n^{th}

node in NSID2. In version 970 and later versions, if the ISORT flag is active, the nodes in NSID2 are automatically sorted to achieve equivalence, so the nodes can be picked by the quickest available method. However, for axisymmetric cyclic symmetry (IGLOBAL = 0), it is assumed that the axis passes through the origin, i.e., only globally defined axes of rotation are possible.

*BOUNDARY_DE_NON_REFLECTING

Purpose: Define a non-reflecting boundary for discrete element.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	CX	CY	CZ				
Type	I	F	F	F				
Default	none	1.0	1.0	1.0				
Remarks	1							

VARIABLE	DESCRIPTION
NSID	Node set ID.
CX	Decimal fraction of critical damping for translations in the x direction
CY	Decimal fraction of critical damping for translations in the y direction
CZ	Decimal fraction of critical damping for translations in the z direction

Remarks:

1. **Boundary Model.** Non-reflecting boundaries are used on the exterior boundaries of an analysis model of an infinite domain, such as a half-space to prevent artificial stress wave reflections generated at the model boundaries from re-entering the model and contaminating the results.

BOUNDARY_FLUX_*OPTION

Available options include:

SEGMENT

SET

Purpose: Apply a flux boundary condition (power/area) on a SEGMENT or SEGMENT_-SET for a thermal analysis. History variables can be associated with the boundary condition which will invoke a call to a user defined boundary flux subroutine for computing the flux.

Card Summary:

Card 1a. This card is included if and only if the SET option is used.

SSID	PSEROD						

Card 1b. This card is included if and only if the SEGMENT option is used.

N1	N2	N3	N4				

Card 2. This card is required.

LCID	MLC1	MLC2	MLC3	MLC4	LOC	NHISV	

Card 3. Include as many of this card as needed to define NHISV history variables.

HISV1	HISV2	HISV3	HISV4	HISV5	HISV6	HISV7	HISV8

Data Cards:

Card 1 for SET option.

Card 1a	1	2	3	4	5	6	7	8
Variable	SSID	PSEROD						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT
PSEROD	Part set ID for updating boundary segments exposed to the environment as solid elements erode; see Remark 5.

Card 1 for SEGMENT option.

Card 1b	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
N1, N2, …	Node IDs that define the segment

Card 2	1	2	3	4	5	6	7	8
Variable	LCID	MLC1	MLC2	MLC3	MLC4	LOC	NHISV	
Type	I	F	F	F	F	I	I	
Default	none	0.	0.	0.	0.	0	0	

VARIABLE	DESCRIPTION
LCID	This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 2) for heat flux. When the reference is to a curve, LCID has the following interpretation: GT.0: the flux is defined by a curve consisting of (time, flux) data pairs using the *DEFINE_CURVE keyword. The flux value applied to the nodal points is the curve value multiplied by the values MLC1, MLC2, MLC3, and MLC4, respectively.

VARIABLE	DESCRIPTION
	EQ.0: a constant flux is applied to each node defined by the values MLC1, MLC2, MLC3, and MLC4, respectively. LT.0: the flux is defined by a curve consisting of (temperature, flux) data pairs using the *DEFINE_CURVE keyword. The flux value applied to the nodal points is the curve value multiplied by the values MLC1, MLC2, MLC3, and MLC4. Enter |−LCID| on the *DEFINE_CURVE keyword.
MLC1	Curve multiplier at node N1.
MLC2	Curve multiplier at node N2.
MLC3	Curve multiplier at node N3.
MLC4	Curve multiplier at node N4.
LOC	For a thick thermal shell, the flux will be applied to the surface identified by LOC. See parameter, THSHEL, on the *CONTROL_SHELL keyword. EQ.-1: lower surface of thermal shell element EQ.0: middle surface of thermal shell element EQ.1: upper surface of thermal shell element
NHISV	Number of history variables associated with the flux definition: GT.0: A user defined subroutine will be called to compute the flux. See Remark 3.

Define as many cards as necessary to initialize NHISV history variables.

Card 3	1	2	3	4	5	6	7	8
Variable	HISV1	HISV2	HISV3	HISV4	HISV5	HISV6	HISV7	HISV8
Type	F	F	F	F	F	F	F	F
Default	0.	0.	0.	0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
HISV1	Initial value of history variable 1
HISV2	Initial value of history variable 2
⋮	⋮
HISV*n*	Initial value of history variable *n*, where *n* = NHISV

Remarks:

1. **Flux Direction.** The segment normal has no bearing on the flux. A negative flux transfers energy into the volume; a positive flux transfers energy out of the volume.

2. **Flux Definition with *DEFINE_FUNCTION.** If LCID references a *DEFINE_-FUNCTION, the heat flux can be a function of the segment centroid coordinates, the segment velocity components, the segment centroid temperature, the environment temperature, and the solution time, that is "f(x, y, z, vx, vy, vz, temp, tinf, time)."

3. **Flux Definition with User Subroutines.** When NHISV>0, the user subroutine

```
subroutine usrflux(fl, flp, ...)
```

   will be called to compute the heat flux (fl). For more details see Appendix S.

4. **SPH Elements.** This keyword is supported for SPH elements to define the flux boundary conditions for a thermal or coupled thermal/structural analysis. The values n_1, n_2, n_3, n_4 from the SPH particles or segments are used to define the flux segments.

5. **Erosion.** When flux is applied to a segment set associated with solid elements that erode, the flux condition on a deleted segment will not by default be transferred to newly exposed segments. It will instead cease to exist. By specifying a part set through the parameter PSEROD, any such new segment, *that is attached to an element in this part set*, will inherit this boundary condition, using the same data as prescribed for all original segments.

*BOUNDARY_FLUX_TRAJECTORY

Purpose: Define a moving surface heat source to model for example laser heated surfaces of solid or shell structures. Motion of the source is described by a nodal path and a prescribed velocity on this path. This keyword is applicable in coupled thermal-structural and thermal-only simulations.

Card Summary:

Card 1. This card is required.

SSID	PSEROD	NSID1	SPD1	NSID2	SPD2	RELVEL	

Card 2. This card is required.

EROD	LOC	LCROT	LCLAT				

Card 3. This card is required.

IFORM	LCTIM	Q	LCINC	ENFOR			

Card 4. This card is required.

P1	P2	P3	P4	P5	P6	P7	P8

Card 5. This card is included if and only if NSID2 = 0.

TX	TY	TZ					

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	PSEROD	NSID1	SPD1	NSID2	SPD2	RELVEL	
Type	I	I	I	F	I	F	I	
Default	none	none	none	0.	none	0.	0	

VARIABLE	DESCRIPTION
SSID	Segment set ID containing segments that are potentially heated by surface heat source (flux).

VARIABLE	DESCRIPTION
PSEROD	Part set ID for updating boundary segments exposed to the environment as solid elements erode; see Remark 5.
NSID1	Node set defining the path of the weld source. The source travels along the path at speed SPD1. The nodes are traversed according to their ordering in the node set. See Remark 1.
SPD1	Speed of the heat source on the weld trajectory GT.0.0: constant speed LT.0.0: |SPD1| is a load curve ID defining weld speed as a function of time.
NSID2	Node or segment set containing information for the weld source aiming direction: GT.0: NSID2 together with SPD2 define a curve in the same way that NSID1 and SPD1 define a curve. Aiming direction is taken to be the vector pointing from the current position along NSID2 (for example your hand holding the torch) to the current position on NSID1 (the weld source). EQ.0: beam aiming direction is (TX, TY, TZ) input on Card 5.
SPD2	Speed of reference point in NSID2 (ignored unless NSID2 > 0) GT.0: constant speed LT.0: |SPD2| is a load curve ID defining weld speed as a function of time.
RELVEL	Defines if SPD1 and SPD2 are relative or absolute speeds in coupled simulations EQ.0: absolute speeds EQ.1: relative speeds with respect to underlying structure

Card 2	1	2	3	4	5	6	7	8
Variable	EROD	LOC	LCROT	LCLAT				
Type	I	I	I	I				
Default	0	none	none	none				

VARIABLE	DESCRIPTION
EROD	Flag for updating boundary segments exposed to the environment as solid elements (defined in PSEROD) erode; see Remark 5. EQ.0: no propagation onto new segments EQ.1: propagation onto new segments
LOC	For a thick thermal shell, the flux will be applied to the surface identified by LOC. See field THSHEL on the *CONTROL_SHELL keyword. EQ.-1: lower surface of thermal shell element EQ.0: middle surface of thermal shell element EQ.1: upper surface of thermal shell element
LCROT	Load curve defining the rotation (angle in degrees) of weld source around the trajectory as function of time. See Remark 2.
LCLAT	Load curve for lateral offset of weld source as function of time. See Remark 2.

Card 3	1	2	3	4	5	6	7	8
Variable	IFORM	LCTIM	Q	LCINC	ENFOR			
Type	I	I	F	I	I			
Default	none	none	0.	none	0			

VARIABLE	DESCRIPTION
IFORM	Geometry description for energy rate density distribution (see Remark 3): EQ.1: double elliptic with constant density EQ.2: double elliptic with Gaussian distribution EQ.3: user defined distribution
LCTIM	Load curve ID for flux energy input rate multiplier $q_1(t)$ as a function of time, see Remark 4. EQ.0: use constant multiplier value $q_1(t) = 1.0$.
Q	Base energy input rate Q_b [energy/time], serves as base multiplier for the energy rate distributions defined by IFORM. See Remark 4 for details.
LCINC	Load curve ID for flux energy input rate multiplier $q_2(\alpha)$ as a function of inclination angle α (in degree), see Remark 4. EQ.0: use constant multiplier value $q_2(\alpha) = 1.0$.
ENFOR	Flag for heat input enforcement option (see Remark 4) EQ.0: no additional scaling of heat source EQ.1: account for inclination angle, α, of heat source by energy input rate multiplier $q_3(\alpha) = \cos(\alpha)$ EQ.2: scale the nodal fluxes by a multiplier $q_4(t)$ such that the resulting heat input equals the user input $Q(t) = Q_b \times q_1(t)$ EQ.3: apply option 1 and 2

Card 4	1	2	3	4	5	6	7	8
Variable	P1	P2	P3	P4	P5	P6	P7	P8
Type	F	F	F	F	F	F	F	F
Default	0.	0.	0.	0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
P*i*	Parameters defining flux geometry, depending on field IFORM. See Remark 3 for details.

Optional Weld Source Aiming Direction Card. Additional card for NSID2 = 0.

Card 5	1	2	3	4	5	6	7	8
Variable	TX	TY	TZ					
Type	F	F	F					
Default	0.	0.	0.					

VARIABLE	DESCRIPTION
TX, TY, TZ	Weld beam direction vector in global coordinates (NSID2 = 0 only)

Remarks:

1. **Heat Source Motion.** This card can be applied to coupled thermal-structure and thermal-only simulations. The source motion can be defined independently form the motion of nodes. This keyword applies to both solid and thermal thick shells.

   If NSID1 consists of work piece nodes, then the heat source will follow the motion of the work piece. By setting field RELVEL to 1 the velocity of the heat source can be defined relative to the motion of the nodes in NSID1 (the work piece).

2. **Heat Source Direction (Tilting the Torch).** There is a natural local coordinate system ($\mathbf{r}, \mathbf{s}, \mathbf{t}$) associated with the motion of the heat source. The relative velocity vector on the trajectory of the heat source defines the "forward" direction $\mathbf{r}$, so that material points that are approaching the heat source are in "front" of the beam. The weld source aiming direction, denoted by $\mathbf{t}$, determines the direction of the weld pool depth. The coordinate direction $\mathbf{s}$ is normal to the plane containing both the relative velocity and the aiming direction; note that $\mathbf{s} = \mathbf{t} \times \mathbf{r}$ to have a right handed coordinate system. It determines the direction of the weld pool width.

   The position and aiming direction of the heat source (for example tilting the torch) can be adjusted by rotating and translating the local coordinate system.

To do this, the system is first rotated around the vector **r** by a value given by the load curve LCROT, resulting in a new local coordinate system $(\mathbf{r}, \mathbf{s}', \mathbf{t}')$. Then, the system is translated in direction $\mathbf{s}'$ using LCLAT, respectively.

3. **Energy Rate Surface Distributions.** Several different heat source geometries, described below, can be defined with this keyword. The local coordinate system needed for the description of the geometry is discussed in Remark 2.

For IFORM = 1 heat is generated in an elliptical region centered at the heat source with a constant energy rate surface density. The half-width a of the ellipse in the $\mathbf{s}'$-direction is given by input parameter P1. The half-widths of the ellipse in **r**-direction are different in front and behind the beam. The half-width in front of the beam is denoted by b_f (input parameter P2) and behind the beam is referred to as b_r (input parameter P3). Consequently, the flux value at a point p in the ellipse is given as

$$q = \frac{F}{\pi a b},$$

where:

$$F = \begin{cases} F_f \text{ if point } p \text{ is in front of beam} \\ F_r \text{ if point } p \text{ is behind beam} \end{cases}$$
$$b = \begin{cases} b_f \text{ if point } p \text{ is in front of beam} \\ b_r \text{ if point } p \text{ is behind beam} \end{cases}$$

It is expected that the sum of the weighting factors, F_f and F_r (defined as input parameters P4 and P5), equals 2.

The normalized surface density q for IFORM = 2 is assumed to be controlled by an exponential decay from the center of the ellipse to the boundary. The geometry of the source and its input correspond to IFORM = 1, but the energy rate surface density is here given as

$$q = \frac{nF}{\pi a b} \exp\left(\frac{-nx^2}{a^2}\right) \exp\left(\frac{-ny^2}{b^2}\right)$$

with the same assumptions for F and b as above and with (x, y) being the first two coordinates of point p with respect to the new local coordinate system $(\mathbf{r}, \mathbf{s}', \mathbf{t}')$. The additional parameter n is defined by input parameter P6.

In contrast to the above, IFORM = 3 refers to a user defined function that determines the surface density q as function of the local coordinates (x, y), the current time t, and the temperature T. Consequently, the definition of an arbitrarily shape equivalent heat source may read as follows:

```
*DEFINE_FUNCTION
1, surface density distribution
q(r,s,time,temp)= …
```

To speed-up the computation, the function is evaluated for nodes within a distance less than a from the current center position. Consequently, the function ID and this distance are the only parameters needed in the input for Card 4.

Note that in all of the above cases, the normalized surface density q is multiplied by the energy rate $Q(t, \alpha)$, which is discussed in Remark 4.

IFORM	1	2	3
P1	a	a	FID
P2	b_f	b_f	a
P3	b_r	b_r	
P4	F_f	F_f	
P5	F_r	F_r	
P6		n	
P7			
P8			

4. **Energy Rate Input and Enforcement.** Naturally the calculation of the surface fluxes as discussed in Remark 3 requires the definition of a base energy input rate Q. It can be defined as a function of time, t, and inclination angle, α:

$$Q(t, \alpha) = Q_b \times q_1(t) \times q_2(\alpha) \times q_3(\alpha) \times q_4(t)$$

The multipliers $q_1(t)$ and $q_2(\alpha)$ are given as user-defined load curves. The multiplier $q_3(\alpha)$, if activated by a corresponding choice of ENFOR, account for the fact that a tilted heat source affects a larger area of the surface and is set to $q_3(\alpha) = \cos(\alpha)$. The value of α ranges from 0° (the segment normal and heat source point in the same direction) to 180° (the segment normal and heat source point in opposite directions). Naturally, the values of $q_2(\alpha)$ and $q_3(\alpha)$ vary among the individual segments.

For some applications it is required that the total heat flux from the boundary condition always agrees with the user input, meaning $Q_b \times q_1(t)$. The integration of the surface fluxes does not always meet this requirement, particularly for coarse meshes and highly curved structures. For that purpose, option ENFOR = 2 or 3 are implemented, which modify the nodal fluxes by a scaling factor $q_4(t)$. Note that this factor is not a user input but internally calculated and the same for all nodes with the particular flux boundary condition.

5. **Erosion.** When flux is applied to a segment set associated with solid elements that erode, the flux condition on a deleted segment will not by default be

transferred to newly exposed segments. It will instead cease to exist. By specifying a part set through the parameter PSEROD and activating the feature with EROD, any such new segment, *which is attached to an element in this part set*, will inherit this boundary condition, using the same data as prescribed for all original segments.

*BOUNDARY_MCOL

Purpose: Define parameters for MCOL coupling. The MCOL Program is a rigid body mechanics program for modeling the dynamics of ships. See Remark 1 for more information.

Card 1	1	2	3	4	5	6	7	8
Variable	NMCOL	MXSTEP	ETMCOL	TSUBC	PRTMCOL			
Type	I	I	F	F	F			
Default	2	none	0.0	0.0	none			
Remarks			2					

Ship Card. Include NMCOL cards, one for each ship.

Card 2	1	2	3	4	5	6	7	8
Variable	RBMCOL	MCOLFILE						
Type	I	A60						
Default		none						

VARIABLE	DESCRIPTION
NMCOL	Number of ships in MCOL coupling.
MXSTEP	Maximum number of time steps allowed in MCOL calculation. If the number of MCOL time steps exceeds MXSTEP, then LS-DYNA will terminate.
ETMCOL	Uncoupling termination time; see Remark 2 below. EQ.0.0: set to LS-DYNA termination time
TSUBC	Time interval for MCOL subcycling. EQ.0.0: no subcycling

VARIABLE	DESCRIPTION
PRTMCOL	Time interval for output of MCOL rigid body data.
RBMCOL	LS-DYNA rigid body material assignment for the ship.
MCOLFILE	Filename containing MCOL input parameters for the ship.

Remarks:

1. **MCOL Coupling.** The basis for MCOL is a convolution integral approach for simulating the equations of motion. A mass and inertia tensor are required as input for each ship. The masses are then augmented to include the effects of the mass of the surrounding water. A separate program determines the various terms of the damping/buoyancy force formulas which are also input to MCOL. The coupling is accomplished in a simple manner: at each time step LS-DYNA computes the resultant forces and moments on the MCOL rigid bodies and passes them to MCOL. MCOL then updates the positions of the ships and returns the new rigid body locations to LS-DYNA. A more detailed theoretical and practical description of MCOL can be found in a separate report (to appear).

2. **ETMCOL.** After the end of the LS-DYNA/MCOL calculation, the analysis can be continued using MCOL alone. ETMCOL is the termination time for this analysis. If ETMCOL is smaller than the LS-DYNA termination time, the uncoupled analysis will not be activated.

3. **Output Files.** The MCOL output is written to the files mcolout (ship position) and mcolenergy (energy breakdown). In LS-PrePost, mcolout can be plotted through the rigid body time history option and MCOLENERGY.

*BOUNDARY_NON_REFLECTING

Purpose: Define a non-reflecting boundary. This option applies to continuum domains modeled with solid or thick shell elements. For geomechanical problems this option is important for limiting the spatial extent of the finite element mesh and thus the number of solid elements.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	AD	AS					
Type	I	F	F					
Default	none	0.0	0.0					
Remarks	1, 2	3	3					

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT.
AD	Default activation flag for dilatational waves. EQ.0.0: on NE.0.0: off
AS	Default activation flag for shear waves. EQ.0.0: on NE.0.0: off

Remarks:

1. **Restrictions.** Non-reflecting boundaries defined with this keyword are only used with three-dimensional solid elements. Boundaries are defined as a collection of segments, and segments are equivalent to element faces on the boundary. Segments are defined by listing the corner nodes in either a clockwise or counterclockwise order.

2. **Model Description.** Non-reflecting boundaries are used on the exterior boundaries of an analysis model of an infinite domain, such as a half-space to prevent artificial stress wave reflections generated at the model boundaries from

reentering the model and contaminating the results. Internally, LS-DYNA computes an impedance matching function for all non-reflecting boundary segments based on an assumption of linear material behavior. Thus, the finite element mesh should be constructed so that all significant nonlinear behavior is contained within the discrete analysis model.

3. **Reflecting Waves.** With the two optional flags, the influence of reflecting waves can be studied.

4. **Dynamic Relaxation.** During the dynamic relaxation phase (optional), nodes on non-reflecting segments are constrained in the normal direction. Nodal forces associated with these constraints are then applied as external loads and held constant in the transient phase while the constraints are replaced with the impedance matching functions. In this manner, soil can be quasi-statically prestressed during the dynamic relaxation phase and dynamic loads (with non-reflecting boundaries) subsequently applied in the transient phase.

5. **Time Step Size.** In explicit analyses, TSSFAC in *CONTROL_TIMESTEP is set to 0.667 by default if not specified, in order to obtain a stable solution. This is typically necessary if three non-reflecting boundary planes meet at a corner. A larger value may be specified to obtain a shorter simulation time if it does not affect stability.

*BOUNDARY_NON_REFLECTING_2D

Purpose: Define a non-reflecting boundary. This option applies to continuum domains modeled with two-dimensional solid elements in the *xy* plane. For geomechanical problems, this option is important for limiting the size of the models. For ALE 2D models, including this keyword without data cards (Card 1) causes the non-reflecting boundary condition to be applied to all the boundary edges of the 2D ALE mesh.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	AD	AS					
Type	I	I	I					
Default	none	0	0					
Remarks	1, 2							

VARIABLE	DESCRIPTION
NSID	Node set ID; see *SET_NODE. See Figure 5-2. LT.0: |NSID| is the ID of *SET_SEGMENT.
AD	Default activation flag for dilatational waves: EQ.0.0: on NE.0.0: off
AS	Default activation flag for shear waves: EQ.0.0: on NE.0.0: off

Remarks:

1. **Boundary Definition.** Non-reflecting boundaries defined with this keyword are only used with two-dimensional solid elements in either plane strain or axisymmetric geometries. Boundaries are defined as a sequential string of nodes moving *counterclockwise* around the boundary.

2. **Model Assumptions.** Non-reflecting boundaries are used on the exterior boundaries of an analysis model of an infinite domain, such as a half-space to prevent artificial stress wave reflections generated at the model boundaries from re-entering the model and contaminating the results. Internally, LS-DYNA computes an impedance matching function for all non-reflecting boundary segments based on an assumption of linear material behavior. Thus, the finite element mesh should be constructed so that all significant nonlinear behavior in contained within the discrete analysis model.

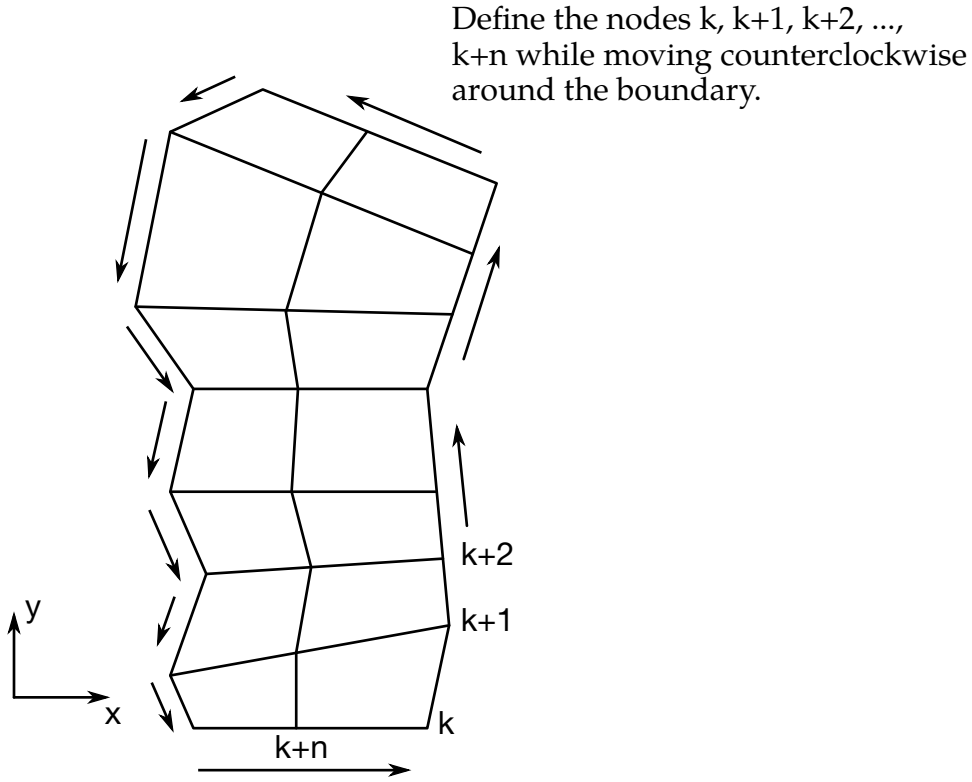

Figure 5-2. When defining a transmitting boundary in 2D define the node numbers in the node set in consecutive order while moving counterclockwise around the boundary.

*BOUNDARY_PAP

Purpose: Define pressure boundary conditions for pore air flow calculation, such as at the structure surface exposed to atmospheric pressure.

Card 1	1	2	3	4	5	6	7	8
Variable	SEGID	LCID	CMULT	CVMASS	BLOCK	TBIRTH	TDEATH	CVRPER
Type	I				F	F	F	F
Default	none	CMULT	none	none	0.0	0.0	10^{20}	1.0
Remarks				1, 2				3

VARIABLE	DESCRIPTION
SEGID	Segment set ID
LCID	Load curve giving pore air pressure as a function of time. EQ.0: constant pressure assumed equal to CMULT
CMULT	Factor on curve or constant pressure head if LCID = 0.
CVMASS	Initial mass of a control volume next to the segment set SEGID
BLOCK	Contact blockage effect, EQ.0: When all segments in SEGID are subject to the pressure defined by LCID and CMULT; EQ.1: When only elements in SEGID not involved in contact are subject to the pressure defined by LCID and CMULT.
TBIRTH	Time at which boundary condition becomes active
TDEATH	Time at which boundary condition becomes inactive
CVRPER	Permeability factor of cover material, where cover refers to a shell layer coating the surface of the solid. Default value is 1.0 when it is not defined. $0.0 \leq \text{CVRPER} \leq 1.0$

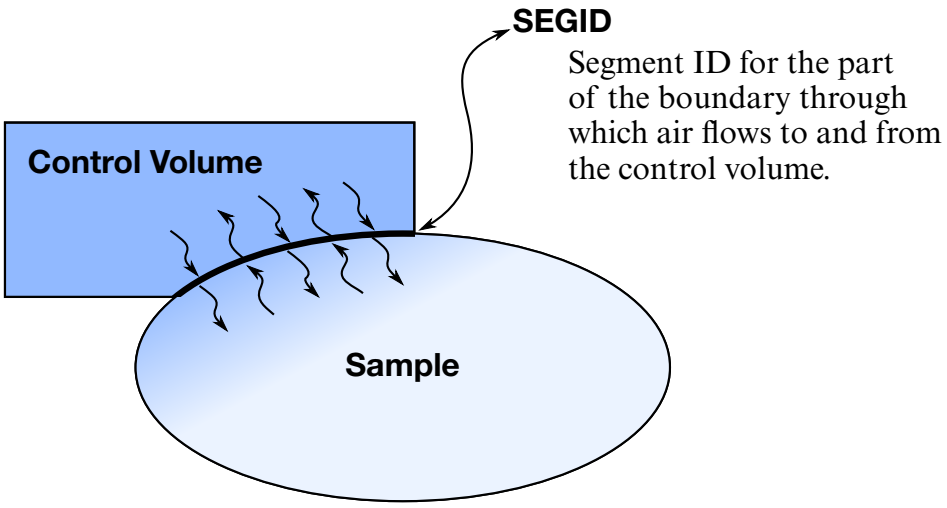

Figure 5-3. Air flows between the control volume and the sample. CVMASS specifies the control volume's initial mass, and CVMULT sets the initial pressure.

Remarks:

1. **Structure Surfaces.** All structure surfaces subject to specified pressure must be defined.

2. **Air Mass Transfer.** A non-zero CVMASS, together with a non-zero CMULT and an un-defined LCID, can be used to simulate air mass transfer between a control volume and a test specimen containing pore air. The control volume is assumed to have a fixed volume, an initial pressure of CMULT, and an initial mass of CVMASS. Air mass transfer happens between the control volume and its neighboring specimen. Such mass transfer results in pressure change in control volume and test specimen.

3. **Porosity Properties.** The porosity properties of the cover material can be modeled using CVRPER. If SEGID is covered by a material of very low permeability (e.g., coated fabric), CVRPER should be set to 0.0. In this case, P_c, the pressure calculated assuming no boundary condition, is applied to SEGID. If SEGID is not covered by any material, CVRPER should be set to 1.0, the default value. In this case, the applied pressure becomes P_b, the boundary pressure determined by CMULT and LCID.

BOUNDARY_PORE_FLUID_*OPTION

Available options include:

PART

SET

Purpose: Define parts that contain pore fluid. Defaults are given on *CONTROL_PORE_-FLUID.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	WTABLE	PF_RHO	ATYPE	PF_BULK	ACURVE	WTCUR	SUCLIM
Type	I	F	F	I	F	I	I	F
Default	none	*	*	*	*	0	0	0.

*Defaults are taken from *CONTROL_PORE_FLUID.

VARIABLE	DESCRIPTION
PID	Part ID or part set ID. All elements within the part must lie below the water table.
WTABLE	Z-coordinate at which pore pressure = 0 (water table)
PF_RHO	Density of pore water in soil skeleton (see Remark 2): EQ.0: Default density specified on *CONTROL_PORE_FLUID card is used.
ATYPE	Analysis type for parts: EQ.0: Default to value specified on *CONTROL_PORE_FLUID EQ.1: Undrained analysis EQ.2: Drained analysis EQ.3: Time dependent consolidation (coupled) EQ.4: Consolidate to steady state (uncoupled) EQ.5: Drained in dynamic relaxation, undrained in transient

VARIABLE	DESCRIPTION
PF_BULK	Bulk modulus of pore fluid: EQ.0: Default to value specified on *CONTROL_PORE_FLUID
ACURVE	Curve of analysis type as a function of time (see Remark 3)
WTCUR	Curve of water table (z-coordinate) as a function of time
SUCLIM	Suction limit (defined in head, that is, length units). It must not be negative. See Remark 4.

Remarks:

1. **Pore Water Parts.** This card must be present for all parts having pore water.

2. **Density.** The density on this card is used only to calculate pressure head. To ensure the correct gravity loading, the density of the soil material should be increased to include the mass associated with the pore water.

3. **Analysis Type Curve.** The y-axis values of the curve of analysis type as a function of time can only be 1, 2, 3, or 4, where these values have the same meanings as for ATYPE. During dynamic relaxation, the analysis type will be taken from the first value on the curve

4. **Suction.** The default for SUCLIM is zero, meaning that the pore fluid cannot generate suction. To allow unlimited suction, set this parameter to a large positive number.

*BOUNDARY_PRECRACK

Purpose: Define pre-cracks in XFEM shell formulations 52 or 54 for purposes of fracture analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	CTYPE	NP					
Type	I	I	I					
Default	none	1	none					

Pre-Crack Point Cards. Include NP cards, one for each point in the pre-crack.

Card 2	1	2	3	4	5	6	7	8
Variable	X	Y	Z					
Type	F	F	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
PID	Part ID where the pre-crack is located.
CTYPE	Type of pre-crack: EQ.1: straight line
NP	Number of points defining the pre-crack.
X, Y, Z	Coordinates of the points defining the pre-crack. The points should be on or close to the shell surface and the line segments should not pass any nodal points in the part.

*BOUNDARY_PRESCRIBED_ACCELEROMETER_RIGID

Purpose: Prescribe the motion of a rigid body based on experimental data obtained from accelerometers affixed to the rigid body.

Note: This feature is available starting with LS-DYNA 971R3.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	SOLV						
Type	I	I						
Default	none	1						

Accelerometer Cards. Define one card for each accelerometer affixed to the rigid body. Input is terminated at the next keyword ("*") card. A minimum of three accelerometers are required (see Remarks below).

Card 2	1	2	3	4	5	6	7	8
Variable	NID	CID	LCIDX	LCIDY	LCIDZ			
Type	I	I	I	I	I			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
PID	Part ID for rigid body whose motion is prescribed.
SOLV	Solver type: EQ.1: Gaussian elimination (default) EQ.2: linear regression
NID	Node ID corresponding to the location of the accelerometer.
CID	Coordinate system ID describing the orientation of the accelerometer's local axes (see *DEFINE_COORDINATE_NODES). All nodes must reside on the same part. Set FLAG = 1.

VARIABLE	DESCRIPTION
LCIDX	Load curve ID containing the local *x*-acceleration time history from the accelerometer.
LCIDY	Load curve ID containing the local *y*-acceleration time history from the accelerometer.
LCIDZ	Load curve ID containing the local *z*-acceleration time history from the accelerometer.

Remarks:

1. **Time Histories.** Acceleration time histories from a minimum of three accelerometers each providing output from three channels are required. Load curves must have the same number of points and data must be uniformly spaced.

2. **Local Axes.** Local axes of the accelerometers must be orthogonal.

*BOUNDARY_PRESCRIBED_FINAL_GEOMETRY

Purpose: The final displaced geometry for a subset of nodal points is defined. The nodes of this subset are displaced from their initial positions specified in the *NODE input to the final geometry along a straight line trajectory. A load curve defines a scale factor as a function of time that is bounded between zero and unity corresponding to the initial and final geometry, respectively. A unique load curve can be specified for each node, or a default load curve can apply to all nodes. The external work generated by the displacement field is included in the energy ratio calculation for the glstat file.

Card 1	1	2	3	4	5	6	7	8
Variable	BPFGID	LCIDF	DEATHD					
Type	I	I	F					
Default	0	0	infinity					

Node Cards. The next "*" keyword card terminates this input.

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	NID	X		Y		Z		LCID	DEATH	
Type	I	F		F		F		I	F	
Default	none	0.		0.		0.		LCIDF	infinity	

VARIABLE	DESCRIPTION
BPFGID	ID for this set of imposed boundary conditions
LCIDF	Default load curve ID. This curve varies between zero and unity.
DEATHD	Default death time. At this time the prescribed motion is inactive and the nodal point is allowed to move freely.

VARIABLE	DESCRIPTION
NID	GT.0: Node ID for which the final position is defined. Nodes defined in this section must also appear under the *NODE input. LT.0: |NID| is a node set ID for which the final projection plane normal to the global *z*-axis is defined. In this case, only the offset Z value is needed, and all the nodes in this node set are displaced from their initial positions to the projected points on the *x*-*y* plane with Z offset. They share the same LCID and DEATH.
X	*x*-coordinate of final geometry
Y	*y*-coordinate of final geometry
Z	*z*-coordinate of final geometry
LCID	Load curve ID for NID. If zero, the default curve ID, LCIDF, is used.
DEATH	Death time for NID. If zero, the default value, DEATHD, is used.

***BOUNDARY_PRESCRIBED_MOTION**_*OPTION1_{OPTION2}_{OPTION3}*

Available options for *OPTION1* include:

NODE

SET

SET_BOX

SET_SEGMENT

RIGID

RIGID_LOCAL

SET_LINE

POINT_UVW

EDGE_UVW

FACE_XYZ

SET_POINT_UVW

SET_EDGE_UVW

SET_FACE_XYZ

OPTION2 allows an optional ID to be given for the single node, node set, segment set, and rigid body options. If you define a heading, LS-DYNA writes the ID and the heading to the beginning of the ASCII file, bndout.

ID

LS-DYNA only supports *OPTION3* for motion imposed on a rigid body. Thus, *OPTION1* must include RIGID in the name.

BNDOUT2DYNAIN

With this feature, LS-DYNA includes the reaction force as a parameter in the output to the dynain file for use in a subsequent simulation. With this output, you can replace the motion with an equivalent force between simulations without manual intervention. We only support this feature for implicit analysis (IMFLAG = 1 on *CONTROL_IMPLICIT_-GENERAL) and only for the lsda format of the dynain file (FTYPE = 3 on *INTERFACE_-SPRINGBACK_LSDYNA).

Purpose: Define an imposed nodal motion (velocity, acceleration, or displacement) on a node or a set of nodes. You can also impose velocities and displacements on rigid bodies. If you activate the local option, LS-DYNA prescribes the motion with respect to the local coordinate system for the rigid body; see field LCO of keyword *MAT_RIGID. This keyword allows translational nodal velocity and acceleration specifications for rigid body nodes. We describe the application of these motions in Remark 6. For nodes on rigid bodies use the NODE option. Do not use the NODE option in *r*-adaptive problems since the node IDs may change during the adaptive step.

The SET_LINE option causes LS-DYNA to include a generated node set comprising existing nodes and new nodes created from *h*-adaptive mesh refinement along the straight line connecting two specified nodes in prescribed boundary conditions.

The POINT_UVW, EDGE_UVW, FACE_XYZ, SET_POINT_UVW, SET_EDGE_UVW, and SET_FACE_XYZ options are used when prescribed boundary conditions are applied to IGA shells.

Card Summary:

Card ID. Include this card if using the ID keyword option.

ID	HEADING

Card 1. This card is required.

TYPEID	DOF	VAD	LCID	SF	VID	DEATH	BIRTH

Card 2. Include this card for the SET_BOX keyword option.

BOXID	TOFFSET	LCBCHK					

Card 3. Additional card that is expected if |DOF| = 9, 10, or 11 or VAD = 4 on Card 1; otherwise skip this card.

OFFSET1	OFFSET2	LRB	NODE1	NODE2			

Card 4. Include this card for the SET_LINE keyword option.

NBEG	NEND						

Card 5. Include this card for the BNDOUT2DYNAIN keyword option.

PRMR							

Card 6. Include this card for the POINT_UVW, EDGE_UVW, FACE_XYZ, SET_-POINT_UVW, SET_EDGE_UVW, and SET_FACE_XYZ keyword options.

FORM	SFD						

Data Card Definitions:

ID Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
ID	PRESCRIBED MOTION set ID to which this node, node set, segment set, or rigid body belongs. This ID does not need to be unique.
HEADING	An optional descriptor for the given ID that will be written into the d3hsp file and the bndout file.

Card 1	1	2	3	4	5	6	7	8
Variable	TYPEID	DOF	VAD	LCID	SF	VID	DEATH	BIRTH
Type	I	I	I	I	F	I	F	F
Default	none	none	0	none	1.0	0	10^{28}	0.0

VARIABLE	DESCRIPTION
TYPEID	Node ID (NID in *NODE), nodal set ID (SID in *SET_NODE), segment set ID (SID in *SET_SEGMENT, see DOF = 12), part ID (PID in *PART) for a rigid body, parametric point ID (PID in *IGA_-POINT_UVW), parametric edge ID (EID in *IGA_EDGE_UVW), physical face ID (FID in *IGA_FACE_XYZ), parametric point set ID (SID in *SET_IGA_POINT_UVW), parametric edge set ID (SID in

VARIABLE	DESCRIPTION
	*SET_IGA_EDGE_UVW) or physical face set ID (SID in *SET_-IGA_FACE_XYZ).
DOF	Applicable degrees-of-freedom:
	EQ.1: x-translational degree-of-freedom,
	EQ.2: y-translational degree-of-freedom,
	EQ.3: z-translational degree-of-freedom,
	EQ.4: Translational motion in direction given by the VID. Movement on plane normal to the vector is permitted.
	EQ.-4: Translational motion in direction given by the VID. Movement on plane normal to the vector is not permitted. This option does not apply to rigid bodies.
	EQ.5: x-rotational degree-of-freedom,
	EQ.6: y-rotational degree-of-freedom,
	EQ.7: z-rotational degree-of-freedom,
	EQ.8: Rotational motion about an axis which is passing through the center-of-gravity of the node, node set, or rigid body and is parallel to vector VID. Rotation about the normal axes, namely, axes in a plane normal to VID, is permitted.
	EQ.-8: Rotational motion about an axis which is passing through the center-of-gravity of the node or node set and is parallel to vector VID. Rotation about the normal axes is not permitted. This option does not apply to rigid bodies.
	EQ.9: Rotation with axis parallel to the x-axis and passing through the yz-plane at y = OFFSET1 and z = OFFSET2. Radial motion is NOT permitted. Not applicable to rigid bodies.
	EQ.-9: Rotation with axis parallel to the x-axis and passing through the yz-plane at y = OFFSET1 and z = OFFSET2. Radial motion is permitted. Not applicable to rigid bodies.
	EQ.10: Rotation with axis parallel to the y-axis and passing through the zx-plane at z = OFFSET1 and x = OFFSET2. Radial motion is NOT permitted. Not applicable to rigid bodies.

VARIABLE	DESCRIPTION
	EQ.-10: Rotation with axis parallel to the y-axis and passing through the zx-plane at $z =$ OFFSET1 and $x =$ OFFSET2. Radial motion is permitted. Not applicable to rigid bodies. EQ.11: Rotation with axis parallel to the z-axis and passing through the xy-plane at $x =$ OFFSET1 and $y =$ OFFSET2. Radial motion is NOT permitted. Not applicable to rigid bodies. EQ.-11: Rotation with axis parallel to the z-axis and passing through the xy-plane at $x =$ OFFSET1 and $y =$ OFFSET2. Radial motion is permitted. Not applicable to rigid bodies. EQ.12: Translational motion in direction given by the normals to the segments. Applicable to SET_SEGMENT option only.
VAD	Velocity/Acceleration/Displacement flag: EQ.0: Velocity (rigid bodies and nodes) EQ.1: Acceleration (rigid bodies and nodes) EQ.2: Displacement (rigid bodies and nodes; see Remark 2) EQ.3: Velocity as a function of displacement (rigid bodies only; see Remark 3) EQ.4: Relative displacement (rigid bodies only; see Remark 4)
LCID	Curve ID or function ID to describe motion value as a function of time; see *DEFINE_CURVE, *DEFINE_CURVE_FUNCTION, or *DEFINE_FUNCTION. If LCID refers to *DEFINE_FUNCTION, the function has four arguments: time and x, y and z coordinates of the node or rigid body, such as $f(t,x,y,z) = 10.0 \times t + \max(x - 100,0.)$. If VAD = 2, the function has one argument which is time, such as $f(t) = 10.0 \times t$ (see Remark 2). See BIRTH below.
SF	Load curve scale factor. Default set to 1.0.
VID	Vector ID for DOF values of 4 or 8; see *DEFINE_VECTOR. The direction of this vector is not updated with time.
DEATH	Removal time for the imposed motion/constraint. For alternatives to DEATH and BIRTH for specifying the transitory application of

VARIABLE	DESCRIPTION
	prescribed motion, see the SET_BOX option, or *DEFINE_-DEATH_TIMES, or *SENSOR_CONTROL. EQ.0.0: default set to 10^{28}
BIRTH	Activation time for the imposed motion/constraint. The prescribed motion begins acting at time = BIRTH but with the motion from the zero abscissa value of the curve or function (*DEFINE_-FUNCTION). In other words, the abscissae are shifted by an amount BIRTH, such that it has the same effect as setting OFFA = BIRTH in *DEFINE_CURVE. Warning: BIRTH is ignored if the LCID is defined as a function, as in *DEFINE_CURVE_FUNCTION.

For the SET_BOX keyword option, define the following additional card.

Card 2	1	2	3	4	5	6	7	8
Variable	BOXID	TOFFSET	LCBCHK					
Type	I	I	I					
Default	none	0	0					

VARIABLE	DESCRIPTION
BOXID	A box ID defining a box region in space in which the constraint is activated. The prescribed motion will *only* be applied to the nodes falling inside the box. If the LCBCHK field is not defined, the box volume is reevaluated every time step to determine the nodes for which the prescribed motion is active. This reevaluation of the volume is referred to as a "box-check."
TOFFSET	Time offset flag for the SET_BOX option: EQ.0: No time offset is applied to LCID. EQ.1: The time value of the load curve, LCID, will be offset by the time when the node enters the box.
LCBCHK	Optional load curve allowing more flexible and efficient use of SET_BOX option. Instead of performing box-check at every time step, discrete box-check times could be given as x-values of LCBCHK. LCBCHK's y-values specify corresponding death times. For

VARIABLE	DESCRIPTION
	example, a curve with points $(20, 30)$ and $(50, 70)$ will result in two box checks. The first will occur at 20, and the prescribed motion will be active from 20 to 30. The second will occur at 50, and the prescribed motion will be active from 50 to 70. A y-value of "0" means the prescribed motion will stay active until next box-check. For example, an additional 3rd point of $(90, 0)$ will lead to another box-check at 90, and the prescribed motion will be active from 90 until the end of the simulation.

Additional card that is expected if |DOF| = 9, 10, or 11 or VAD = 4 on Card 1; otherwise skip this card.

Card 3	1	2	3	4	5	6	7	8
Variable	OFFSET1	OFFSET2	LRB	NODE1	NODE2			
Type	F	F	I	I	I			
Default	0.	0.	0	0	0			

VARIABLE	DESCRIPTION
OFFSET1	Offset for DOF types 9 - 11 (y, z, x directions)
OFFSET2	Offset for DOF types 9 - 11 (z, x, y directions)
LRB	Lead rigid body for measuring the relative displacement (for VAD = 4).
NODE1	Optional orientation node, n_1, for relative displacement (for VAD = 4).
NODE2	Optional orientation node, n_2, for relative displacement (for VAD = 4).

For the SET_LINE keyword option, include the following card.

Card 4	1	2	3	4	5	6	7	8
Variable	NBEG	NEND						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
NBEG	Node ID of a starting node
NEND	Node ID of an ending node. All existing nodes and new nodes generated by *h*-adaptive mesh refinement along the straight line connecting NBEG and NEND will be included in the prescribed boundary motions.

For the BNDOUT2DYNAIN keyword option, include the following card.

Card 5	1	2	3	4	5	6	7	8
Variable	PRMR							
Type	A							
Default	none							

VARIABLE	DESCRIPTION
PRMR	String representing the name of the parameter to be output to the dynain file. Its value will be the reaction force from the constraint at the end of the simulation. PRMR is only an A9 string because when the dynain file is read the rules for parameters apply (see *PARAMETER for details). Thus, make sure to not use the first character position.

For the POINT_UVW, EDGE_UVW, FACE_XYZ, SET_POINT_UVW, SET_EDGE_UVW and SET_FACE_XYZ keyword options, include the following card (see Remark 8).

Card 6	1	2	3	4	5	6	7	8
Variable	FORM	SFD						
Type	I	F						
Default	0	1.0						

VARIABLE	DESCRIPTION
FORM	Formulation type: EQ.0: Penalty method
SFD	Scale factor for penalty stiffness

Remarks:

1. **Rotational degrees-of-freedom.** When DOF = 5, 6, 7, or 8, nodal rotational degrees-of-freedom are prescribed in the case of deformable nodes (*OPTION1* = NODE or SET) whereas body rotations are prescribed in the case of a rigid body (*OPTION1* = RIGID). In the case of a rigid body, the axis of prescribed rotation always passes through the body's center of mass. For |DOF| = 8, the axis of the prescribed rotation is parallel to vector VID. To prescribe a body rotation of a set of deformable nodes, with the axis of rotation parallel to global axes x, y, or z, use *OPTION1* = SET with |DOF| = 9, 10, or 11, respectively. The load curve scale factor can be used for simple modifications or unit adjustments.

2. **Limitation for prescribed displacement.** VAD = 2 cannot be used if LCID references a *DEFINE_CURVE_FUNCTION which involves anything other than arithmetic functions or the variable "time". This limitation is because velocities must be computed from the displacement curve using an interpolation scheme which requires data for a future time step; those future data are unknown if the curve function involves simulation response.

3. **Velocity as a function of displacement.** For VAD = 3, the LCID gives velocity as a function of displacement for the rigid body in the direction specified by DOF.

4. **Relative displacement.** The relative displacement prescribed motion (VAD = 4) can be measured in either of two ways:

   a) Along a straight line between the mass centers of the rigid bodies.

   b) Along a vector beginning at node n_1 and terminating at node n_2.

   With the first option, a positive displacement will move the rigid bodies further apart, and, likewise, a negative motion will move the rigid bodies closer together. The mass centers of the rigid bodies must not be coincident when this option is used. With the second option, the relative displacement is measured along the vector, and the rigid bodies may be coincident. Note that the motion of the lead rigid body is not directly affected by VAD = 4, that is, no forces are generated on the lead rigid body.

5. **Activation time.** The activation time, BIRTH, is the time during the solution that the constraint begins to act. Until this time, the prescribed motion card is ignored. The function value of the load curves will be evaluated at the offset time given by the difference of the solution time and BIRTH (solution time - BIRTH). Relative displacements that occur prior to reaching BIRTH are ignored. Only relative displacements that occur after BIRTH are prescribed.

6. **Rigid body nodes.** When the node is on a rigid body, LS-DYNA imposes the translational motion without altering the angular velocity of the rigid body by calculating the appropriate translational velocity for the center of mass of the rigid body using the equation:

$$\mathbf{v}_{\text{cm}} = \mathbf{v}_{\text{node}} - \boldsymbol{\omega} \times (\mathbf{x}_{\text{cm}} - \mathbf{x}_{\text{node}}) .$$

   Here $\mathbf{v}_{\text{cm}}$ is the velocity of the center of mass, $\mathbf{v}_{\text{node}}$ is the specified nodal velocity, $\boldsymbol{\omega}$ is the angular velocity of the rigid body, $\mathbf{x}_{\text{cm}}$ is the current coordinate of the mass center, and $\mathbf{x}_{\text{node}}$ is the current coordinate of the nodal point. Extreme care must be used when prescribing motion of a rigid body node. Typically, for nodes on a given rigid body, the motion of no more than one node should be prescribed or unexpected results may be obtained.

7. **Rigid body rotations.** When the RIGID option is used to prescribe rotation of a rigid body, the axis of rotation will always be shifted such that it passes through the center of mass of the rigid body. By using *PART_INERTIA or *CONSTRAINED_NODAL_RIGID_BODY_INERTIA, one can override the internally-calculated location of the center-of-mass.

   When the RIGID_LOCAL option is invoked, the orientation of the local coordinate system rotates with time in accordance with rotation of the rigid body. The local coordinate system is specified with LCO in *MAT_020. If LCO = 0, the local coordinate system defaults to the principal inertia directions of the rigid body (refer to "principal directions" in the mass summary section of the d3hsp file).

Angular displacements are applied in an incremental fashion; hence, a successive set of rotations about multiple axes cannot be correctly prescribed. In light of this, the command *BOUNDARY_PRESCRIBED_ORIENTATION_RIGID should be used for the purpose of prescribing the general orientation of a rigid body.

8. **Prescribed boundary conditions on IGA shells.** The keyword options for boundary conditions on IGA shells support DOF = 1 to 8 and VAD = 0 to 2. The penalty parameter is set to the Young modulus of the corresponding IGA shell.

   For boundary conditions to be applied to IGA shells, the point and edge IDs specified in TYPEID have to be included in the parametric point set (PSID) and parametric edge set (ESID) in *IGA_FACE_XYZ of the corresponding *IGA_SHELL. This does not apply to the edges already in *IGA_1D_BREP.

   When boundary conditions are prescribed for physical faces and parametric edges, the boundary conditions will be directly imposed on the control points if these faces are untrimmed and these edges are the actual edges of the patch. In this case, FORM and SFD are ignored.

BOUNDARY_PRESCRIBED_ORIENTATION_RIGID_*OPTION1_{OPTION2}

Available options for *OPTION1* include:

DIRCOS

ANGLES

EULERP

VECTOR

OPTION2 allows an optional ID:

ID

The defined ID can be referred to by *SENSOR_CONTROL.

Purpose: Prescribe the orientation of rigid body as a function of time.

Card Summary:

Card ID. Include this card if using the ID option.

ID	HEADING

Card 1. This card is required.

PIDB	PIDA	INTRP	BIRTH	DEATH	TOFFSET		

Card 2a.1. Include this card if using the DIRCOS option.

LCIDC11	LCIDC12	LCIDC13	LCIDC21	LCIDC22	LCIDC23	LCIDC31	LCIDC32

Card 2a.2. Include this card if using the DIRCOS option.

	LCIDC33						

Card 2b. Include this card if using the ANGLES option.

LCIDQ1	LCIDQ2	LCIDQ3	ISEQ	ISHFT	BODY		

Card 2c. Include this card if using the EULERP option.

LCIDE1	LCIDE2	LCIDE3	LCIDE4				

Card 2d. Include this card if using the VECTOR option.

LCIDV1	LCIDV2	LCIDV3	LCIDS	VALSPIN			

Data Cards:

ID Card. Optional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
ID	Optional ID for PRESCRIBED ORIENTATION that can be referred to by *SENSOR_CONTROL. When not defined, the sequential definition order will be used as ID when referred to by *SENSOR_CONTROL.
HEADING	An optional descriptor for the given ID

Card 1	1	2	3	4	5	6	7	8
Variable	PIDB	PIDA	INTRP	BIRTH	DEATH	TOFFSET		
Type	I	I	I	F	F	I		
Default	none	↓	1	0.	10^{20}	0		

VARIABLE	DESCRIPTION
PIDB	Part ID for rigid body B whose orientation is prescribed
PIDA	Part ID for rigid body A. The orientation of PIDB is measured with respect to the coordinate system of PIDA, as defined by LCO on *MAT_RIGID. If zero, then the orientation of PIDB is measured with respect to the global reference frame except for when BODY = 1 for the ANGLES option; see Remark 5.

VARIABLE	DESCRIPTION
INTRP	Interpolation method used on time history curves: EQ.1: Linear interpolation (default)
BIRTH	Prior to this time the body moves freely under the action of other agents.
DEATH	The body is freed at this time and subsequently allowed to move under the action of other agents.
TOFFSET	Time offset flag: EQ.0: No time offset is applied. EQ.1: The time value of all load curves will be offset by the birth time.

Cosine Card 1. Additional card for DIRCOS option.

Card 2a.1	1	2	3	4	5	6	7	8
Variable	LCIDC11	LCIDC12	LCIDC13	LCIDC21	LCIDC22	LCIDC23	LCIDC31	LCIDC32
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

Cosine Card 2. Additional card for DIRCOS option.

Card 2a.2	1	2	3	4	5	6	7	8
Variable	LCIDC33							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
LCIDC*ij*	Load curve ID specifying direction cosine C_{ij} as a function of time. C_{ij} is defined as:

VARIABLE	DESCRIPTION
	$$C_{ij} = \mathbf{a}_i \cdot \mathbf{b}_j$$ where the $\{\mathbf{a}_i\}$ are mutually perpendicular unit vectors fixed in PIDA and the $\{\mathbf{b}_j\}$ are mutually perpendicular unit vectors fixed in PIDB. If PIDA = 0 then the $\{\mathbf{a}_i\}$ are unit vectors aligned with the global x, y, and z. See Remark 1.

Angles Card. Additional card for ANGLES option, see Remark 5.

Card 2b	1	2	3	4	5	6	7	8
Variable	LCIDQ1	LCIDQ2	LCIDQ3	ISEQ	ISHFT	BODY		
Type	I	I	I	I	I	I		
Default	none	none	none	none	1	0		

VARIABLE	DESCRIPTION
LCIDQ*i*	Load curve ID specifying the orientation angle q_i in radians as a function of time. See Remark 1.
ISEQ	Specifies the sequence in which the rotations are performed. In this first set of sequences, three unique axes are involved. This sequence is associated with what are commonly called Cardan or Tait-Bryan angles. *All angles must be in units of radians.* Whether these rotations are intrinsic or extrinsic is determined by the BODY field. EQ.123: The first rotation is performed about the x-axis through an angle of q_1, the second about the y-axis through an angle of q_2, and the third about the z-axis through an angle of q_3. EQ.231: The first rotation is performed about the y-axis through an angle of q_1, the second about the z-axis through an angle of q_2, and the third about the x-axis through an angle of q_3. EQ.312: The first rotation is performed about the z-axis through an angle of q_1, the second about the x-axis through an angle of q_2, and the third about the y-axis through an angle of q_3.

VARIABLE	DESCRIPTION

EQ.132: The first rotation is performed about the x-axis through an angle of q_1, the second about the z-axis through an angle of q_2, and the third about the y-axis through an angle of q_3.

EQ.213: The first rotation is performed about the y-axis through an angle of q_1, the second about the x-axis through an angle of q_2, and the third about the z-axis through an angle of q_3.

EQ.321: The first rotation is performed about the z-axis through an angle of q_1, the second about the y-axis through an angle of q_2, and the third about the z-axis through an angle of q_3.

The second set of sequences involve only two unique axes where the first and third are repeated. This sequence is associated with what are commonly called Euler angles.

EQ.121: The first rotation is performed about the x-axis through an angle of q_1, the second about the y-axis through an angle of q_2, and the third about the x-axis through an angle of q_3.

EQ.131: The first rotation is performed about the x-axis through an angle of q_1, the second about the z-axis through an angle of q_2, and the third about the x-axis through an angle of q_3.

EQ.212: The first rotation is performed about the y-axis through an angle of q_1, the second about the x-axis through an angle of q_2, and the third about the y-axis through an angle of q_3.

EQ.232: The first rotation is performed about the y-axis through an angle of q_1, the second about the z-axis through an angle of q_2, and the third about the y-axis through an angle of q_3.

EQ.313: The first rotation is performed about the z-axis through an angle of q_1, the second about the x-axis through an angle of q_2, and the third about the z-axis through an angle of q_3.

EQ.323: The first rotation is performed about the z-axis through an angle of q_1, the second about the y-axis through an angle of q_2, and the third about the z-axis through an angle of q_3.

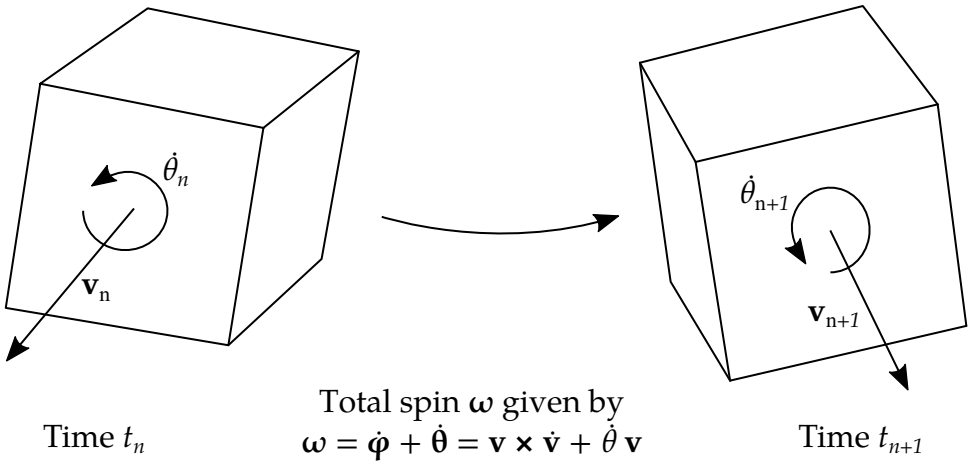

Figure 5-5. Orientation of rigid body computed using the VECTOR option.

VARIABLE	DESCRIPTION
ISHFT	Angle shift. EQ.1: Angle curves are unaltered. EQ.2: Shifts angle data in the LCIDQ*i* curves as necessary to eliminate discontinuities. If angles are confined to the range $[-\pi, \pi]$ and the data contains excursions exceeding π, then set ISHFT = 2.
BODY	Reference axes: EQ.0: Rotations are performed about axes fixed to PIDA (extrinsic rotation, default). The coordinate system in question is the one defined by LCO on *MAT_RIGID for body A. EQ.1: Rotations are performed about axes fixed to PIDB (intrinsic rotation). The coordinate system in question is the one defined by LCO on *MAT_RIGID for body B.

Euler Parameter Card. Additional card for EULERP option.

Card 2c	1	2	3	4	5	6	7	8
Variable	LCIDE1	LCIDE2	LCIDE3	LCIDE4				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
LCIDEi	Load curve ID specifying Euler parameter e_i as a function of time. See Remark 1. The Euler parameters are defined as follows: $$\varepsilon_i = \boldsymbol{\varepsilon} \cdot \mathbf{a}_i = \boldsymbol{\varepsilon} \cdot \mathbf{b}_i, \qquad (i = 1,2,3)$$ $$\varepsilon_4 = \cos\left(\frac{\theta}{2}\right)$$ where $\boldsymbol{\varepsilon}$ is the Euler vector, $\{\mathbf{a}_i\}$ and $\{\mathbf{b}_i\}$ are dextral sets of unit vectors fixed in PIDA and PIDB, respectively, and θ (in radians) is associated with the rotation of PIDB in PIDA about Euler vector. If PIDA = 0, then the $\{\mathbf{a}_i\}$ are unit vectors aligned, respectively, with the global x, y, and z-axes. See Remark 2.

Vector Card. Additional card for VECTOR option.

Card 2d	1	2	3	4	5	6	7	8
Variable	LCIDV1	LCIDV2	LCIDV3	LCIDS	VALSPIN			
Type	I	I	I	I	F			
Default	none	none	none	0	0.			

VARIABLE	DESCRIPTION
LCIDVi	Load curve ID specifying the vector measure number v_i as a function of time. See Remark 1. The vector measure numbers are defined as follows: $$v_i = \mathbf{v} \cdot \mathbf{n}_i, \qquad i = 1,2,3.$$ where $\mathbf{v}$ is a vector and $\{\mathbf{n}_i\}$ are unit vectors aligned, respectively, with the global axes x, y, and z-axes. Note that the vector $\mathbf{v}$ is attached to the body in question, so changing the direction of this vector will induce a rotation of the body defined by $\dot{\boldsymbol{\varphi}} = \mathbf{v} \times \dot{\mathbf{v}}$. See Figure 5-5.
LCIDS	Load curve ID which specifies the overlayed spin speed $\dot{\theta}$ of PIDB about the axis parallel to the vector $\mathbf{v}$. EQ.0: A constant spin speed as defined by VALSPIN is used. GT.0: Load curve for spin speed (radians per unit time)

VARIABLE	DESCRIPTION
VALSPIN	Value for the constant spin speed of PIDB (radians per unit time $\dot{\theta}$). This field is ignored if the load curve number defined above is non-zero.

Remarks:

1. **Load Curves.** All load curves must contain the same number of points and the data must be uniformly spaced.

2. **Euler Parameters.** The Euler parameters are defined as

$$\boldsymbol{\varepsilon} = \sin\left(\frac{\theta}{2}\right)\mathbf{n}$$

$$\varepsilon_4 = \cos\left(\frac{\theta}{2}\right)$$

where $\mathbf{n}$ is a unit vector defining the axis of rotation and θ is the angle with which the rotation occurs. Consequently, the four parameters are subjected to the condition

$$\boldsymbol{\varepsilon}^T\boldsymbol{\varepsilon} + \varepsilon_4^2 = 1\ .$$

It is therefore recommended that the control points of the curves already fulfil this or else LS-DYNA will internally normalize these values. From the Euler parameters at time t, a unique rotation matrix $\mathbf{Q}_t$ is computed that is used to determine the total orientation $\mathbf{Q}$. The rotation is performed with respect to the *reference state* $\mathbf{Q}_0$ given by the Euler parameters at time 0. In general, $\mathbf{Q}_0 \neq \boldsymbol{I}$ and the rotation of the rigid body is given by $\mathbf{Q} = \mathbf{Q}_t\mathbf{Q}_0^T$. If the parameters are initially $\boldsymbol{\varepsilon} = \mathbf{0}$ and $\varepsilon_4 = 1$, then the reference state is $\mathbf{Q}_0 = \mathbf{I}$ and $\mathbf{Q} = \mathbf{Q}_t$ defines the orientation of the rigid body.

For a nonzero PIDA, the rotation matrix $\mathbf{Q}$ as defined above is expressed in a system that is fixed in rigid body A. If this system is denoted $\mathbf{R}_t$ at time t, and assuming $\mathbf{R}_0 = \mathbf{I}$, the orientation with respect to a global system is $\mathbf{RQ}$.

3. **Coordinate System.** LC0 in *MAT_RIGID must be used to identify a coordinate system for each rigid body. The coordinate system must be defined with *DEFINE_COORDINATE_NODES and FLAG = 1. Nodes used in defining the coordinate system must reside on the same body.

4. **Incompatibilities.** This feature is incompatible with *DEFINE_CURVE_FUNCTION.

5. **ANGLES Option.** For the ANGLES option we assume that bodies A and B are defined by local systems attached to the bodies, $\mathbf{R}_a$ for body A and consequently

$\mathbf{R}_b$ for body B, and we intend to determine the latter. The initial configurations are determined by the parameter LCO on each respective *MAT_RIGID card. If this parameter is absent, the initial system is taken as the configuration of principal inertia directions, so we recommend defining it whenever PIDA or BODY are nonzero. We denote the initial ($t = 0$) configuration matrices for each body $\mathbf{R}_A$ and $\mathbf{R}_B$, respectively. We, also, define rotation matrices $\mathbf{Q}_i$, $i = 1, 2, 3$ as functions of time according to the formula

$$\mathbf{Q}_i = \cos q_i\left(\mathbf{u}_i\mathbf{u}_i^T + \mathbf{v}_i\mathbf{v}_i^T\right) + \sin q_i\left(\mathbf{v}_i\mathbf{u}_i^T - \mathbf{u}_i\mathbf{v}_i^T\right) + \mathbf{w}_i\mathbf{w}_i^T \ .$$

Here $\{\mathbf{u}_i, \mathbf{v}_i, \mathbf{w}_i\}$ is an arbitrary orthonormal system with $\mathbf{w}_i$ being the rotation direction associated with the parameter ISEQ. *This system is fixed in time*. Furthermore, q_i is the rotation angle associated with LCIDQ*i and is thus time dependent*. More specifically, for a "1" in ISEQ we have $\mathbf{w}_i^T = (1 \quad 0 \quad 0)$, for a "2" we have $\mathbf{w}_i^T = (0 \quad 1 \quad 0)$, and for a "3" we have $\mathbf{w}_i^T = (0 \quad 0 \quad 1)$. Depending on the values of BODY and PIDA, we define the configuration of body B at time t as

$$\mathbf{R}_b = \begin{cases} \mathbf{Q}_3\mathbf{Q}_2\mathbf{Q}_1\mathbf{R}_B & \text{if BODY} = 0 \text{ and PIDA} = 0 \\ \mathbf{R}_a\mathbf{Q}_3\mathbf{Q}_2\mathbf{Q}_1\mathbf{R}_A^T\mathbf{R}_B & \text{if PIDA} \neq 0 \\ \mathbf{R}_B\mathbf{Q}_1\mathbf{Q}_2\mathbf{Q}_3 & \text{if BODY} = 1 \text{ and PIDA} = 0 \end{cases}$$

BOUNDARY_PRESSURE_OUTFLOW_*OPTION

Available options include:

SEGMENT

SET

Purpose: Define pressure outflow boundary conditions. These boundary conditions are attached to solid elements using the Eulerian ambient formulation (refer to ELFORM in *SECTION_SOLID_ALE) and defined to be pressure outflow ambient elements (refer to AET in *SECTION_SOLID_ALE).

Card 1 for SET option.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID							
Type	I							
Default	none							

Card 1 for SEGMENT option.

Card 1	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
SSID	Segment set ID
N1, N2, …	Node ID's defining segment

BOUNDARY_PWP_*OPTION1_{OPTION2}

Purpose: Define pressure boundary conditions for pore water, such as at soil surface. The TABLE/TABLE_SET option applies to a whole part/part set, while the other options apply to specified nodes.

OPTION1 is required. The available choices for *OPTION1* are:

NODE

SET

TABLE

TABLE_SET

OPTION2 is optional. It allows an optional ID to be given that applies to this boundary condition:

ID

If defined, the ID may be referenced by *SENSOR_CONTROL to activate and/or deactivate the boundary condition. The ID has no other function in LS-DYNA.

Card Summary:

Card ID. This card is included if *OPTION2* is ID

ID							

Card 1a. This card is included if *OPTION1* is NODE or SET.

Card 2b. This card is included if *OPTION1* is TABLE or TABLE_SET

	ITOTEX		TABLE				

Data Card Definitions:

ID Card. Additional card for the ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	ID							
Type	I							
Default	none							

VARIABLE	DESCRIPTION
ID	ID for this boundary condition

Node Card. This card is included if the keyword *OPTION1* is NODE or SET.

Card 1a	1	2	3	4	5	6	7	8
Variable	NID	LC	CMULT	LCDR	TBIRTH	TDEATH		
Type	I	F	F	I	F	F		
Default	none	none	0.0	none	0.0	10^{20}		

VARIABLE	DESCRIPTION
NID	Node ID (option = NODE) or node set ID (option = SET)
LC	Load curve or function giving pore water pressure head (length units) as a function of time (see Remark 5). EQ.0: Constant pressure head assumed equal to CMULT.
CMULT	Factor on curve or constant pressure head if LC = 0
LCDR	Load curve or function giving pore water pressure head during dynamic relaxation. EQ.0: During dynamic relaxation, use first pressure head value on LC.

VARIABLE	DESCRIPTION
TBIRTH	Time at which boundary condition becomes active
TDEATH	Time at which boundary condition becomes inactive

Table Card. This card is included if the keyword *OPTION1* is TABLE or TABLE_SET.

Card 1b	1	2	3	4	5	6	7	8
Variable	PID				TBIRTH	TDEATH		
Type	I				F	F		
Default	none				0.0	10^{20}		

VARIABLE	DESCRIPTION
PID	Part ID (option = TABLE) or part set ID (option = TABLE_SET)
TBIRTH	Time at which boundary condition becomes active
TDEATH	Time at which boundary condition becomes inactive

This card is included if the keyword *OPTION1* is NODE or SET.

Card 2a	1	2	3	4	5	6	7	8
Variable	IPHRE	ITOTEX	IDRFLAG		LCLEAK	CLEAK	LCPUMP	
Type	I	I	I		I	F	I	
Default	0	0	0		0	0.0	optional	

VARIABLE	DESCRIPTION
IPHRE	Phreatic behavior option: EQ.0: Default behavior EQ.1: For phreatic behavior (water can be removed by the boundary condition but not added, such as at a sloping free surface). See Remark 7.

VARIABLE	DESCRIPTION
ITOTEX	Flag for type of pressure boundary condition (see Remark 8): EQ.0: Total head EQ.1: Excess head EQ.2: Hydraulic head EQ.4: z-coord where head = 0 (piezometric level)
IDRFLAG	Active flag: EQ.0: Active only in transient analysis EQ.1: Active only in dynamic relaxation EQ.2: Active in all analysis phases
LCLEAK	Optional load curve ID (see *DEFINE_CURVE) applicable to IPHRE = 1 only, giving area of the hole through which pore fluid leaks to the zero pressure boundary condition. See Remark 9.
CLEAK	Discharge coefficient, applicable when LCLEAK is nonzero
LCPUMP	Optional load curve ID (see *DEFINE_CURVE) giving volumetric outflow rate per node. The curve x-axis is time while the y-axis is in units of volume per unit time. If defined, LCPUMP overrides all other input fields on Card 2. See Remark 11.

This card is included if the keyword *OPTION1* is TABLE or TABLE_SET.

Card 2b	1	2	3	4	5	6	7	8
Variable		ITOTEX		TABLE				
Type		I		I				
Default		0		0				

VARIABLE	DESCRIPTION
ITOTEX	Flag for type of pressure boundary condition (see Remark 8): EQ.0: Total head EQ.1: Excess head

VARIABLE	DESCRIPTION
	EQ.2: Hydraulic head
TABLE	Table ID for TABLE/TABLE_SET option only. See Remark 6.

Remarks:

1. **Pressure Dimensions.** Pressure should be given as pressure head in length units. Pressure head is defined as pressure/ρg where ρ is the fluid density given on *BOUNDARY_PORE_FLUID and g is the acceleration due to gravity given on *CONTROL_PORE_FLUID.

2. **Applicability of NODE and SET options.** The NODE and SET options should be applied only to nodes belonging to parts whose analysis type (see ATYPE and ACURVE on *BOUNDARY_PORE_FLUID) is Undrained, Time-dependent consolidation or Steady-state consolidation. The NODE and SET options have no effect on the pore pressure in Drained parts.

3. **Applicability of TABLE and TABLE_SET options.** The TABLE and TABLE_SET options should be used *only* with Drained parts. They have no effect on the pore pressure in parts with other pore fluid analysis types.

4. **Nodal Boundary Conditions.** *BOUNDARY_PWP_NODE or SET overrides pressure head from *BOUNDARY_PWP_TABLE or TABLE_SET at nodes where both are present. This situation can arise at the boundary between Drained and Undrained parts.

5. **Input Arguments for LC Function.** If LC is a *DEFINE_FUNCTION, the input arguments are $(\text{time}, x, y, z, x0, y0, z0)$, where x, y, and z are the current coordinates and $x0$, $y0$, and $z0$ are the initial coordinates of the node.

6. **TABLE and TABLE_SET Options.** The table consists of a list of times in ascending order, followed immediately by curves of z-coordinate versus pore pressure head. Each curve represents the pore water pressure head distribution with z-coordinate at the corresponding time. There must be the same number of curves as time values, arranged immediately after the *DEFINE_TABLE and in the correct order to correspond to the time values. Each curve should be arranged in ascending order of z-coordinate – they look upside-down on the page. The z-coordinate is the x-axis of the curve, the pore water pressure head (in length units) is the y-axis. Each curve should have the same z-coordinates (x-values) and use the same value of LCINT. Ensure that the range of z-coordinates in the curve exceeds by at least 5% the range of z-coordinates of the nodes belonging to the parts to which the boundary condition is applied.

7. **IPHRE.** "Phreatic" means that water can be removed by the boundary condition but not added. The boundary condition enforces the pressure head being less than or equal to zero. This condition occurs when the free surface of the soil is sloping so that any water emerging from the soil runs away down the slope. When IPHRE is nonzero, the input fields LC, CMULT, LCDR and ITOTEX are ignored. See also Remark 9 below.

8. **ITOTEX.** Descriptions for the different types of pressure conditions are as follows:

   a) For ITOTEX = 0, the value from the curve or table is total head. This may be used with any pore pressure analysis type.

   b) For ITOTEX = 1, the value from the curve or table is excess head. Total head will be determined by adding the hydrostatic head. This option cannot be used with drained analysis, which sets excess head to zero.

   c) For ITOTEX = 2, the value from the curve or table is hydraulic head, to which excess head may be added due to volume change in the soil if the analysis type is not drained.

   d) For ITOTEX = 4, the curve value is the z-coordinate of the water surface; pore pressure head at any node in this boundary condition, $h_{BC,node}$, is given by,

   $$h_{BC,node} = z_{\text{surface}} - z_{\text{node}}$$

   This option allows a single boundary condition to be used for nodes at any depth, provided that the pressure distribution is hydrostatic below the given surface. This option is not available for the TABLE and TABLE_SET options.

9. **Phreatic condition with leakage.** If IPHRE and LCLEAK are nonzero, then the boundary condition models outflow through a hole. At time t, the y-axis value of LCLEAK, $A(t)$, is the area of the hole, while CLEAK is a non-dimensional discharge coefficient, C. LCLEAK should be defined with time on the x-axis and hole area on the y-axis. When the pore pressure head at the affected node, h, is positive, the volume outflow rate from that node, $\dot{Q}$, is given by

   $$\dot{Q} = CA(t)\sqrt{2hg}$$

   When h is negative, this boundary condition is inactive, meaning no inflow occurs. For the SET option, the same hole area, $A(t)$, and discharge coefficient, C, are applied to every node in the set.

10. **Activation by Sensor.** Optionally, *BOUNDARY_PWP_NODE_ID or *BOUNDARY_PWP _SET_ID can be activated by *SENSOR_CONTROL with TYPE set to BPWPN. In this case the sensor overrides TBIRTH and TDEATH.

11. **LCPUMP.** LCPUMP represents situations where water is pumped out of the soil at a known rate. Instead of constraining the pore pressure, the boundary condition removes water from the nodes to which it applies. The *y*-axis of the curve gives the outflow rate (volume per unit time) at each node to which this boundary condition applies. Therefore, the *y*-axis values of the curve should be set equal to the desired total water volume outflow rate divided by the number of nodes. Water is removed by the boundary condition only while the pore pressure at the affected node is above the suction limit (see SUCLIM on *BOUNDARY_PORE_FLUID). For nodes at the suction limit, the boundary condition has no effect.

*BOUNDARY_PZEPOT

Purpose: Define prescribed electric potential on a node set for a piezoelectric material; see *MAT_ADD_PZELECTRIC.

Include as many cards as necessary. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	NSID	LCID	SF				
Type	I	I	I	I				
Default	none	none	0	none				

VARIABLE	DESCRIPTION
ID	ID of this boundary condition, which can be referred to by *SENSOR_CONTROL with TYPE='PZBC' or *DEFINE_CURVE_FUNCTION with FUNCTION='ECHGBC'
NSID	Node set ID, see *SET_NODE
LCID	Load curve giving prescribed electric potential as a function of time
SF	Scale factor on curve or constant electric potential if LCID = 0.

***BOUNDARY_RADIATION**_*OPTION1_{OPTION2}_{OPTION3}*

Available values for *OPTION1* include:

SET

SEGMENT

ENCLOSURE

Available values for *OPTION2* include (available if *OPTION1* is **not** ENCLOSURE):

VF_READ

VF_CALCULATE

<BLANK>

Available values for *OPTION3* include (available if *OPTION1* is **not** ENCLOSURE):

RESTART

<BLANK>

OPTION1 specifies radiation boundary surface definition by a surface set (SET) or by a segment list (SEGMENT). The option ENCLOSURE can be used to transfer heat between segments in an enclosure. The ENCLOSURE option is available in LS-DYNA MPP only.

OPTION2 indicates the radiation boundary surface is part of an enclosure. When set to VF OPTION2 specifies the use of view factors. The suffix, READ, indicates that the view factors should be read from the file "viewfl". The suffix, CALCULATE, indicates that the view factors should be calculated. The Stefan Boltzmann constant must be defined for radiation in an enclosure on the *CONTROL_THERMAL_SOLVER keyword. The parameter DTVF entered on the CONTROL_THERMAL_SOLVER keyword defines the time interval between VF updates for moving geometries.

OPTION3 is the keyword suffix RESTART. This is only applicable in combination with the keyword VF_CALCULATE. In very long runs, it may be necessary to halt execution. This is accomplished by entering Ctrl-C followed by sw1. To restart the view factor calculation, add the suffix RESTART to all VF_CALCULATE keywords in the input file.

The status of an in-progress view factor calculation can be determined by using the sense switch. This is accomplished by first typing Control-C followed by:

sw1.	Stop run and save viewfl file for restart
sw2.	Viewfactor run statistics

A list of acceptable keywords are:

*BOUNDARY_RADIATION_ENCLOSURE

*BOUNDARY_RADIATION_SEGMENT

*BOUNDARY_RADIATION_SEGMENT_VF_READ

*BOUNDARY_RADIATION_SEGMENT_VF_CALCULATE

*BOUNDARY_RADIATION_SET

*BOUNDARY_RADIATION_SET_VF_READ

*BOUNDARY_RADIATION_SET_VF_CALCULATE

Remarks:

In models that include radiation boundary conditions, a thermodynamic temperature scale is required, i.e., zero degrees must correspond to absolute zero. The Kelvin and Rankine temperature scales meet this requirement whereas Celsius and Fahrenheit temperature scales do not.

*BOUNDARY_RADIATION_ENCLOSURE

Purpose: Define an enclosure by a list of segment sets to be used for a thermal radiation analysis. This keyword is only available in LS-DYNA MPP.

Card Summary:

Card 1. This card is required.

BRENCID	ENCNAME

Card 2. This card is required.

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	BRENCID	ENCNAME						
Type	I	A70						
Default	none	none						

VARIABLE	DESCRIPTION
BRENCID	Boundary radiation ID for this enclosure
ENCNAME	Name of enclosure, used for output purposes

Card 2	1	2	3	4	5	6	7	8
Variable	CALOPT	OUTOPT	CONOPT					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
CALOPT	Calculation option: EQ.0: view factors
OUTOPT	Output option: EQ.0: no output EQ.1: output in LSDA format
CONOPT	Control option: EQ.0: calculate view factors matrix and preform thermal analysis

Card 3	1	2	3	4	5	6	7	8
Variable	FILENAME							
Type	A80							
Default	<jobid>.viewfactor.<suffix>							

VARIABLE	DESCRIPTION
FILENAME	Name of view factor output file

Card 4	1	2	3	4	5	6	7	8
Variable	SMFLAG	SMMAXI	SMABST	SMRELT				
Type	I	I	F	F				
Default	0	500	10^{-10}	10^{-6}				

VARIABLE	DESCRIPTION
SMFLAG	View factor matrix smoothing flag: EQ.0: no smoothing EQ.1: smoothing
SMMAXI	Maximum number of iterations for view factor matrix smoothing (default = 500)
SMABST	Absolute convergence tolerance for view factor matrix smoothing (default = 10^{-10})
SMRELT	Relative convergence tolerance for view factor matrix smoothing (default = 10^{-6})

Card 5	1	2	3	4	5	6	7	8
Variable	STYPE	SLMAXI	SLABST	SLRELT	SLMLEV			
Type	I	I	F	F	I			
Default	0	500	10^{-10}	10^{-6}	0			

VARIABLE	DESCRIPTION
STYPE	Solver type: EQ.0: reverse conjugated gradient
SLMAXI	Maximum number of iterations for radiosity solver (default = 500)
SLABST	Absolute convergence tolerance for radiosity solver (default is 10^{-10})
SLRELT	Relative convergence tolerance for radiosity solver (default = 10^{-6})
SLMLEV	Radiosity solver message level: EQ.0: no output EQ.1: debug output level I EQ.2: debug output level II EQ.3: debug output level III

Segment Set Card. Repeat pairs of Cards 6.1 and 6.2 until all segment sets which form the enclosure are listed. This input ends at the next keyword ("*") card.

Card 6.1	1	2	3	4	5	6	7	8
Variable	SSID							
Type	I							
Default	none							

Segment Set Characteristics Card. Repeat pairs of Cards 6.1 and 6.2 until all segment sets which form the enclosure are listed. This input ends at the next keyword ("*") card.

Card 6.2	1	2	3	4	5	6	7	8
Variable	NINT	BLOCK	SELCID	SEMULT	LOC			
Type	I	I	I	F	I			
Default	none	0	0	0.	0			

VARIABLE	DESCRIPTION
SSID	SSID specifies the ID for a set of segments that comprise a portion of, or possibly, the entire enclosure. See *SET_SEGMENT.
NINT	Number of integration points for view factor calculation, 1 ≤ NINT ≤ 10 EQ.0: LS-DYNA determines the number of integration points based on the segment size and separation distance.
BLOCK	Flag indicating if this surface blocks the view between any other 2 surfaces: EQ.0: no blocking (default) EQ.1: blocking
SELCID	Load curve ID for surface emissivity (see *DEFINE_CURVE): GT.0: surface emissivity as a function of time EQ.0: use constant multiplier value, SEMULT LT.0: surface emissivity as a function of temperature. The value of –SELCID must be an integer, and it is interpreted as a load curve ID.
SEMULT	Curve multiplier for surface emissivity; see *DEFINE_CURVE
LOC	Application of surface for thermal shell elements (see THSHEL in the *CONTROL_SHELL input): EQ.-1: lower surface of thermal shell element EQ.0: middle surface of thermal shell element

VARIABLE	DESCRIPTION
	EQ.1: upper surface of thermal shell element

Remarks:

1. **Temperature Scale.** In models that include radiation boundary conditions, a thermodynamic temperature scale is required, meaning zero degrees must correspond to absolute zero. The Kelvin and Rankine temperature scales meet this requirement whereas Celsius and Fahrenheit temperature scales do not.

*BOUNDARY_RADIATION_SEGMENT

Purpose: Apply a radiation boundary condition on a segment to transfer heat between the segment and the environment.

Include the following 2 cards for each segment. Setting TYPE = 1 on Card 1 below indicates that the segment transfers heat to the environment.

Card 1	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	TYPE			
Type	I	I	I	I	I			
Default	none	none	none	none	1			

Card 2	1	2	3	4	5	6	7	8
Variable	FLCID	FMULT	TLCID	TMULT	LOC			
Type	I	F	I	F	I			
Default	none	0.	none	0.	0			

VARIABLE	DESCRIPTION
N1, N2, N3, N4	Node ID's defining segment
TYPE	Radiation type: EQ.1: Radiation to environment
FLCID	Radiation heat transfer coefficient, $f = \sigma\varepsilon F$, specification where σ is the Stefan Boltzmann constant, ε is the surface emissivity, F is the surface view factor. See Remark 1. This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 2). When the reference is to a curve, FLCID has the following interpretation: GT.0: f is defined as a function of time, t, having points consisting of $(t, f(t))$ data pairs.

VARIABLE	DESCRIPTION
	EQ.0: f is a constant defined by the value FMULT. LT.0: f is defined as a function of temperature, T, by a curve consisting of $(T, f(T))$ data pairs. Enter |FLCID| on the *DEFINE_CURVE keyword.
FMULT	Radiation heat transfer coefficient, f, curve multiplier
TLCID	Environment temperature, T_∞, specification. This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 3). When the reference is to a curve, TLCID has the following interpretation: GT.0: T_∞ is defined as a function of time, t, by a curve consisting of $(t, T_\infty(t))$ data pairs. EQ.0: T_∞ a constant defined by the value TMULT.
TMULT	Environment temperature, T_∞, curve multiplier
LOC	For a thick thermal shell, the radiation will be applied to the surface identified by LOC. See the parameter THSHEL on the *CONTROL_SHELL keyword. EQ.-1: lower surface of thermal shell element EQ.0: middle surface of thermal shell element EQ.1: upper surface of thermal shell element

Remarks:

1. **Radiation Boundary Condition.** A radiation boundary condition is calculated using

$$\dot{q}'' = \sigma\varepsilon F\left(T_{\text{surface}}^4 - T_\infty^4\right) = f\left(T_{\text{surface}}^4 - T_\infty^4\right) ,$$

where f is the radiation heat transfer coefficient. If f is a function of temperature, f is evaluated at the surface temperature, $T_{surface}$.

2. **FLCID Function Arguments.** If FLCID references a *DEFINE_FUNCTION, the radiation heat transfer coefficient can be a function of the segment centroid coordinates, the segment centroid velocity components, the segment centroid temperature, the environment temperature (T_∞), and the solution time, that is, "f(x, y, z, vx, vy, vz, temp, tinf, time)."

3. **TLCID Function Arguments.** If TLCID references a *DEFINE_FUNCTION, the environment temperature, T_∞, can be a function of the segment centroid coordinates, the segment centroid velocity components, and the solution time, that is "f(x, y, z, vx, vy, vz, time)."

BOUNDARY_RADIATION_SEGMENT_VF_*OPTION

Available options include:

READ

CALCULATE

Purpose: Apply a radiation boundary condition on a SEGMENT to transfer heat between the segment and an enclosure surrounding the segment using view factors.

The file viewfl must be present for the READ option, whereas it will be created with the CALCULATE option. If the file viewfl exists when using the CALCULATE option, LS-DYNA will terminate with an error message to prevent overwriting the file. The file viewfl contains the surface-to-surface area × view factor products (that is, A_iF_{ij}). These products are stored by row and formatted as 5E16.0.

Include the following two cards for each segment. The enclosure is defined by additional segments using this keyword. Setting TYPE = 2 on Card 1 below specifies that the segment belongs to an enclosure.

Card 1	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	TYPE	BLOCK	NINT	
Type	I	I	I	I	I	I	I	
Default	none	none	none	none	2	0	0	

Card 2	1	2	3	4	5	6	7	8
Variable	SELCID	SEMULT						
Type	I	F						
Default	SEMULT	0.						

VARIABLE	DESCRIPTION
N1, N2, N3, N4	Node ID's defining segment

VARIABLE	DESCRIPTION
TYPE	Radiation type: EQ.2: Radiation within an enclosure
BLOCK	Flag indicating if this surface blocks the view between any other 2 surfaces. EQ.0: no blocking (default) EQ.1: blocking
NINT	Number of integration points for viewfactor calculation: EQ.0: LS-DYNA determines the number of integration points based on the segment size and separation distance GT.0: User specified number between (and including) 1 and 10.
SELCID	Load curve ID for surface emissivity (see *DEFINE_CURVE) GT.0: surface emissivity as a function of time EQ.0: use constant multiplier value, SEMULT LT.0: surface emissivity as a function of temperature. The value of –SELCID must be an integer, and it is interpreted as a load curve ID.
SEMULT	Curve multiplier for surface emissivity; see *DEFINE_CURVE.

*BOUNDARY_RADIATION_SET

Purpose: Apply a radiation boundary condition on a SEGMENT_SET to transfer heat between the segment set and the environment.

Include the following 2 cards for each set. Setting TYPE = 1 on Card 1 below indicates that the segment transfers energy to the environment.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	TYPE					PSEROD	
Type	I	I					I	
Default	none	1					none	

Card 2	1	2	3	4	5	6	7	8
Variable	FLCID	FMULT	TLCID	TMULT	LOC			
Type	I	F	I	F	I			
Default	none	0.	none	0.	0			

VARIABLE	DESCRIPTION
SSID	SSID specifies the ID for a set of segments that comprise a portion of, or possibly, the entire enclosure. See *SET_SEGMENT.
TYPE	Radiation type: EQ.1: radiation to environment
PSEROD	Part set ID for updating boundary segments exposed to the environment as solid elements erode; see Remark 4.
FLCID	Radiation heat transfer coefficient, $f = \sigma\varepsilon F$, specification, where σ is the Stefan Boltzmann constant, ε is the surface emissivity, F is the surface view factor. See Remark 1.This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DE-

VARIABLE	DESCRIPTION
	FINE_FUNCTION and Remark 2). When the reference is to a curve, FLCID has the following interpretation: GT.0: f is defined as a function of time, t, by a curve consisting of $(t,f(t))$ data pairs. EQ.0: f is a constant defined by the value FMULT. LT.0: f is defined as a function of temperature, T, by a curve consisting of $(T,f(T))$ data pairs. Enter |FLCID| on the *DEFINE_CURVE keyword.
FMULT	Curve multiplier of f (see FLCID)
TLCID	Environment temperature, T_∞ , specification. This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 3). When the reference is to a curve, TLCID has the following interpretation: GT.0: T_∞ is defined as a function of time, t, by a curve consisting of $(t, T_\infty(t))$ data pairs. EQ.0: T_∞ a constant defined by the value TMULT
TMULT	Curve multiplier for T_∞
LOC	For a thick thermal shell, the radiation will be applied to the surface identified by LOC. See the parameter THSHEL on the *CONTROL_SHELL keyword. EQ.-1: lower surface of thermal shell element EQ.0.: middle surface of thermal shell element EQ.1: upper surface of thermal shell element

Remarks:

1. **Radiation Boundary Condition.** A radiation boundary condition is calculated using

$$\dot{q}'' = \sigma\varepsilon F\left(T_{\text{surface}}^4 - T_\infty^4\right) = f\left(T_{\text{surface}}^4 - T_\infty^4\right) ,$$

where f is the radiation heat transfer coefficient. If f is a function of temperature, f is evaluated at the surface temperature, $T_{surface}$.

2. **FLCID Function Arguments.** If FLCID references a *DEFINE_FUNCTION, the radiation heat transfer coefficient can be a function of the segment centroid

coordinates, the segment centroid velocity components, the segment centroid temperature, the environment temperature (T_∞), and the solution time, that is, "f(x, y, z, vx, vy, vz, temp, tinf, time)."

3. **TLCID Function Arguments.** If TLCID references a *DEFINE_FUNCTION, the environment temperature can be a function of the segment centroid coorodinates, the segment centroid velocity components, and the solution time, that is, "f(x, y, z, vx, vy, vz, time)."

4. **Erosion.** When radiation is applied to a segment set associated with solid elements that erode, the radiation condition on a deleted segment will not by default be transferred to newly exposed segments but ceases to exist. By specifying a part set through the parameter PSEROD, any such new segment, *that is attached to an element in this part set*, will inherit this boundary condition, using the same data as prescribed for all original segments.

BOUNDARY_RADIATION_SET_VF_*OPTION

Available options include:

READ

CALCULATE

Include the following 2 cards for each set. This keyword applies a radiation boundary condition on a segment set to transfer heat using view factors between the segment set and an enclosure surrounding the segments. Segments contained in the segment set may form the enclosure. Setting TYPE = 2 on Card 1 below specifies that the segment set belongs to an enclosure.

The file "viewfl" must be present for the READ option. The file "viewfl" will be created for the CALCULATE option. If the file "viewfl" exists when using the CACULATE option, LS-DYNA will terminate with an error message to prevent overwriting the file. The file "viewfl" contains the surface-to-surface area × view factor products (i.e. $A_i F_{ij}$). These products are stored by row and formatted as 5E16.0.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	TYPE	RAD_GRP	FILE_NO	BLOCK	NINT		
Type	I	I	I	I	I	I		
Default	none	2	0	0	0	0		

Card 2	1	2	3	4	5	6	7	8
Variable	SELCID	SEMULT						
Type	I	F						
Default	none	0.						

VARIABLE	DESCRIPTION
SSID	SSID specifies the ID for a set of segments that comprise a portion of, or possibly, the entire enclosure. See *SET_SEGMENT.

VARIABLE	DESCRIPTION
TYPE	Radiation type: EQ.2: Radiation within an enclosure
RAD_GRP	Radiation enclosure group ID. The segment sets from all radiation enclosure definitions with the same group ID are augmented to form a single enclosure definition. If RAD_GRP is not specified or set to zero, then the segments are placed in group zero. All segments defined by the SEGMENT option are placed in set zero.
FILE_NO	File number for view factor file. FILE_NO is added to "viewfl_" to form the name of the file containing the view factors. For example, if FILE_NO is specified as 22, then the view factors are read from viewfl_22. For radiation enclosure group zero FILE_NO is ignored, and view factors are read from viewfl. The same file may be used for different radiation enclosure group definitions.
BLOCK	Flag indicating if this surface blocks the view between any other 2 surfaces. EQ.0: No blocking (default) EQ.1: Blocking
NINT	Number of integration points for view factor calculation EQ.0: LS-DYNA determines the number of integration points based on the segment size and separation distance GE.11: Not allowed
SELCID	Load curve ID for surface emissivity, see *DEFINE_CURVE GT.0: Function of time EQ.0: Use constant multiplier value, SEMULT LT.0: Function of temperature. |SELCID| is a load curve ID.
SEMULT	Curve multiplier for surface emissivity

Remarks:

Multiple enclosures can be modeled when using view factors. Consider the following example input. The order of segments in the view factor file follows the order the sets are assigned to the boundary radiation definition.

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$

```

Enclosure radiation group 9 is composed of all the segments in segment set 15 followed by those in segment set 12. The view factors are stored in the file viewfl_10. Enclosure radiation group 8 is composed of the segments in segment set 13. The view factors are stored in the file viewfl_21.

*BOUNDARY_SALE_MESH_FACE

Purpose: Define boundary conditions at S-ALE mesh faces. This keyword acts as a macro for other keywords to simplify specifying the boundary conditions. As a result, you can use a single keyword to apply boundary conditions.

During the keyword reader phase, this keyword translates to a combination of several different keywords. Those keywords include *SET_NODE_GENERAL (with SALEFAC option), *SET_SEGMENT_GENERAL (with SALEFAC option), *BOUNDARY_SPC_SET, and *BOUNDARY_NON_REFLECTING.

Include as many cards as needed with each card representing one boundary condition. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	BCTYPE	MSHID	NEGX	POSX	NEGY	POSY	NEGZ	POSZ
Type	A	I	I	I	I	I	I	I
Default	none	none	0	0	0	0	0	0

VARIABLE	DESCRIPTION
BCTYPE	Available boundary conditions: EQ.FIXED: All nodes at the face are fixed in all directions. EQ.NOFLOW: No flow allowed through the face. EQ.SYM: The face is a symmetric plane (same as NOFLOW). EQ.NONREFL: Non-reflective boundary condition
MSHID	S-ALE Mesh ID
NEG[X,Y,Z], POS[X,Y,Z]	Determine where the boundary condition is applied to the mesh. NEGX, POSX, NEGY, POSY, NEGZ, or POSZ means the mesh faces with an outward normal vector in the local -x, +x, -y, +y, -z, or +z-directions, respectively. EQ.0: The boundary condition is *not* applied to faces with this outward normal. EQ.1: The boundary condition is applied to faces with this outward normal.

Example:

The following input specifies no flow boundary conditions on faces with normal vectors in the -*y* and -*z*-directions and non-reflecting boundary conditions on the faces with normal vectors in the -*x*, +*x*, +*y*, and +*z*-directions.

```
*BOUNDARY_SALE_MESH_FACE
$   option     mshid      NEGX      POSX      NEGY      POSY      NEGZ      POSZ
    NOFLOW         1                              1                 1
   NONREFL         1         1         1                 1                   1
```

Internally, the above input is translated to the following keywords:

```
*BOUNDARY_SPC_SET
         1                   0         1         0
*BOUNDARY_SPC_SET
         2                   0         0         1
*SET_NODE_GENERAL
$       SID
         1
$   OPTION     MSHID       XMN       XMX       YMN       YMX       ZMN       ZMX
   SALEFAC         1                              1
*SET_NODE_GENERAL
$       SID
         2
$   OPTION     MSHID       XMN       XMX       YMN       YMX       ZMN       ZMX
   SALEFAC         1                                                   1
*BOUNDARY_NON_REFLECTING
$       SID
        11
*SET_SEGMENT_GENERAL
$       SID
        11
$   OPTION     MSHID       XMN       XMX       YMN       YMX       ZMN       ZMX
   SALEFAC         1         1         1                 1                   1
```

In comparison to the translated version, *BOUNDARY_SALE_MESH_FACE provides a more streamlined, intuitive approach to facilitate the boundary condition setup for S-ALE models. This method is particularly useful when the mesh is tilted since the local coordinate system is already assumed.

*BOUNDARY_SLIDING_PLANE

Purpose: Define a sliding symmetry plane. This option applies to continuum domains modeled with solid elements.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	VX	VY	VZ	COPT			
Type	I	F	F	F	I			
Default	none	0	0	0	0			

VARIABLE	DESCRIPTION
NSID	Nodal set ID, see *SET_NODE
VX	x-component of vector defining normal or vector
VY	y-component of vector defining normal or vector
VZ	z-component of vector defining normal or vector
COPT	Option: EQ.0: node moves on normal plane. EQ.1: node moves only in vector direction.

Remarks:

Any node may be constrained to move on an arbitrarily oriented plane or line depending on the choice of COPT. Each boundary condition card defines a vector originating at (0,0,0) and terminating at the coordinates defined above. Since an arbitrary magnitude is assumed for this vector, the specified coordinates are non-unique and define only a direction. Use of *BOUNDARY_SPC is preferred over *BOUNDARY_SLIDING_PLANE as the boundary conditions imposed using the latter have been seen to break down somewhat in lengthy simulations owing to numerical roundoff.

***BOUNDARY_SPC**_*OPTION1_{OPTION2}_{OPTION3}*

OPTION1 is required since it specifies whether the SPC applies to a single node or to a set. The two choices are:

NODE

SET

OPTION2 allows optional birth and death times to be assigned the single node or node set:

BIRTH_DEATH

This option requires one additional line of input. The BIRTH_DEATH option is inactive during the dynamic relaxation phase, which allows the SPC to be removed during the subsequent normal analysis phase. The BIRTH_DEATH option can be used only once for any given node and if used, no other *BOUNDARY_SPC commands can be used for that node.

OPTION3 allows an optional ID to be given that applies either to the single node or to the entire set:

ID

If a heading is defined with the ID, then the ID with the heading will be written at the beginning of the ASCII file, spcforc. A node which appears in more than one SPC set containing an ID will only be associated with one of those IDs in spcforc.

Purpose: Define nodal single point constraints. Do not use this option in r-adaptive problems since the nodal point ID's change during the adaptive step. If possible use CONSTRAINED_GLOBAL instead.

ID Card. Additional card for the ID keyword option.

Optional	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	NID/NSID	CID	DOFX	DOFY	DOFZ	DOFRX	DOFRY	DOFRZ
Type	I	I	I	I	I	I	I	I
Default	none	0	0	0	0	0	0	0

Birth/Death Card. Additional card for the BIRTH_DEATH keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	BIRTH	DEATH						
Type	F	F						
Default	0.0	10^{20}						

VARIABLE	DESCRIPTION
ID	Optional SPC set ID to which this node or node set belongs. This ID does not need to be unique
HEADING	An optional SPC descriptor that will be written into the d3hsp file and the spcforc file.
NID/NSID	Node ID or nodal set ID, see *SET_NODE.
CID	Coordinate system ID, see *DEFINE_COORDINATE_SYSTEM.
DOFX	Insert 1 for translational constraint in local x-direction.
DOFY	Insert 1 for translational constraint in local y-direction.
DOFZ	Insert 1 for translational constraint in local z-direction.
DOFRX	Insert 1 for rotational constraint about local x-axis.
DOFRY	Insert 1 for rotational constraint about local y-axis.
DOFRZ	Insert 1 for rotational constraint about local z-axis.

VARIABLE	DESCRIPTION
BIRTH	Activation time for SPC constraint. The birth time is ignored during dynamic relaxation.
DEATH	Deactivation time for the SPC constraint. The death time is ignored during dynamic relaxation.

Remarks:

Constraints are applied if for each DOF*ij* field set to 1. A value of zero means no constraint. No attempt should be made to apply SPCs to nodes belonging to rigid bodies (see *MAT_RIGID for application of rigid body constraints).

*BOUNDARY_SPC_SYMMETRY_PLANE_{OPTION}

Purpose: Constrain nodes that are within some distance (a tolerance) of a plane to have no motion orthogonal to that plane. This keyword is usually used for a geometric symmetry plane, so that the full geometry does not have to be modeled. This keyword supports both *h*- and *r*-adaptivity. Related keywords are: *BOUNDARY_SPC_SET, *CONSTRAINED_GLOBAL and *CONSTRAINED_LOCAL. Note this keyword should not be used on any node that also has *BOUNDARY_SPC applied. This keyword is supported for shells, thick shells, solids, and beams.

Available options include:

<BLANK>

SET

Card Sets. For each symmetry plane input one pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	IDSP	PID/PSID	X	Y	Z	VX	VY	VZ
Type	I	I	F	F	F	F	F	F
Default	none	none	0.0	0.0	0.0	0.0	0.0	0.0

Card 2	1	2	3	4	5	6	7	8
Variable	TOL							
Type	F							
Default	0.0/0.2							

VARIABLE	DESCRIPTION
IDSP	Identification number of the constraint. Must be unique.

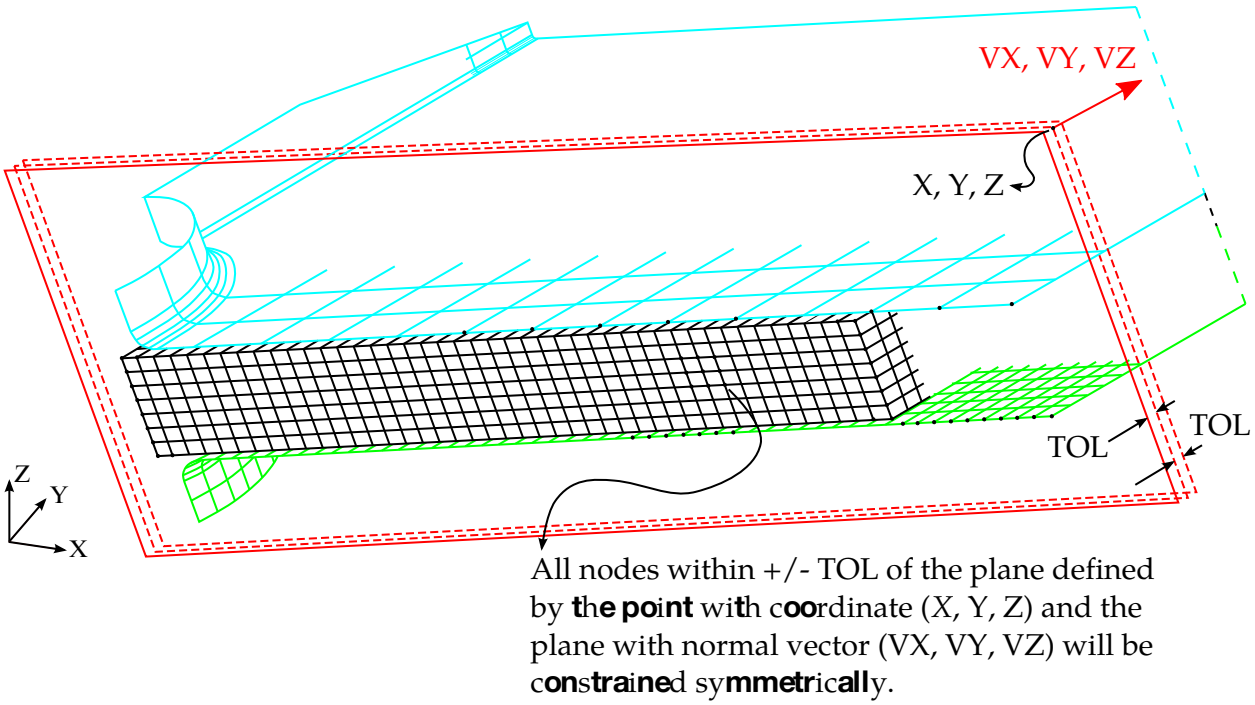

Figure 5-6. The nodes within a tolerance of the plane shown above are constrained by this keyword.

VARIABLE	DESCRIPTION
PID/PSID	When the option is blank, PID is a part ID specifying the part on which the constraint will be imposed. When the SET option is active, this field must contain a part set ID specifying the parts on which the constraint will be imposed.
X, Y, Z	Position coordinates on the symmetry plane.
VX, VY, VZ	Vector components of the symmetry plane's normal.
TOL	A distance tolerance value within which the nodes on the deformable part will be constrained. For shell elements, the default tolerance is 0.2.

Remarks:

1. **Removed Keyword Restrictions.** Originally designed for metal forming simulation only, this feature has garnered enough interest that many of the limitations have been removed, so it can be applied to other simulation fields. Two of the eliminated restrictions are:

   a) Only two such (symmetry plane) definitions can be used when the symmetry planes are not parallel to the global *XY*, *YZ*, or *ZX* planes, and,

b) For multiple symmetry planes, position coordinates defined by the variables X, Y, and Z on all symmetry planes must have the same values for these fields.

Starting from Dev Revision 124156, more than two symmetric planes can be defined even if they are not aligned with the global coordinate systems. Each symmetric plane can also be defined with distinctive point coordinates.

2. **Plane Definition.** As shown in Figure 5-6, a symmetric plane's position is defined using a point's coordinates X, Y and Z, and the plane's orientation is defined by the vector component VX, VY and VZ. All nodes within a specified tolerance TOL will be constrained in motion orthogonal to the plane.

3. **Tailor-Welded Blanks.** The option SET allows for symmetric boundary conditions to be applied on tailor-welded blanks (TWB), where two pieces of sheet metal with different thickness or properties are welded in the butt joint configuration.

Example:

The following input creates symmetric constraints on nodes (from PID 11) within distance of 0.1 mm from the defined symmetry plane having a normal vector (1.0,1.0,1.0) passing through point $(10.5, 40.0, 20.0)$.

```

$      TOL
      0.10
```

Revision Information:

This feature is available starting in Dev Revision 85404. The option SET is available starting in Dev Revision 113355. Limitations are removed in Dev Revision 124156 on the number of planes and point coordinates defining the plane's position.

*BOUNDARY_SPH_FLOW

Purpose: Define a flow of particles. This option applies to continuum domains modeled with SPH elements.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	STYP	DOF	VAD	LCID	SF	DEATH	BIRTH
Type	I	I	I	I	I	F	F	F
Default	none	none	none	0	none	1.0	10^{20}	0.0

Card 2	1	2	3	4	5	6	7	8
Variable	NODE	VID						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
NSID, PID	Nodal set ID (NSID) or part ID (PID).
STYP	Set type: EQ.1: part set ID, see *SET_PART, EQ.2: part ID, see *PART, EQ.3: node set ID, see *SET_NODE.
DOF	Applicable degrees-of-freedom: EQ.1: x-translational degree-of-freedom, EQ.2: y-translational degree-of-freedom, EQ.3: z-translational degree-of-freedom, EQ.4: translational motion in direction given by VID. Movement on plane normal to the vector is permitted.

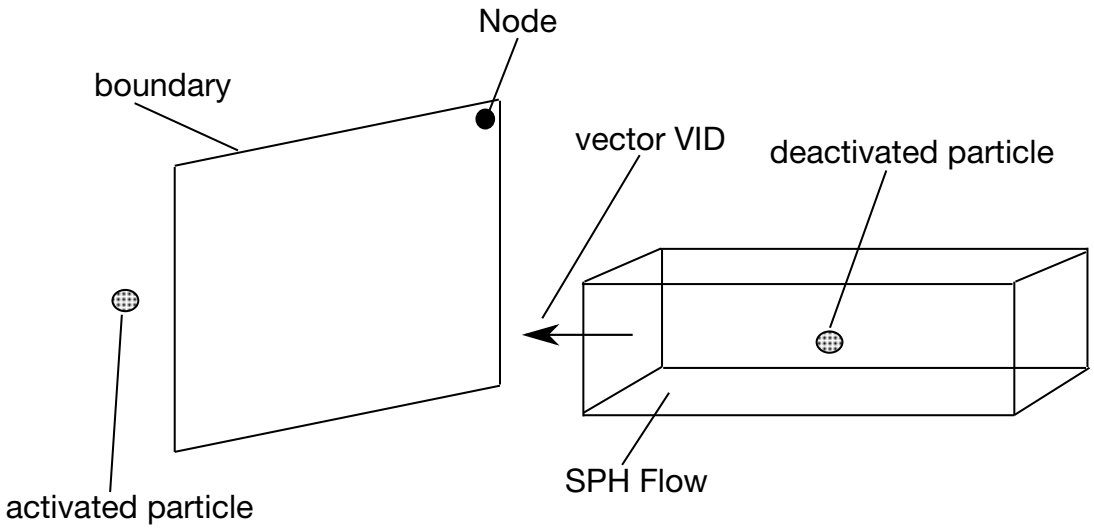

Figure 5-7. Vector VID determines the orientation of the SPH flow

VARIABLE	DESCRIPTION
VAD	Velocity / Acceleration / Displacement flag applied to SPH elements before activation: EQ.0: velocity, EQ.1: acceleration, EQ.2: displacement.
LCID	Load curve ID to describe motion value as a function of time; see *DEFINE_CURVE.
SF	Load curve scale factor.
DEATH	Time imposed motion / constraint is removed: EQ.0.0: default set to 10^{20}.
BIRTH	Time imposed motion / constraint is activated.
NODE	Node fixed in space which determines the boundary between activated particles and deactivated particles.
VID	Vector ID for defining the orientation of the SPH flow; see *DEFINE_VECTOR.

Remarks:

Initially, the user defines the set of particles that are representing the flow of particles during the simulation. At time t = 0, all the particles are deactivated which means that

no particle approximation is calculated. The boundary of activation is a plane determined by the NODE and normal to the vector VID. The particles are activated when they reached the boundary. When they are activated, particle approximation begins.

*BOUNDARY_SPH_NON_REFLECTING

Purpose: Define a non-reflecting boundary plane for SPH. This option applies to continuum domains modeled with SPH elements.

Card 1	1	2	3	4	5	6	7	8
Variable	VTX	VTY	VTZ	VHX	VHY	VHZ		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
VTX	x-coordinate of tail of a normal vector originating on the wall (tail) and terminating in the body (head); that is, the vector points from the non-reflecting boundary plane to the body.
VTY	y-coordinate of tail
VTZ	z-coordinate of tail
VHX	x-coordinate of head
VHY	y-coordinate of head
VHZ	z-coordinate of head

Remarks:

1. **Non-reflecting Boundary Plane Orientation.** The non-reflecting boundary plane has to be normal to either the x, y or z direction.

2. **Non-reflecting Boundary Plane Location.** The non-reflecting boundary plane has to be placed $h/2$ away from the SPH part, where h is the interparticle distance.

*BOUNDARY_SPH_NOSLIP

Purpose: Impose a no-slip boundary condition for continuum domains modeled with SPH elements. This is accomplished by doing the following to dummy particles: (1) adding a user-specified fictitious velocity to the (possibly non-zero) existing velocity, (2) ensuring the density stays constant throughout the simulation, (3) interpolating pressure using only the neighboring particles that are not part of the no-slip boundary condition, (4) zeroing out forces due to other SPH phenomena, and (5) subtracting the fictitious velocity at the end of the time step.

Card 1	1	2	3	4	5	6	7	8
Variable	DPID	DPIDTYP	CID	VID	LCID			
Type	I	I	I	I	I			
Default	none	none	0	none	none			

VARIABLE	DESCRIPTION
DPID	Node, nodal set, part, or part set ID used to identify dummy particles.
DPIDTYP	ID type: EQ.1: Node ID, see *NODE, EQ.2: Node set ID, see *SET_NODE, EQ.3: Part ID, see *PART, EQ.4: Part set ID, see *SET_PART.
CID	Local coordinate system ID used to define the components of the velocity vector; see *DEFINE_COORDINATE_SYSTEM for example.
VID	Vector ID for defining the fictitious velocity applied to no-slip particles; see *DEFINE_VECTOR.
LCID	Load curve ID to describe the scaling factor for the velocity vector as a function of time; see *DEFINE_CURVE.

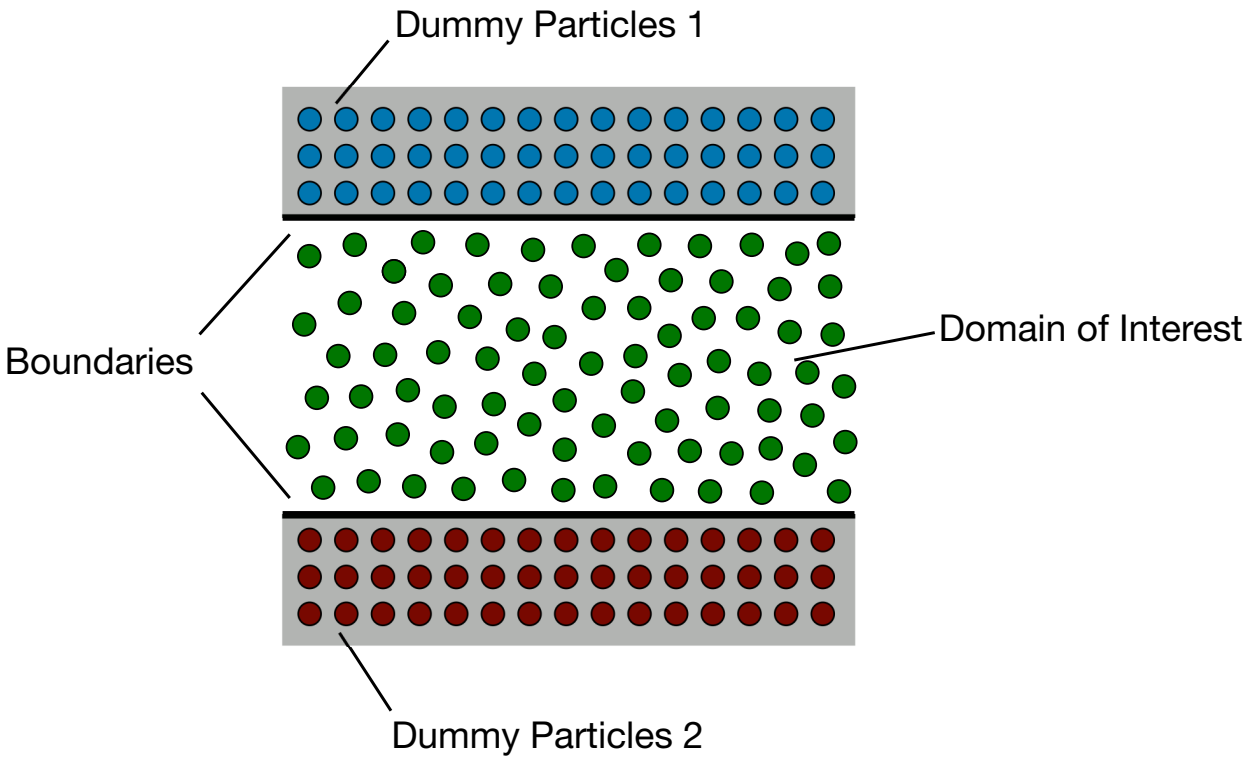

Figure 5-8. Neighboring particles (dummy particles 1 and 2) beyond the boundary must be defined in the input file

Remarks:

1. **SPH Elements.** The SPH elements used to impose the no-slip boundary conditions are dummy particles that extend beyond the domain of interest and must be defined in the input file. We recommend using three to four layers of dummy particles as shown in Figure 5-8.

2. **Velocity.** The velocity specified here is added to any other imposed velocity when calculating internal forces that involve the dummy particles but omitted when computing displacement of said dummy particles. Hence, this keyword can be used in combination with others that assign a velocity to SPH particles.

*BOUNDARY_SPH_SYMMETRY_PLANE

Purpose: Define a symmetry plane for SPH. This option applies to continuum domains modeled with SPH elements.

Card 1	1	2	3	4	5	6	7	8
Variable	VTX	VTY	VTZ	VHX	VHY	VHZ		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
VTX	x-coordinate of tail of a normal vector originating on the wall (tail) and terminating in the body (head) (that is, vector points from the symmetry plane into the body).
VTY	y-coordinate of tail
VTZ	z-coordinate of tail
VHX	x-coordinate of head
VHY	y-coordinate of head
VHZ	z-coordinate of head

Remarks:

1. **SPH Elements.** A plane of symmetry is assumed for all SPH elements defined in the model.

2. **Plane Orientation.** The plane of symmetry has to be normal to either the x, y or z-direction.

3. **Plane Location.** The plane of symmetry is typically placed $h/2$ away from the SPH part, where h is the interparticle distance.

4. **Axisymmetric SPH.** For axisymmetric SPH analysis, IDIM = -2 (see *CONTROL_SPH), a plane of symmetry centered at the global origin and normal to x-direction is automatically created by LS-DYNA.

*BOUNDARY_SYMMETRY_FAILURE

Purpose: Define a symmetry plane with a failure criterion. This option applies to continuum domains modeled with solid elements.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	FS	VTX	VTY	VTZ	VHX	VHY	VHZ
Type	I	F	F	F	F	F	F	F
Default	none	0.	0.	0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT
FS	Tensile failure stress > 0.0. The average stress in the elements surrounding the boundary nodes in a direction perpendicular to the boundary is used.
VTX	x-coordinate of tail of a normal vector originating on the wall (tail) and terminating in the body (head), that is, vector points from the symmetry plane into the body.
VTY	y-coordinate of tail
VTZ	z-coordinate of tail
VHX	x-coordinate of head
VHY	y-coordinate of head
VHZ	z-coordinate of head

Remarks:

A plane of symmetry is assumed for the nodes on the boundary at the tail of the vector given above. Only the motion perpendicular to the symmetry plane is constrained. After failure the nodes are set free.

BOUNDARY_TEMPERATURE_*OPTION

Available options include:

NODE

SET

Purpose: Define temperature boundary conditions for a thermal or coupled thermal/structural analysis. In a structural-only analysis, use *LOAD_THERMAL_OPTION to define temperatures (see also SOLN in *CONTROL_SOLUTION).

Card 1	1	2	3	4	5	6	7	8
Variable	NID	TLCID	TMULT	LOC	TDEATH	TBIRTH		
Type	I	I	F	I	F	F		
Default	none	0	0.	0	10^{20}	0.		

VARIABLE	DESCRIPTION
NID	Node or node set ID
TLCID	Temperature, T, specification. This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 2). When the reference is to a curve, TLCID has the following interpretation: GT.0: T is defined by a curve consisting of (t, T) data pairs. EQ.0: T is a constant defined by the value TMULT.
TMULT	Temperature, T, curve multiplier.
LOC	Application of surface for thermal shell elements, see parameter, THSHEL, in the *CONTROL_SHELL input: EQ.-1: Lower surface of thermal shell element EQ.0: Middle surface of thermal shell element EQ.1: Upper surface of thermal shell element
TDEATH	Deactivation time for temperature boundary condition. At this point in time the temperature constraint is removed.

VARIABLE	DESCRIPTION
TBIRTH	Activation time for temperature boundary condition. Before this point in time the temperature constraint is ignored.

Remarks:

1. **SPH Particles.** This keyword can be used to apply temperature boundary conditions to SPH particles.

2. **Temperature Function.** If TLCID references a *DEFINE_FUNCTION, temperature may be a function of the nodal point coordinates, the nodal point velocity components, and the solution time, that is, "f(x,y,z,vx,vy,vz,time)."

*BOUNDARY_TEMPERATURE_PERIODIC_SET

Purpose: Specify different kinds of periodic boundary conditions for temperature.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID1	PTYPE	SSID2	TDLCID	AXE	NID	ANGLE	
Type	I	I	I	I	I	I	F	
Default	none	none	none	0	none	none	none	

VARIABLE	DESCRIPTION
SSID1	First segment set on which the periodic temperature boundary condition will be applied. See Remark 1.
PTYPE	Type of periodic boundary condition: EQ.1: Rotation boundary condition defined by an axis, an origin point and a rotation angle EQ.2: Reflective boundary condition defined by an axis and origin point EQ.3: Sliding boundary condition
SSID2	Second segment set on which the periodic temperature boundary condition will be applied.
TDCLID	Optional load curve specifying the temperature drop, T_{drop}, between the two surfaces in the periodic boundary condition as a function of time. Note that $T_{drop} = T_1 - T_2$ where T_1 is the temperature of the surface specified with SSID1 and T_2 is the temperature of the surface specified with SSID2. EQ.0: No temperature drop between that surfacs, that is, $T_{drop} = 0.0$
AXE	Axis for PTYPE = 1 or 2: EQ.1: X-axis EQ.2: Y-axis EQ.3: Z-axis

VARIABLE	DESCRIPTION
	Flag for meaning of ANGLE for PTYPE = 3. Setting AXE = 1 means that ANGLE is the contact distance. Otherwise, it is a scale factor on the contact distance search.
NID	Node ID giving the origin point coordinates
ANGLE	Rotation angle if PTYPE = 1. Scaling factor on contact distance search if PTYPE = 3 (default applies a scale factor of 0.3 on local element size). If AXE = 1 and PTYPE = 3, then ANGLE becomes the contact distance.

Remarks:

1. **Constraint-based method.** LS-DYNA applies these boundary conditions with a constraint-based method. For each node in SSID1 LS-DYNA finds a host face in SSID2 and applies correct weights to define a new constraint to add to the system. For PTYPE = 1 and 2, the meshes on both sides do not have to be identical, but we recommend matching meshes. PTYPE = 3 can be used to define a "perfect" thermal contact between two solids.

*BOUNDARY_TEMPERATURE_RSW

Purpose: Define temperature boundary conditions within an ellipsoidal region of the solid or shell structure. Temperatures are prescribed to nodes found in a region defined by this keyword. The boundary condition is tailored to represent the so-called weld nuggets evolving during resistive spot welding (RSW) processes. It is applicable to a thermal or coupled thermal/structural analysis.

Card 1	1	2	3	4	5	6	7	8
Variable	SID	OPTION	NID1	NID2	TDEATH	TBIRTH	LOC

Default	none	0	none	none	10^{20}	0.	0	

Geometry and Temperature Card.

Card 2	1	2	3	4	5	6	7	8
Variable	DIST	H1	H2	R	TEMPC	TEMPB	LCIDT	
Type	F	F	F	F	F	F	I	
Default	0.	0.	0.	0.	0.	0.	none	

Heat Affected Zone Card. Additional card for OPTION = 1.

Card 3	1	2	3	4	5	6	7	8
Variable	HZ1	HZ2	RZ	TEMPZB				
Type	R	F	F	R				
Default	0.	0.	0.	0.				

VARIABLE	DESCRIPTION
SID	Node Set ID; see *SET_NODE_*OPTION*. Nodes in the set will be checked to see if they are in the nugget or heat affected zone. If

VARIABLE	DESCRIPTION
	they are, the boundary condition will be applied. The boundary condition will not be applied to nodes in these regions if they are not included in the set.
NID1	Node defining the tail of the orientation vector (axis of rotation of the ellipsoidal region) and the base for positioning of the nugget. See Remarks 1 and 2.
NID2	Node defining the head of the orientation vector (axis of rotation of the ellipsoidal region). See Remarks 1 and 2.
OPTION	Option for heat affected zone around the weld nugget: EQ.0: No heat affected zone EQ.1: Ellipsoidal region considered
TDEATH	Deactivation time for temperature boundary condition. At this point in time the temperature constraint is removed.
TBIRTH	Activation time for temperature boundary condition. Before this point in time the temperature constraint is ignored.
LOC	Application of surface for thermal shell elements; see parameter, THSHEL, in the *CONTROL_SHELL input: EQ.-1: Lower surface of thermal shell element EQ.0: Middle surface of thermal shell element EQ.1: Upper surface of thermal shell element
DIST	Position of center of nugget on the axis of rotation. Parameter defines the distance to NID1 along the orientation vector. See Remark 1.
H1	Half width h_1 of nugget in the lower half, meaning in direction to NID1. See Remark 2.
H2	Half width h_2 of nugget in the upper half, meaning in direction to NID2. See Remark 2.
R	Radius r_{weld} of the nugget in surface normal to orientation vector. See Remark 2.
TEMPC	Base temperature at the center of the nugget. See Remark 3.
TEMPB	Base temperature at the boundary of the nugget. See Remark 3.

VARIABLE	DESCRIPTION
LCIDT	|LCIDT| refers to the load curve ID prescribing the temperature evolution in the nugget as a function of time. The abscissa of the load curve will be normalized between the birth and death times of the boundary condition. GT.0: The ordinate values of the load curve scale the respective base temperature of a particular point. EQ.0: No temperature evolution. Base temperatures are used. LT.0: The ordinate values of the load curve are used to define a linear combination between the temperature at the birth time and the base temperature of a particular point. Load curve ordinate values should range between 0.0 and 1.0. We recommend LCIDT < 0 to ensure a smooth temperature evolution. See Remark 3.
HZ1	Half width h_{z1} of heat affected zone in the lower half, meaning in direction to NID1. Only active for OPTION = 1. See Remark 4.
HZ2	Half width h_{z2} of heat affected zone in the upper half, meaning in direction to NID1. Only active for OPTION = 1. See Remark 4.
RZ	Radius r_{haz} of the heat affected zone in surface normal to orientation vector. See Remark 4.
TEMPBZ	Base temperature at the boundary of the heat affected zone for OPTION = 1. See Remark 4.

Remarks:

1. **Positioning.** The position of the center of the nugget is defined starting from a base node (NID1). It is then translated by a distance DIST along the orientation vector **v** of the nugget. Vector **v** points from NID1 to NID2. See Figure 5-9.

2. **Geometry of the Nugget.** Orientation vector **v** defines the axis of rotational symmetry for the ellipsoidal region, which reflects the weld nugget. The radius around this axis is defined by r_{weld}. The nugget consists of two half ellipsoids of possibly different height. The lower half, i.e. the half between NID1 and the center, has a height of h_1, wheras the upper half has a height of h_2. See Figure 5-9.

3. **Prescribing Temperature Values.** You can prescribe the base temperatures at the boundary and the center of the nugget with TEMPC and TEMPB,

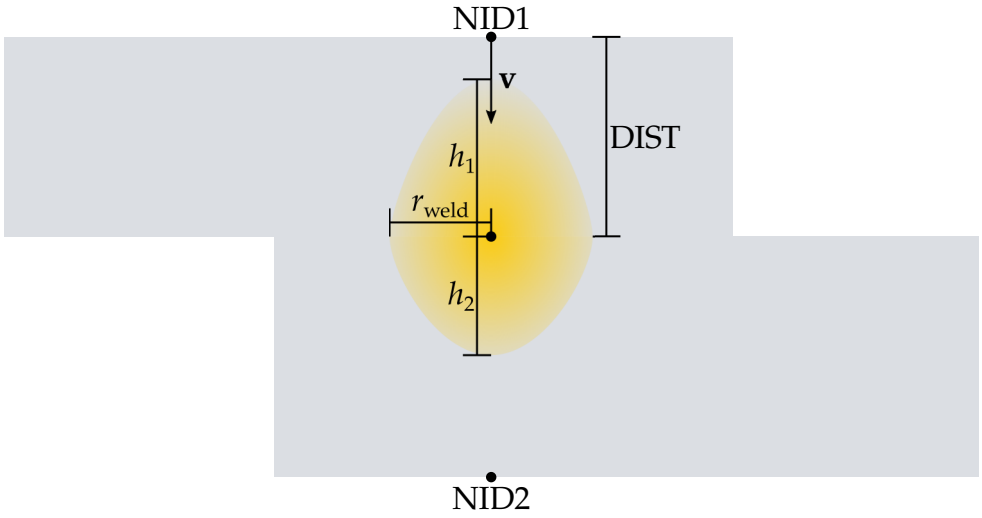

Figure 5-9. Example of geometry for OPTION = 0

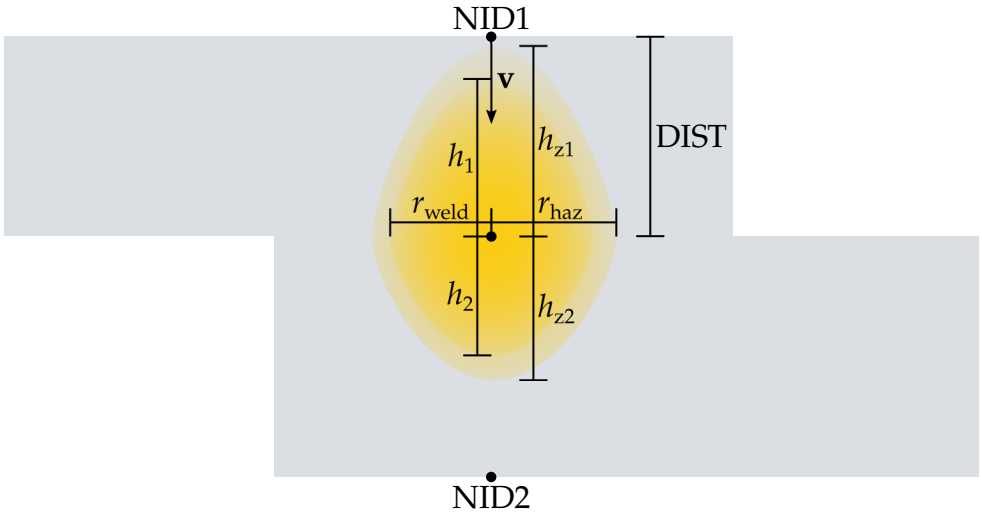

Figure 5-10. Example of geometry with OPTION = 1 (heat affected zone)

respectively. In between LS-DYNA calculates the base temperature in the nugget, $T_{\mathrm{nug},b}(x,y,z)$, with a quadratic interpolation.

For this boundary condition you must provide activation and deactivation times, t_{ac} and t_{deac}, respectively. With LCIDT, you can specify the temperatures as a function, $\theta(\tilde{t})$, of the normalized time, $\tilde{t} = (t - t_{\mathrm{ac}})/(t_{\mathrm{deac}} - t_{\mathrm{ac}})$, within this time span. For positive values of field LCIDT, a simple scaling is applied:

$$T_{\mathrm{nug}}(x,y,z,t) = T_{\mathrm{nug},b}(x,y,z) \times \theta(\tilde{t}(t)) \quad .$$

For negative values of LCIDT, a smooth evolution of the temperature from the birth time is ensured, so we recommend this type of load curve. The temperature is given by:

$$T_{\mathrm{nug}}(x,y,z,t) = T_{\mathrm{ac}}(x,y,z) + \Big(T_{\mathrm{nug},b}(x,y,z) - T_{\mathrm{ac}}(x,y,z)\Big) \times \theta(\tilde{t}) \quad .$$

Here T_{ac} corresponds to the temperature of a particular point right before the birth time.

4. **Heat Affected Zone.** With input field OPTION set to 1, the boundary condition expands to a heat affected zone that has the same general shape definition as the weld nugget described in Remark 2. The dimensions are here given by r_{haz}, h_{z1}, and h_{z2}. See Figure 5-10.

   You can prescribe the base temperature value at the boundary of the heat affected zone. LS-DYNA finds the base temperature in the heat affected zone, $T_{HAZ,b}(x,y,z)$ with a linear interpolation between the base boundary temperature of the nugget and the base boundary temperature of the heat affected zone. The load curve LCIDT governs the temperature evolution of the heat affected zone as described in Remark 3.

*BOUNDARY_TEMPERATURE_TRAJECTORY

Purpose: Apply a temperature boundary condition on nodes enclosed in either a cylindrical or rectangular prism volume moving along a trajectory. The center of the volume moves along the trajectory defined by a nodal path at a prescribed velocity. This keyword applies only to solid elements.

Card 1	1	2	3	4	5	6	7	8

Optional Volume Orientation Card. Additional card for NSID2 = 0.

Card 4	1	2	3	4	5	6	7	8
Variable	TX	TY	TZ					
Type	F	F	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
PID	Part ID or part set ID to which the temperature boundary condition will be applied
PTYP	PID type: EQ.1: Part ID EQ.2: Part set ID
NSID1	Node set defining the path of the moving volume. The moving volume travels along the path at speed SPD1. The nodes are traversed according to their order in the node set. See Remark 1.
SPD1	Speed of the moving volume on the trajectory: GT.0.0: Constant speed LT.0.0: |SPD1| is a load curve ID defining the speed as a function of time.
NSID2	Node or segment set that specifies the orientation of the moving volume's center axis. GT.0: NSID2 together with SPD2 define a curve in the same way that NSID1 and SPD1 define a curve. Orientation of the moving volume's center axis is defined as a vector pointing from the current position on NSID2 to the current position on NSID1. EQ.0: The moving volume's center axis is oriented as (TX, TY, TZ) input on Card 4.

VARIABLE	DESCRIPTION
	LT.0: |NSID2| specifies a segment set. The moving volume's center axis is aligned with normals to segments in this set. To ensure that the axis orientation can be unambiguously determined at each point of the nodal path, LS-DYNA requires that each pair of consecutive nodes in NSID1 must both be in at least one segment of |NSID2|. When the center of the moving volume is on a node that is part of more than one segment in |NSID2|, the direction is determined by averaging the adjacent segment normals.
SPD2	Speed of reference point in NSID2 (ignored unless NSID2 > 0): GT.0: Constant speed LT.0: |SPD2| is a load curve ID defining the speed as a function of time.
RELVEL	Flag for whether SPD1 and SPD2 are relative or absolute speeds in a thermo-mechanical coupled analysis: EQ.0: Absolute speeds EQ.1: Relative speeds with respect to underlying structures
IFORM	Geometric description of the moving volume. See Remark 3 for details.
LCID	Load curve ID for temperature as a function of time. EQ.0: Temperature is a constant defined by the value TMULT.
TMULT	Curve multiplier for temperature
LCROT	Load curve defining the rotation angle (in degrees) of the moving volume around the trajectory as a function of time. See Remark 2.
LCMOV	Load curve defining the offset of the moving volume along its center axis as a function of time. See Remark 2.
LCLAT	Load curve defining the lateral offset of the moving volume as a function of time. See Remark 2.
P*i*	Parameters defining the moving volume's geometry. The meaning of each parameter depends on field IFORM. See Remark 3 and Figure 5-11 for details.

VARIABLE	DESCRIPTION
TX, TY, TZ	Orientation vector of the moving volume's center axis in global coordinates (NSID2 = 0 only)

Remarks:

1. **Volume Motion.** If NSID1 consists of nodes belonging to a certain part, the moving volume will follow the motion of the part. By setting field RELVEL to 1 the velocity of the moving volume can be defined relative to the motion of the nodes in NSID1.

2. **Volume Orientation.** There is a natural local coordinate system $(\mathbf{r}, \mathbf{s}, \mathbf{t})$ associated with the motion of the moving volume. The relative velocity vector on the trajectory of the moving volume defines the "forward" direction $\mathbf{r}$. The orientation vector aligned with the moving volume's center axis is denoted by $\mathbf{t}$. $\mathbf{s}$ is defined as $\mathbf{s} = \mathbf{t} \times \mathbf{r}$ by the right-handed rule and denotes the lateral direction.

   The position and orientation of the moving volume can be adjusted by rotating and translating the local coordinate system. Note that the system is always first rotated around the vector $\mathbf{r}$ by a value given by the load curve LCROT, resulting in a new local coordinate system $(\mathbf{r}, \mathbf{s}', \mathbf{t}')$. Then, the system is translated in directions $\mathbf{t}'$ and $\mathbf{s}'$ according to values specified by LCMOV and LCLAT, respectively.

3. **Volume Geometry.** The moving volume can be either a cylinder or rectangular prism, depending on the values defined in field IFORM (see Figure 5-11).

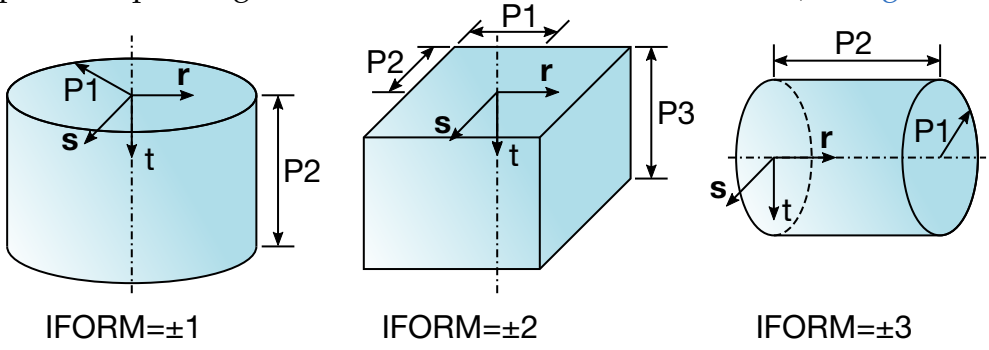

Figure 5-11. Definition of the geometry parameters

   a) *Cylinder (IFORM = 1* or *IFORM = -1).* P1 denotes the radius of the cylinder and P2 denotes the height of the cylinder. In the case that *IFORM = -1*, P1 and P2 are load curves that define the cylinder radius and height as functions of time.

b) *Rectangular Prism (IFORM = 2* or *IFORM = -2).* P1 denotes half the length of the rectangular prism, P2 denotes half width of the rectangular prism, and P3 denotes the height of the rectangular prism. In the case that *IFORM = -2*, P1, P2 and P3 are load curves that define the prism's half length, half width and heig ht as functions of time.

c) *Radially Oriented Cylinder (IFORM = 3* or *IFORM = -3).* P1 denotes the radius of the cylinder and P2 denotes the height of the cylinder. In the case that *IFORM = -3*, P1 and P2 are load curves that define the cylinder radius and height as functions of time. This cylinder differs from that defined by IFORM = ±1 in that the orientation vector, **t**, is along a radial direction instead of the length of the cylinder.

BOUNDARY_THERMAL_BULKFLOW_*OPTION1_OPTION2

Purpose: Used to define bulk fluid flow elements.

OPTION1 is required since it specifies whether the BULKFLOW applies to an element or set.

ELEMENT

SET

OPTION2 if used turns on the fluid upwind algorithm

UPWIND

Card 1	1	2	3	4	5	6	7	8
Variable	EID/SID	LCID	MDOT					
Type	I	I	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
EID / SID	Beam element ID (EID) for ELEMENT option Beam set ID (SID) for SET option
LCID	Load Curve ID for mass flow rate versus time.
MDOT	Mass flow rate (e.g. kg/sec).

*BOUNDARY_THERMAL_BULKNODE

Purpose: Used to define thermal bulk nodes.

Card 1	1	2	3	4	5	6	7	8
Variable	NID	PID	NBNSEG	VOL	LCID	H	AEXP	BEXP
Type	I	I	I	F	I	F	F	F
Default	none	none	0	none	0	0.	0.	0.

Bulk Node Cards. Include NBNSEG cards, one for each bulk node segment.

Card 2	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4				
Type	I	I	I	I				

VARIABLE	DESCRIPTION
NID	Bulk node number.
PID	Bulk node part ID.
VOL	Bulk node volume.
NBNSEG	Number of element surface segments that transfer heat with this bulk node.
N1, N2, N3, N4	Nodal point numbers
LCID	Load curve ID for H
H	Heat transfer coefficient
AEXP	*a* exponent
BEXP	*b* exponent

Remarks:

The heat flow between a bulk node (T_B) and a bulk node segment (T_S) is given by

$$q = h(T_B^a - T_B^a)^b$$

1. For convection, set $a = b = 1$.

2. For radiation, set $a = 4,\ b = 1$.

3. For flux, set $a = b = 0$. Mathematically, anything to the 0 power is 1. This produces the expression, $\left(T_B^0 - T_S^0\right)^0 = (1-1)^0 = 0^0 = 1$. However, some computer operating systems don't recognize 0^0. It is safer to set $a = b =$ very small number.

*BOUNDARY_THERMAL_WELD

Purpose: Define a moving heat source to model welding. Only applicable for coupled thermal-structural simulations in which the weld source or work piece is moving.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	PTYP	NID	NFLAG	X0	Y0	Z0	N2ID
Type	I	I	I	I	F	F	F	I
Default	none	1	↓	1	↓	↓	↓	none

Card 2	1	2	3	4	5	6	7	8
Variable	a	b	cf	cr	LCID	Q	Ff	Fr
Type	F	F	F	F	I	F	F	F
Default	none	none	none	none	Q	none	none	none

Beam Aiming Direction Card. Additional card for N2ID = -1.

Card 3	1	2	3	4	5	6	7	8
Variable	TX	TY	TZ					
Type	F	F	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
PID	Part ID or Part Set ID to which weld source is applied
PTYP	PID type: EQ.1: PID defines a single part ID EQ.2: PID defines a part set ID

VARIABLE	DESCRIPTION
NID	Node ID giving location of weld source EQ.0: location defined by $(X0, Y0, Z0)$ below
NFLAG	Flag controlling motion of weld source EQ.1: source moves with node NID EQ.2: source is fixed in space at original position of node NID
X0, Y0, Z0	Coordinates of weld source, which remains fixed in space (ignored if NID is nonzero)
N2ID	Second node ID for weld beam aiming direction GT.0: beam is aimed from N2ID to NID, moves with these nodes EQ.-1: beam aiming direction is (TX, TY, TZ) input on Card 3
a	Weld pool radius (i.e., half width)
b	Weld pool depth (in beam aiming direction)
cf	Weld pool forward direction
cr	Weld pool rearward direction
LCID	Load curve ID for weld energy input rate as a function of time EQ.0: use constant multiplier value Q.
Q	Curve multiplier for weld energy input rate [energy/time, e.g., Watt] LT.0.0: use absolute value and accurate integration of heat
Ff	Forward distribution function
Fr	Rear distribution function (Note:$F_f + F_r = 2.0$)
TX, TY, TZ	Weld beam direction vector in global coordinates (N2ID = -1 only)

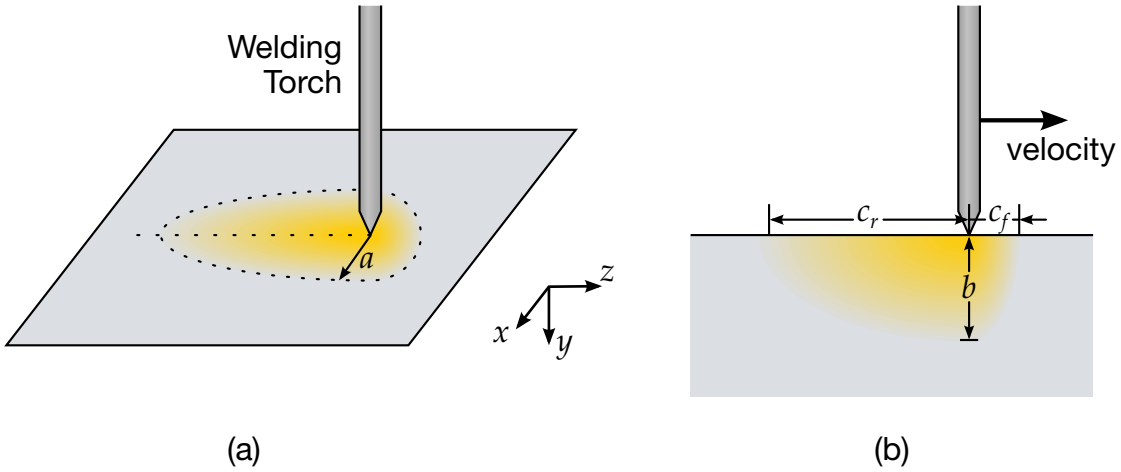

Figure 5-12. Schematic illustration of welding with moving torch. The left figure (a) shows the surface of the material from above, while the right figure (b) shows a slice along the dotted line in the y-z plane.

Remarks:

1. **Boundary Condition Model.** This boundary condition allows simulation of a moving weld heat source, following the work of Goldak, Chakravarti, and Bibby [1984]. Heat is generated in an ellipsoidal region centered at the weld source, and decaying exponentially with distance according to:

$$q = \frac{6\sqrt{3}FQ}{\pi\sqrt{\pi}abc}\exp\left(\frac{-3x^2}{a^2}\right)\exp\left(\frac{-3y^2}{b^2}\right)\exp\left(\frac{-3z^2}{c^2}\right),$$

where

$$\begin{aligned} q &= \text{weld source power density} \\ (x,y,z) &= \text{coordinates of point } p \text{ in weld material} \\ F &= \begin{cases} \mathrm{F_f} \text{ if point } p \text{ is in front of beam} \\ \mathrm{F_r} \text{ if point } p \text{ is behind beam} \end{cases} \\ c &= \begin{cases} \mathrm{c_f} \text{ if point } p \text{ is in front of beam} \\ \mathrm{c_r} \text{ if point } p \text{ is behind beam} \end{cases} \end{aligned}$$

A local coordinate system center at the heat source is constructed as shown in Figure 5-12. The relative velocity vector of the heat source defines the "forward" direction, so material points that are approaching the heat source are in "front" of the beam. The beam aiming direction is used to compute the weld pool depth. The weld pool width is measured normal to the relative velocity - aiming direction plane.

If Q is defined as a negative quantity in the input, then the formula above uses the absolute value of Q, and a more accurate integration of the heat source is performed with some additional cost in CPU time.

2. **Fixed Welding Torch Simulation.** To simulate a welding process during which the welding torch is fixed in space, NID and N2ID must be set to 0 and -1 respectively. The X0, Y0, and Z0 fields specify the global coordinates of the welding torch, and the TX, TY, and TZ fields specify the direction of the welding beam. The motion of the work piece is prescribed using the *BOUNDARY_PRESCRIBED_MOTION keyword.

3. **Fixed Work Piece Simulation.** To simulate a welding process for which the work piece fixed in space, NID and N2ID specify both the beam source location and direction. The X0, Y0, Z0, TX, TY, and TZ fields *are ignored*. The motion of welding source is prescribed with using the *BOUNDARY_PRESCRIBED_MOTION keyword applied to the two nodal points specified in the NID and N2ID fields.

*BOUNDARY_THERMAL_WELD_TRAJECTORY

Purpose: Define a moving heat source to model welding of solid or shell structures. Motion of the source is described by a nodal path and a prescribed velocity on this path. This keyword is applicable in coupled thermal-structural and thermal-only simulations (see Remark 1) and also supports thermal dumping. Different equivalent heat source descriptions are implemented.

Optional Weld Source Aiming Direction Card. Additional card for NSID2 = 0.

Card 4	1	2	3	4	5	6	7	8
Variable	TX	TY	TZ					
Type	F	F	F					
Default	none	none	none					

VARIABLE	DESCRIPTION
PID	Part ID or part set ID of solid and/or shell elements that are heated by the weld source. In the case of shell elements present in the heated structure, the thermal thick element formulation must be activated. See field THSHEL on *CONTROL_SHELL or field ITHELFM on *SECTION_SHELL_THERMAL.
PTYP	PID type: EQ.1: Part ID EQ.2: Part set ID
NSID1	Node set defining the path of the weld source. The source travels along the path at speed SPD1. The nodes are traversed according to their ordering in the node set. See Remark 1.
SPD1	Speed of the heat source on the weld trajectory: GT.0.0: Constant speed LT.0.0: |SPD1| is a load curve ID defining weld speed as a function of time.
NSID2	Node or segment set containing information for the weld source aiming direction: GT.0: NSID2 together with SPD2 define a curve in the same way that NSID1 and SPD1 define a curve. Aiming direction is taken to be the vector pointing from the current position along NSID2 (for example your hand holding the torch) to the current position on NSID1 (the weld source). EQ.0: Beam aiming direction is (TX, TY, TZ), input on Card 4. LT.0: |NSID2| specifies a segment set. The heat source is aimed perpendicularly to segments in this set. To ensure that a

VARIABLE	DESCRIPTION
	direction can be unambiguously associated with each point of the weld path, LS-DYNA requires that each pair of consecutive nodes in NSID1 must *both* be in at least one segment of |NSID2|. When the source is on a node that part of more than one segment in |NSID2|, then the direction is determined by averaging the adjacent segment normal vectors.
SPD2	Speed of reference point in NSID2 (ignored unless NSID2 > 0) GT.0: Constant speed LT.0: |SPD2| is a load curve ID defining weld speed as a function of time.
NCYC	Number of sub-steps for sub-cycling in evaluation of boundary condition. Allows thermal dumping. See Remark 3.
RELVEL	Defines if SPD1 and SPD2 are relative or absolute speeds in coupled simulations EQ.0: Absolute speeds EQ.1: Relative speeds with respect to underlying structure
IFORM	Geometry description for energy rate density distribution (see Remark 4): EQ.1: Goldak-type heat source EQ.2: Double ellipsoidal heat source with constant density EQ.3: Double conical heat source with constant density EQ.4: Frustum-shaped heat source with constant density EQ.5: User-defined function
LCID	Load curve ID for weld energy input rate as a function of time EQ.0: Use constant multiplier value *Q*.
Q	Curve multiplier for weld energy input rate [energy/time] LT.0: Take absolute value and accurate integration of heat using integration cells with edge length DISC.
LCROT	Load curve defining the rotation (angle in degrees) of weld source around the trajectory as function of time. See Remark 2.

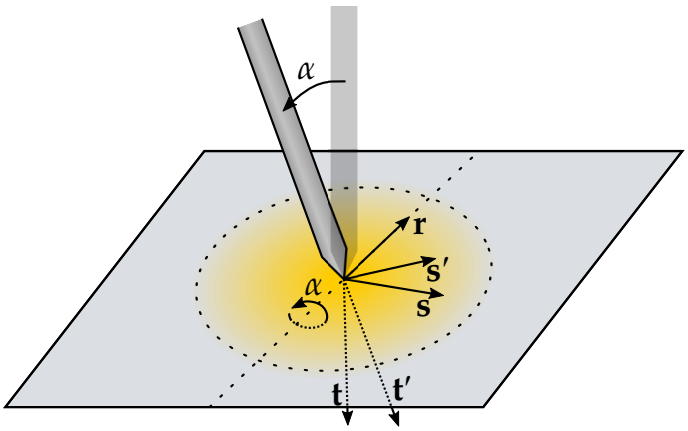

Figure 5-13. Local coordinates of the welding torch. These coordinates can be rotated about the **r**-axis to tilt the welding torch, forming a new set of local coordinates.

VARIABLE	DESCRIPTION
LCMOV	Load curve for offset of weld source in direction of the weld beam as function of time. See Remark 2.
LCLAT	Load curve for lateral offset of weld source as function of time. See Remark 2.
DISC	Resolution for accurate integration. Parameter defines edge length for integration cubes. Default is 5% of weld pool depth.
ENFOR	Flag for heat input enforcement option. If set, the nodal heat input is scaled such that the resulting heat inputs equals the user input as given by Q and LCID.
P*i*	Parameters defining for weld pool geometry, depending on field IFORM. See Remark 4 and Table 5-1 for details.
TX, TY, TZ	Weld beam direction vector in global coordinates (NSID2 = 0 only)

Remarks:

1. **Heat source motion.** As with the *BOUNDARY_THERMAL_WELD card this card can be applied to coupled thermal-structure simulations. Additionally, since the source motion can be defined independently form the motion of nodes, this card can be applied to thermal-only simulations. This keyword applies to both solid and thermal thick shells.

   If NSID1 consists of work piece nodes, then the heat source will follow the motion of the work piece. By setting field RELVEL to 1 the velocity of the heat

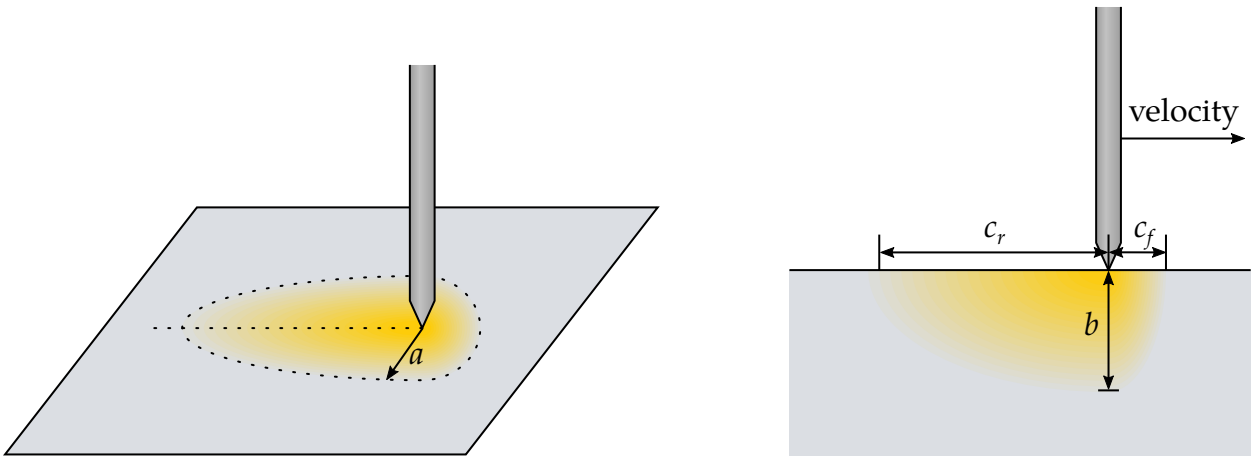

Figure 5-14. Heat source distribution geometry for IFORM = 1 and IFORM = 2

source can be defined relative to the motion of the nodes in NSID1 (the work piece).

2. **Heat source direction (tilting the torch).** There is a natural local coordinate system $(\mathbf{r}, \mathbf{s}, \mathbf{t})$ associated with the motion of the heat source. The relative velocity vector on the trajectory of the heat source defines the "forward" direction $\mathbf{r}$, so that material points that are approaching the heat source are in "front" of the beam. The weld source aiming direction, denoted by $\mathbf{t}$, determines the direction of the weld pool depth. The coordinate direction $\mathbf{s}$ is normal to the plane containing both the relative velocity and the aiming direction; note that $\mathbf{s} = \mathbf{t} \times \mathbf{r}$ to have a right handed coordinate system. It determines the direction of the weld pool width.

   The position and aiming direction of the heat source (for example tilting the torch) can be adjusted by rotating and translating the local coordinate system. To do this, the system is first rotated around the vector $\mathbf{r}$ by a value given by the load curve LCROT, resulting in a new local coordinate system $(\mathbf{r}, \mathbf{s}', \mathbf{t}')$. Then, the system is translated in directions $\mathbf{t}'$ and $\mathbf{s}'$ using LCMOV and LCLAT, respectively. See Figure 5-13.

3. **Weld source sub-cycling.** The sub-cycling method introduces an individual time step size for the weld source evaluation. During each step of the heat transfer solver, NCYC steps are used to determine the energy rate distribution of the weld source. In each sub-step, the geometry of the weld pool is updated. Therefore, even with larger thermal time steps a relatively smooth temperature field around the weld source can be obtained and a jumping heat source across elements can be suppressed.

4. **Energy rate distribution geometries.** Several different heat source geometries that can be used with this keyword are described below. The local coordinate system needed for the description of the geometry is discussed in Remark 2.

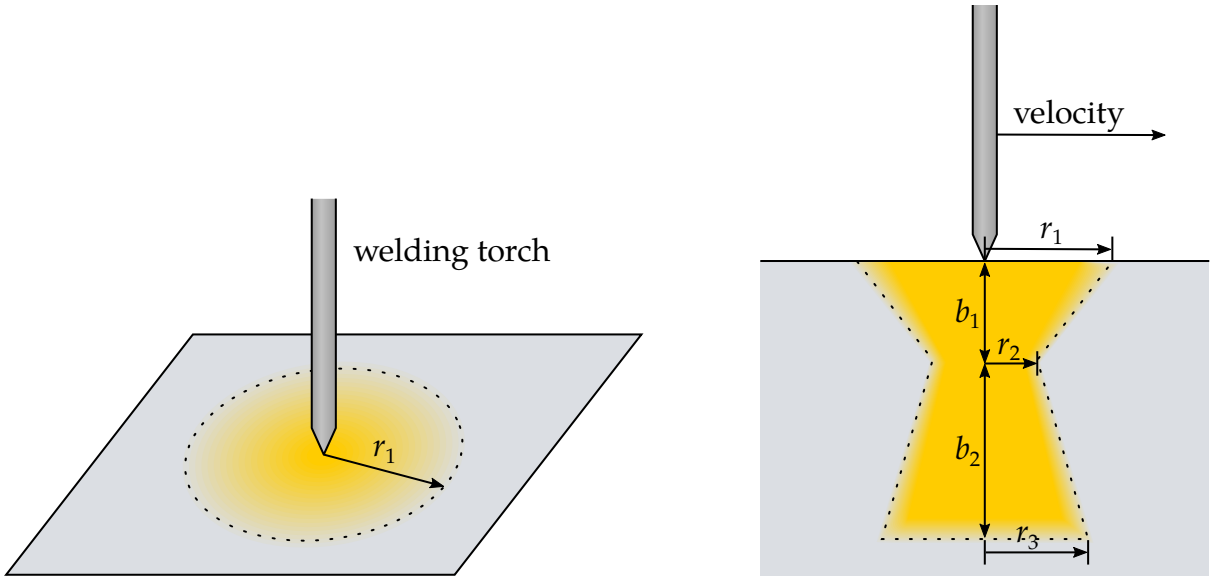

Figure 5-15. Heat source distribution geometry for IFORM = 3

For IFORM = 1 heat is generated in an ellipsoidal region centered at the weld source and decaying exponentially with distance according to the work of Goldak, Chakravarti, and Bibby [1984]. Energy rate distribution is governed by

$$q = \frac{2n\sqrt{n}FQ}{\pi\sqrt{\pi}abc}\exp\left(\frac{-nx^2}{a^2}\right)\exp\left(\frac{-ny^2}{b^2}\right)\exp\left(\frac{-nz^2}{c^2}\right),$$

where:

$$F = \begin{cases} \mathrm{F_f} \text{ if point } p \text{ is in front of beam} \\ \mathrm{F_r} \text{ if point } p \text{ is behind beam} \end{cases}$$
$$c = \begin{cases} \mathrm{c_f} \text{ if point } p \text{ is in front of beam} \\ \mathrm{c_r} \text{ if point } p \text{ is behind beam} \end{cases}$$

The local coordinates of point p are denoted by (x, y, z) and it is expected that the sum of the weighting factors $F_\mathrm{f}, F_\mathrm{r}$ equals 2. The half-width of the ellipsoid is given by a, the welding depth by b. See Figure 5-14. The complete set of parameters $(a, b, c_\mathrm{f}, c_\mathrm{r}, F_\mathrm{f}, F_\mathrm{r}, n)$ is input in the fields P1 to P7; see Table 5-1.

The energy rate density q for IFORM = 2 is assumed to be constant in the double ellipsoidal region as defined for Goldak-type heat sources. Its value is given by

$$q = \frac{3FQ}{2\pi abc}$$

with the same assumptions for F and c as above. The set of parameters consequently reduces to $(a, b, c_\mathrm{f}, c_\mathrm{r}, F_\mathrm{f}, F_\mathrm{r})$ which are input in fields P1 to P6.

In contrast to the above, IFORM = 3 defines an equivalent heat source with a constant energy rate density on a double conical region. The shape is defined

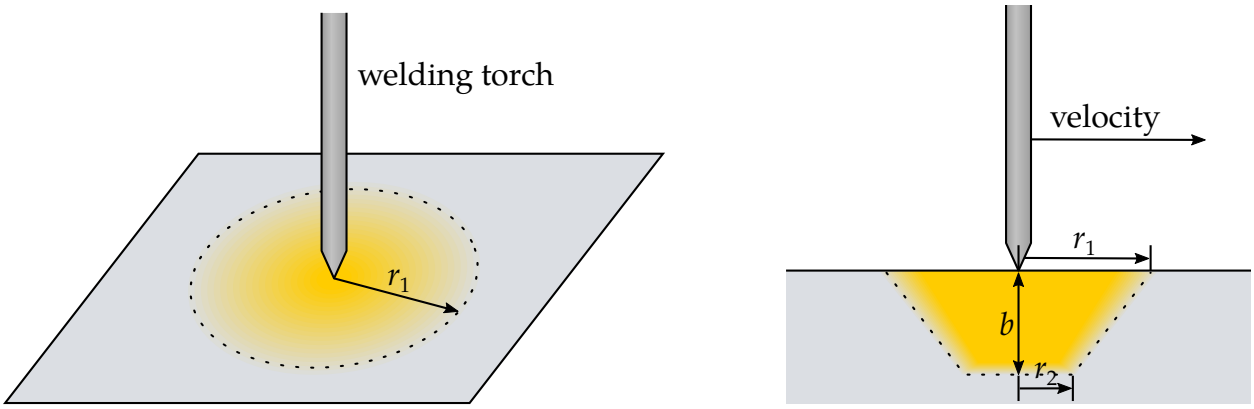

Figure 5-16. Heat source distribution geometry for IFORM = 4

by three radii $r_1, r_2, r_3$and two values b_1, b_2 defining the heights of the two parts of the shape. See Figure 5-15. The respective power densities of the parts are given by

$$q_i = \frac{3F_iQ}{2\pi b_i(r_i^2 + r_{i+1}^2 + r_i r_{i+1})}, \qquad i = 1,2\,.$$

The parameter set $(r_1, r_2, r_3, b_1, b_2, F_1, F_2)$ is input in fields P1 to P7.

The last pre-defined form is IFORM = 4, which defines a constant power density over a frustum shaped region. See Figure 5-16. The density and the shape can easily be described using three geometrical parameters P1 to P3 corresponding to the radii r_1(at the heat source origin) and r_2 and the height b:

$$q = \frac{3Q}{\pi b(r_1^2 + r_2^2 + r_1 r_2)}$$

Finally, with IFORM = 5 the user can define an arbitrarily shaped equivalent heat source with the *DEFINE_FUNCTION keyword. The input of the function comprises the coordinates in the local coordinate system $(\mathbf{r}, \mathbf{s}', \mathbf{t}')$, as discussed in Remark 2, the time and the weld speed. It may thus read as follows:

```
*DEFINE_FUNCTION
1,user heat source
heat(r,s,t,time,weldspd)= …
```

To speed-up the computation, the function is evaluated for nodes within a distance less than a from the current center position. Consequently, the function ID and this distance are the only parameters needed in Card 3 of the input.

IFORM	1	2	3	4	5
P1	a	a	r_1	r_1	FID
P2	b	b	r_2	r_2	a

P8					

Table 5-1. Parameters defining each weld pool geometry

*BOUNDARY_USA_SURFACE

Purpose: Define a surface for coupling with the USA code [DeRuntz 1993]. The outward normal vectors should point into the fluid media. The coupling with USA is operational in explicit transient and in implicit natural frequency analyses.

Card	1	2	3	4	5	6	7	8
Variable	SSID	WETDRY	NBEAM					
Type	I	I	I					
Default	none	0	0					

VARIABLE	DESCRIPTION
SSID	Segment set ID, see *SET_SEGMENT
WETDRY	Wet surface flag: EQ.0: Dry, no coupling for USA DAA analysis, or Internal fluid coupling for USA CASE analysis EQ.1: Wet, coupled with USA for DAA analysis, or External fluid coupling for USA CASE analysis
NBEAM	The number of nodes touched by USA Surface-of-Revolution (SOR) elements. It is not necessary that the LS-DYNA model has beams where USA has beams (i.e., SOR elements), merely that the LS-DYNA model has nodes to receive the forces that USA will return.

Remarks:

The underwater shock analysis code is an optional module. To determine availability, contact Ansys sales (https://www.ansys.com/contact-us).

The wet surface of 3 and 4-noded USA general boundary elements is defined in LS-DYNA with a segment set of 4-noded surface segments, where the fourth node can duplicate the third node to form a triangle. The segment normal vectors should be directed into the USA fluid. If USA overlays are going to be used to reduce the size of the DAA matrices, the user should nonetheless define the wet surface here as if no overlay were being used.

If Surface-of -Revolution elements (SORs) are being used in USA, then NBEAM should be non-zero on one and only one card in this section.

The wet surface defined here can cover structural elements or acoustic fluid volume elements, but it cannot touch both types in one model.

When running a coupled problem with USA, the procedure requires an additional input file of USA keyword instructions. These are described in a separate USA manual. The name of this input file is identified on the command line with the usa = flag:

LSDYNA.USA i=**inf** usa=**uin**

where **uin** is the USA keyword instruction file.

BOUNDARY_ELEMENT_METHOD_*OPTION

Available options include:

CONTROL

FLOW

NEIGHBOR

SYMMETRY

WAKE

Purpose: Define input parameters for boundary element method analysis of incompressible fluid dynamics or fluid-structure interaction problems.

The boundary element method (BEM) can be used to compute the steady state or transient fluid flow about a rigid or deformable body. The theory which underlies the method (see the LS-DYNA Theory Manual) is restricted to inviscid, incompressible, attached fluid flow. The method should not be used to analyze flows where shocks or cavitation are present.

In practice the method can be successfully applied to a wider class of fluid flow problems than the assumption of inviscid, incompressible, attached flow would imply. Many flows of practical engineering significance have large Reynolds numbers (above 1 million). For these flows the effects of fluid viscosity are small if the flow remains attached, and the assumption of zero viscosity may not be a significant limitation. Flow separation does not necessarily invalidate the analysis. If well-defined separation lines exist on the body, then wakes can be attached to these separation lines and reasonable results can be obtained. The Prandtl-Glauert rule can be used to correct for non-zero Mach numbers in a gas, so the effects of aerodynamic compressibility can be correctly modeled (as long as no shocks are present).

The BOUNDARY_ELEMENT_METHOD_FLOW card turns on the analysis, and is mandatory.

This capability is available only with shared memory parallel (SMP) LS-DYNA executables.

*BOUNDARY_ELEMENT_METHOD_CONTROL

Purpose: Control the execution time of the boundary element method calculation. Using the CONTROL keyword option is highly recommended. The BEM calculations can easily dominate the total execution time of an LS-DYNA run unless the parameters on this card (especially DTBEM and/or IUPBEM) are used appropriately.

The field DTBEM is used to increase the time increment between calls to the BEM routines. This can usually be done with little loss in accuracy since the characteristic times of the structural dynamics and the fluid flow can differ by several orders of magnitude. The characteristic time of the structural dynamics in LS-DYNA is given by the size of the smallest structural element divided by the speed of sound of its material. For a typical problem this characteristic time might be equal to 1 microsecond. Since the fluid in the boundary element method is assumed to be incompressible (infinite speed of sound), the characteristic time of the fluid flow is given by the streamwise length of the smallest surface in the flow divided by the fluid velocity. For a typical problem this characteristic time might be equal to 10 milliseconds. For this example DTBEM might be set to 1 millisecond with little loss of accuracy. Thus, for this example, the boundary element method would be called only once for every 1000 LS-DYNA iterations, saving an enormous amount of computer time.

The field IUPBEM is used to increase the number of times the BEM routines are called before the matrix of influence coefficients is recomputed and factored (these are time-consuming procedures). If the motion of the body is entirely rigid body motion, there is no need to ever recompute and factor the matrix of influence coefficients after initialization, and the execution time of the BEM can be significantly reduced by setting IUPBEM to a very large number. For situations where the structural deformations are modest an intermediate value, such as 10, for IUPBEM can be used.

Card 1	1	2	3	4	5	6	7	8
Variable	LWAKE	DTBEM	IUPBEM	FARBEM				
Type	I	F	I	F				
Default	50	0.	100	2.0				
Remarks	1			2				

VARIABLE	DESCRIPTION
LWAKE	Number of elements in the wake of lifting surfaces. Wakes must be defined for all lifting surfaces.
DTBEM	Time increment between calls to the boundary element method. The fluid pressures computed during the previous call to the BEM will continue to be used for subsequent LS-DYNA iterations until a time increment of DTBEM has elapsed.
IUPBEM	The number of times the BEM routines are called before the matrix of influence coefficients is recomputed and refactored.
FARBEM	Non-dimensional boundary between near-field and far-field calculation of influence coefficients.

Remarks:

1. **Wakes.** Wakes convect with the free-stream velocity. The number of elements in the wake should be set to provide a total wake length equal to 5-10 times the characteristic streamwise length of the lifting surface to which the wake is attached. Note that each wake element has a streamwise length equal to the magnitude of the free stream velocity multiplied by the time increment between calls to the boundary element method routines. This time increment is controlled by DTBEM.

2. **FARBEM.** The most accurate results will be obtained with FARBEM set to 5 or more, while values as low as 2 will provide slightly reduced accuracy with a 50% reduction in the time required to compute the matrix of influence coefficients.

*BOUNDARY_ELEMENT_METHOD_FLOW

Purpose: Turn on the boundary element method calculation, specify the set of shells which define the surface of the bodies of interest, and specify the onset flow.

The *BOUNDARY_ELEMENT_METHOD_FLOW card turns on the BEM calculation. This card also identifies the shell elements which define the surfaces of the bodies of interest, and the properties of the onset fluid flow. The onset flow can be zero for bodies which move through a fluid which is initially at rest.

Card 1	1	2	3	4	5	6	7	8
Variable	SSID	VX	VY	VZ	RO	PSTATIC	MACH	
Type	I	F	F	F	F	F	F	
Default	none	none	none	none	none	0.	0.	
Remark	1					2	3	

VARIABLE	DESCRIPTION
SSID	Shell set ID for the set of shell elements which define the surface of the bodies of interest (see *SET_SHELL). The nodes of these shells should be ordered so that the shell normal vectors point into the fluid.
VX, VY, VZ	x, y, and z components of the free-stream fluid velocity
RO	Fluid density
PSTATIC	Fluid static pressure
MACH	Free-stream Mach number

Remarks:

1. **Recommended Model Setup.** Using the NULL material (see *MAT_NULL) for the shell segments in the SSID set is recommended. Fluid pressures can then be displayed in the post-processor. For triangular shells the 4th node number should be the same as the 3rd node number. For fluid-structure interaction problems the boundary element shells should use the same nodes and be coincident

with the structural shell elements (or the outer face of solid elements) which define the surface of the body. This approach guarantees that the boundary element segments will move with the surface of the body as it deforms.

2. **Fluid Static Pressure.** A pressure of PSTATIC is applied uniformly to all segments in the segment set. If the body of interest is hollow, then PSTATIC should be set to the free-stream static pressure minus the pressure on the inside of the body.

3. **Subsonic Compressibility.** The effects of subsonic compressibility on gas flows can be included using a non-zero value for MACH. The pressures which arise from the fluid flow are increased using the Prandtl-Glauert compressibility correction. MACH should be set to zero for water or other liquid flows.

*BOUNDARY_ELEMENT_METHOD_NEIGHBOR

Purpose: Define the neighboring elements for a given boundary element segment.

The pressure at the surface of a body is determined by the gradient of the doublet distribution on the surface (see the LS-DYNA Theory Manual). The "Neighbor Array" is used to specify how the gradient is computed for each boundary element segment. Ordinarily, the Neighbor Array is set up automatically by LS-DYNA, and no user input is required. The NEIGHBOR option is provided for those circumstances when the user desires to define this array manually.

Elements Cards. Include as many cards as desired. This input ends at the next keyword ("*") card.

Card 1	1	2	3	4	5	6	7	8
Variable	NELEM	NABOR1	NABOR2	NABOR3	NABOR4			
Type	I	I	I	I	I			
Default	none	none	none	none	none			

VARIABLE	DESCRIPTION
NELEM	Element number
NABOR1	Neighbor for side 1 of NELEM.
NABOR2	Neighbor for side 2 of NELEM.
NABOR3	Neighbor for side 3 of NELEM.
NABOR4	Neighbor for side 4 of NELEM.

Remarks:

Each boundary element has 4 sides (Figure 6-1). Side 1 connects the 1st and 2nd nodes, side 2 connects the 2nd and 3rd nodes, etc. The 4th side is null for triangular elements.

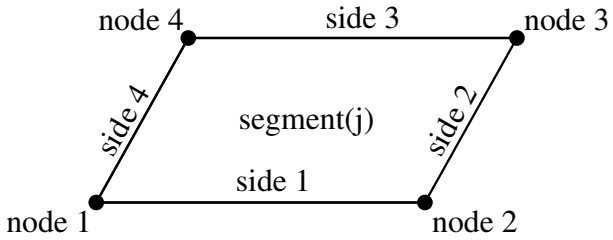

Figure 6-1. Each segment has 4 sides.

For most elements the specification of neighbors is straightforward. For the typical case a quadrilateral element is surrounded by 4 other elements, and the neighbor array is as shown in Figure 6-2.

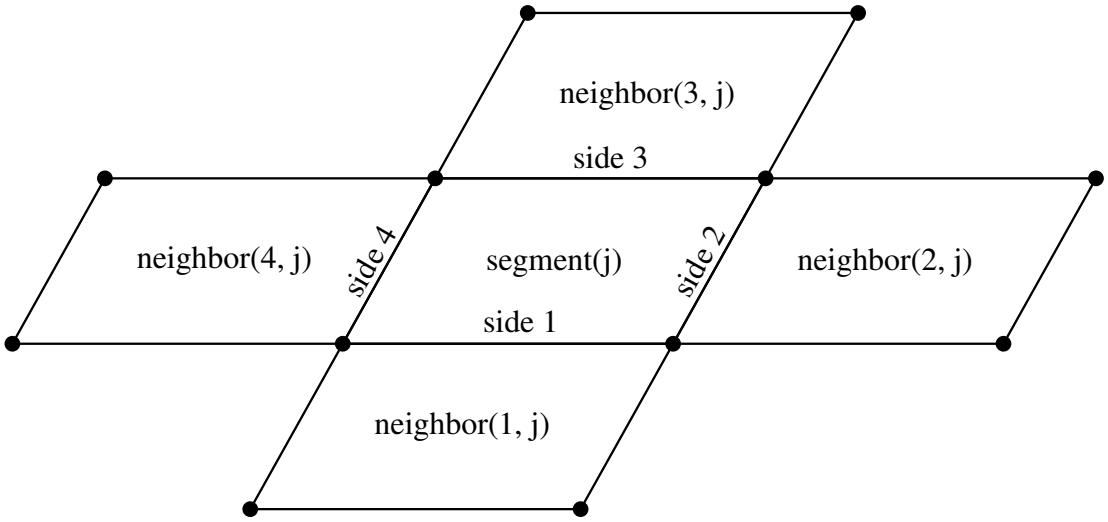

Figure 6-2. Typical neighbor specification.

There are several situations for which the user may desire to directly specify the neighbor array for certain elements. For example, boundary element wakes result in discontinuous doublet distributions, and neighbors which cross a wake should not be used. Figure 6-3 illustrates a situation where a wake is attached to side 2 of segment j. For this situation two options exist. If neighbor(2,j) is set to zero, then a linear computation of the gradient in the side 2 to side 4 direction will be made using the difference between the doublet strengths on segment j and segment neighbor(4,j). This is the default setup used by LS-DYNA when no user input is provided. By specifying neighbor(2,j) as a negative number a more accurate quadratic curve fit will be used to compute the gradient. The curve fit will use segment j, segment neighbor(4,j), and segment -neighbor(2,j); which is located on the opposite side of segment neighbor(4,j) as segment j.

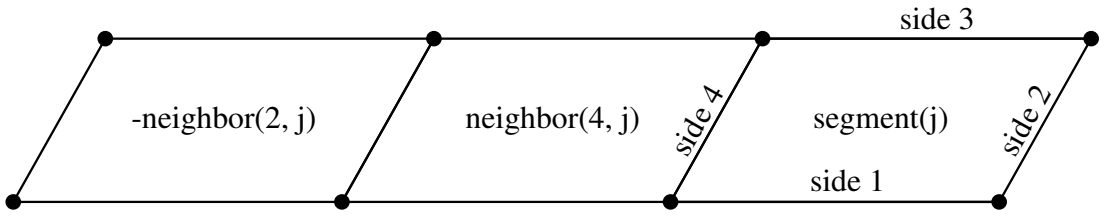

Figure 6-3. If neighbor(2,j) is a negative number, it is assumed to lie on the opposite side of neighbor(4,j) as segment j.

Another possibility is that no neighbors at all are available in the side 2 to side 4 direction. In this case both neighbor(2,j) and neighbor(4,j) can be set to zero, and the gradient in that direction will be assumed to be zero. This option should be used with caution, as the resulting fluid pressures will not be accurate for three-dimensional flows. However, this option is occasionally useful where quasi-two dimensional results are desired. All of the above options apply to the side 1 to side 3 direction in the obvious ways.

For triangular boundary elements side 4 is null. Gradients in the side 2 to side 4 direction can be computed as described above by setting neighbor(4,j) to zero for a linear derivative computation (this is the default setup used by LS-DYNA when no user input is provided) or to a negative number to use the segment on the other side of neighbor(2,j) and a quadratic curve fit. There may also be another triangular segment which can be used as neighbor(4,j) (see Figure 6-4).

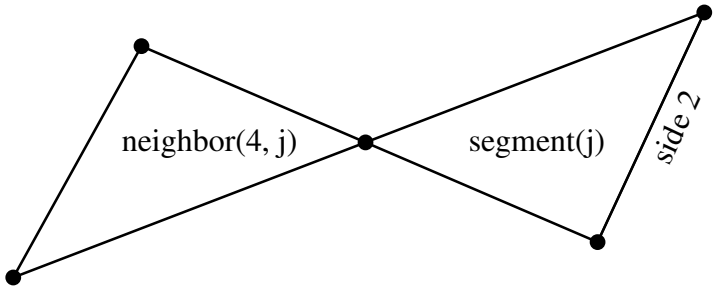

Figure 6-4. Sometimes another triangular boundary element segment can be used as neighbor (4,j).

The rules for computing the doublet gradient in the side 2 to side 4 direction can be summarized as follows (the side 1 to side 3 case is similar):

NABOR2	NABOR4	Doublet Gradient Computation
GT.0	GT.0	Quadratic fit using elements j, NABOR2, and NABOR4.
LT.0	GT.0	Quadratic fit using elements j, -NABOR2, and NABOR4. -NABOR2 is assumed to lie on the opposite side of NABOR4 as segment j (see Fig. 6-3).
GT.0	LT.0	Quadratic fit using elements j, NABOR2, and -NABOR4. -NABOR4 is assumed to lie on the opposite side of NABOR2 as segment j.
EQ.0	GT.0	Linear fit using elements j and NABOR4.
GT.0	EQ.0	Linear fit using elements j and NABOR2.
EQ.0	EQ.0	Zero gradient.

Table 6-5. Surface pressure computation for element j.

*BOUNDARY_ELEMENT_METHOD_SYMMETRY

Purpose: To define a plane of symmetry for the boundary element method. The SYMMETRY option can be used to reduce the time and memory required for symmetric configurations. For these configurations the reduction in the number of boundary elements by a factor of 2 will reduce the memory used by the boundary element method by a factor of 4 and will reduce the compute time required to factor the matrix of influence coefficients by a factor of 8. Only 1 plane of symmetry can be defined.

Card 1	1	2	3	4	5	6	7	8
Variable	BEMSYM							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
BEMSYM	Defines symmetry plane for boundary element method. EQ.0: no symmetry plane is defined EQ.1: $x = 0$ is a symmetry plane EQ.2: $y = 0$ is a symmetry plane EQ.3: $z = 0$ is a symmetry plane

*BOUNDARY_ELEMENT_METHOD_WAKE

Purpose: To attach wakes to the trailing edges of lifting surfaces. Wakes should be attached to boundary elements at the trailing edge of a lifting surface (such as a wing, propeller blade, rudder, or diving plane). Wakes should also be attached to known separation lines when detached flow is known to exist (such as the sharp leading edge of a delta wing at high angles of attack). Wakes are required for the correct computation of surface pressures for these situations. As described above, two segments on opposite sides of a wake should never be used as neighbors.

Element Cards. (The next "*" card terminates the input.)

Card 1	1	2	3	4	5	6	7	8
Variable	NELEM	NSIDE						
Type	I	I						
Default	none	none						
Remarks	1							

VARIABLE	DESCRIPTION
NELEM	Element number to which a wake is attached.
NSIDE	The side of NELEM to which the wake is attached (see Figure 6-1). This should be the "downstream" side of NELEM.

Remarks:

1. **Elements and Wake.** Normally two elements meet at a trailing edge (one on the "upper" surface and one on the "lower" surface). The wake can be attached to either element, but not to both.

*CASE

The *CASE command provides a way of running multiple LS-DYNA analyses (or cases) sequentially by submitting a single input file. When *CASE commands are used to define multiple cases, some portions of the input will be shared by some or all of the cases and other portions will be unique to each case. Because the cases are run sequentially, the results from one case, e.g., a dynain file, can be used in the analysis of a different, subsequent case. Each case creates a unique set of output file names by prepending "case***n**." to the default file name, e.g., case101.d3plot, case102.glstat.

When the *CASE keyword appears in an input deck, it becomes necessary to append the word "CASE" to the LS-DYNA execution line. For example, an SMP LS-DYNA execution line might look something like

path_to_ls-dyna i=**input.k** ncpu=**-4** CASE

An MPP LS-DYNA execution line might look something like

mpirun –np 4 path_to_mpp971 i=**input.k** CASE

The default behavior is to run all the cases defined in the input deck sequentially in increasing numeric order. If any of the cases fail to run to normal termination, the subsequent cases will not be run.

To run a subset of the cases defined in the input deck, specify the case ID numbers following the word "CASE" on the execution line, for example, "CASE = 10,20,47" will only run case IDs 10, 20 and 47, and skip any other cases. There can be NO spaces before or after " = " or ",". The specified cases will be run in increasing numeric order and not necessarily in the order given on the command line.

*__CASE__*_{OPTION}*

Available options include:

<BLANK>

BEGIN_*N*

END_*N*

Purpose: Define a series of cases and perhaps subcases. The options *CASE_BEGIN_*n* and *CASE_END_*n* appear in pairs and *n* is a numeric ID of a subcase. Subcase IDs may be referenced by the *CASE command in defining a case. In other words, a case may consist of one or more subcases. All keywords appearing between *CASE_BEGIN_*n* and *CASE_END_*n* comprise subcase *n*. If no *CASE command is defined, then subcases defined by *CASE_BEGIN_*n* and *CASE_END_*n* then become cases. *CASE_BE-

GIN/*CASE_END can be nested, overlapped, and disjointed. Examples below demonstrate the use of these options.

An alternative way of defining subcases is by appending the string "CID = *n*" to the end of any keyword command. Any keyword so tagged will then be active only for those cases that reference subcase *n*. There can be more than one space between the keyword and "CID = *n*".

Any keyword in the input deck not associated with a subcase is active for all cases.

The following input syntax applies only to the *CASE command, not to *CASE_BEGIN/*CASE_END.

Card 1	1	2	3	4	5	6	7	8
Variable	CASEID	JOBID						
Type	I	C						
Default	none	none						

Command Line Argument Cards. Command line cards set additional command line arguments for the case CASEID (see Card 1, above). Include as many as needed, or as few as none. Command line cards end when the first character of the next card is numeric.

Card 2	1	2	3	4	5	6	7	8
Variable	COMMANDS							
Type	A							
Default	Not Required							

Subcase ID Cards. Define active subcase IDs for case CASEID (see Card 1, above). These cards continue until the next keyword ("*") card.

Card 3	1	2	3	4	5	6	7	8
Variable	SCID1	SCID2	…	…	…	…	…	…
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
CASEID	Identification number for case.
JOBID	Optional string (no spaces) to be used as the jobid for this case. If no JOBID is specified, the string CASEXX is used, where XX is the CASEID in field 1
COM-MANDS	Command line arguments.
SCIDn	Subcase ID active for case CASEID.

Remarks:

1. If no *CASE keyword appears, subcases defined with *CASE_BEGIN/*CASE_-END commands become cases and *CASE_BEGIN can optionally be followed by extra command line arguments.

2. If no *CASE keyword appears, it is an error to append "CID = n" to any keyword.

3. If multiple *CASE or *CASE_BEGIN keywords appear that have the same ID, their command line arguments and active commands are merged.

4. The *CASE or *CASE_BEGIN keywords cannot be used within an include (*INCLUDE) file.

Example 1:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$ Define case 101 which includes subcase 1.

Example 2 above will generate d3thdt and nodout for CID = 5, and nodout and elout for CID = 3.

***COMMENT**_*{OPTION}*

Available options include:

<BLANK>

NOECHO

All input that falls between a *COMMENT command and the subsequent line of input that has an asterisk in the first column thereby signaling the start of another keyword command, is not acted on by LS-DYNA. This provides a convenient way to interject multiple, successive lines of commentary anywhere inside an input deck.

*COMMENT also provides a convenient way to comment out an existing keyword command and all its associated input data as shown in an example below.

Unless you append keyword option NOECHO, lines of input that are deactivated by *COMMENT are echoed on the screen and to the messag and d3hsp files.

Card 1	1	2	3	4	5	6	7	8
Variable	COMMENT							
Type	A							
Default	none							

VARIABLE	DESCRIPTION
COMMENT	Any comment line.

Example:

In this excerpt from an input deck, 5 lines of comments including blank lines, are added to the input deck.

```
*KEYWORD
*COMMENT
Units of this model are mks.

Input prepared by John Doe.
Input checked by Jane Doe.

*CONTROL_TERMINATION
1.E-02

*COMPONENT

The keyword *COMPONENT provides a way of incorporating specialized components and features. The keyword control cards in this section are defined in alphabetical order:

COMPONENT_GEBOD_*OPTION

COMPONENT_GEBOD_JOINT_*OPTION

*COMPONENT_HYBRIDIII

COMPONENT_HYBRIDIII_JOINT_*OPTION

***COMPONENT_GEBOD**_OPTION

Purpose: Generate a rigid body dummy based on dimensions and mass properties from the GEBOD database. The motion of the dummy is governed by equations integrated within LS-DYNA separately from the finite element model. Default joint characteristics (stiffnesses, stop angles, etc.) are set internally and should give reasonable results, however, they may be altered using the *COMPONENT_GEBOD_JOINT command. Contact between the segments of the dummy and the finite element model is defined using the *CONTACT_GEBOD command. The use of a positioning file is essential with this feature; see Appendix N for further details.

OPTION specifies the human subject type. The male and female types represent adults while the child is genderless.

MALE

FEMALE

CHILD

Card 1	1	2	3	4	5	6	7	8
Variable	DID	UNITS	SIZE					
Type	I	I	F

COMPONENT_GEBOD_JOINT_*OPTION

Purpose: Alter the joint characteristics of a GEBOD rigid body dummy. Setting a joint parameter value to zero retains the default value set internally. See Appendix N for further details.

The following options are available.

PELVIS	RIGHT_ELBOW
WAIST	LEFT_HIP
LOWER_NECK	RIGHT_HIP
UPPER_NECK	LEFT_KNEE
LEFT_SHOULDER	RIGHT_KNEE
RIGHT_SHOULDER	LEFT_ANKLE
LEFT_ELBOW	RIGHT_ANKLE

Card 1	1	2	3	4	5	6	7	8
Variable	DID	LC1	LC2	LC3	SCF1	SCF2	SCF3	
Type	F	I	I	I	F	F	F	

VARIABLE	DESCRIPTION
DID	Dummy ID, see *COMPONENT_GEBOD_*OPTION*.
LC*i*	Load curve ID specifying the loading torque as a function of rotation (in radians) for the i^{th} degree of freedom of the joint.
SCF*i*	Scale factor applied to the load curve of the i^{th} joint degree of freedom.

Card 2	1	2	3	4	5	6	7	8
Variable	C1	C2	C3	NEUT1	NEUT2	NEUT3		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
C*i*	Linear viscous damping coefficient applied to the i^{th} DOF of the joint. Units are torque × time/radian, where the units of torque and time depend on the choice of UNITS in Card 1 of *COMPONENT_GEBOD_*OPTION*.
NEUT*i*	Neutral angle (degrees) of the joint's i^{th} DOF.

Card 3	1	2	3	4	5	6	7	8
Variable	LOSA1	HISA1	LOSA2	HISA2	LOSA3	HISA3		
Type	F	F	F	F	F	F		

VARIABLE	DESCRIPTION
LOSA*i*	Value of the low stop angle (degrees) for the i^{th} DOF of this joint.
HISA*i*	Value of the high stop angle (degrees) for the i^{th} DOF of this joint.

Card 4	1	2	3	4	5	6	7	8
Variable	UNK1	UNK2	UNK3					
Type	F	F	F					
Default	0.	0.	0.					

VARIABLE	DESCRIPTION
UNK*i*	Unloading stiffness (torque/radian) for the i^{th} degree of freedom of the joint. This must be a positive number. Units of torque depend on the choice of UNITS in Card 1 of *COMPONENT_GEBOD_*OPTION*.

Example 1:

*COMPONENT_HYBRIDIII

Purpose: Define a HYBRID III dummy. The motion of the dummy is governed by equations integrated within LS-DYNA separately from the finite element model. The dummy interacts with the finite element structure through contact interfaces. Joint characteristics (stiffnesses, damping, friction, etc.) are set internally and should give reasonable results, however, they may be altered using the *COMPONENT_HYBRIDIII_JOINT command. Joint force and moments can be written to an ASCII file (see *DATABASE_H3OUT).

Card 1	1	2	3	4	5	6	7	8

***COMPONENT_HYBRIDIII_JOINT**_OPTION

Purpose: Alter the joint characteristics of a HYBRID III dummy. Setting a joint parameter value to zero retains the default value set internally. Joint force and moments can be written to an ASCII file (see *DATABASE_H3OUT). Further details pertaining to the joints are found in the Hybrid III Dummies section of Appendix N.

The following options are available:

LUMBAR	RIGHT_ELBOW	RIGHT_KNEE
LOWER_NECK	LEFT_WRIST	LEFT_ANKLE
UPPER_NECK	RIGHT_WRIST	RIGHT_ANKLE
LEFT_SHOULDER	LEFT_HIP	STERNUM
RIGHT_SHOULDER	RIGHT_HIP	LEFT_KNEE_SLIDER
LEFT_ELBOW	LEFT_KNEE	RIGHT_KNEE_SLIDER

VARIABLE	DESCRIPTION
DID	Dummy ID, see *COMPONENT_HYBRIDIII
Q*i*	Initial value of the joint's i^{th} degree of freedom. Units of degrees are defined for rotational DOF. See Appendix N for a listing of the applicable DOF.
FRIC	Friction load on the joint.
C*i*	Linear viscous damping coefficient applied to the i^{th} DOF of the joint.
ALO*i*	Linear coefficient for the low regime spring of the joint's i^{th} DOF.
BLO*i*	Cubic coefficient for the low regime spring of the joint's i^{th} DOF.
AHI*i*	Linear coefficient for the high regime spring of the joint's i^{th} DOF.
BHI*i*	Cubic coefficient for the high regime spring of the joint's i^{th} DOF.
QLO*i*	Value at which the low regime spring definition becomes active.
QHI*i*	Value at which the high regime spring definition becomes active.
SCLK*i*	Scale value applied to the stiffness of the joint's i^{th} DOF (default = 1.0).

*CONSTRAINED_TIEBREAK

*CONSTRAINED_TIED_NODES_FAILURE

*CONSTRAINED_ADAPTIVITY

Purpose: Constrains a node created during *h*-adaptivity of three-dimensional shells to the midpoint along an edge of an element. This keyword is automatically created by LS-DYNA during an *h*-adaptive simulation involving three-dimensional shells. See the theory manual for details about this type of adaptivity.

Card 1	1	2	3	4	5	6	7	8
Variable	DNID	NID1	NID2					
Type	I	I	I					
Default	none	none	none					

VARIABLE	DESCRIPTION
DNID	Dependent node. This is the node constrained at the midpoint of an edge of an element.
NID1	Node at one end of an element edge
NID2	Node at the other end of that same element edge

Remarks:

Not all nodes created during *h*-adaptivity are constrained to an element edge. It only occurs when a node on the edge of an element created during an adaptive step is *not* on the boundary of the mesh and is *not* a node belonging to an element on the other side of the edge. If the element on the other side of the edge is adapted, then this constraint may be deleted.

Figure 10-1 illustrates which elements become dependent after adapting a single element mesh. The left element is adapted to create the elements on the right. In this figure, the red dots are dependent nodes while the blue dots are the edge nodes constraining the dependent nodes. For instance, node 2 is a dependent node constrained at the midpoint of the edge between nodes 1 and 3 and node 5 is a dependent node constrained at the midpoint of the edge between nodes 4 and 6.

Suppose that the element to the left of node 2 is adapted once. Then node 2 is no longer a dependent node and node 3 is no longer a constraining node as shown in Figure 10-2. These nodes are purple dots to illustrate that they are no longer part of a *CON-

STRAINED_ADAPTIVITY definition. However, node 1 continues to constrain the node to its right and now constrains the node to its left (node 7) with node 8.

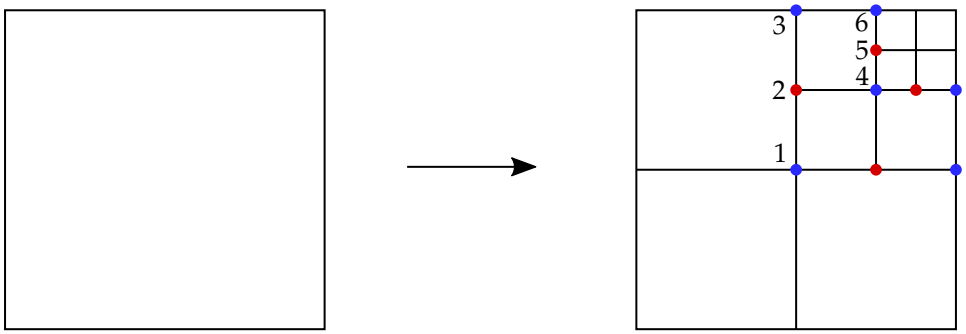

Figure 10-1. Illustration of which nodes are constrained after adaptive steps. The red nodes are dependent while the blue nodes constrain the dependent node that shares the edge.

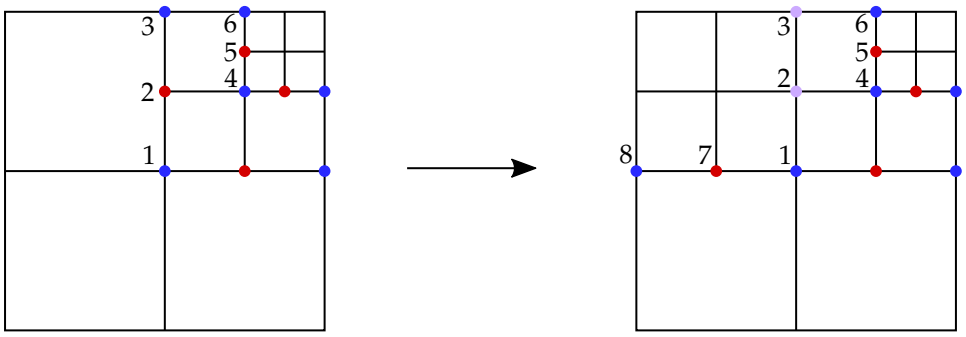

Figure 10-2. Illustration of which nodes are constrained after the element to the left of Node 2 is adapted. The purple nodes indicate which ones are no longer part of constraints.

*CONSTRAINED_BEAM_IN_SOLID_{OPTION1}_{OPTION2}

This keyword could take the following two forms:

*CONSTRAINED_BEAM_IN_SOLID

*CONSTRAINED_BEAM_IN_SOLID_PENALTY

To define an ID and heading, the following options are available:

ID

TITLE

Purpose: This keyword provides either constraint-based or penalty-based coupling between beams embedded in solid or thick shell elements. For shells embedded in solid or thick shell elements, see *CONSTRAINED_SHELL_IN_SOLID.

*CONSTRAINED_BEAM_IN_SOLID invokes constraint-based coupling. It constrains beam structures to move with Lagrangian solids/tshells. Both acceleration and velocity are constrained. This feature is intended to sidestep certain limitations in the CTYPE = 2 implementation of *CONSTRAINED_LAGRANGE_IN_SOLID. Notable features of this keyword include:

1. **CDIR = 1 Feature.** With the CDIR = 1 option, coupling occurs only in the normal directions. This option allows for releasing the constraints along the beam axial direction and provides a means to model the debonding process.

2. **Axial Coupling Force.** Debonding processes can be modeled if a shear force-slip relationship is given and CDIR is set to 1 to release the axial constraints. There are three ways to specify the bond force-slip relationship:

   a) A function defined with *DEFINE_FUNCTION. To activate this, set the AXFOR flag to a negative integer which refers to the *DEFINE_FUNCTION ID.

   b) A user-defined subroutine. You provide a subroutine giving the axial shear force based on the slip between rebar nodes and concrete solid elements. To enable this, you set AXFOR to a number greater than 1000, and the user must modify the subroutine `rebar_bondslip_get_force()` in the user-defined subroutine Fortran files to add in one or more debonding laws, each tagged with a "lawid." An AXFOR value greater than 1000 will call the user subroutine and pass AXFOR in as "lawid."

   c) A general built-in force-slip relationship. Starting with R14.0, AXFOR = 999 invokes a general bond force-slip relationship based on Bulletin 65 of the fib Model Code for Concrete Structures 2010.

3. **NCOUP Feature.** NCOUP is used to invoke coupling at both beam nodes and coupling points between the two beam nodes of each beam element. This implementation resolves the errors in energy balance observed when using the alternative implementation, *CONSTRAINED_LAGRANGE_IN_SOLID, CTYPE = 2.

4. **Tetrahedral and Pentahedral Solid Elements.** These element shapes are supported in this keyword and are no longer treated as degenerated hexahedra as in the *CONSTRAINED_LAGRANGE_IN_SOLID CTYPE = 2 implementation.

5. **Constraints on Nodes.** The *CONSTRAINED_LAGRANGE_IN_SOLID CTYPE = 2 implementation does not constrain beam nodes embedded in elements whose nodes have prescribed motion or other constraints.

6. **R-Adaptivity Support.** Severely deformed solid elements could terminate the simulation prematurely. One way to address this problem is to use LS-DYNA's 3D tetrahedral *r*-adaptivity method to remesh and restart. This keyword supports *r*-adaptivity and can be used to model manufacturing processes with severe deformations, such as compression molding with embedded fibers.

7. **Implicit Support.** Both SMP and MPP are supported.

8. **Optimized Sorting.** The sorting subroutine is optimized for larger problems to achieve better performance with less memory usage.

9. **Thermal Support.** In case the implicit thermal solver is invoked to perform either a thermal analysis (SOLN = 1 in *CONTROL_SOLUTION) or a coupled structural thermal analysis (SOLN = 2 in *CONTROL_SOLUTION), the temperature field is also constrained between beam and solid nodes.

*CONSTRAINED_BEAM_IN_SOLID_PENALTY invokes penalty-based coupling. A penalty spring is attached between coupling points on the beam and in the solid/tshell element. Penalty spring stiffness is calculated based on the geometric mean of the beam and the solid's bulk moduli. The magnitude of this coupling force can be controlled through field PSSF (penalty spring stiffness scale factor). This penalty coupling conserves kinetic energy much better in transient problems like blast loading. Please note that the CDIR and AXFOR fields only work with constraint-based coupling and are not available with penalty-based coupling.

Card Summary:

Card ID. This card is included if the TITLE or ID keyword option is used.

COUPID	TITLE

Card 1. This card is required.

BSID	SSID	BSTYP	SSTYP			NCOUP	CDIR

Card 2. This card is required.

START	END		AXFOR		PSSF		XINT

Card 3. This card is included if AXFOR = 999.

BONDC	BAREA	FCM	S1	S2	CLEAR	ALPHA	

Data Card Definitions:

Title Card. Additional card for TITLE and ID keyword options.

Card ID	1	2	3	4	5	6	7	8
Variable	COUPID	TITLE						
Type	I	A70						

VARIABLE	DESCRIPTION
COUPID	Coupling (card) ID number (I10). If not defined, LS-DYNA will assign an internal coupling ID based on the order of appearance in the input deck.
TITLE	A description of this coupling definition

Card 1	1	2	3	4	5	6	7	8
Variable	BSID	SSID	BSTYP	SSTYP			NCOUP	CDIR
Type	I	I	I	I			I	I
Default	none	none	0	0			0	0

VARIABLE	DESCRIPTION
BSID	Part or part set ID of the Lagrangian beam structure (see *PART, *SET_PART).
SSID	Part or part set ID of the Lagrangian solid elements or thick shell elements (see *PART or *SET_PART).
BSTYP	Set type of BSID: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID)
SSTYP	Set type of SSID: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID)
NCOUP	Number of coupling points generated in one beam element. If set to 0, coupling only happens at beam nodes. Otherwise, coupling is done at both the beam nodes and those automatically generated coupling points.
CDIR	Coupling direction. Only available in constraint form. EQ.0: Constraint applied along all directions. EQ.1: Constraint only applied along normal directions; along the beam axial direction, there is no constraint.

Card 2	1	2	3	4	5	6	7	8
Variable	START	END		AXFOR		PSSF		XINT
Type	F	F		I		F		F
Default	0	10^{20}		0		0.1		10^{16}

VARIABLE	DESCRIPTION
START	Start time to activate the coupling: LT.0.0: Start time is set to |START|. When negative, start time is followed during the dynamic relaxation phase of the

VARIABLE	DESCRIPTION
	calculation. After the completion of dynamic relaxation, coupling is activated regardless of the value of END. EQ.0.0: Start time is inactive, meaning coupling is always active GT.0.0: If END = -9999, START is interpreted as the curve or table ID defining multiple pairs of start-time and end-time. Otherwise, if END > 0, the start time applies during and after dynamic relaxation.
END	End time to deactivate the coupling: LT.0.0: If END = -9999, START is interpreted as the curve or table ID defining multiple pairs of start-time and end-time. Otherwise, negative END indicates that coupling is inactive during dynamic relaxation. After dynamic relaxation, the start and end times are followed and set to |START| and |END|, respectively. EQ.0.0: END defaults to 10^{20}. GT.0.0: END sets the time at which the coupling is deactivated.
AXFOR	Function that calculates the coupling force in the beam axial direction. Only available in constraint form with CDIR = 1. GE.0.and.LT.999: Off LT.0: |AXFOR| is a function ID; see *DEFINE_FUNCTION. See Example 1. EQ.999: General bond stress-slip relationship, which follows Bulletin 65 of fib Model Code for Concrete Structures 2010. GT.1000: Debonding law ID, "lawid," in the user-defined subroutine `rebar_bond-slip_get_force()`. See Example 2.
PSSF	Penalty spring stiffness scale factor. Only available in penalty form.
XINT	Interval distance. This field is designed to deal with beam elements with wide length variations. Coupling points are generated at an interval of length equal to XINT. Hence the number of coupling points in a beam element is no longer a fixed number (NCOUP) but instead variable, depending on the length of the beam element.

VARIABLE	DESCRIPTION
	This field can be used together with NCOUP. In that case, we will take the larger number of coupling points from these two options in each element.

General Bond Stress-Slip Relationship Card. Additional card if AXFOR = 999.

Card 3	1	2	3	4	5	6	7	8
Variable	BONDC	BAREA	FCM	S1	S2	CLEAR	ALPHA	
Type	I	F	F	F	F	F	F	
Default	none	none	none	none	none	none	none	

VARIABLE	DESCRIPTION
BONDC	Bond condition flag. BONDC consists of a two-digit integer, BONDC = [BA]: $$\text{BONDC} = B \times 10 + A$$ The 1's digit controls the transverse reinforcement: A.EQ.0: Unconfined A.EQ.1: Stirrups The 10's digit controls the bond condition: B.EQ.0: Good bond condition B.EQ.1: All other bond condition
BAREA	Beam area
FCM	Concrete compression strength
S1	Slip at maximum stress (pull-out)
S2	Slip at the end of stress plateau (pull-out)
CLEAR	Clearance distance between ribs
ALPHA	α, see Bulletin 65 of fib Model Code for Concrete Structures 2010

Examples:

1. **Function for Modeling Debonding.** The example below shows how to define and use a function to prescribe the debonding process. User-defined functions are supported. The function computes the debonding force and has two internally calculated arguments: slip and leng. Slip is the relative axial displacement between the beam node (or coupling point) and the material in which the beam is embedded. Leng is the tributary length of the beam node or coupling point. Implicit calculations require a third argument which is output by the function: stiff. Stiff is the debonding spring stiffness. The asterisk in front of stiff (*stiff) is required to indicate that it is called by reference, meaning that its value is returned after the function is evaluated. Please note that this asterisk cannot be placed in the first column of the function body because the LS-DYNA keyword reader assumes asterisks start new keywords.

      endif
      return
      end
```

*CONSTRAINED_BUTT_WELD

Purpose: Define a line of coincident nodes that represent a structural butt weld between two parts defined by shell elements. Failure is based on nodal plastic strain for ductile failure and stress resultants for brittle failure. This input is much simpler than the alternative approach for defining butt welds, *CONSTRAINED_GENERALIZED_WELD_BUTT. With this keyword, LS-DYNA automatically determines the local coordinate system, the effective length, and thickness for each pair of butt welded nodes. For *CONSTRAINED_GENERALIZED_WELD_BUTT, these quantities must be defined in the input.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID1	NSID2	EPPF	SIGF	BETA			
Type	I	I	F	F	F			
Default	none	none	0.	10^{16}	1.0			
Remarks		1, 2	3, 4	3	3			

VARIABLE	DESCRIPTION
NSID1	Node set ID for one side of the butt weld, see *SET_NODE_*OPTION*.
NSID2	Node set ID for the other side of the butt weld
EPPF	Plastic strain at failure
SIGF	σ_f, stress at failure for brittle failure
BETA	β, failure parameter for brittle failure

Remarks:

1. **Butt Weld Geometry and Node Sets.** Nodes in NSID1 and NSID2 must be given in the order they appear as one moves along the edge of the surface. An equal number of coincident nodes must be defined in each set. In a line weld the first and last node in a string of nodes can be repeated in the two sets. If the first and last pair of nodal points are identical, LS-DYNA assume the geometry

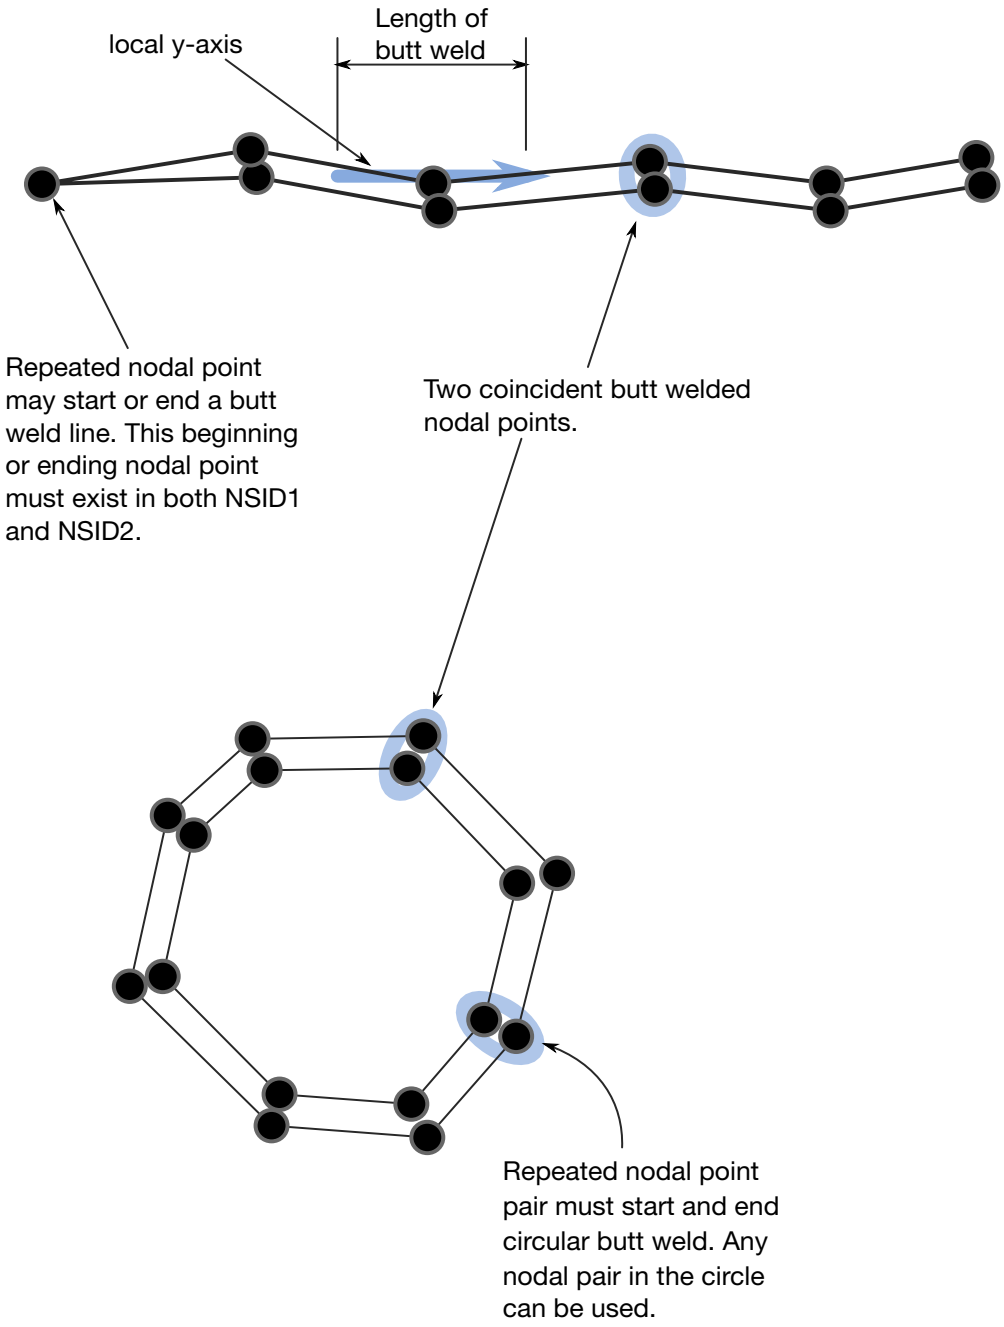

Figure 10-3. Definition of butt welds are shown above. The butt weld can be represented by a line of nodal points or by a closed loop

of the butt weld is circular or a closed loop. See Figure 10-3, where the line butt weld and closed loop weld are illustrated.

2. **Restrictions.** Butt welds may not cross. For complicated welds, this keyword can be combined with the input in *CONSTRAINED_GENERALIZED_WELD_-BUTT to handle the case where crossing occurs. Nodes in a butt weld must not be members of rigid bodies.

3. **Failure Model.** If the average volume-weighted effective plastic strain in the shell elements adjacent to a node exceeds the specified plastic strain at failure, the node is released. Brittle failure of the butt welds occurs when:

$$\beta\sqrt{\sigma_n^2 + 3(\tau_n^2 + \tau_t^2)} \geq \sigma_f$$

where,

σ_n = normal stress (local x)
τ_n = shear stress in direction of weld (local y)
τ_t = shear stress normal to weld (local z)
σ_f = failure stress
β = failure parameter

The component σ_n is nonzero for tensile values only. The nodes on each side of the butt weld must coincide.

The local coordinates at each set of coincident nodes are determined as follows. The normal vector (local x) is found by summing the unit normal vectors of all the shell elements on the *NSID2 side* sharing the butt welded node. The direction of the normal vector at the node is chosen so that the local x-direction points towards the elements on the NSID1 side in order to identify tensile versus compressive stresses. The local y-axis is taken as the vector in the direction of a line connecting the mid-points of the line segments lying on either side of the node in NSID2 (see Figure 10-3). The local z-axis at a node in NSID2 is normal to the plane of the butt weld at the node determined by looking at the *NSID2 side*.

The thickness and length of the butt weld are needed to compute the stress values. The thickness is based on the average thickness of the shell elements that share the butt welded nodal pair, and the chosen length of the butt weld is shown in Figure 10-3.

4. **Failure along a Line.** Butt welds may be used to simulate the effect of failure along a predetermined line, such as a seam or structural joint. When the failure criterion is reached at a nodal pair, the nodes begin to separate. As this effect propagates, the weld will appear to "unzip," thus simulating failure of the connection.

***CONSTRAINED_COORDINATE**_{OPTION}

To define constraints based on position coordinates the following options are available:

<BLANK>

LOCAL

Purpose: Define constraints on position coordinates for springback simulations. With the frequent application of an adaptive mesh in stamping simulations, nodes needed for springback constraints are often unavailable until the last process simulation before springback is complete, making defining the springback constraints in the beginning of the simulation process setup impossible. On the other hand, if the nodes are available, their positions may not be exactly at the desired locations required for springback constraints. With this keyword, it is possible to define constraints in both scenarios. Note that we designed this keyword for stamping simulations. This simulation type mostly uses shell elements. Thus, we do not support solid elements for this keyword.

Card 1	1	2	3	4	5	6	7	8
Variable	ID	PID	IDIR	X1	Y1	Z1	CID	
Type	I	I	I	F	F	F	I	
Default	none	none	none	0.0	0.0	0.0	0	

VARIABLE	DESCRIPTION
ID	Identification number of the constraint
PID	Part or part set to be constrained: GT.0: Part ID LT.0: |PID| is a part set ID.
IDIR	Constraint flag. IDIR > 0 works for implicit (not explicit dynamic) simulations only with no active adaptive refinement (adaptive blank is acceptable); the magnitude of IDIR defines the degrees-of-freedom below to be constrained at (X1,Y1,Z1). IDIR < 0 works for both implicit and explicit simulations with active adaptive refinement; the magnitude of IDIR determines the degrees-of-freedom below to be constrained at the node nearest to (X1,Y1,Z1). |IDIR|.EQ.1: x translational degree-of-freedom

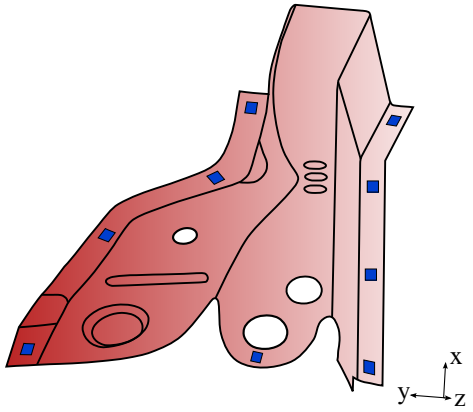

Figure 10-4. Constrained locations of a trim panel (NUMISHEET 2005 cross member).

VARIABLE	DESCRIPTION
	|IDIR|.EQ.2: y translational degree-of-freedom
	|IDIR|.EQ.3: z translational degree-of-freedom
	|IDIR|.EQ.11: x rotational degree-of-freedom
	|IDIR|.EQ.12: y rotational degree-of-freedom
	|IDIR|.EQ.13: z rotational degree-of-freedom
	|IDIR|.EQ.14: x and y rotational degrees-of-freedom
	|IDIR|.EQ.15: y and z rotational degrees-of-freedom
	|IDIR|.EQ.16: z and x rotational degrees-of-freedom
	|IDIR|.EQ.17: x, y and z rotational degrees-of-freedom
X1, Y1, Z1	X, Y, Z coordinates of the location being constrained
CID	Local coordinate system ID

Remarks:

1. **Constraint IDs.** The identification number of a constraint must be unique; the IDs must be unique even for two constraints with the same (X,Y,Z) position that constrain different degrees of freedom. When the LOCAL option is invoked, a local coordinate system ID (see *DEFINE_COORDINATE_*{OPTION}*) should be provided in the CID field.

2. **Moving Parts.** Starting with Revision 127848, the constraints defined by this keyword will take effect after the deformable part is moved by *PART_MOVE. This is necessary, for example, in the case of a formed panel springback

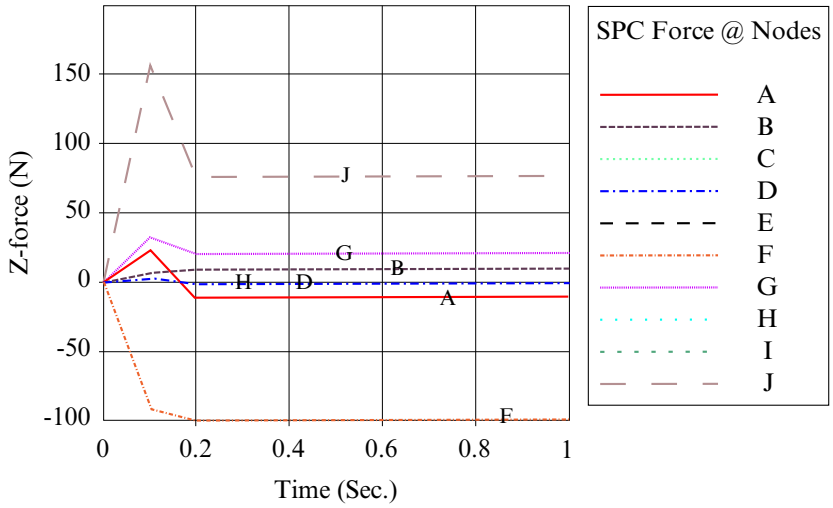

Figure 10-5. SPC Z-forces at 10 nodes

supported by a checking fixture, where the panel is automatically positioned by *CONTROL_FORMING_AUTOPOSITION.

3. **SPC Forces.** It is possible to output SPC forces on the coordinates constrained. For each position coordinate set, an extra node will be generated and SPC forces are calculated and output to the SPCFORC file. The frequency of the output is specified with the keyword *DATABASE_SPCFORC. For example, Figure 10-4 shows the Z-constrained locations on the trimmed panel (half with symmetric conditions at the smaller end) of the NUMISHEET 2005 cross member. SPC forces in the Z-direction of these 10 locations were recovered after a multi-step static implicit springback with this over-constrained boundary condition (see Figure 10-5). The summation of these Z-forces is shown in Figure 10-6, and it approaches zero as the residual stresses are balanced out by the springback shape absent of gravity.

Example:

A partial keyword input deck is shown below. A part with PID 18 is constrained in 6 locations in a local coordinate system with ID 9. Constrained DOFs are indicated by IDIR.

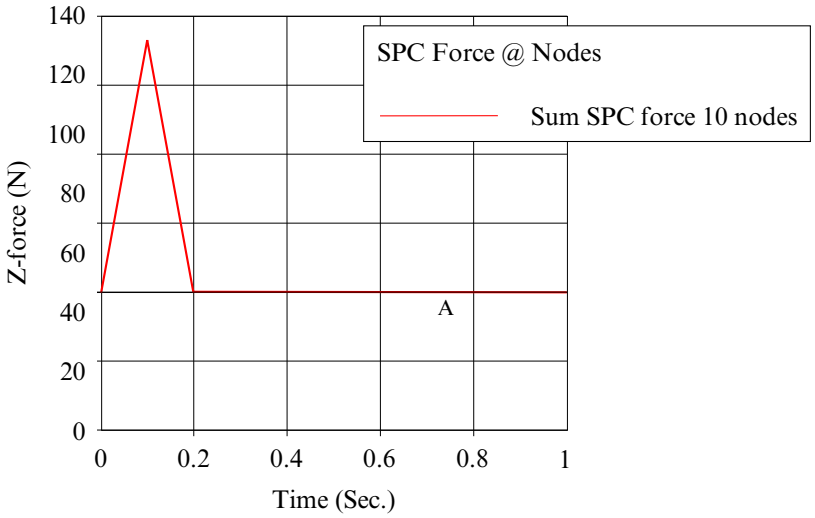

Figure 10-6. SPC Z-force summation of the 10 nodes

Revision Information:

This feature is available in LS-DYNA Dev52619. Revision history is as follows:

1. The SPC output feature: in Dev62560, in both SMP and MPP.
2. IDIR of greater than 10: Dev123340.
3. IDIR of less than 0: Dev127524.
4. Constraints applied after *PART_MOVE: Dev127848.

*CONSTRAINED_EULER_IN_EULER

Purpose: Define the coupling interaction between Eulerian materials in two overlapping, geometrically similar, multi-material Eulerian mesh sets. The command allows a frictionless "contact" between two or more different Eulerian materials.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID1	PSID2	PFAC					
Type	I	I	F					
Default	0	0	0.1					

VARIABLE	DESCRIPTION
PSID1	Part set ID of the 1st ALE or Eulerian set of mesh(es)
PSID2	Part set ID of the 2nd ALE or Eulerian set of mesh(es)
PFAC	A penalty factor for the coupling interaction between the two PSIDs

Remarks:

1. **Model Description.** The 2 meshes must be of Eulerian formulation (the meshes are fixed in space, not moving). Consider 2 overlapping Eulerian meshes. Each Eulerian mesh contains 2 physical materials, say a vacuum and a metal. This keyword provides a frictionless "contact" or interaction between the 2 metals since each resides in a different Eulerian mesh system. Due to its restrictive nature, this option is currently only an experimental feature.

2. **Contact Pressure.** Contact pressure is built up in two overlapping Eulerian elements if their combined material fill fraction exceeds 1.0 (penalty formulation).

3. **Materials.** This feature needs to be combined with *MAT_VACUUM (element formulation 11).

Example:

Consider an ALE/Eulerian multi-material model (ELFORM = 11) consisting of:

PID 1 = *MAT_NULL (material 1)

PID 2 = *MAT_VACUUM ⇒ PID 1 is merged at its boundary to PID 2.

PID 3 = *MAT_NULL (material 3)

PID 4 = *MAT_VACUUM ⇒ PID 3 is merged at its boundary to PID 4.

The mesh set containing PID 1 & 2 intersects or overlaps with the mesh set containing PID 3 & 4. PID 1 is given an initial velocity in the positive *x*-direction. This will cause material 1 to contact material 3 (note that materials 2 & 4 are void). The interaction between materials 1 & 3 is possible by defining this coupling command. In this case material 1 can flow within the mesh region of PID 1 & 2 only, and material 3 can flow within the mesh region of PID 3 & 4 only.

***CONSTRAINED_EXTRA_NODES**_*OPTION*

Available options include:

NODE

SET

Purpose: Define extra nodes for rigid body.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	NID/NSID	IFLAG					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
PID	Part ID of rigid body to which the nodes will be added, see *PART.
NID / NSID	Node (keyword option: NODE) or node set ID (keyword option: SET), see *SET_NODE, of added nodes.
IFLAG	This flag is meaningful if and only if the inertia properties of the Part ID are defined in PART_INERTIA. If set to unity, the center-of-gravity, the translational mass, and the inertia matrix of the PID will be updated to reflect the merged nodal masses of the node or node set. If IFLAG is defaulted to zero, the merged nodes will not affect the properties defined in PART_INERTIA since it is assumed the properties already account for merged nodes.

Remarks:

Extra nodes for rigid bodies may be placed anywhere, even outside the body, and they are assumed to be part of the rigid body. They have many uses including:

1. The definition of draw beads in metal forming applications by listing nodes along the draw bead.

2. Placing nodes where joints will be attached between rigid bodies.

3. Defining a node where point loads are to be applied or where springs may be attached.

4. Defining a lumped mass at a particular location.

The coordinates of the extra nodes are updated according to the rigid body motion.

Examples:

CONSTRAINED_GENERALIZED_WELD_*WELDTYPE_{OPTION}

CONSTRAINED_GENERALIZED_WELD_*WELDTYPE is a family of keywords all sharing a common set of data cards and option flags. The available weld variants are:

SPOT

FILLET

BUTT

CROSS_FILLET

COMBINED

To define an ID for the weld use the option:

ID

Purpose: Define spot, fillet, butt, and other types of welds. Coincident nodes are permitted if the local coordinate ID is defined. For the spot weld a local coordinate ID is not required if the nodes are offset. Failures can include both the plastic and brittle failures. These can be used either independently or together. Failure occurs when either criteria is met. The welds may undergo large rotations since the equations of rigid body mechanics are used to update their motion. Weld constraints between solid element nodes are not supported.

Card Summary:

Card ID. This card is included if and only if the ID keyword option is used.

WID							

Card 1. This card is required.

NSID	CID	FILTER	WINDOW	NPR	NPRT		

Card 2a. This card is included if and only if the weld type is SPOT.

TFAIL	EPSF	SN	SS	N	M		

Card 2b. This card is included if and only if the weld type is FILLET.

TFAIL	EPSF	SIGF	BETA	L	W	A	ALPHA

Card 2c. This card is included if and only if the weld type is BUTT.

TFAIL	EPSF	SIGY	BETA	L	D		

Card 2d.1. This card is included if and only if the weld type is CROSS_FILLET.

TFAIL	EPSF	SIGY	BETA	L	W	A	ALPHA

Card 2d.2. This card is included if and only if the weld type is CROSS_FILLET. Include NPR of this card.

NODEA	NODEB	NCID					

Card 2e.1. This card is included if and only if the weld type is COMBINED. Read in NPR pairs of Cards 2e.1 and 2e.2 for a total of 2 × NPR cards.

TFAIL	EPSF	SIGY	BETA	L	W	A	ALPHA

Card 2e.2. This card is included if and only if the weld type is COMBINED. Read in NPR pairs of Cards 2e.1 and 2e.2 for a total of 2 × NPR cards.

NODEA	NODEB	NCID	WTYP				

Data Card Definitions:

ID Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	WID							
Type	I							

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	CID	FILTER	WINDOW	NPR	NPRT		
Type	I	I	I	I	I	I		
Default	none	0	0	0	↓	0		

VARIABLE	DESCRIPTION
WID	Optional weld ID
NSID	Nodal set ID, see *SET_NODE
CID	Coordinate system ID for output of spot weld data to SWFORC in local system; see *DEFINE_COORDINATE_*OPTION*. CID is not required for spot welds if the nodes are not coincident.
FILTER	Number of force vectors saved for filtering. This option can eliminate spurious failures due to numerical force spikes; however, memory requirements are significant since 6 force components are stored with each vector. LE.1: No filtering GE.2: Simple average of force components divided by FILTER or the maximum number of force vectors that are stored for the time window option below.
WINDOW	Time window for filtering. This option requires the specification of the maximum number of steps (defined by FILTER) which can occur within the filtering time window. A time weighted average is used. If the time step decreases too far, then the filtering time window will be ignored and the simple average is used. EQ.0: Time window is not used.
NPR	Number of individual nodal pairs in the cross fillet or combined general weld.
NPRT	Print option in file rbdout. EQ.0: Default from the control card, *CONTROL_OUTPUT, is used; see variable name IPRTF. EQ.1: Data is printed. EQ.2: Data is not printed.

Spot Weld Card. Additional Card required for the SPOT keyword option.

Card 2a	1	2	3	4	5	6	7	8
Variable	TFAIL	EPSF	SN	SS	N	M		
Type	F	F	F	F	F	F		
Default	10^{16}	10^{16}	10^{16}	10^{16}	2.0	2.0		

VARIABLE	DESCRIPTION
TFAIL	Failure time for constraint set, t_f
EPSF	Effective plastic strain at failure, ϵ^p_{fail}, defines ductile failure.
SN	S_n, normal force at failure; only for the brittle failure of spot welds
SS	S_s, shear force at failure; only for the brittle failure of spot welds
N	n, exponent for normal force; only for the brittle failure of spot welds
M	m, exponent for shear force; only for the brittle failure of spot welds

Remarks:

Spot weld failure due to plastic straining occurs when the effective nodal plastic strain exceeds the input value, $\varepsilon^p_{\text{fail}}$. This option can model the tearing out of a spot weld from the sheet metal since the plasticity is in the material that surrounds the spot weld, not the spot weld itself. A least squares algorithm is used to generate the nodal values of plastic strains at the nodes from the element integration point values. The plastic strain is integrated through the element and the average value is projected to the nodes using a least square fit. This option should only be used for the material models related to metallic plasticity and can result in slightly increased run times.

Brittle failure of the spot welds occurs when:

$$\left[\frac{\max(f_n, 0)}{S_n}\right]^n + \left[\frac{|f_s|}{S_s}\right]^m \geq 1 \ ,$$

where f_n and f_s are the normal and shear interface force. Component f_n contributes for tensile values only. When the failure time, t_f, is reached the nodal rigid body becomes inactive, and the constrained nodes may move freely. In Figure 10-7 the ordering of the

nodes is shown for the 2 node and 3 node spot welds. This order is with respect to the local coordinate system where the local z-axis determines the tensile direction. The nodes in the spot weld may coincide. The failure of the 3 node spot weld may occur gradually with first one node failing and later the second node may fail. For n noded spot welds the failure is progressive starting with the outer nodes (1 and n) and then moving inward to nodes 2 and $n-1$. Progressive failure is necessary to preclude failures that would create new rigid bodies.

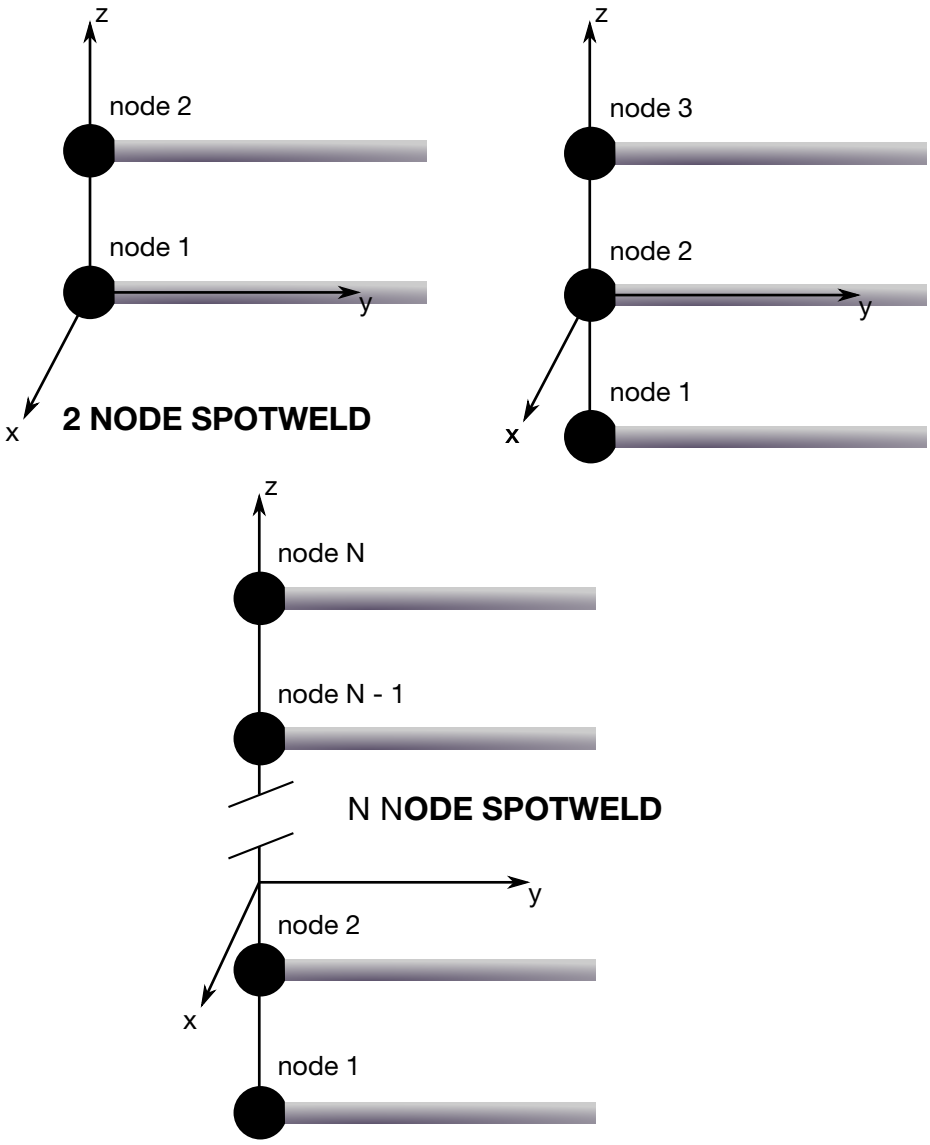

Figure 10-7. Nodal ordering and orientation of the local coordinate system is important for determining spotweld failure.

Fillet Weld Card. Additional Card required for the FILLET keyword option.

Card 2b	1	2	3	4	5	6	7	8
Variable	TFAIL	EPSF	SIGF	BETA	L	W	A	ALPHA
Type	F	F	F	F	F	F	F	F
Default	10^{16}	10^{16}	10^{16}	1.0	none	none	none	none

VARIABLE	DESCRIPTION
TFAIL	Failure time for constraint set, t_f
EPSF	Effective plastic strain at failure, ϵ^p_{fail}, defines ductile failure.
SIGF	σ_f, stress at failure for brittle failure
BETA	β, failure parameter for brittle failure
L	L, length of fillet weld (see Figure 10-8)
W	w, separation of parallel fillet welds (see Figure 10-8)
A	a, fillet weld throat dimension (see Figure 10-8)
ALPHA	α, weld angle (see Figure 10-8) in degrees

Remarks:

Ductile fillet weld failure, due to plastic straining, is treated identically to spot weld failure. Brittle failure occurs when the following weld stress condition is met on the narrowest fillet weld cross section (across the throat):

$$\beta\sqrt{\sigma_n^2 + 3(\tau_n^2 + \tau_t^2)} \geq \sigma_f \quad ,$$

where

σ_n = normal stress
τ_n = shear stress in local zx-plane
τ_t = shear stress in local-y direction
σ_f = failure stress
β = failure parameter

The component σ_n is nonzero for tensile values only. When the failure time, t_f , is reached the nodal rigid body becomes inactive and the constrained nodes may move freely.

Figure 10-8 shows the ordering of the nodes for the 2 node and 3 node fillet welds. This order is with respect to the local coordinate system where the local z-axis determines the tensile direction. The initial orientation of the local coordinate system is defined by CID. If CID = 0, then the global coordinate system is used. The local coordinate system is updated according to the rotation of the rigid body representing the weld. The failure of the 3 node fillet weld may occur gradually with first one node failing and later the second node may fail.

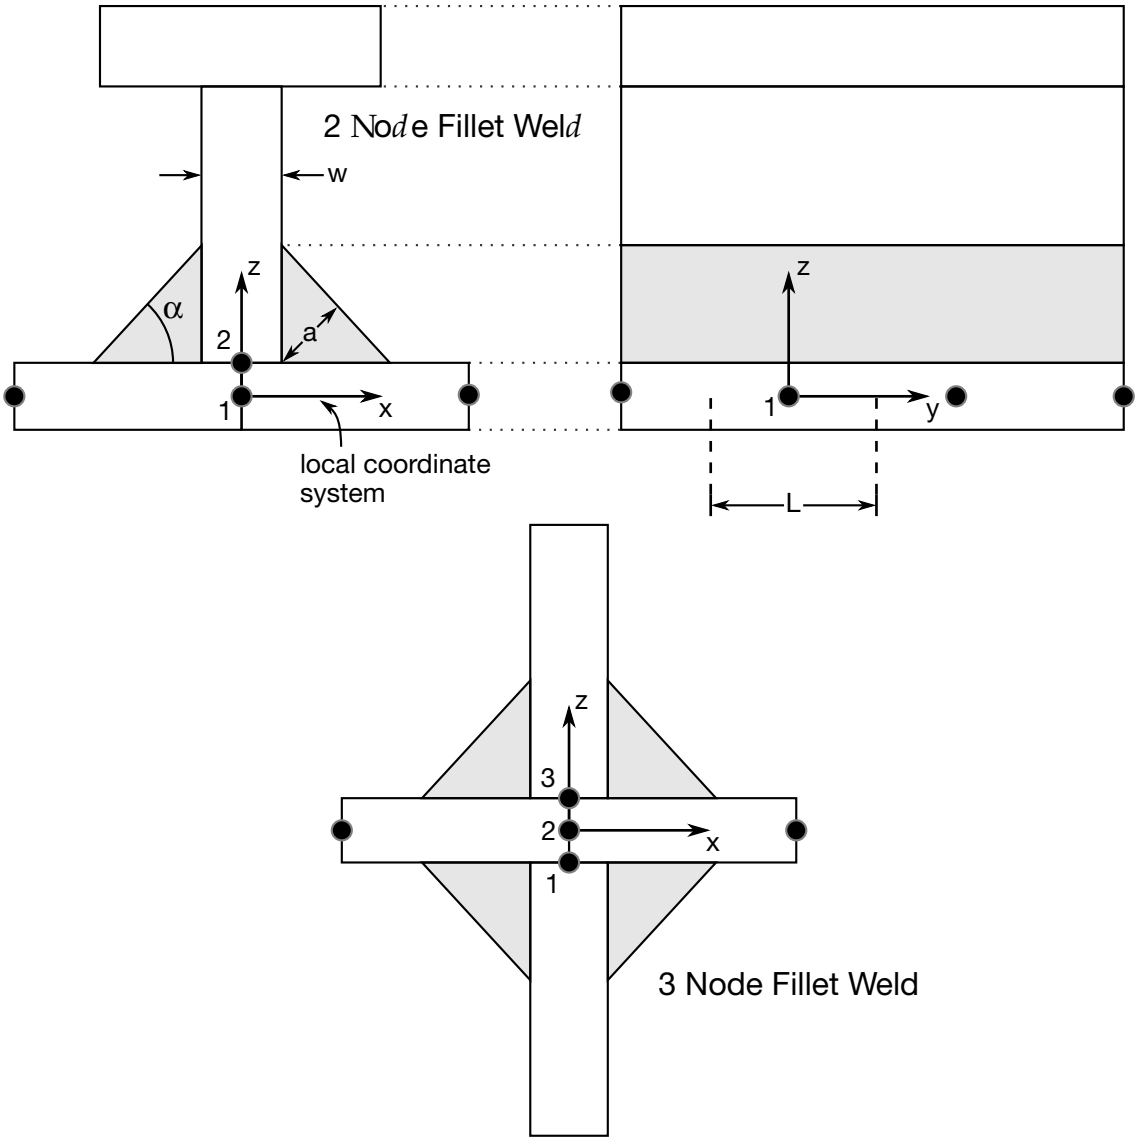

Figure 10-8. Nodal ordering and orientation of the local coordinate system is shown for fillet weld failure. The angle is defined in degrees.

Butt Weld Card. Additional Card required for the BUTT keyword option.

Card 2c	1	2	3	4	5	6	7	8
Variable	TFAIL	EPSF	SIGY	BETA	L	D		
Type	F	F	F	F	F	F		
Default	10^{16}	10^{16}	10^{16}	1.0	none	none		

VARIABLE	DESCRIPTION
TFAIL	Failure time for constraint set, t_f
EPSF	Effective plastic strain at failure, ϵ^p_{fail}, defines ductile failure.
SIGY	σ_f, stress at failure for brittle failure
BETA	β, failure parameter for brittle failure
L	L, length of butt weld (see Figure 10-9)
D	d, thickness of butt weld (see Figure 10-9)

Remarks:

Ductile butt weld failure, due to plastic straining, is treated identically to spot weld failure. Brittle failure of the butt welds occurs when:

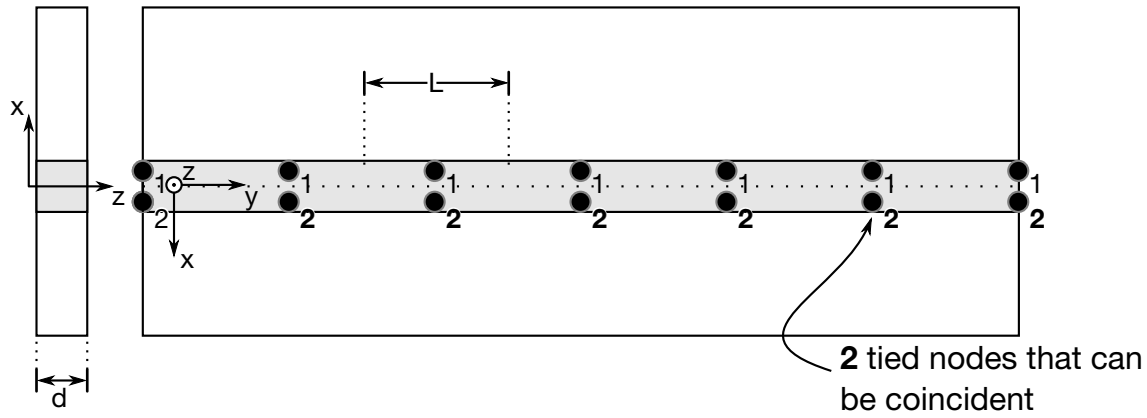

Figure 10-9. Orientation of the local coordinate system and nodal ordering is shown for butt weld failure.

$$\beta\sqrt{\sigma_n^2 + 3(\tau_n^2 + \tau_t^2)} \geq \sigma_f \ ,$$

where

σ_n = normal stress
τ_n = shear stress in direction of weld (local y)
τ_t = shear stress normal to weld (local z)
σ_f = failure stress
β = failure parameter

The component σ_n is nonzero for tensile values only. When the failure time, t_f, is reached the nodal rigid body becomes inactive and the constrained nodes may move freely. The nodes in the butt weld may coincide.

Example:

Card 2d.2	1	2	3	4	5	6	7	8
Variable	NODEA	NODEB	NCID					
Type	I	I	I					

VARIABLE	DESCRIPTION
TFAIL	Failure time for constraint set, t_f
EPSF	Effective plastic strain at failure, ϵ^p_{fail}, defines ductile failure
SIGY	σ_f, stress at failure for brittle failure
BETA	β, failure parameter for brittle failure
L	L, length of fillet weld (see Figure 10-8)
W	w, separation of parallel fillet welds (see Figure 10-8)
A	a, throat dimension of fillet weld (see Figure 10-8)
ALPHA	α, weld angle (see Figure 10-8) in degrees
NODEA	Node ID, A, in weld pair. See Figure 10-10.
NODEB	Node ID, B, in weld pair
NCID	Local coordinate system ID

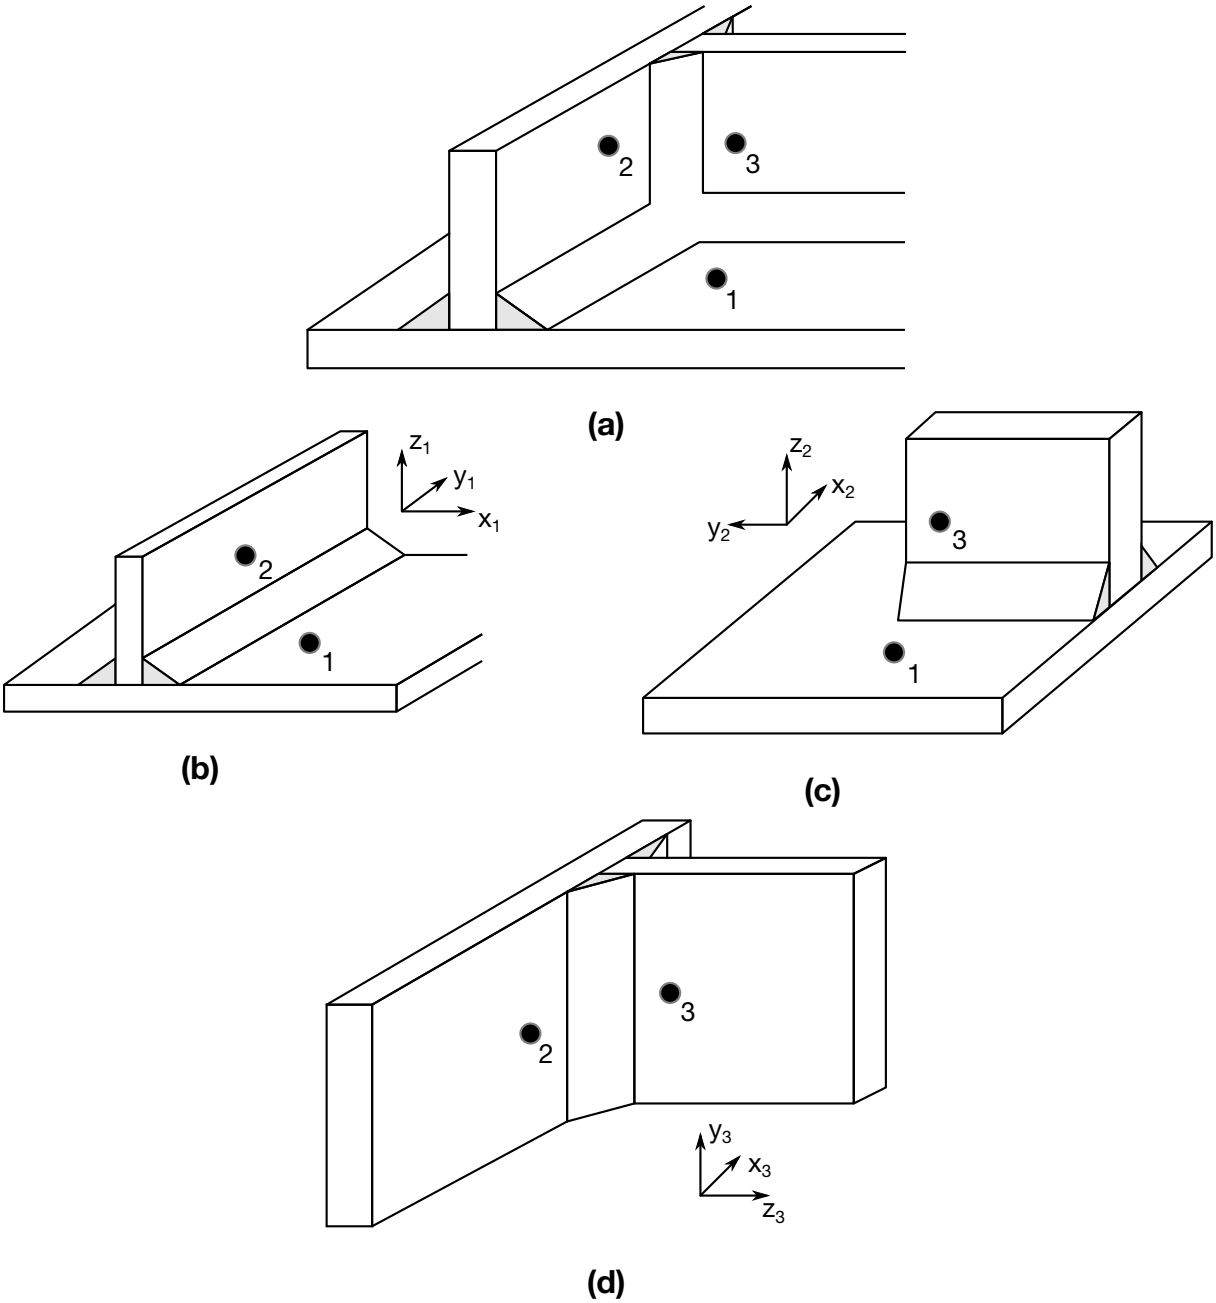

Figure 10-10. A simple cross fillet weld illustrates the required input. Here NPR = 3 with nodal pairs (A = 2, B = 1), (A = 3, B = 1), and (A = 3, B = 2). The local coordinate axes are shown. These axes are fixed in the rigid body and are referenced to the local rigid body coordinate system which tracks the rigid body rotation.

Combined Weld Cards:
Additional cards for the COMBINED keyword option. Read in NPR pairs of Cards 2e.1 and 2e.2 for a total of 2 × NPR cards.

Card 2e.1	1	2	3	4	5	6	7	8
Variable	TFAIL	EPSF	SIGY	BETA	L	W	A	ALPHA
Type	F	F	F	F	F	F	F	F
Default	10^{16}	10^{16}	10^{16}	1.0	none	none	none	none

Card 2e.2	1	2	3	4	5	6	7	8
Variable	NODEA	NODEB	NCID	WTYP				
Type	I	I	I	I				

VARIABLE	DESCRIPTION
TFAIL	Failure time, t_f, for constraint set
EPSF	Effective plastic strain at failure, ϵ^p_{fail}, defines ductile failure.
SIGY	σ_f, stress at failure for brittle failure.
BETA	β, failure parameter for brittle failure.
L	L, length of fillet/butt weld (see Figure 10-8 and 10-9).
W	w, width of flange (see Figure 10-8).
A	a, width of fillet weld (see Figure 10-8).
ALPHA	α, weld angle (see Figure 10-8) in degrees.
NODEA	Node ID, A, in weld pair
NODEB	Node ID, B, in weld pair
NCID	Local coordinate system ID

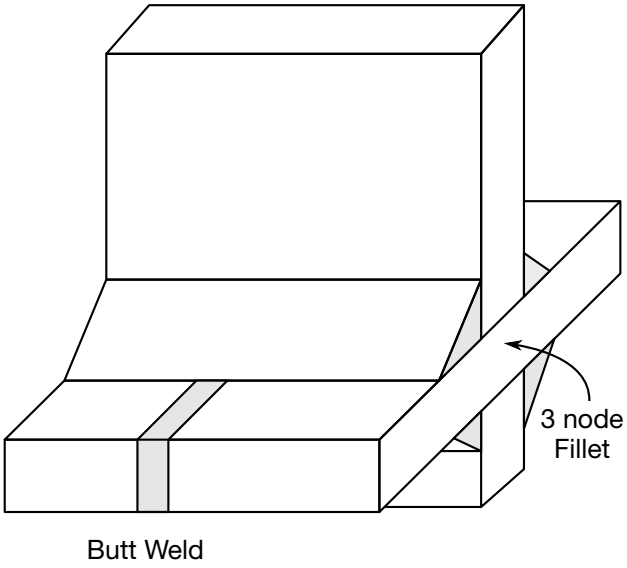

Figure 10-11. A combined weld is a mixture of fillet and butt welds.

VARIABLE	DESCRIPTION
WTYPE	Weld pair type. See Figure 10-11. EQ.0: Fillet weld EQ.1: Butt weld

*CONSTRAINED_GLOBAL

Purpose: Define a global boundary constraint plane. This card implements the trivial constraint equation; namely, constrained degrees of freedom are held fixed in time.

Card 1	1	2	3	4	5	6	7	8
Variable	TC	RC	DIR	X	Y	Z	TOL	
Type	I	I	I	F	F	F	F	
Default	0	0	none	0.0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
TC	Translational Constraint: EQ.0: no translational constraints EQ.1: constrained x translation EQ.2: constrained y translation EQ.3: constrained z translation EQ.4: constrained x and y translations EQ.5: constrained y and z translations EQ.6: constrained x and z translations EQ.7: constrained x, y, and z translations
RC	Rotational Constraint: EQ.0: no rotational constraints EQ.1: constrained x-rotation EQ.2: constrained y-rotation EQ.3: constrained z-rotation EQ.4: constrained x and y rotations EQ.5: constrained y and z rotations EQ.6: constrained z and x rotations EQ.7: constrained x, y, and z rotations

VARIABLE	DESCRIPTION
DIR	Direction of normal for constraint plane: EQ.1: global x EQ.2: global y EQ.3: global z
X	Global x-coordinate of a point on the constraint plane
Y	Global y-coordinate of a point on the constraint plane
Z	Global z-coordinate of a point on the constraint plane
TOL	User-defined tolerance in length units. If non-zero, the internal mesh-size dependent tolerance gets replaced by this value.

Remarks:

Nodes within a mesh-size-dependent tolerance are constrained on a global plane. This option is recommended for use with *r*-method adaptive remeshing where nodal constraints are lost during the remeshing phase. See *CONSTRAINED_LOCAL for specifying constraints to nodes lying on a local plane.

*CONSTRAINED_IMMERSED_IN_SPG

Purpose: Define coupling of beams and SPG solid elements through immerse method.

Card 1	1	2	3	4	5	6	7	8
Variable	SPGPID							
Type	I							
Default	none							

FEM Beams Card. Include this card as many times as needed. Input ends at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	IPID1	IPID2	IPID3	IPID4	IPID5	IPID6	IPID7	IPID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
SPGPID	Part ID of SPG solids into which where FEM beams are immersed
IPID*i*	Part IDs of FEM beams

*CONSTRAINED_INTERPOLATION_{OPTION}

Available options include:

<BLANK>

LOCAL

Purpose: Define an interpolation constraint. With this constraint type, the motion of a single dependent node is interpolated from the motion of a set of independent nodes.

This option is useful for the redistribution of a load applied to the dependent node by the surrounding independent nodes. This load may be a translational force or a rotational moment. This keyword is typically used to model shell-brick and beam-brick interfaces.

The mass and rotary inertia of the dependent nodal point is also redistributed. This constraint is applied in the global coordinate system unless the option LOCAL is active. *One *CONSTRAINED_INTERPOLATION card is required for each constraint definition.* The input list of independent nodes is terminated when the next keyword ("*") card is found.

In explicit calculations, the independent and dependent nodes cannot be dependent nodes in other constraints, such as nodal rigid bodies; however, implicit calculations are not bound by this limitation. See Remark 2.

Card 1	1	2	3	4	5	6	7	8
Variable	ICID	DNID	DDOF	CIDD	ITYP	IDNSW	FGM	
Type	I	I	I	I	I	I	I	
Default	none	none	123456	global	0	1	0	

Independent Node Card Sets:

If LOCAL option is not set, for each independent node include the following card; if the LOCAL keyword option is set, include the following *pair* of cards. The next keyword ("*") card terminates this input.

Card 2	1	2	3	4	5	6	7	8
Variable	INID	IDOF	TWGHTX	TWGHTY	TWGHTZ	RWGHTX	RWGHTY	RWGHTZ
Type	I	I	F	F	F	F	F	F
Default	0	123456	1.0	TWGHTX	TWGHTX	TWGHTX	TWGHTX	TWGHTX

Local Coordinate Card. Additional card for the LOCAL keyword option to be paired with Card 2.

Card 3	1	2	3	4	5	6	7	8
Variable	CIDI							
Type	I							
Default	global							

VARIABLE	DESCRIPTION
ICID	Interpolation constraint ID.
DNID	Dependent node ID. This node should not be a member of a rigid body, or elsewhere constrained in the input.
DDOF	Dependent degrees-of-freedom. The list of dependent degrees-of-freedom consists of a number with up to six digits, with each digit representing a degree of freedom. For example, the value 1356 indicates that degrees of freedom 1, 3, 5, and 6 are controlled by the constraint. The default is 123456. DDOF are in the global coordinate system regardless of whether the LOCAL option is used or not. Digit degree of freedom ID's: EQ.1: x

VARIABLE	DESCRIPTION
	EQ.2: y
	EQ.3: z
	EQ.4: Rotation about x axis
	EQ.5: Rotation about y axis
	EQ.6: Rotation about z axis
CIDD	Local coordinate system ID if LOCAL option is active. If blank, the global coordinate system is assumed.
ITYP	Specifies the meaning of INID.
	EQ.0: INID is a node ID
	EQ.1: INID is a node set ID
INDSW	Switch for controlling the explicit solution when an independent (or dependent) node is deleted.
	EQ.0: Default to option 1.
	EQ.1: Terminate the explicit analysis when an independent node or the dependent node is deleted.
	EQ.2: Continue the explicit analysis with the constraints unchanged.
FGM	Flag for special treatment of this constraint for implicit problems only:
	EQ.0: Use standard constraint processing for implicit.
	EQ.1: Use special processing for this constraint for implicit only; see Remarks.
INID	Independent node ID or node set ID
IDOF	Independent degrees-of-freedom using the same form as for the dependent degrees-of-freedom, DDOF, above.
TWGHTX	Weighting factor for node INID with active degrees-of-freedom IDOF. This weight scales the x-translational component. It is normally sufficient to define only TWGHTX even if its degree-of-freedom is inactive since the other factors are set equal to this input value as the default. There is no requirement on the values that are chosen as the weighting factors, that is, that they sum to unity. The default value for the weighting factor is unity.

VARIABLE	DESCRIPTION
TWGHTY	Weighting factor for node INID with active degrees-of-freedom IDOF. This weight scales the y-translational component.
TWGHTZ	Weighting factor for node INID with active degrees-of-freedom IDOF. This weight scales the z-translational component.
RWGHTX	Weighting factor for node INID with active degrees-of-freedom IDOF. This weight scales the x-rotational component.
RWGHTY	Weighting factor for node INID with active degrees-of-freedom IDOF. This weight scales the y-rotational component.
RWGHTZ	Weighting factor for node INID with active degrees-of-freedom IDOF. This weight scales the z-rotational component.
CIDI	Local coordinate system ID if LOCAL option is active. If blank the global coordinate system is assumed.

Remarks:

1. **Dependent node not attached to the finite element model.** This constraint is sometimes used with a dependent node that is not attached to the finite element model. If point loads or discrete masses are put on this dependent node, then this constraint transfers the point load or the mass to the set of independent nodes. In another case, a dependent node can track a particular point in the geometry through this constraint as the model deforms and rotates, such as a point on the axis of rotation of a turbine. For these cases, where the dependent node is not attached to the finite element model but is an artificial node used to distribute forces and/or masses or to track a geometric position, we recommend setting FGM to 1.

2. **Limitations in enforcing constraints with the explicit solver.** As mentioned previously, dependent and independent nodes in this constraint cannot be dependent nodes for other constraints when using the explicit solver. LS-DYNA sequentially enforces constraints in explicit. Thus, there is no guarantee that LS-DYNA will evaluate the constraints in the desired order. For instance, suppose we have the following two constraints:

$$\text{constraint 1:} \quad x_1 = x_2$$
$$\text{constraint 2:} \quad x_2 = x_3$$

Then, at time step $n+1$, $x_1^{n+1} = x_2^n$ and $x_2^{n+1} = x_3^{n+1}$ because of the order of evaluation. Thus, we get a result that doesn't match the desired result of $x_1^{n+1} = x_2^{n+1} = x_3^{n+1}$.

Note that between different types of constraints (such as a rigid body constraint and a *CONSTRAINED_INTERPOLATION), the last evaluated constraint overwrites the previous results. Thus, one constraint may have no influence on the results and be effectively ignored.

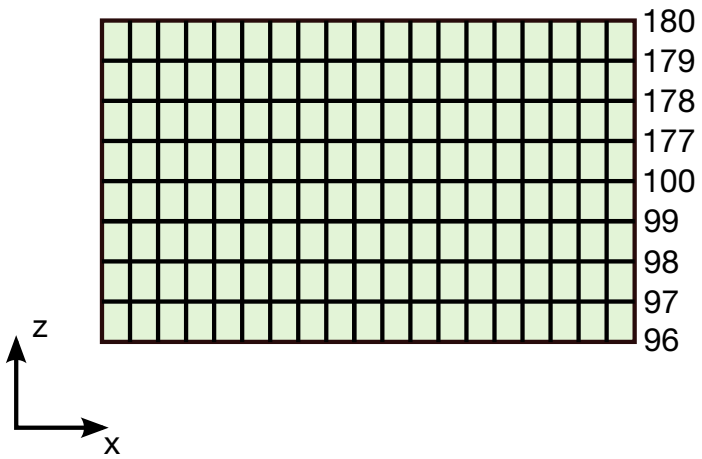

Figure 10-13. Illustration of Example 2.

*CONSTRAINED_INTERPOLATION_SPOTWELD

(prior notation *CONSTRAINED_SPR3 still works)

Purpose: Define a spot weld with failure. This feature uses a plasticity-damage model that reduces the force and moment resultants to zero as the spot weld fails. A single node specifies the location of the spot weld at the center of two connected sheets. A radius, approximately equal to the spot weld's radius, gives the domain of influence. LS-DYNA performs a normal projection from the two sheets to the spot weld node and locates all nodes within the domain of influence. The numerical implementation of this feature is similar to the SPR2 model (*CONSTRAINED_SPR2).

Starting with LS-DYNA R13.1, not only shell element parts can be connected using this approach, but also solid elements. However, the new capability is still in an experimental stage and should be treated with care. For instance, it is advantageous if the solid element parts still have some kind of obvious planar structure.

Card Summary:

Card 1. This card is required.

PID1	PID2	NSID	THICK	R	STIFF	ALPHA1	MODEL

Card 2. This card is required.

RN	RS	BETA1	LCF	LCUPF	LCUPR	DENS	INTP

Card 3. This card is included when MODEL = 2, 12, or 22.

UPFN	UPFS	ALPHA2	BETA2	UPRN	UPRS	ALPHA3	BETA3

Card 4. This card is included when MODEL = 2, 12, or 22.

MRN	MRS						

Card 5. This card is read only when MODEL = 1, 11, or 21. It is optional.

STIFF2	STIFF3	STIFF4	LCDEXP	GAMMA	SROPT	PIDVB	

Card 6. This card is read only when MODEL = 1, 11, or 21. It is optional.

SCARN	SCARS						

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PID1	PID2	NSID	THICK	R	STIFF	ALPHA1	MODEL
Type	I	I	I	F	F	F	F	F
Default	none	none	none	none	none	none	none	1.0

VARIABLE	DESCRIPTION
PID1	Part ID or part set ID of first sheet GT.0: Part ID LT.0: |PID1| is part set ID (for in-plane composed sheets, such as Tailored Blanks).
PID2	Part ID or part set ID of second sheet. PID2 can be identical to PID1 if the spot weld location nodes from NSID lie in between the shell elements that should be self-connected. GT.0: Part ID LT.0: |PID2| is part set ID (for in-plane composed sheets sheets, such as Tailored Blanks).
NSID	Node set ID of spot weld location nodes
THICK	Total thickness of both sheets
R	Spot weld radius
STIFF	Elastic stiffness. Function ID if MODEL > 10 (see Remark 2). GT.0: Constant value LT.0: |STIFF| refers to separate material data in *MAT_CONSTRAINED_SPR3 (*MAT_265).
ALPHA1	Scaling factor α_1. Function ID if MODEL > 10 (see Remark 2).
MODEL	Material behavior and damage model (see Remarks 3 and 4). EQ.1: SPR3 (default) EQ.2: SPR4

VARIABLE	DESCRIPTION
	EQ.11: Same as 1 with selected material parameters as functions
	EQ.12: Same as 2 with selected material parameters as functions
	EQ.21: Same as 11 with slight modification
	EQ.22: Same as 12 with slight modification

Card 2	1	2	3	4	5	6	7	8
Variable	RN	RS	BETA1	LCF	LCUPF	LCUPR	DENS	INTP
Type	F	F	F	I	I	I	F	F
Default	none	none	none	none	↓	↓	none	0

VARIABLE	DESCRIPTION
RN	Tensile strength factor, R_n.
	GT.0.0: Constant value unless MODEL > 10. Function ID if MODEL > 10 (see Remark 2).
	LT.0.0: Load curve with ID |RN| giving R_n as a function of peel ratio (see Remark 5)
RS	Shear strength factor, R_s. Function ID if MODEL > 10 (see Remark 2).
BETA1	Exponent for plastic potential β_1. Function ID if MODEL > 10 (see Remark 2).
LCF	Load curve or table ID. Load curve ID describing force as a function of plastic displacement, that is, $F^0(\bar{u}^{\text{pl}})$. Table ID describing force as a function of mode mixity (table values) and plastic displacement (curves), that is, $F^0(\bar{u}^{\text{pl}}, \kappa)$.
LCUPF	Load curve ID describing plastic initiation displacement as a function of mode mixity, that is, $\bar{u}_0^{\text{pl}}(\kappa)$. Only for MODEL = 1, 11, or 21. For MODEL = 1, LCUPF can also be a table ID giving plastic initiation displacement as a function of peel ratio (table values) and mode mixity (curves). See Remark 5.

VARIABLE	DESCRIPTION
LCUPR	Load curve ID describing plastic rupture displacement as a function of mode mixity, that is, $\bar{u}_f^{\text{pl}}(\kappa)$. Only for MODEL = 1, 11, or 21. For MODEL = 1, LCUPF can also be a table ID giving plastic initiation displacement as a function of peel ratio (table values) and mode mixity (curves). See Remark 5.
DENS	Spot weld density (necessary for time step calculation).
INTP	Flag for interpolation. EQ.0: Linear (default), EQ.1: Uniform, EQ.2: Inverse distance weighting.

Additional Card for MODEL = 2, 12, or 22.

Card 3	1	2	3	4	5	6	7	8
Variable	UPFN	UPFS	ALPHA2	BETA2	UPRN	UPRS	ALPHA3	BETA3
Type	F	F	F	F	F	F	F	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
UPFN	Plastic initiation displacement in normal direction, $\bar{u}_{0,\text{ref}}^{\text{pl},n}$.
UPFS	Plastic initiation displacement in shear direction, $\bar{u}_{0,\text{ref}}^{\text{pl},s}$.
ALPHA2	Plastic initiation displacement scaling factor, α_2.
BETA2	Exponent for plastic initiation displacement, β_2.
UPRN	Plastic rupture displacement in normal direction, $\bar{u}_{f,\text{ref}}^{\text{pl},n}$.
UPRS	Plastic rupture displacement in shear direction, $\bar{u}_{f,\text{ref}}^{\text{pl},s}$.
ALPHA3	Plastic rupture displacement scaling factor, α_3.
BETA3	Exponent for plastic rupture displacement, β_3.

Additional Card for MODEL = 2, 12, or 22.

Card 4	1	2	3	4	5	6	7	8
Variable	MRN	MRS						
Type	F	F						
Default	none	none						

VARIABLE	DESCRIPTION
MRN	Proportionality factor for dependency, m_{R_n}.
MRS	Proportionality factor for dependency, m_{R_s}.

Optional Card for MODEL = 1, 11, or 21.

Card 5	1	2	3	4	5	6	7	8
Variable	STIFF2	STIFF3	STIFF4	LCDEXP	GAMMA	SROPT	PIDVB	
Type	F	F	F	F	F	F	F	
Default	STIFF	STIFF	STIFF	0.0	0.0	0.0	0.0	

VARIABLE	DESCRIPTION
STIFF2	Elastic shear stiffness
STIFF3	Elastic bending stiffness
STIFF4	Elastic torsional stiffness
LCDEXP	Load curve for damage exponent as a function of mode mixity
GAMMA	Scaling factor, γ_1
SROPT	Shear rotation option that defines local kinematics system: EQ.0: Pure shear does not create normal component (default). EQ.1: Pure shear creates normal component.

VARIABLE	DESCRIPTION
PIDVB	Part ID for beams used to represent SPR3 in post-processing. EQ.0: Part ID automatically set (default). GT.0: PIDVB defines the part ID. LT.0: |PIDVB| defines the part ID, but an alternative type of beam representation (deformation) is invoked. Also, beams are deleted after failure.

Optional Card for MODEL = 1, 11, or 21.

Card 6	1	2	3	4	5	6	7	8
Variable	SCARN	SCARS						
Type	F	F						
Default	1.0	1.0						

VARIABLE	DESCRIPTION
SCARN	Scale factor for tensile strength factor RN. This option also scales the displacements in LCF, LCUPF, and LCUPR so that the shape of the force-displacement curve stays similar.
SCARS	Scale factor for tensile strength factor RS. This option also scales the displacements in LCF, LCUPF, and LCUPR so that the shape of the force-displacement curve stays similar.

Remarks:

1. **Drilling rotation constraint method.** With this keyword, we recommend using the drilling rotation constraint method for the connected components in explicit analysis. To do this, specify DRPSID of *CONTROL_SHELL to include all shell parts involved in INTERPOLATION_SPOTWELD connections.

2. **Function inputs.** If MODEL is chosen to be greater than 10, then 5 variables must be defined as function IDs: STIFF, ALPHA1, RN, RS, and BETA1. These functions incorporate the following input values: thicknesses of both weld partners (t1, t2) and maximum engineering yield stresses, also called necking points (sm1, sm2). For ALPHA1 = 100 such a function could look like,

```
*DEFINE_FUNCTION
       100
func(t1,t2,sm1,sm2)=sm1/sm2
```

(This function is only a demonstration; it does not make any physical sense.) For MODEL = 11 or 12, first sheet (PID1) is the first weld partner represented by t1 and sm1. For MODEL = 21 or 22, the thinner part is the first weld partner. Since material parameters must be identified from both weld partners during initialization, this feature is only available for a subset of material models, namely, materials 24, 120, 123, and 124.

3. **Model = 1, 11, or 21 ("SPR3").** This numerical model is similar to the self-piercing rivet model SPR2 (see *CONSTRAINED_SPR2) but with some differences to make it more suitable for spot welds. The first difference is symmetric behavior of the spot weld connection, that is, there is no distinction between an upper sheet and a lower sheet. This symmetry is done by averaging the normals of both parts and always distributing the balance moments equally to both sides.

   The second difference is that there are not only two but three (or four if STIFF4 > 0) quantities to describe the kinematics, namely the normal relative displacement δ_n, the tangential relative displacement δ_t, and the relative rotation ω_b (and the relative twist ω_t) - all with respect to the plane-of-maximum opening, that is, a relative displacement vector is defined as

$$\mathbf{u} = (\delta_n, \delta_t, \omega_b) \ .$$

   The third difference is the underlying material model. With the described kinematic quantities, an elastic effective force vector is computed first:

$$\tilde{\mathbf{f}} = (f_n, f_t, m_b) = \text{STIFF} \times \mathbf{u} = \text{STIFF} \times (\delta_n, \delta_t, \omega_b) \ .$$

   Or, if individual stiffnesses are defined on optional Card 5, each component is treated separately like this (also allows torsional stiffness to be added):

$$f_n = \text{STIFF} \times \delta_n$$

$$f_t = \text{STIFF2} \times \delta_t$$

$$m_b = \text{STIFF3} \times \omega_b$$

$$m_t = \text{STIFF4} \times \omega_t$$

   From that, two resultant forces for the normal and tangential directions (shear), respectively, are computed using

$$F_n = \langle f_n \rangle + \alpha_1 m_b, \qquad F_s = f_t + \gamma_1 |m_t| \ .$$

   A yield function is defined for plastic behavior

$$\phi(\tilde{\mathbf{f}}, \bar{u}^{\text{pl}}) = P(\tilde{\mathbf{f}}) - F^0(\bar{u}^{\text{pl}}) \leq 0$$

   with the potential

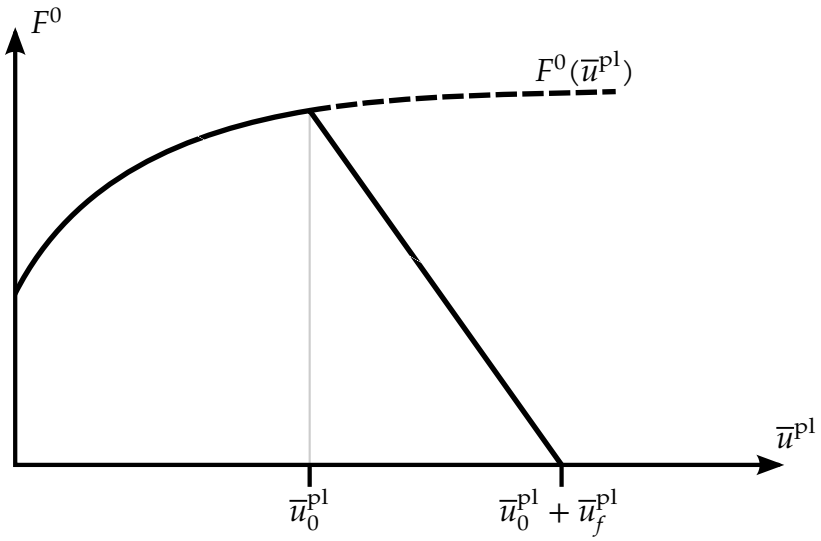

Figure 10-14. Force-displacement curve: plasticity and linear damage

$$P(\tilde{\mathbf{f}}) = \left[\left(\frac{F_n}{R_n} \right)^{\beta_1} + \left(\frac{F_s}{R_s} \right)^{\beta_1} \right]^{1/\beta_1} ,$$

and isotropic hardening described by load curve LCF (see Figure 10-14):

$$F^0 = F^0\left(\bar{u}^{\mathrm{pl}}\right) .$$

Therefore, the relative plastic displacement, $\bar{u}^{\mathrm{pl}}$, is calculated using the following relation:

$$P(\tilde{\mathbf{f}})\ \bar{u}^{\mathrm{pl}} = \sum_i F_i\ u_i^{\mathrm{pl}}, \qquad i = \{n, s\} .$$

In addition, a linear softening evolution is incorporated, where damage is defined as:

$$d = \frac{\bar{u}^{\mathrm{pl}} - \bar{u}_0^{\mathrm{pl}}(\kappa)}{\bar{u}_f^{\mathrm{pl}}(\kappa)}, \qquad 0 < d < 1$$

with mode mixity

$$\kappa = \frac{2}{\pi} \arctan\left(\frac{F_n}{F_s} \right), \qquad 0 < \kappa < 1 .$$

Alternatively, nonlinear damage evolution can be invoked by using LCDEXP, where the damage exponent m is defined as a function of the mode mixity:

$$d = \frac{1 - \exp\left(-m\dfrac{\bar{u}^{\mathrm{pl}} - \bar{u}_0^{\mathrm{pl}}(\kappa)}{\bar{u}_f^{\mathrm{pl}}(\kappa)}\right)}{1 - \exp(-m)}, \qquad 0 < d < 1 \ .$$

Finally, the nominal force is computed as:

$$\mathbf{f} = (1 - d)\tilde{\mathbf{f}} \ .$$

4. **MODEL = 2, 12, or 22 ("SPR4").** In this approach, the relative displacement vector is defined as in Model = 1:

$$\mathbf{u} = (\delta_n, \delta_t) \ .$$

The elastic effective force vector is computed using the elastic stiffness STIFF

$$\tilde{\mathbf{f}} = (f_n, f_t) = \mathrm{STIFF} \times \mathbf{u} = \mathrm{STIFF} \times (\delta_n, \delta_t) \ .$$

A yield function is defined for plastic behavior as

$$\phi(\tilde{\mathbf{f}}, \bar{u}^{\mathrm{pl}}) = P(\tilde{\mathbf{f}}) - F^0(\bar{u}^{\mathrm{pl}}) \le 0$$

with relative plastic displacement $\bar{u}^{\mathrm{pl}}$ and potential

$$P(\tilde{\mathbf{f}}) = \left[\left(\frac{f_n}{\tilde{R}_n}\right)^{\beta_1} + \left(\frac{f_t}{\tilde{R}_s}\right)^{\beta}\right]^{1/\beta_1}$$

in which $\tilde{R}_n$ and $\tilde{R}_s$ represents the load capacity in the normal and tangential directions, respectively. They are calculated using the values of R_n and R_s as follows with the influence of relative rotation angle, ω_b, scaled by α_1:

$$\tilde{R}_s = R_s$$
$$\tilde{R}_n = R_n(1 - \alpha_1\omega_b)$$

In addition, a linear softening evolution is incorporated, where damage is defined as:

$$d = \frac{\bar{u}^{\mathrm{pl}} - \bar{u}_0^{\mathrm{pl}}}{\bar{u}_f^{\mathrm{pl}}}, \qquad 0 < d < 1 \ .$$

The values of $\bar{u}_0^{\mathrm{pl}}$ and $\bar{u}_f^{\mathrm{pl}}$ are calculated by solving the following equations

$$\left\{\left[\frac{\bar{u}_0^{\mathrm{pl},n}}{\bar{u}_{0,\mathrm{ref}}^{\mathrm{pl},n}(1 - \alpha_2\omega_b)}\right]^{\beta_2} + \left(\frac{\bar{u}_0^{\mathrm{pl},s}}{\bar{u}_{0,\mathrm{ref}}^{\mathrm{pl},s}}\right)^{\beta_2}\right\}^{1/\beta_2} - 1 = 0, \qquad \begin{aligned}\bar{u}_0^{\mathrm{pl},n} &= \sin(\varphi)\,\bar{u}_0^{\mathrm{pl}} \\ \bar{u}_0^{\mathrm{pl},s} &= \cos(\varphi)\,\bar{u}_0^{\mathrm{pl}}\end{aligned}$$

$$\left\{\left[\frac{\bar{u}_f^{\mathrm{pl},n}}{\bar{u}_{f,\mathrm{ref}}^{\mathrm{pl},n}(1 - \alpha_3\omega_b)}\right]^{\beta_3} + \left(\frac{\bar{u}_f^{\mathrm{pl},s}}{\bar{u}_{f,\mathrm{ref}}^{\mathrm{pl},s}}\right)^{\beta_3}\right\}^{1/\beta_3} - 1 = 0, \qquad \begin{aligned}\bar{u}_f^{\mathrm{pl},n} &= \sin(\varphi)\,\bar{u}_f^{\mathrm{pl}} \\ \bar{u}_f^{\mathrm{pl},s} &= \cos(\varphi)\,\bar{u}_f^{\mathrm{pl}}\end{aligned}$$

in which the load angle is

$$\varphi = \arctan\left(\frac{f_n}{f_s}\right) .$$

For rate dependent behavior a plastic deformation rate $\dot{\bar{u}}^{\mathrm{pl}}$ is defined by

$$\dot{\bar{u}}^{\mathrm{pl}} = \frac{\Delta \bar{u}^{\mathrm{pl}}}{\Delta t}$$

where $\Delta \bar{u}^{\mathrm{pl}}$ is the plastic increment in the current time step and Δt is the time step size. If MRN and MRS are defined, $\tilde{R}_n$ and $\tilde{R}_s$ are calculated as

$$\tilde{R}_n\left(\dot{\bar{u}}^{\mathrm{pl}}\right) = \left(R_n + m_{R_n}\dot{\bar{u}}^{\mathrm{pl}}\right)(1 - \alpha_1\,\omega_b)$$
$$\tilde{R}_s\left(\dot{\bar{u}}^{\mathrm{pl}}\right) = R_s + m_{R_s}\dot{\bar{u}}^{\mathrm{pl}}$$

A detailed description of the SPR4 approach (MODEL = 2) is given in Bier and Sommer [2013], where this model is called "SPR3_IWM".

5. **Peel ratio.** For MODEL = 1, you can optionally define R_n (RN), $\bar{u}_0^{\mathrm{pl}}$ (LCUPF), and $\bar{u}_f^{\mathrm{pl}}$ (LCUPR) to be dependent on the peel ratio. The peel ratio is the ratio of the bending moment to the resultant axial force. This value is kept constant when plastic yield is reached.

6. **History variables output.** If NEIPB = 7 is defined on *DATABASE_-EXTENT_-BINARY, then the following history variables are written to the d3plot database for SPR3 beams:

History Variable	Description
1	Load state (0,…, 1 = elastic, 1,…, 2 = plastic, 2,…, 3 = damage)
2	Resultant normal force, F_n
3	Resultant shear force, F_s
4	Normal relative displacement
5	Tangential relative displacement
6	Relative rotation (bending)
7	Relative twist (torsion), only if STIFF4 > 0

***CONSTRAINED_JOINT**_*TYPE_{OPTION}_{OPTION}_{OPTION}*

Purpose: Define a joint between two rigid bodies.

CONSTRAINED_JOINT_*TYPE is a family of keywords all sharing a common set of data cards and option flags. The available joint variants are (one is mandatory):

*CONSTRAINED_JOINT_SPHERICAL

*CONSTRAINED_JOINT_REVOLUTE

*CONSTRAINED_JOINT_CYLINDRICAL

*CONSTRAINED_JOINT_PLANAR

*CONSTRAINED_JOINT_UNIVERSAL

*CONSTRAINED_JOINT_TRANSLATIONAL

*CONSTRAINED_JOINT_LOCKING

*CONSTRAINED_JOINT_TRANSLATIONAL_MOTOR

*CONSTRAINED_JOINT_ROTATIONAL_MOTOR

*CONSTRAINED_JOINT_GEARS

*CONSTRAINED_JOINT_RACK_AND_PINION

*CONSTRAINED_JOINT_CONSTANT_VELOCITY

*CONSTRAINED_JOINT_PULLEY

*CONSTRAINED_JOINT_SCREW

If the force output data is to be transformed into a local coordinate, use the option:

LOCAL

to define a joint ID and heading the following option is available:

ID

and to define failure for penalty-based joints (LMF = 0 in *CONTROL_RIGID) use:

FAILURE

The ordering of the bracketed options is arbitrary.

For the first seven joint types above excepting the Universal joint, the nodal points within the nodal pairs (1, 2), (3, 4), and (5, 6) (see Figures 10-16 through 10-22) should coincide in the initial configuration, and the nodal pairs should be as far apart as possible to obtain the best behavior. For the Universal Joint the nodes within the nodal pair (3, 4) do not coincide, but the lines drawn between nodes (1, 3) and (2, 4) must be perpendicular.

For the Gear joint the nodes within the nodal pair (1, 2) must not coincide, but for implicit the nodes within the pair (5, 6) must coincide and be located at the contact point of the gear teeth for correct results.

For cylindrical joints, by setting node 3 to zero, it is possible to use a cylindrical joint to join a node that is not on a rigid body (node 1) to a rigid body (nodes 2 and 4).

Card Summary:

NXX	NYY	NZZ	MXX	MYY	MZZ		

Data Card Definitions:

ID Card. Additional card for ID keyword option. The heading is picked up by some of the peripheral LS-DYNA codes to aid in post-processing.

Card ID	1	2	3	4	5	6	7	8
Variable	JID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
JID	Joint ID. This must be a unique number.
HEADING	Joint descriptor. It is suggested that unique descriptions be used.

Card 1	1	2	3	4	5	6	7	8
Variable	N1	N2	N3	N4	N5	N6	RPS	DAMP
Type	I	I	I	I	I	I	F	F
Default	0	0	0	0	0	0	1.0	1.0

VARIABLE	DESCRIPTION
N1	Node 1, in rigid body A. Define for all joint types.
N2	Node 2, in rigid body B. Define for all joint types.
N3	Node 3, in rigid body A. Define for all joint types except SPHERICAL.
N4	Node 4, in rigid body B. Define for all joint types except SPHERICAL.
N5	Node 5, in rigid body A. Define for joint types TRANSLATIONAL, LOCKING, ROTATIONAL_MOTOR, CONSTANT_VELOCITY, GEARS, RACK_AND_PINION, PULLEY, and SCREW. For implicit GEARS, N5 should coincide with N6 and be located at the contact point of the gear teeth.

VARIABLE	DESCRIPTION
N6	Node 6, in rigid body B. Define for joint types TRANSLATIONAL, LOCKING, ROTATIONAL_MOTOR, CONSTANT_VELOCITY, GEARS, RACK_AND_PINION, PULLEY, and SCREW. For implicit GEARS, N6 should coincide with N5 and be located at the contact point of the gear teeth.
RPS	Relative penalty stiffness (default = 1.0): GT.0.0: Constant value, LT.0.0: Time dependent value given by load curve ID = -RPS (only for SPHERICAL, REVOLUTE, and CYLINDRICAL).
DAMP	Damping scale factor on default damping value. (Revolute and Spherical Joints): EQ.0.0: Default is set to 1.0, GT.0.0.AND.LE.0.01: No damping is used.

Rotational Properties Card. Additional card for joint types MOTOR, GEARS, RACK_AND_PINION, PULLEY, and SCREW.

Card 2	1	2	3	4	5	6	7	8
Variable	PARM	LCID	TYPE	R1	H_ANGLE			
Type	F	I	I	F	F			
Default	none	0	none	↓	0.0			

VARIABLE	DESCRIPTION
PARM	Parameter, which is a function of joint type: Gears: Define R_2/R_1 Rack and Pinion: Define h Pulley: Define R_2/R_1 Screw: Define $\dot{x}/\omega$ Motors: Leave blank
LCID	Define load curve ID for MOTOR joints.

VARIABLE	DESCRIPTION
TYPE	Define integer flag for MOTOR joints as follows: EQ.0: Translational/rotational velocity EQ.1: Translational/rotational acceleration EQ.2: Translational/rotational displacement
R1	Radius, R_1, for the gear and pulley joint type. If undefined, nodal points 5 and 6 are assumed to be on the outer radius. The values of R1 and R2 affect the outputted reaction forces. The forces are calculated from the moments by dividing them by the radii.
H_ANGLE	Helix angle in degrees. This is only necessary for the gear joint if the gears do not mesh tangentially, such as worm gears. See Remark 2 below for a definition. See Remark 4 for a discussion of which joint formulation to use.

Local Card. Additional card required for LOCAL keyword option.

Card 3	1	2	3	4	5	6	7	8
Variable	RAID	LST						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
RAID	Rigid body or accelerometer ID. The force resultants are output in the local system of the rigid body or accelerometer.
LST	Flag for local system type: EQ.0: rigid body EQ.1: accelerometer

Failure Card 1. Additional card for FAILURE keyword option.

Card 4	1	2	3	4	5	6	7	8
Variable	CID	TFAIL	COUPL					
Type	I	F	F					
Default	global	0.	0.					

Failure Card 2. Additional card for FAILURE keyword option.

Card 5	1	2	3	4	5	6	7	8
Variable	NXX	NYY	NZZ	MXX	MYY	MZZ		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
CID	Coordinate ID for resultants in the failure criteria. EQ.0: global coordinate system
TFAIL	Time for joint failure. EQ.0.0: joint never fails.
COUPL	Coupling between the force and moment failure criteria. LE.0.0: the failure criteria are identical to that of spotwelds. GT.0.0: the force and moment results are considered independently. See the Remark 1 below.
NXX	Axial force resultant N_{xx_F} at failure. EQ.0.0: failure due to this component is not considered.
NYY	Force resultant N_{yy_F} at failure. EQ.0.0: failure due to this component is not considered.

VARIABLE	DESCRIPTION
NZZ	Force resultant N_{zz_F} at failure. EQ.0.0: failure due to this component is not considered.
MXX	Torsional moment resultant M_{xx_F} at failure. EQ.0.0: failure due to this component is not considered.
MYY	Moment resultant M_{yy_F} at failure. EQ.0.0: failure due to this component is not considered.
MZZ	Moment resultant M_{zz_F} at failure. EQ.0.0: failure due to this component is not considered.

Remarks:

1. **Failure Criteria.** The moments for the revolute, cylindrical, planar, translational, and locking joints are calculated at the midpoint of nodes N1 and N3. The moments for the spherical, universal, constant velocity, gear, pulley, and rack and pinion joints are calculated at node N1. When COUPL is less than or equal to zero, the failure criterion is

$$\left(\frac{N_{xx}}{N_{xx_F}}\right)^2+\left(\frac{N_{yy}}{N_{yy_F}}\right)^2+\left(\frac{N_{zz}}{N_{zz_F}}\right)^2+\left(\frac{M_{xx}}{M_{xx_F}}\right)^2+\left(\frac{M_{yy}}{M_{yy_F}}\right)^2+\left(\frac{M_{zz}}{M_{zz_F}}\right)^2-1=0\ .$$

   Otherwise, it consists of both

$$\left(\frac{N_{xx}}{N_{xx_F}}\right)^2+\left(\frac{N_{yy}}{N_{yy_F}}\right)^2+\left(\frac{N_{zz}}{N_{zz_F}}\right)^2-1=0\ ,$$

   and

$$\left(\frac{M_{xx}}{M_{xx_F}}\right)^2+\left(\frac{M_{yy}}{M_{yy_F}}\right)^2+\left(\frac{M_{zz}}{M_{zz_F}}\right)^2-1=0\ .$$

2. **Helix Angle for Gear Joints.** For a gear joint, the relative direction and magnitude of rotation between the two gears is determined by the *helix angle*. Let $\mathbf{e}_1$ be the unit vector directed from node 2 to 4, which corresponds to the second gear's rotation axis. See Figure 10-25. Let $\mathbf{e}_2$ be defined as the positively oriented tangent vector to motion of the teeth when spun about the $\mathbf{e}_1$ axis (the gear's axis). See Figure 10-15. The helix angle α characterizes the deviation of the teeth axis from the gear axis. In particular, α is defined as the angle between the direction of teeth, called $\mathbf{e}_3$, and the axis of the gear $\mathbf{e}_1$,

$$\mathbf{e}_3=\cos\alpha\mathbf{e}_1+\sin\alpha\mathbf{e}_2\ .$$

The gears are assumed to be setup so that the teeth initially fit having matching $\mathbf{e}_3$ directions. A nonzero helix angle is typically used to model worm gears.

3. **Penalty Formulation.** When the penalty formulation is used (see LMF on *CONTROL_RIGID), at each time step, the relative penalty stiffness is multiplied by a function dependent on the step size to give the maximum stiffness that will not destroy the stability of the solution. Instabilities can result in the explicit time integration scheme if the penalty stiffness is too large. If instabilities occur, the recommended way to eliminate these problems is to decrease the time step or reduce the scale factor on the penalties.

4. **Joint Formulation for Gear Joints with a Helix Angle.** If a gear joint requires a helix angle (such as a worm joint), we recommend using the Lagrange multiplier formulation (LMF = 1 on *CONTROL_RIGID) instead of the default penalty formulation (LMF = 0). The penalty formulation does not account for the helix angle and will give incorrect results.

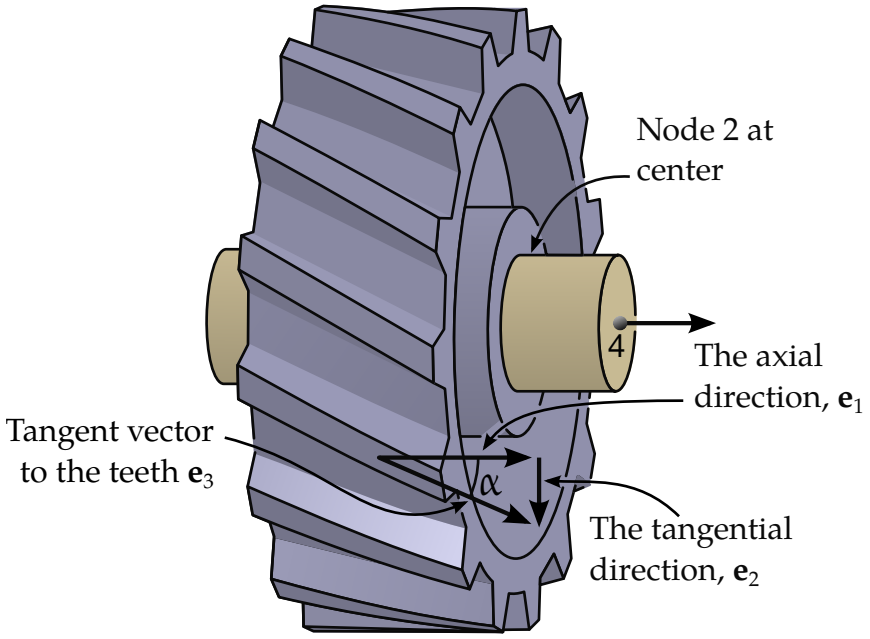

Figure 10-15. Helix angle α definition, gear #2 viewed from the extension of node n_2 to node n_6.

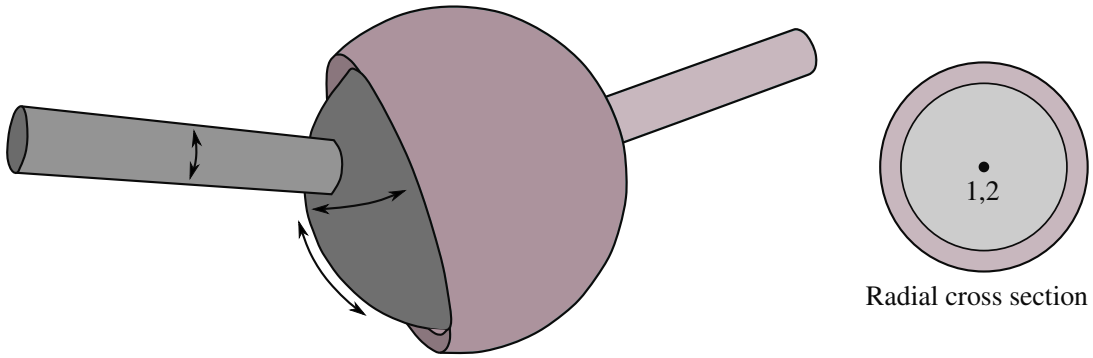

Figure 10-16. *Spherical joint.* The relative motion of the rigid bodies is constrained so that nodes which are initially coincident remain coincident. In the above figure the socket's node is not interior to the socket—LS-DYNA does not require that a rigid body's nodes be interior to the body.

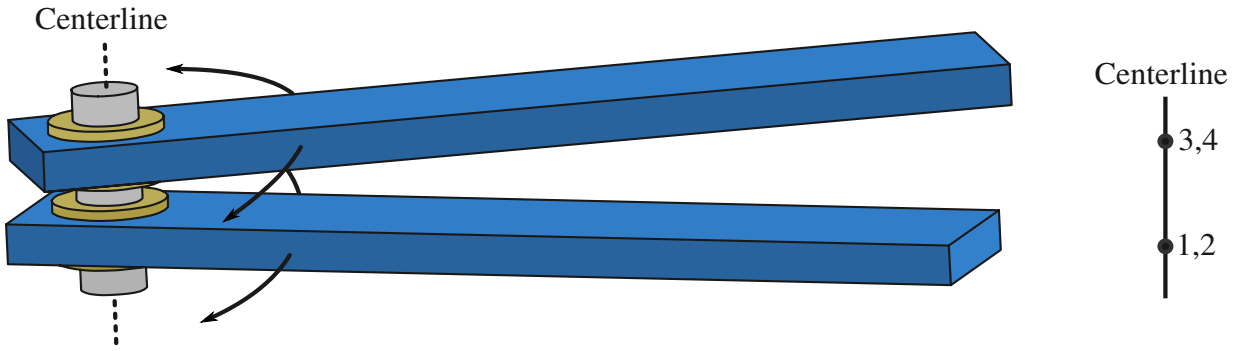

Figure 10-17. *Revolute Joint.* Nodes 1 and 2 are coincident; nodes 3 and 4 are coincident. Nodes 1 and 3 belong to rigid body A; nodes 2 and 4 belong to rigid body B. The relative motion of the two rigid bodies is restricted to rotations about the axis formed by the two pairs of coincident nodes. This axis is labeled the "centerline."

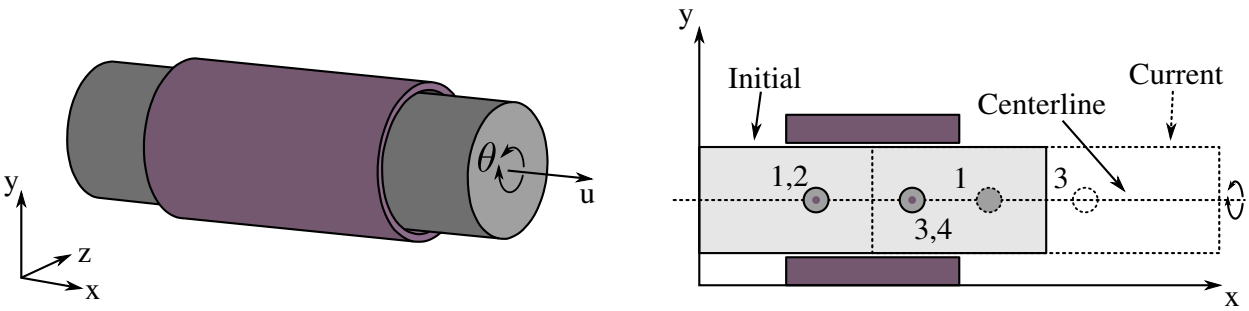

Figure 10-18. *Cylindrical Joint*. This joint is derived from the rotational joint by relaxing the constraints along the centerline. This joint admits relative rotation and translation along the centerline.

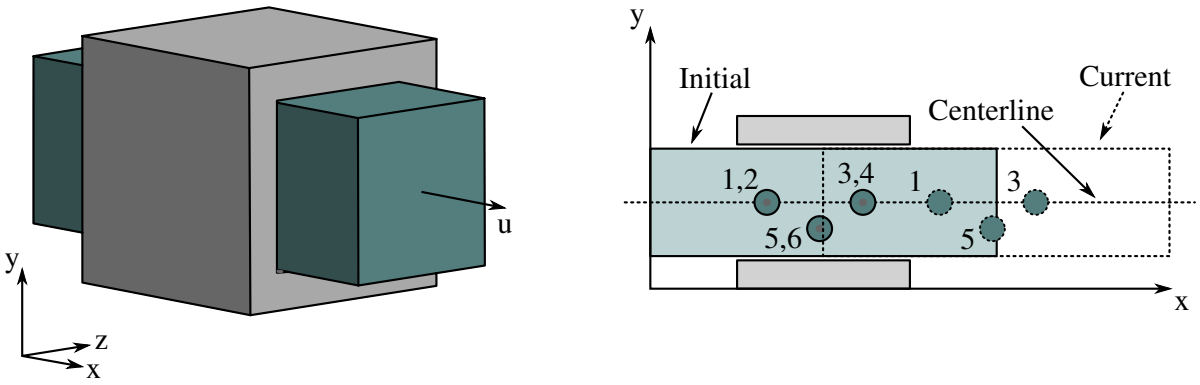

Figure 10-19. *Translational joint*. This is a cylindrical joint with a third pair of off-centerline nodes which restrict rotation. Aside from translation along the centerline, the two rigid bodies are stuck together.

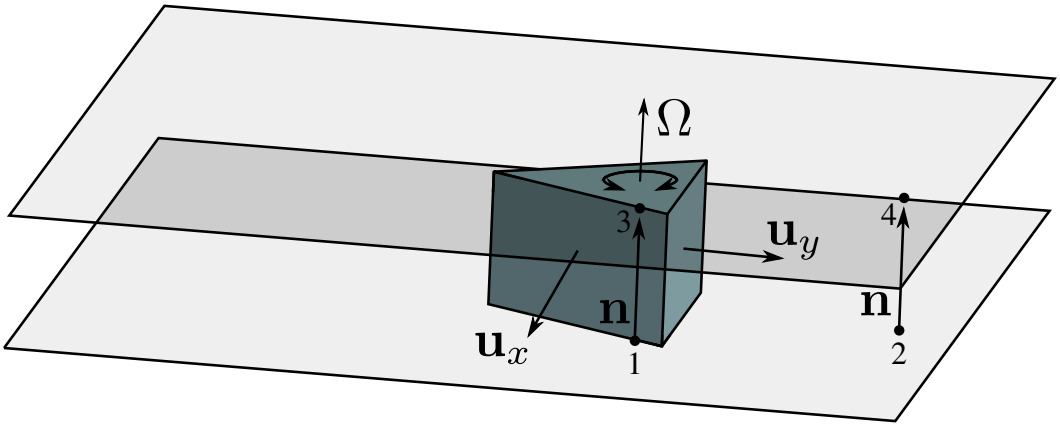

Figure 10-20. *Planar joint*. This joint is derived from the rotational joint by relaxing the constraints normal to the centerline. Relative displacements along the direction of the centerline are excluded.

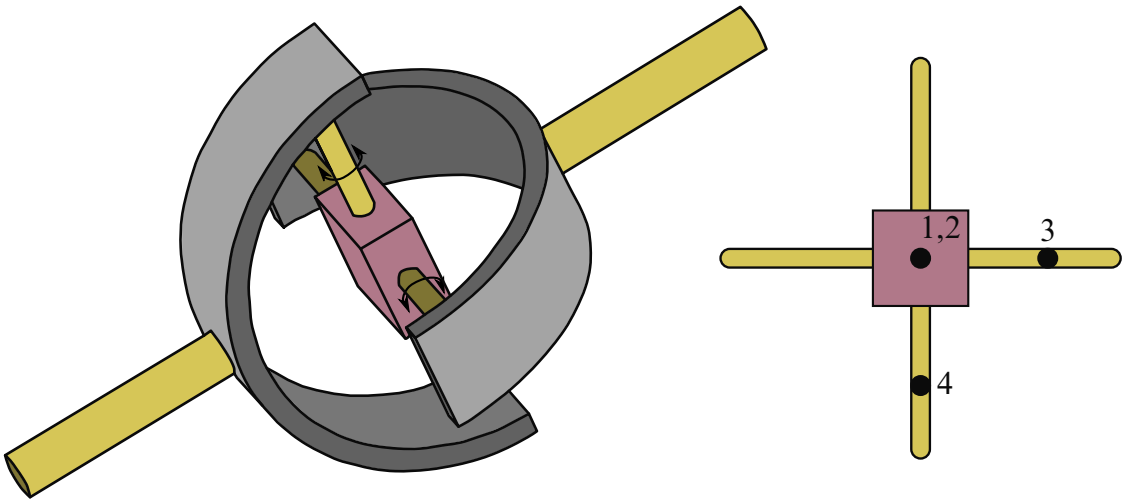

Figure 10-21. *Universal Joint*. Nodes 1 and 2 are initially coincident. The segments formed by nodal pairs (1, 3) and (2, 4) must be orthogonal; they serve as axes about which the two bodies may undergo relative rotation. The universal joint excludes all other relative motion and the axes remain orthogonal at all time.

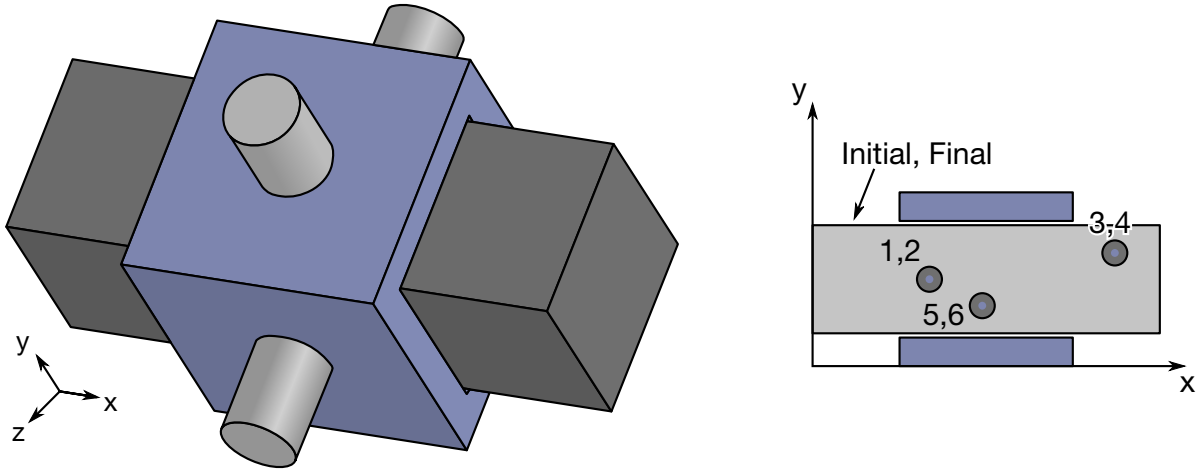

Figure 10-22. *Locking Joint*. A locking joint couples two rigid bodies in all six degrees-of-freedom. The forces and moments required to form this coupling are written to the jntforc file (*DATABASE_JNTFORC). As stated in the Remarks, forces and moments in jntforc are calculated halfway between N1 and N3. Nodal pairs (1, 2), (3, 4) and (5, 6) must be coincident. The three spatial points corresponding to three nodal pairs must be neither collocated nor collinear.

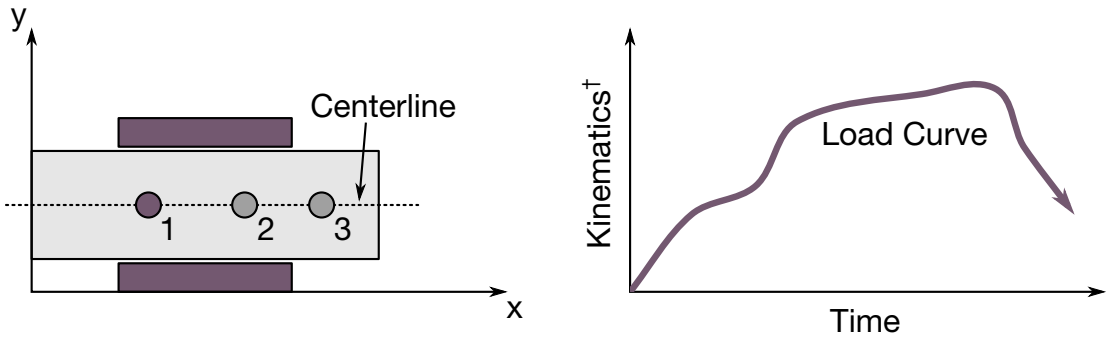

Figure 10-23. *Translational motor joint*. This joint is usually used in combination with a translational or a cylindrical joint. Node 1 and node 2 belong to the first rigid body and the second rigid body, resp. Furthermore, nodes 1 and 2 must be *coincident*. Node 3 may belong to either rigid body. Curve LCID defines the velocity/acceleration/displacement of N1 minus that of N2, where velocity/acceleration/displacement is measured in the direction of the vector N2-to-N3. Node 4 is not used and can be left blank. The value of the load curve may specify any of several kinematic measures; see TYPE.

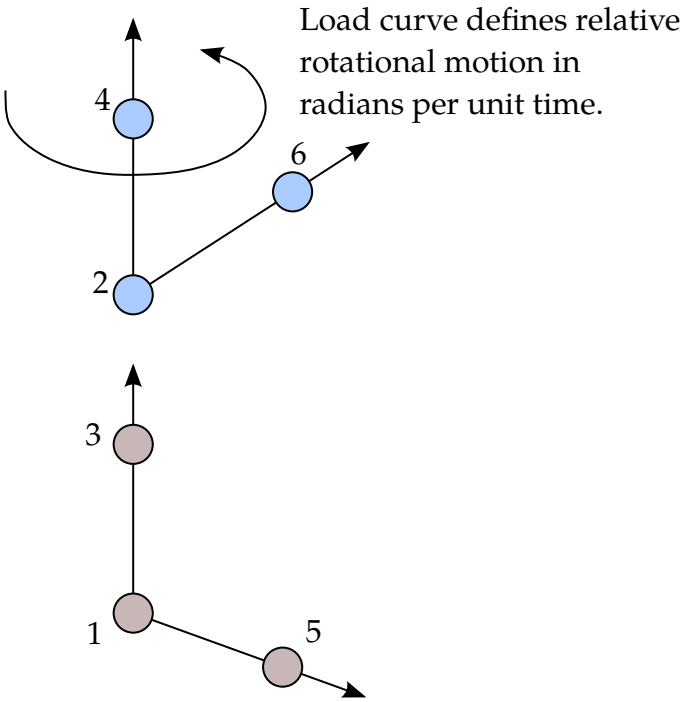

Figure 10-24. *Rotational motor joint*. This joint can be used in combination with other joints such as the revolute or cylindrical joints.

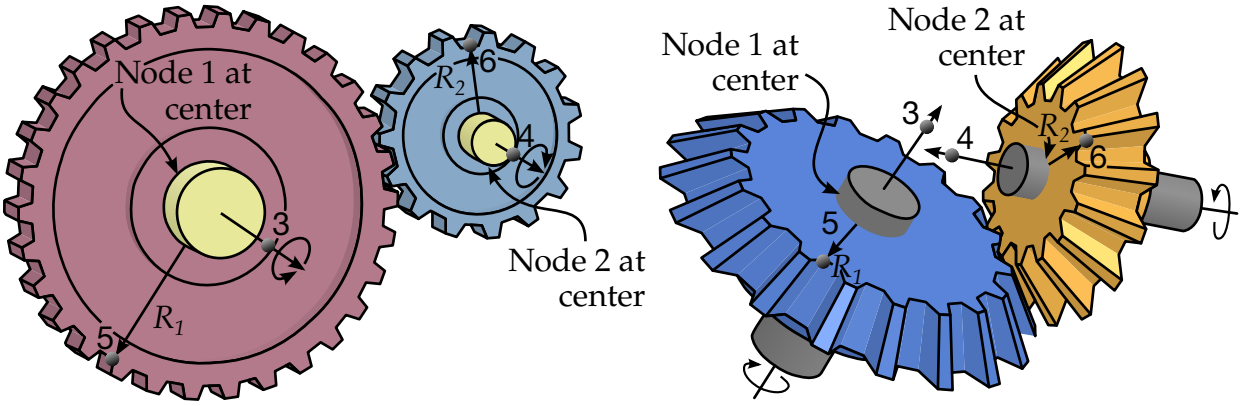

Figure 10-25. *Gear joints*. Nodal pairs (1, 3) and (2, 4) define axes that are orthogonal to the gears. Nodal pairs (1, 5) and (2, 6) define vectors in the plane of the gears. The ratio R_2/R_1 is specified but need not necessarily correspond to the geometry, if for instance the gear consists of spiral grooves. Note that the gear joint in itself does not maintain the contact point but this requires additional treatment, such as accompanying it with other joints. For implicit, nodes 5 and 6 must initially coincide for correct result in general.

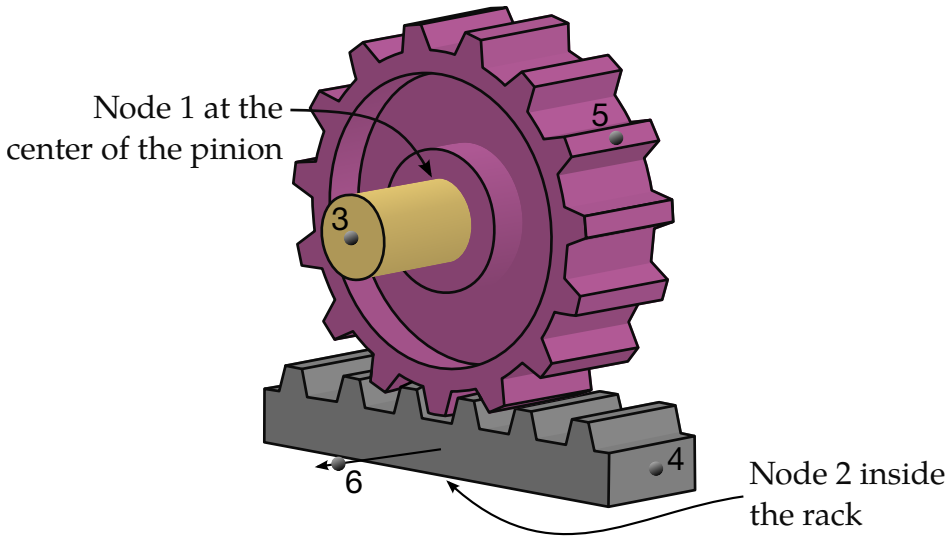

Figure 10-26. *Rack and pinion joint*. Nodal pair (1, 3) defines the axis of rotation of the first body (the pinion). Nodal pair (1, 5) is a vector in the plane of the pinion and is orthogonal to nodal pair (1, 3). Nodal pair (2, 4) defines the direction of travel for the second body (the rack). Nodal pair (2, 6) is parallel to the axis of the pinion and is thus parallel to nodal pair (1, 3). The value h is specified. The velocity of the rack is $h\omega_{\text{pinion}}$.

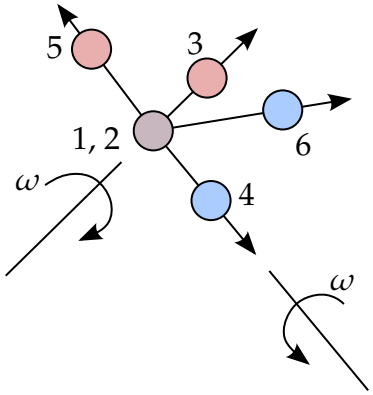

Figure 10-27. *Constant velocity joint*. Nodal pairs (1, 3) and (2, 4) define axes for the constant angular velocity. Nodal pairs (1, 5) and (2, 6) are orthogonal to nodal pairs (1, 3) and (2, 4), respectively. Here nodal points 1 and 2 must be coincident.

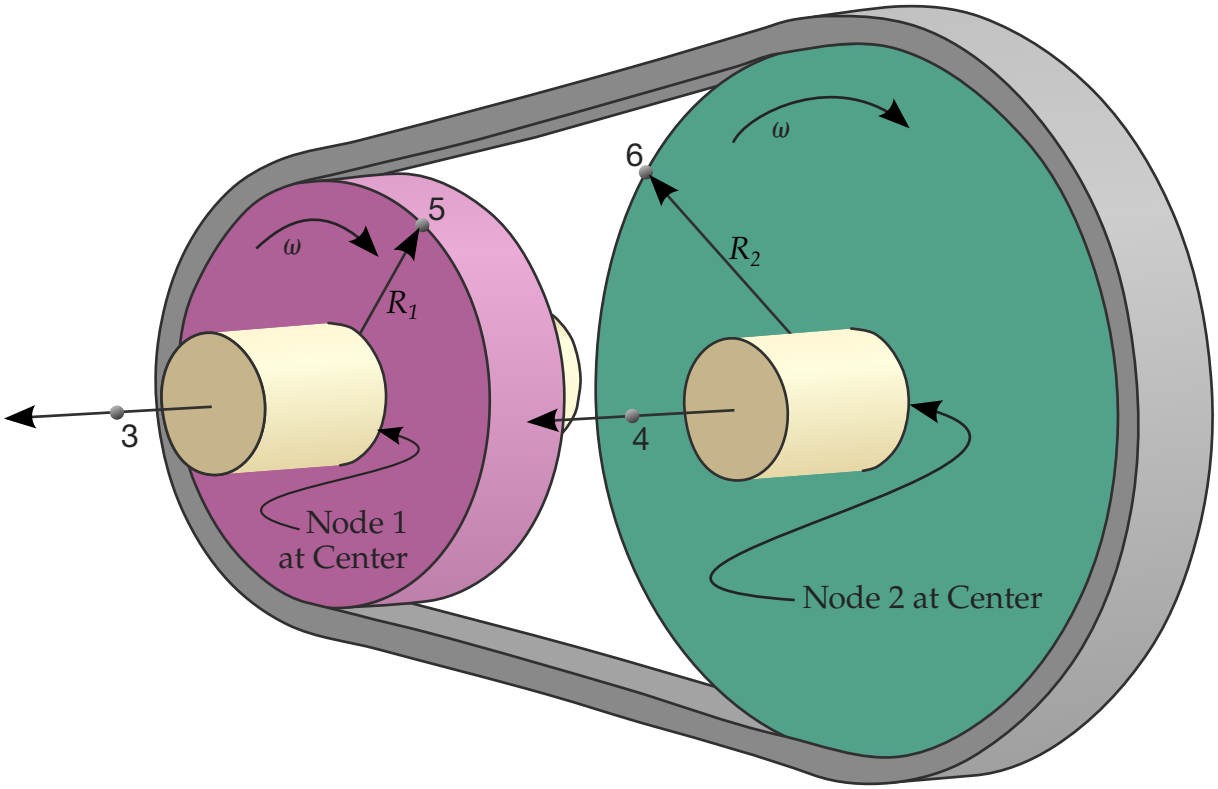

Figure 10-28. *Pulley joint*. Nodal pairs (1, 3) and (2, 4) define axes that are orthogonal to the pulleys. Nodal pairs (1, 5) and (2, 6) define vectors in the plane of the pulleys. The ratio R_2/R_1 is specified.

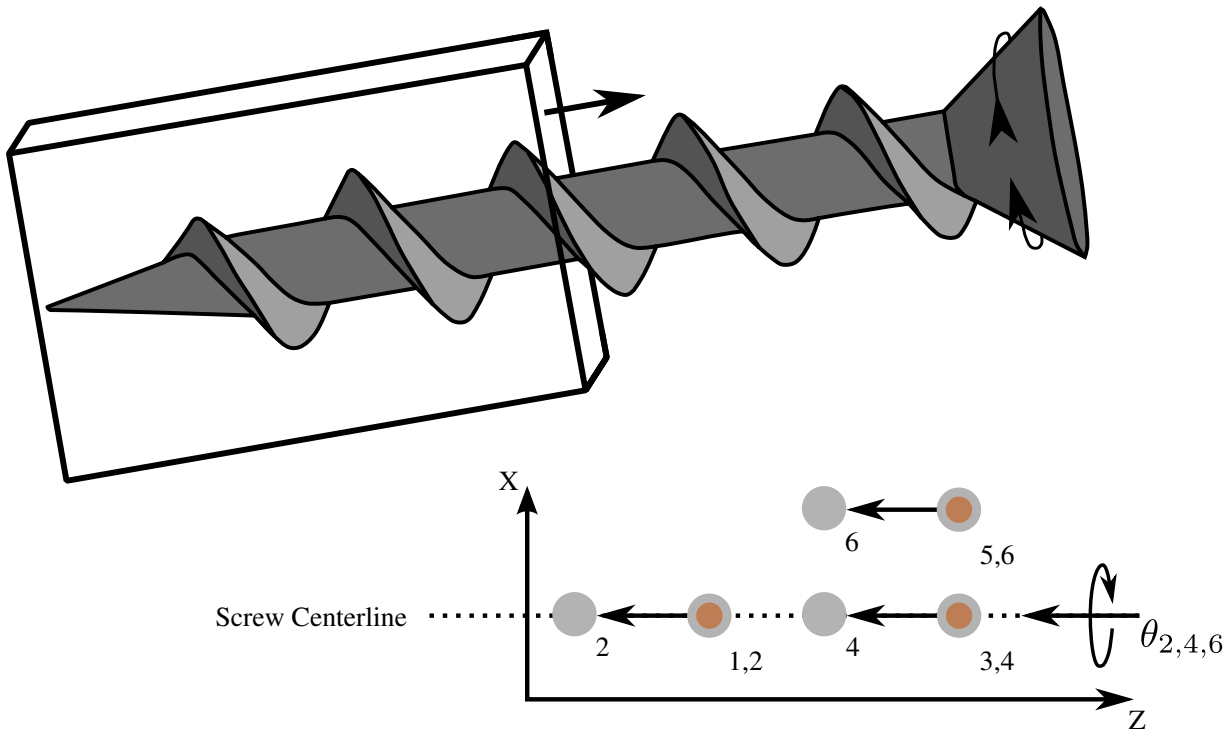

Figure 10-29. *Screw joint*. The second body (nodes 2, 4, and 6) translates in response to the spin of the first body (nodes 1, 3, and 5). Nodal pairs (1, 3) and (2, 4) lie along the same axis and nodal pairs (1, 5) and (2, 6) are orthogonal to the axis. PARM on Card 2 sets the helix ratio, $\dot{x}/\omega$. Note that, for a positive spin, the second body moves in the direction from node 1 to node 5.

CONSTRAINED_JOINT_COOR_*TYPE_{OPTION}_{OPTION}_{OPTION}

CONSTRAINED_JOINT_COOR_*TYPE is a family of keywords all sharing a common set of data cards and option flags. The available joint variants are (one is mandatory):

*CONSTRAINED_JOINT_COOR_SPHERICAL

*CONSTRAINED_JOINT_COOR_REVOLUTE

*CONSTRAINED_JOINT_COOR_CYLINDRICAL

*CONSTRAINED_JOINT_COOR_PLANAR

*CONSTRAINED_JOINT_COOR_UNIVERSAL

*CONSTRAINED_JOINT_COOR_TRANSLATIONAL

*CONSTRAINED_JOINT_COOR_LOCKING

*CONSTRAINED_JOINT_COOR_TRANSLATIONAL_MOTOR

*CONSTRAINED_JOINT_COOR_ROTATIONAL_MOTOR

*CONSTRAINED_JOINT_COOR_GEARS

*CONSTRAINED_JOINT_COOR_RACK_AND_PINION

*CONSTRAINED_JOINT_COOR_CONSTANT_VELOCITY

*CONSTRAINED_JOINT_COOR_PULLEY

*CONSTRAINED_JOINT_COOR_SCREW

If the force output data is to be transformed into a local coordinate, use the option:

LOCAL

to define a joint ID and heading the following option is available:

ID

and to define failure for penalty-based joints (LMF = 0 in *CONTROL_RIGID) use:

FAILURE

The ordering of the bracketed options is arbitrary.

Purpose: Define a joint between two rigid bodies; see Figures 10-16 through 10-29 of the *CONSTRAINED_JOINT section. The connection coordinates are given instead of the

nodal point IDs required in the previous section, *CONSTRAINED_JOINT_{*OPTION*}. Nodes are automatically generated for each coordinate and are constrained to the rigid body. Where coincident nodes are expected in the initial configuration, only one connection coordinate is needed since the connection coordinate for the second node, if given, is ignored. The created nodal IDs are chosen to exceed the maximum user ID. The coordinates of the joint nodes are specified on Cards 2 - 7. The input which follows Card 7 is identical to that in the previous section.

In the first seven joint types above excepting the Universal joint, the coordinate points within the nodal pairs (1, 2), (3, 4), and (5, 6) (see Figures 10-16 through 10-22) should coincide in the initial configuration, and the nodal pairs should be as far apart as possible to obtain the best behavior. For the Universal Joint the nodes within the coordinate pair (3, 4) do not coincide, but the lines drawn between nodes (1, 3) and (2, 4) must be perpendicular.

For the Gear joint the nodes within the coordinate pair (1, 2) must not coincide.

For cylindrical joints, by setting node 3 to zero, it is possible to use a cylindrical joint to join a node that is not on a rigid body (node 1) to a rigid body (nodes 2 and 4).

Card 3	1	2	3	4	5	6	7	8
Variable	X2	Y2	Z2					
Type	F	F	F					

Card 4	1	2	3	4	5	6	7	8
Variable	X3	Y3	Z3					
Type	F	F	F					

Card 5	1	2	3	4	5	6	7	8
Variable	X4	Y4	Z4					
Type	F	F	F					

Card 6	1	2	3	4	5	6	7	8
Variable	X5	Y5	Z5					
Type	F	F	F					

Card 7	1	2	3	4	5	6	7	8
Variable	X6	Y6	Z6					
Type	F	F	F					

VARIABLE	DESCRIPTION
X1, Y1, Z1	Coordinate of point 1, in rigid body A. Define for all joint types.
X2, Y2, Z2	Coordinate of point 2, in rigid body B. If points 1 and 2 are coincident in the specified joint type, the coordinate for point 1 is used.
X3, Y3, Z3	Coordinate of point 3, in rigid body A. Define for all joint types.
X4, Y4, Z4	Coordinate of point 4, in rigid body B. If points 3 and 4 are coincident in the specified joint type, the coordinate for point 3 is used.
X5, Y5, Z5	Coordinate of point 5, in rigid body A. Define for all joint types.

VARIABLE	DESCRIPTION
X6, Y6, Z6	Coordinate of point 6, in rigid body B. If points 5 and 6 are coincident in the specified joint type, the coordinate for point 5 is used.

Rotational Properties Card. Additional card for joint types MOTOR, GEARS, RACK_AND_PINION, PULLEY, and SCREW.

Card 8	1	2	3	4	5	6	7	8
Variable	PARM	LCID	TYPE	R1				
Type	F	I	I	F				
Default	none	0	0	↓				

VARIABLE	DESCRIPTION
PARM	Parameter, which is a function of joint type: Gears: define R_2/R_1 Rack and Pinion: define h Pulley: define R_2/R_1 Screw: define $\dot{x}/\omega$ Motors: leave blank
LCID	Define load curve ID for MOTOR joints.
TYPE	Define integer flag for MOTOR joints as follows: EQ.0: translational/rotational velocity EQ.1: translational/rotational acceleration EQ.2: translational/rotational displacement
R1	Radius, R_1, for the gear and pulley joint type. If left undefined, nodal points 5 and 6 are assumed to be on the outer radius. R1 is the moment arm that goes into calculating the joint reaction forces. The ratio R_2/R_1 gives the transmitted moments, but not the forces. The force is moment divided by distance R1.

Local Card. Additional card for LOCAL keyword option.

Card 9	1	2	3	4	5	6	7	8
Variable	RAID	LST						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
RAID	Rigid body or accelerometer ID. The force resultants are output in the local system of the rigid body or accelerometer.
LST	Flag for local system type: EQ.0: rigid body EQ.1: accelerometer

Failure Card 1. Additional card for the FAILURE keyword option.

Card 10	1	2	3	4	5	6	7	8
Variable	CID	TFAIL	COUPL					
Type	I	F	F					
Default	global	0.0	0.0					

Failure Card 2. Additional card for the FAILURE keyword option.

Card 11	1	2	3	4	5	6	7	8
Variable	NXX	NYY	NZZ	MXX	MYY	MZZ		
Type	F	F	F	F	F	F		
Default	0.	0.	0.	0.	0.	0.		

VARIABLE	DESCRIPTION
CID	Coordinate ID for resultants in the failure criteria. EQ.0: global coordinate system
TFAIL	Time for joint failure. EQ.0.0: joint never fails.
COUPL	Coupling between the force and moment failure criteria: LE.0.0: failure criteria are identical to that of spotwelds. GT.0.0: the force and moment results are considered independently. See the remarks in *CONSTRAINED_JOINT_{OPTION}.
NXX	Axial force resultant N_{XX_F} at failure. EQ.0.0: failure due to this component is not considered.
NYY	Force resultant N_{YY_F} at failure. EQ.0.0: failure due to this component is not considered.
NZZ	Force resultant N_{ZZ_F} at failure. EQ.0.0: failure due to this component is not considered.
MXX	Torsional moment resultant M_{XX_F} at failure. EQ.0.0: failure due to this component is not considered.
MYY	Moment resultant M_{YY_F} at failure. EQ.0.0: failure due to this component is not considered.

VARIABLE	DESCRIPTION
MZZ	Moment resultant M_{ZZ_F} at failure. EQ.0.0: failure due to this component is not considered.

Remarks:

1. **Penalty Method.** When the penalty method is used (see *CONTROL_RIGID), at each time step, the relative penalty stiffness is multiplied by a function dependent on the step size to give the maximum stiffness that will not destroy the stability of the solution. LS-DYNA's explicit time integrator can become unstable when the penalty stiffness is too large. If instabilities occur, the recommended way to eliminate these problems is to decrease the time step or reduce the scale factor on the penalties.

2. **Joint Nodes.** The coordinates specified in this formulation are used to generate up to six nodes and assign them to the appropriate rigid body for updating. RBID_A updates coordinates 1, 3, and 5, while RBID_B updates coordinates 2, 4, and 6. There is no method for LS-DYNA to detect when the wrong bodies are assigned, and therefore the user has to make sure that the ordering of RBID_A and RBID_B is correct. For some joints, such as the spherical joint, the coordinate points are the same and the ordering does not matter. However, for others, such as the rack and pinion, the ordering is critical.

3. **Mass and Inertia.** Unless the rigid bodies are massless, or nearly massless, there is usually no need to add mass or inertia to the rigid bodies, and TMASS and RMASS may be safely set to zero. Specifying values that are larger than necessary may perturb the motion of the bodies and result in significant errors. Since the masses and inertias are included in the mass calculations in the output, the values should be set to zero if the masses and inertia tensors are to be used outside of LS-DYNA.

***CONSTRAINED_JOINT_STIFFNESS**_OPTION_{OPTION}

Available options include:

FLEXION-TORSION

GENERALIZED

TRANSLATIONAL

CYLINDRICAL

If desired a description of the joint stiffness can be provided with the option:

TITLE

which is written into the d3hsp and jntforc files.

Purpose: Define optional rotational, translational or cylindrical joint stiffness for joints defined by *CONSTRAINED_JOINT_*OPTION*. These definitions apply to all joints even though degrees of freedom that are considered in the joint stiffness capability may be constrained out in some joint types. The energy that is dissipated with the joint stiffness option is written for each joint in joint force file with the default name, jntforc. In the global energy balance this energy is included with the energy of the discrete elements, that is, the springs and dampers.

Card Summary:

Card Title. This card is included if and only if the TITLE keyword option is used.

TITLE

Card 1. This card is required.

JSID	PIDA	PIDB	CIDA	CIDB	JID	RPS	

Card 2a.1. This card is included if the FLEXION-TORSION keyword option is used.

Data Card Definitions:

Title Card. Additional card for the TITLE keyword option.

Card Title	1	2	3	4	5	6	7	8
Variable	TITLE							
Type	A80							

Card 1	1	2	3	4	5	6	7	8
Variable	JSID	PIDA	PIDB	CIDA	CIDB	JID	RPS	
Type	I	I	I	I	I	I	F	
Default	none	none	none	none	CIDA	0	1.0	

VARIABLE	DESCRIPTION
TITLE	Description of joint stiffness for output files jntforc and d3hsp
JSID	Joint stiffness ID
PIDA	Part ID for rigid body A; see *PART.
PIDB	Part ID for rigid body B; see *PART.
CIDA	Coordinate ID for rigid body A; see *DEFINE_COORDINATE_OPTION. For the translational and cylindrical stiffnesses, the local coordinate system must be defined by nodal points, *DEFINE_COORDINATE_NODES, since the first nodal point in each coordinate system is used to track the motion.
CIDB	Coordinate ID for rigid body B. If zero, the coordinate ID for rigid body A is used; see *DEFINE_COORDINATE_OPTION. For the translational and cylindrical stiffnesses, the local coordinate system must be defined by nodal points, *DEFINE_COORDINATE_NODES, since the first nodal point in each coordinate system is used to track the motion.
JID	Joint ID for the joint reaction forces. If zero, tables can not be used in place of load curves for defining the frictional moments.

VARIABLE	DESCRIPTION
RPS	Relative penalty stiffness used for joint friction calculation. It is the same parameter as RPS in *CONSTRAINED_JOINT_*TYPE*. It only applies for keyword options TRANSLATIONAL and CYLINDRICAL. FS and FD must be defined in either Card 2c. 3 or Card 2d. 3. It can be used to calculate the joint force, so we can define it here instead of in *CONSTRAINED_JOINT_*TYPE*.

Flexion-Torsion Joint Stiffness Cards:

Card 2 for FLEXION-TORSION option.

Card 2a.1	1	2	3	4	5	6	7	8
Variable	LCIDAL	LCIDG	LCIDBT	DLCIDAL	DLCIDG	DLCIDBT		
Type	I	I	I	I	I	I		
Default	0.0	1.0	0.0	0	1.0	0		

VARIABLE	DESCRIPTION
LCIDAL	Load curve ID for α-moment as a function of rotation in radians. See Figure 10-30 where it should be noted that $0 \le \alpha \le \pi$. See *DEFINE_CURVE. EQ.0: The applied moment is set to 0.0.
LCIDG	Load curve ID for γ as a function of a scale factor which scales the bending moment due to the α rotation. This load curve should be defined in the interval $-\pi \le \gamma \le \pi$. See *DEFINE_CURVE. EQ.0: The scale factor defaults to 1.0.
LCIDBT	Load curve ID for β-torsion moment as a function of twist in radians. See *DEFINE_CURVE. EQ.0: The applied twist is set to 0.0.
DLCIDAL	Load curve ID for α-damping momentas a function of rate of rotation in radians per unit time. See *DEFINE_CURVE. EQ.0: damping is not considered.
DLCIDG	Load curve ID for γ-damping scale factor as a function of rate of rotation in radians per unit time. This scale factor scales the α-damping moment. See *DEFINE_CURVE. EQ.0: The scale factor defaults to 1.0.
DLCIDBT	Load curve ID for β-damping torque as a function of rate of twist. See *DEFINE_CURVE. EQ.0: Damping is not considered.

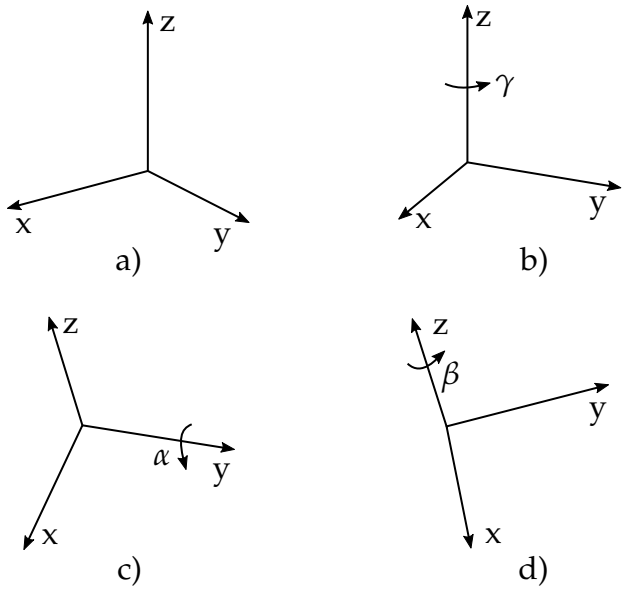

Figure 10-30. The angles γ, α, and β align rigid body one with rigid body two for the FLEXION-TORSION option, using z-y-z Euler angles (in the order shown by the figure labels) to calculate the moments. An illustrative version of this figure is shown in Figure 10-31.

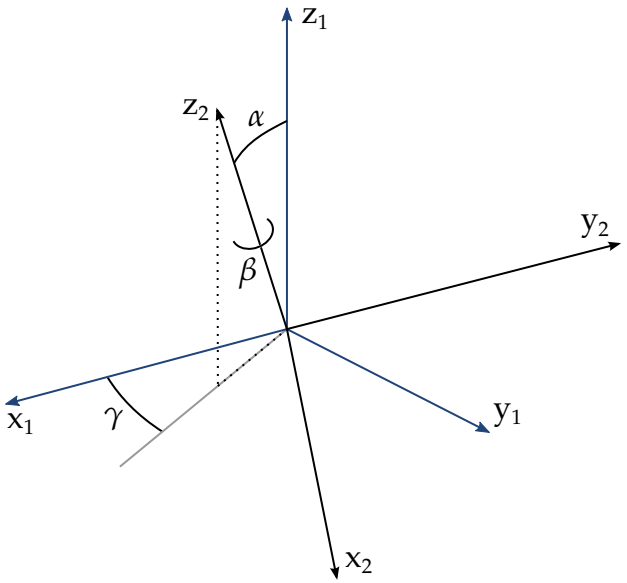

Figure 10-31. Flexion-torsion joint angles. If the initial positions of the local coordinate axes of the two rigid bodies connected by the joint do not coincide, the angles, α and γ, are initialized and torques will develop instantaneously based on the defined load curves. The angle β is also initialized but no torque will develop about the local axis on which β is measured. Rather, β will be measured relative to the computed offset.

Card 3 for FLEXION-TORSION option.

Card 2a.2	1	2	3	4	5	6	7	8
Variable	ESAL	FMAL	ESBT	FMBT				
Type	F	F/I	F	F/I				
Default	0.0	0.0	0.0	0.0				

VARIABLE	DESCRIPTION
ESAL	Elastic stiffness per unit radian for friction and stop angles for α rotation. See Figure 10-32. EQ.0.0: Friction and stop angles are inactive for α rotation.
FMAL	Frictional moment limiting value for α rotation. This option may also be thought of as an elastic-plastic spring. See Figure 10-32. EQ.0.0: Friction is inactive for α rotation. LT.0: -FMAL is the load curve or table ID defining the yield moment as a function of α rotation. A table permits the moment to also be a function of the joint reaction force and requires the specification of JID on Card 1.
ESBT	Elastic stiffness per unit radian for friction and stop angles for β twist. EQ.0.0: Friction and stop angles are inactive for β twist.
FMBT	Frictional moment limiting value for β twist. This option may also be thought of as an elastic-plastic spring. EQ.0.0: The friction is inactive for β twist. LT.0: -FMBT is the load curve or table ID defining the yield moment versus β rotation. A table permits the moment to also be a function of the joint reaction force and requires the specification of JID on Card 1.

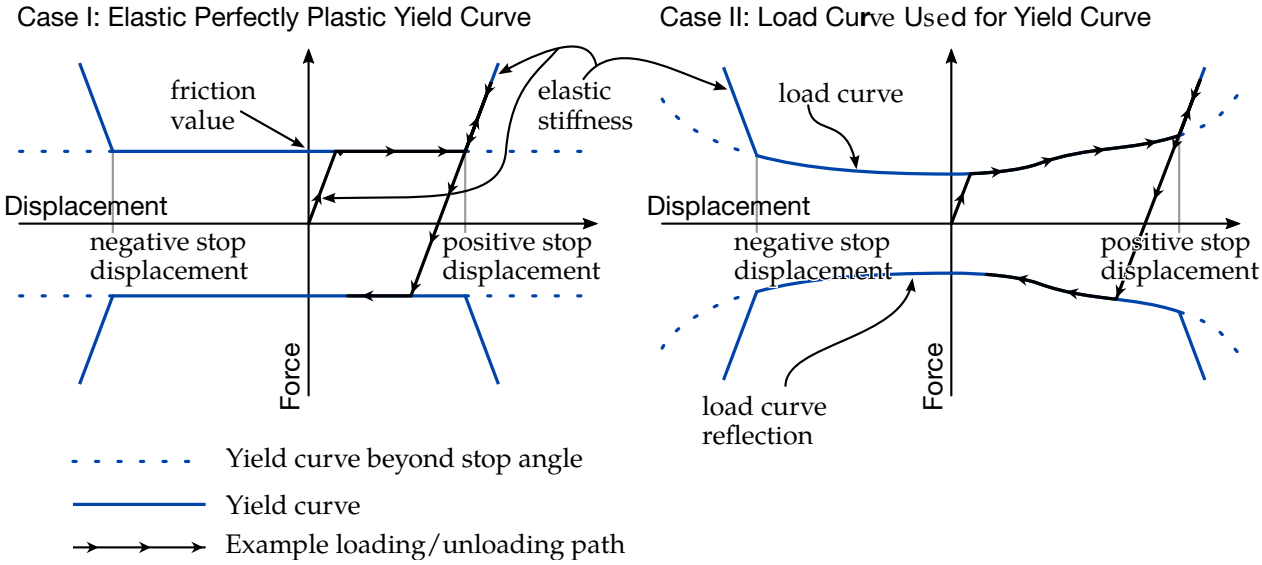

Figure 10-32. *Friction model.* The friction model is motivated by plasticity, and it is implemented for both rotational and translational joints. In the context of a rotational joint, the y-axis is to be interpreted as moment (rotational force) and the x-axis is to be interpreted as rotation. *Case I* (left) is activated by a positive friction value. *Case II* (right) is activated by a negative integer friction value, the absolute value of which specifies a load curve. *See the friction, elastic, and stop angle/displacement parameters from the input cards* (FM[var], ES[var], NSA[var], PSA[var]).

Card 4 for FLEXION-TORSION option.

Card 2a.3	1	2	3	4	5	6	7	8
Variable	SAAL	NSABT	PSABT					
Type	F	F	F					
Default	0.0	0.0	0.0					

VARIABLE	DESCRIPTION
SAAL	Stop angle in degrees for α rotation where $0.0 \leq \alpha \leq \pi$. Ignored if zero. See Figure 10-32.
NSABT	Stop angle in degrees for negative β rotation. Ignored if zero.
PSABT	Stop angle in degrees for positive β rotation. Ignored if zero.

Remarks:

This option simulates the flexion-torsion behavior of a joint in a slightly different fashion than with the generalized joint option.

After the stop angles are reached, the torques increase linearly to resist further angular motion using the stiffness values on Card 2a.2. If the stiffness value is too low or zero, the stop will be violated.

The moment resultants generated from the moment as a function of rotation curve, damping moment as a function of rate-of-rotation curve, and friction are evaluated independently and are added together.

Generalized Joint Stiffness Cards:

Card 2 for GENERALIZED stiffness option.

Card 2b.1	1	2	3	4	5	6	7	8
Variable	LCIDPH	LCIDT	LCIDPS	DLCIDPH	DLCIDT	DLCIDPS		
Type	I	I	I	I	I	I		
Default	0.0	0.0	0.0	0	0	0		

VARIABLE	DESCRIPTION
LCIDPH	Load curve ID for ϕ-moment as a function of rotation in radians. See Figure 10-33. See *DEFINE_CURVE. EQ.0: The applied moment is set to 0.0.
LCIDT	Load curve ID for θ-moment as a function of rotation in radians. See *DEFINE_CURVE. EQ.0: The applied moment is set to 0.0.
LCIDPS	Load curve ID for ψ-moment as a function of rotation in radians. See *DEFINE_CURVE. EQ.0: The applied moment is set to 0.0.
DLCIDPH	Load curve ID for ϕ-damping moment as a function of rate of rotation in radians per unit time. See *DEFINE_CURVE. EQ.0: Damping is not considered.
DLCIDT	Load curve ID for θ-damping moment as a function of rate of rotation in radians per unit time. See *DEFINE_CURVE. EQ.0: Damping is not considered.
DLCIDPS	Load curve ID for ψ-damping torque as a function of rate of rotation in radians per unit time. See *DEFINE_CURVE. EQ.0: Damping is not considered.

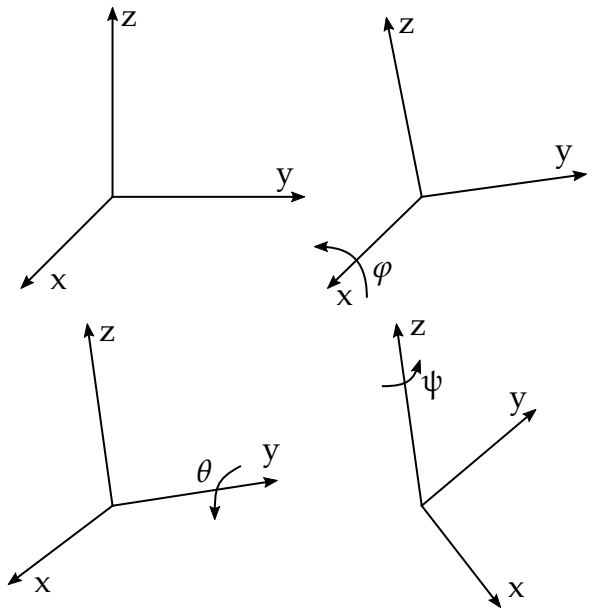

Figure 10-33. Definition of angles for the GENERALIZED joint stiffness.

Card 3 for GENERALIZED stiffness option.

Card 2b.2	1	2	3	4	5	6	7	8
Variable	ESPH	FMPH	EST	FMT	ESPS	FMPS		
Type	F	F/I	F	F/I	F	F/I		
Default	0.0	0.0	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
ESPH	Elastic stiffness per unit radian for friction and stop angles for ϕ rotation. EQ.0.0: Friction and stop angles are inactive for ϕ rotation.
FMPH	Frictional moment limiting value for ϕ rotation. This option may also be thought of as an elastic-plastic spring. See Figure 10-32. EQ.0.0: Friction is inactive for ϕ rotation. LT.0: -FMPH is the load curve or table ID defining the yield moment as a function of ϕ rotation. A table permits the moment to also be a function of the joint reaction force and requires the specification of JID on Card 1.

VARIABLE	DESCRIPTION
EST	Elastic stiffness per unit radian for friction and stop angles for θ rotation. See Figure 10-32. EQ.0.0: Friction and stop angles are inactive for θ rotation.
FMT	Frictional moment limiting value for θ rotation. This option may also be thought of as an elastic-plastic spring. EQ.0.0: Friction is inactive for θ rotation. LT.0: -FMT is the load curve or table ID defining the yield moment as a function of θ rotation. A table permits the moment to also be a function of the joint reaction force and requires the specification of JID on Card 1.
ESPS	Elastic stiffness per unit radian for friction and stop angles for ψ rotation. EQ.0.0: Friction and stop angles are inactive for ψ rotation.
FMPS	Frictional moment limiting value for ψ rotation. This option may also be thought of as an elastic-plastic spring. EQ.0.0: Friction is inactive for ψ rotation. LT.0: -FMPS is the load curve or table ID defining the yield moment as a function of ψ rotation. A table permits the moment to also be a function of the joint reaction force and requires the specification of JID on Card 1.

Card 4 for GENERALIZED stiffness option.

Card 2b.3	1	2	3	4	5	6	7	8
Variable	NSAPH	PSAPH	NSAT	PSAT	NSAPS	PSAPS		
Type	F	F	F	F	F	F		
Default	0.0	0.0	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
NSAPH	Stop angle in degrees for negative ϕ rotation. See Figure 10-32. Ignored if zero.

VARIABLE	DESCRIPTION
PSAPH	Stop angle in degrees for positive ϕ rotation. Ignored if zero.
NSAT	Stop angle in degrees for negative θ rotation. Ignored if zero.
PSAT	Stop angle in degrees for positive θ rotation. Ignored if zero.
NSAPS	Stop angle in degrees for negative ψ rotation. Ignored if zero.
PSAPS	Stop angle in degrees for positive ψ rotation. Ignored if zero.

Remarks:

After the stop angles are reached, the torques increase linearly to resist further angular motion using the stiffness values on Card 2b.2. Reasonable stiffness values must be chosen. If the stiffness values are too low or zero, the stop will be violated.

If the initial local coordinate axes do not coincide, the angles, ϕ, θ, and ψ, will be initialized and torques will develop instantaneously based on the defined moment as a function of rotation curves.

There are two methods available to calculate the rotation angles between the coordinate systems. For more information, see the JNTF parameter on *CONTROL_RIGID.

Translational Joint Stiffness Cards:

Card 2 for TRANSLATIONAL stiffness option.

Card 2c.1	1	2	3	4	5	6	7	8
Variable	LCIDX	LCIDY	LCIDZ	DLCIDX	DLCIDY	DLCIDZ		
Type	I	I	I	I	I	I		
Default	0.0	0.0	0.0	0	0	0		

VARIABLE	DESCRIPTION
LCIDX	Load curve ID for x-force as a function of x-distance between the origins of CIDA and CIDB based on the x-direction of CIDB. See *DEFINE_CURVE. EQ.0: The applied force is set to 0.0.
LCIDY	Load curve ID for y-force as a function of y-distance between the origins of CIDA and CIDB based on the y-direction of CIDB. See *DEFINE_CURVE. EQ.0: The applied force is set to 0.0.
LCIDZ	Load curve ID for z-force as a function of z-distance between the origins of CIDA and CIDB based on the z-direction of CIDB. See *DEFINE_CURVE. EQ.0: The applied force is set to 0.0.
DLCIDX	Load curve ID for x-damping force as a function of rate of x-translational displacement per unit time between the origins of CIDA and CIDB based on the x-direction of CIDB. See *DEFINE_CURVE. EQ.0: Damping is not considered.
DLCIDY	Load curve ID for y-damping force as a function of rate of y-translational displacement per unit time between the origins of CIDA and CIDB based on the y-direction of CIDB. See *DEFINE_CURVE. EQ.0: Damping is not considered.

VARIABLE	DESCRIPTION
DLCIDZ	Load curve ID for z-damping force as a function of rate of z-translational displacement per unit time between the origins of CIDA and CIDB based on the z-direction of CIDB. See *DEFINE_CURVE. EQ.0: Damping is not considered.

Card 3 TRANSLATIONAL stiffness option.

Card 2c.2	1	2	3	4	5	6	7	8
Variable	ESX	FFX	ESY	FFY	ESZ	FFZ		
Type	F	F/I	F	F/I	F	F/I		
Default	0.0	0.0	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
ESX	Elastic stiffness for friction and stop displacement for x-translation. See Figure 10-32. EQ.0.0: Friction and stop angles are inactive for x-translation.
FFX	Frictional force limiting value for x-translation. This option may also be thought of as an elastic-plastic spring. See Figure 10-32. EQ.0.0: Friction is inactive for x-translation. LT.0: -FFX is the load curve ID defining the yield force as a function x-translation.
ESY	Elastic stiffness for friction and stop displacement for y-translation. EQ.0.0: Friction and stop angles are inactive for y-translation.
FFY	Frictional force limiting value for y-translation. This option may also be thought of as an elastic-plastic spring. EQ.0.0: Friction is inactive for y-translation. LT.0: -FFY is the load curve ID defining the yield force as a function of y-translation.

VARIABLE	DESCRIPTION
ESZ	Elastic stiffness for friction and stop displacement for z-translation. EQ.0.0: Friction and stop angles are inactive for z-translation.
FFZ	Frictional force limiting value for z-translation. This option may also be thought of as an elastic-plastic spring. EQ.0.0: Friction is inactive for z-translation. LT.0: -FFZ is the load curve ID defining the yield force as a function of z-translation.

Card 4 for TRANSLATIONAL stiffness option.

Card 2c.3	1	2	3	4	5	6	7	8
Variable	NSDX	PSDX	NSDY	PSDY	NSDZ	PSDZ	FS	FD
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
NSDX	Stop displacement for negative x-translation. Ignored if zero. See Figure 10-32.
PSDX	Stop displacement for positive x-translation. Ignored if zero.
NSDY	Stop displacement for negative y-translation. Ignored if zero.
PSDY	Stop displacement for positive y-translation. Ignored if zero.
NSDZ	Stop displacement for negative z-translation. Ignored if zero.
PSDZ	Stop displacement for positive z-translation. Ignored if zero.
FS	Static friction coefficient.
FD	Dynamic friction coefficient.

Remarks:

After the stop displacements are reached, the force increases linearly to resist further translational motion using the stiffness values on Card 2c.2. Reasonable stiffness values must be chosen. If the stiffness values are too low or zero, the stop will be violated.

Cylindrical Joint Stiffness Cards:

Card 2 for CYLINDRICAL stiffness option.

Card 2d.1	1	2	3	4	5	6	7	8
Variable	LCIDR		LCIDZ	DLCIDR	DLCIDP	DLCIDZ	LCIDT	DLCIDT
Type	I		I	I	I	I	I	I
Default	0		0	0	0	0	0	0

VARIABLE	DESCRIPTION
LCIDR	Load curve ID for *r*-force as a function of *r*-distance between the origins of CIDA and CIDB. See *DEFINE_CURVE. EQ.0: The applied force is set to 0.0.
LCIDZ	Load curve ID for *z*-force as a function of *z*-distance between the origins of CIDA and CIDB. See *DEFINE_CURVE. EQ.0: The applied force is set to 0.0.
DLCIDR	Load curve or table ID for *r*-damping force as a function of rate of *r*-distance per unit time and optionally *r*-distance (if table) between the origins of CIDA and CIDB. See *DEFINE_CURVE or *DEFINE_TABLE. EQ.0: Damping is not considered.
DLCIDP	Load curve or table ID for *p*-damping force as a function of rate of *p*-distance per unit time and optionally *r*-distance (if table) between the origins of CIDA and CIDB. See *DEFINE_CURVE or *DEFINE_TABLE. EQ.0: Damping is not considered.
DLCIDZ	Load curve or table ID for *z*-damping force as a function of rate of *z*-distance per unit time and optionally *r*-distance (if table) between the origins of CIDA and CIDB. See *DEFINE_CURVE or *DEFINE_TABLE. EQ.0: Damping is not considered.

VARIABLE	DESCRIPTION
LCIDT	Load curve ID for θ-moment as a function of angle θ between the z-directions of CIDA and CIDB. See *DEFINE_CURVE. EQ.0: The applied moment is set to 0.0.
DLCIDT	Load curve ID for θ-moment as a function of rate of angle θ between the z-directions of CIDA and CIDB. See *DEFINE_CURVE. EQ.0: The applied moment is set to 0.0.

Card 3 CYLINDRICAL stiffness option.

Card 2d.2	1	2	3	4	5	6	7	8
Variable	ESR	FFR			ESZ	FFZ	RAD1	RAD2
Type	F	F/I			F	F/I	F	F
Default	0.0	0.0			0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
ESR	Elastic stiffness for friction and stop displacement for r-translation. See Figure 10-32. EQ.0.0: Friction and stop angles are inactive for r-translation.
FFR	Frictional force limiting value for r-translation. This option may also be thought of as an elastic-plastic spring. See Figure 10-32. EQ.0.0: Friction is inactive for r-translation. LT.0: -FFR is the load curve ID defining the yield force as a function r-translation.
ESZ	Elastic stiffness for friction and stop displacement for z-translation. EQ.0.0: Friction and stop angles are inactive for z-translation.
FFZ	Frictional force limiting value for z-translation. This option may also be thought of as an elastic-plastic spring. EQ.0.0: Friction is inactive for z-translation.

VARIABLE	DESCRIPTION
	LT.0: -FFZ is the load curve ID defining the yield force as a function of z-translation.
RAD1	Radius of pin, must be strictly positive.
RAD2	Radius of hole, must be strictly larger than RAD1 to model play in the connection.

Card 4 for CYLINDRICAL stiffness option.

Card 2d.3	1	2	3	4	5	6	7	8
Variable		PSDR			NSDZ	PSDZ	FS	FD
Type		F			F	F	F	F
Default		0.0			0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
PSDR	Stop displacement for r-translation. Ignored if zero.
NSDZ	Stop displacement for negative z-translation. Ignored if zero.
PSDZ	Stop displacement for positive z-translation. Ignored if zero.
FS	Static friction coefficient.
FD	Dynamic friction coefficient.

Remarks:

As shown in Figure 10-34, the cylindrical joint stiffness models a pin in a hole with a gap. The pin has a radius r_1 (RAD1) while the hole has a radius r_2 (RAD2), with $0 < r_1 < r_2$, so the gap is at most $g = r_2 - r_1$. This joint stiffness needs no associated joint, but all directions can be constrained by appropriate usage of this keyword.

Let $\mathbf{x}_i$ be the origin of coordinate system associated with body i, $i = 1, 2$, defined by *DEFINE_COORDINATE_NODES. Then the radial distance to be used in the curves/tables is defined as

$$r = \left|\left(\mathbf{I} - \mathbf{z}\mathbf{z}^T\right)(\mathbf{x}_2 - \mathbf{x}_1)\right| \ ,$$

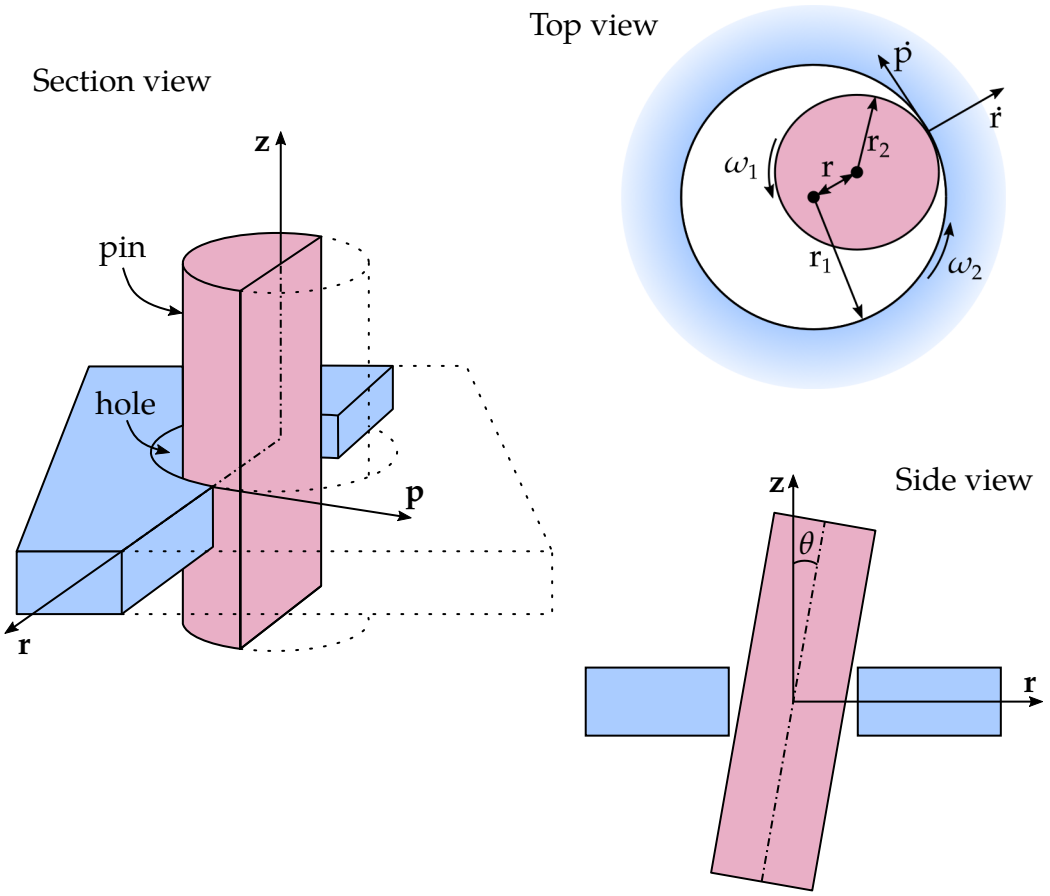

Figure 10-34. Cylindrical joint stiffness models a pin in a hole.

and the radial direction is defined as

$$\mathbf{r} = \frac{\left(\mathbf{I} - \mathbf{z}\mathbf{z}^T\right)(\mathbf{x}_2 - \mathbf{x}_1)}{r} \ .$$

See LCIDR, ESR, FFR and PSDR. Here $\mathbf{I}$ is the unit matrix, and $\mathbf{z}$ is the local z-direction of the coordinate system in body 2. We basically assign a cylindrical coordinate system $\{\mathbf{r}, \mathbf{p}, \mathbf{z}\}$ with the z-direction co-linear with the cartesian z-direction in body 2. The radial distance is thus the (non-directional) distance between body 1 and body 2 in the local xy-plane of body 2.

Likewise, we define the z-distance to be used in the curves/tables as

$$z = \left|\mathbf{z}^T(\mathbf{x}_2 - \mathbf{x}_1)\right| \ ,$$

which is the *directional* distance from body 1 to body 2 in the z-direction. See LCIDZ, ESZ, FFZ, NSDZ and PSDZ.

From this, the rate of r and z are obtained by taking the time derivative quantities, $\dot{r}$ and $\dot{z}$, that are also used in curves/tables for damping purposes; see DLCIDR and DLCIDZ. If these are defined by tables, the second argument is the radial distance, r, which can be used to not apply any damping when the gap is positive. For numerical purposes, and

for the sake of introducing a hysteresis, $\dot{r}$ is always positive, so DLCIDR only needs to be defined for positive $\dot{r}$.

Last, we define **p** as the cross production of **z** and **r**, that is,

$$\mathbf{p} = \mathbf{z} \times \mathbf{r}$$

This is the tangential direction along the circumference of the pin or the hole, depending on how you observe it. The tangential velocity is defined as

$$\dot{p} = \mathbf{p}^T(\dot{\mathbf{x}}_2 - (r_1 + r)\boldsymbol{\omega}_2 \times \mathbf{r} - \dot{\mathbf{x}}_1 + r_1\boldsymbol{\omega}_1 \times \mathbf{r}) \ ,$$

where $\boldsymbol{\omega}_1$ and $\boldsymbol{\omega}_2$ are the rotational velocities of bodies 1 and 2, respectively. The interpretation of this is the relative velocity of the contact point between the hole (body 2) and the pin (body 1) in direction **p** when the gap is zero. This can be used to define damping in the p-direction (see DLCIDP) as a type of simplified friction model. Also, here a table can be used with r as the second argument.

To maintain co-linearity of the z-directions of the pin and hole, the angle θ is defined as illustrated in the picture. This quantity, and its time derivative $\dot{\theta}$, can be used to enforce this co-linearity; see LCIDT and DLCIDT. For numerical purposes, and for the sake of introducing hysteresis, $\dot{\theta}$ is always positive so DLCIDT only needs to be defined for positive $\dot{\theta}$.

*CONSTRAINED_JOINT_USER_FORCE

Purpose: Define input data for a user subroutine to generate force resultants as a function of time and joint motion.

Card 1	1	2	3	4	5	6	7	8
Variable	FID	JID	NHISV					
Type	I	I	I					
Default	none	none	0					

User Subroutine Constants Cards. Define up to 48 optional user constants (6 cards total) for the user subroutine. This input is terminated after 48 constants are defined or when the next keyword ("*") card is encountered.

Card 2	1	2	3	4	5	6	7	8
Variable	CONST1	CONST2	CONST3	CONST4	CONST5	CONST6	CONST7	CONST8
Type	F	F	F	F	F	I	I	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
FID	Joint user force ID.
JID	Joint ID for which this user force input applies.
NHISV	Number of history variables required for this definition. An array NHISV long is allocated and passed into the user subroutine. This array is updated in the user subroutine.
CONST*n*	A constant which is passed into the user subroutine.

*CONSTRAINED_LAGRANGE_IN_SOLID_{OPTION1}_{OPTION2}

Purpose: This command provides the coupling mechanism for modeling Fluid-Structure Interaction (FSI). The structure can be constructed from Lagrangian shell and/or solid entities. The multi-material fluids are modeled by ALE formulation.

Available options for *OPTION1* include:

<BLANK>

EDGE

This option may be used to allow the coupling between the edge of a shell part or part set and one or more ALE multi-material groups (AMMG). It accounts for the shell thickness in the coupling calculation. The edge thickness is the same as the shell thickness. This option only works when the Lagrangian set is defined as a part or a part set ID. It will not work for a segment set. One application of this option is a simulation of a Lagrangian blade (a shell part) cutting through some ALE material.

Available options for *OPTION2* include:

<BLANK>

TITLE

To define a coupling (card) ID number and title for each coupling card. If a title is not defined, LS-DYNA will automatically create an internal title for this coupling definition. The ID number can be used to delete coupling action in a restart input deck using the *DELETE_FSI card.

Card Summary:

Card ID. This card is included if and only if the TITLE keyword option is used.

COUPID	TITLE

Card 1. This card is required.

LSTRSID	ALESID	LSTRSTYP	ALESTYP	NQUAD	CTYPE	DIREC	MCOUP

Card 2. This card is required.

START	END	PFAC	FRIC	FRCMIN	NORM	NORMTYP	DAMP

Card 3. This card is required.

K	HMIN	HMAX	ILEAK	PLEAK	LCIDPOR	NVENT	IBLOCK

Card 4. This card is required for CTYPE = 11 and 12. Otherwise it is optional. If Card 5 is included, then this card must be included.

IBOXID	IPENCHK	INTFORC	IALESOF	LAGMUL	PFACMM	THKF	

Card 5. This card is required for CTYPE = 11 and 12. Otherwise it is optional. If this card is included, then Card 4 must be included.

A1	B1	A2	B2	A3	B3		POREINI

Card 6. NVENT of this card must be defined (one card for defining each vent hole). The last NVENT cards for *CONSTRAINED_LAGRANGE_IN_SOLID are assumed to be Card(s) 6; therefore, Cards 4 and 5 are not mandatory when Card(s) 6 are defined.

VENTSID	VENTYP	VTCOEF	POPPRES	COEFLC			

Data Card Definitions:

Title Card. Additional card for the TITLE keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	COUPID	TITLE						
Type	I	A70						

VARIABLE	DESCRIPTION
COUPID	Coupling (card) ID number. If not defined, LS-DYNA will assign an internal coupling ID based on the order of appearance in the input deck.
TITLE	A description of this coupling definition (A70).

Card 1	1	2	3	4	5	6	7	8
Variable	LSTRSID	ALESID	LSTRSTYP	ALESTYP	NQUAD	CTYPE	DIREC	MCOUP
Type	I	I	I	I	I	I	I	I
Default	none	none	0	0	0	2	1	0

VARIABLE	DESCRIPTION
LSTRSID	Set ID defining a part, part set, or segment set ID of the Lagrangian structure (see *PART, *SET_PART or *SET_SEGMENT). See Remark 1.
ALESID	Set ID defining a part or part set ID of the ALE solid elements (see *PART or *SET_PART). See Remark 1.
LSTRSTYP	LSTRSID set type (see Remark 1): EQ.0: Part set ID (PSID) EQ.1: Part ID (PID) EQ.2: Segment set ID (SSID)
ALESTYP	ALESID set type (see Remark 1): EQ.0: Part set ID (PSID) EQ.1: Part ID (PID)
NQUAD	Number of coupling points distributed over each coupled Lagrangian surface segment. See Remark 2. EQ.0: NQUAD will be set by default to 2, GT.0: An NQUAD × NQUAD coupling points distribution over each Lagrangian segment is defined, LT.0: NQUAD is reset to a positive value. Coupling at nodes is obsolete.
CTYPE	Fluid-Structure coupling method. CTYPEs 1 and 2 are not supported in MPP. EQ.1: Constrained acceleration EQ.2: Constrained acceleration and velocity (default, see Remark 3) EQ.3: Constrained acceleration and velocity, normal direction only EQ.4: Penalty coupling for shell and solid elements (without erosion)

NOTE: For RIGID Lagrangian structure PARTS a penalty coupling method (CTYPE = 4) must be used.

VARIABLE	DESCRIPTION
	EQ.5: Penalty coupling allowing erosion in the Lagrangian entities EQ.6: Penalty coupling designed for airbag modeling which automatically controls the DIREC parameter internally. It is equivalent to setting {CTYPE = 4; DIREC = 1} for the unfolded region; and {CTYPE = 4; DIREC = 2} for the folded region. For both cases: {ILEAK = 2; FRCMIN = 0.3}. EQ.11: Coupling designed to couple Lagrangian porous shell to ALE material. When this option is used, THKF, the 7th column parameter of optional Card 4a and the first 2 parameters of optional Card 4b must be defined. See *LOAD_BODY_POROUS and Remark 13 below. EQ.12: Coupling designed to couple Lagrangian porous solid to ALE material. When this option is used, Ai & Bi parameters of optional Card 4b must be defined (Card 4a must be defined but can be blank). See *LOAD_BODY_POROUS and Remark 14 below.
DIREC	For CTYPE = 4 or 5 Coupling direction (see Remark 4): EQ.1: Normal direction, compression, and tension (default) EQ.2: Normal direction, compression only EQ.3: All directions For CTYPE = 12 Flag to activate an element coordinate system: EQ.0: The forces are applied in the global directions. EQ.1: The forces are applied in a local system attached to the Lagrangian solid. The system is consistent with AOPT = 1 in *LOAD_BODY_POROUS. (See Remark 14).
MCOUP	For CTYPE = 4, 5, 6, 11, or 12 Multi-material option (see Remark 5): EQ.0: Couple with all multi-material groups EQ.1: Couple with material with highest density

VARIABLE	DESCRIPTION
	LT.0: MCOUP must be an integer. -MCOUP refers to a set ID of an ALE multi-material group. See *SET_MULTI-MATERIAL_GROUP.

Card 2	1	2	3	4	5	6	7	8
Variable	START	END	PFAC	FRIC	FRCMIN	NORM	NORMTYP	DAMP
Type	F	F	F	F	F	I	I	F
Default	0.0	10^{10}	0.1	0.0	0.5	0	0	0.0

VARIABLE	DESCRIPTION
START	Start time for coupling.
END	End time for coupling. If less than zero, coupling will be turned off during dynamic relaxation. After dynamic relaxation phase is finished, the absolute value will be taken as end time.
PFAC	For CTYPE = 4,5 or 6 Penalty factor. PFAC is a scale factor for scaling the estimated stiffness of the interacting (coupling) system. It is used to compute the coupling forces to be distributed on the Lagrangian and ALE parts GT.0: Fraction of estimated critical stiffness. LT.0: PFAC must be an integer, and -PFAC is a load curve ID. The curve defines the coupling pressure on the *y*-axis as a function of the penetration along the *x*-axis. (See "How to Correct Leakage") For CTYPE = 11 or 12 Time step factor
FRIC	Coefficient of friction (used with DIREC = 1 and 2 only).
FRCMIN	Minimum volume fraction of a coupled ALE multi-material group (AMMG) or fluid in a multi-material ALE element to activate coupling. Default value is 0.5. Reducing FRCMIN (typically, between 0.1 and 0.3) would turn on coupling earlier to prevent leakage in high velocity impact cases.

VARIABLE	DESCRIPTION
NORM	A Lagrangian segment will couple to fluid on only one side of the segment. NORM determines which side. See Remark 6. EQ.0: Couple to fluid (AMMG) on head-side of Lagrangian segment normal vector. EQ.1: Couple to fluid (AMMG) on tail-side of Lagrangian segment normal vector.
NORMTYP	Penalty coupling spring (or force) direction (DIREC = 1 or 2): EQ.0: Normal vectors are interpolated from nodal normals. (default). EQ.1: Normal vectors are interpolated from segment normals. This is sometimes a little more robust for sharp Lagrangian corners, and folds.
DAMP	Damping factor for penalty coupling. This is a coupling-damping scaling factor. Typically, it may be between 0.0 and 1.0 (see Remark 7).

Card 3	1	2	3	4	5	6	7	8
Variable	K	HMIN	HMAX	ILEAK	PLEAK	LCIDPOR	NVENT	IBLOCK
Type	F	F	F	I	F	I	I	I
Default	0.0	none	none	0	0.1	0	0	0

VARIABLE	DESCRIPTION
K	Thermal conductivity of a virtual fluid between the Lagrangian structure surface and the ALE material. See Remark 8.
HMIN	The absolute value is minimum air gap in heat transfer, $h_{\min}$ (See Remark 8). LT.0.0: Turn on constraint based thermal nodal coupling between LAG structure and ALE fluids. GE.0.0: Minimum air gap. If zero, default to 10^{-6}.

VARIABLE	DESCRIPTION
HMAX	Maximum air gap in heat transfer, h_{max}. There is no heat transfer above this value. See Remark 8.
ILEAK	Coupling leakage control flag (Remark 9): EQ.0: None (default), EQ.1: Weak, leakage control is turned off if penetrating volume fraction > FRCMIN + 0.2 EQ.2: Strong, with improved energy consideration. Leakage control is turned off if penetrating volume fraction > FRCMIN + 0.4
PLEAK	Leakage control penalty factor, 0 < PLEAK < 0.2 is recommended. This factor influences the additional coupling force magnitude to prevent leakage. It is conceptually similar to PFAC. Almost always, the default value (0.1) is adequate.
LCIDPOR	If this is a positive integer, a load curve ID (LCID) defining porous flow through coupling segment: Abscissa = x = ($P_{up} - P_{down}$) Ordinate = y = relative porous fluid velocity Where P_{up} and P_{down} are, respectively, the upstream and downstream pressures across of the porous coupling segment. The relative porous velocity is the ALE fluid velocity relative to the moving Lagrangian segment. This experimental data curve must be provided by the user. If LCIDPOR is a negative integer: The porous flow is controlled by the parameters FLC, FAC, ELA under *MAT_FABRIC card. **CAUTION:** The pressure under the FAC load curve is "absolute upstream pressure" (see Remark 10). Abscissa = x = absolute upstream pressure Ordinate = y = relative porous fluid velocity For CTYPE = 11 or CTYPE = 12 and POREINI = 0.0: LT.0: The load curve |LCIDPOR| is a factor versus time of the porous force computed by the Ergun equation. See Remark 13.

VARIABLE	DESCRIPTION
	GT.0: The load curve LCIDPOR is a porous force versus velocity, which replaces the force computed by the Ergun equation. See Remark 13.
	For CTYPE = 11 or CTYPE = 12 and POREINI > 0.0:
	NE.0: The load curve |LCIDPOR| is a factor versus time of the porous force computed by the Ergun equation. See Remark 13.
NVENT	The number of vent surface areas to be defined. Each venting flow surface is represented by one or more Lagrangian segments (or surfaces). For airbag applications, this may be referred to as "isentropic" venting where the isentropic flow equation is used to compute the mass flow rate based on the ratio of the upstream and downstream pressures P_{up}/P_{down}. For each of the NVENT vent surfaces, an additional card of format 6 defining the geometrical and flow properties for each vent surface will be read in. The vented mass will simply be deleted from the system and cannot be visualized as in the case of physical venting. See Remark 11.
IBLOCK	Flag to control the venting (or porous) flow blockage due to Lagrangian contact during ALE computation. EQ.0: Off EQ.1: On The venting definition is defined in this command. However, the venting flow may be defined through either the LCIDPOR parameter in this command or via the *MAT_FABRIC parameters (FLC, FAC, ELA). However, note that FVOPT (blocking) parameter under *MAT_FABRIC applies only to CV computation.

Card 4. This card is required for CTYPE 11 & 12 but is otherwise optional.

Card 4	1	2	3	4	5	6	7	8
Variable	IBOXID	IPENCHK	INTFORC	IALESOF	LAGMUL	PFACMM	THKF	
Type	I	I	I	I	F	I	F	
Default	0	0	0	0	0.0	0	0.0	

VARIABLE **DESCRIPTION**

IBOXID A box ID defining a box region in space in which ALE coupling is activated.

GT.0: At time = 0.0, the Lagrangian segments inside this box are remembered. In subsequent coupling computation steps, there is no need to search for the Lagrangian segments again.

LT.0: At each FSI bucket sort, the Lagrangian segments inside this box are marked as active coupling segments. This makes the coupling operate more efficiently when a structured mesh is approaching ALE domain, such as hydroplaning and bird strike.

IPENCHK Only for CTYPE = 4

Initial penetration check flag (See Remark 12):

EQ.0: Do not check for initial penetration.

EQ.1: Check and save initial ALE material penetration across a Lagrangian surface (d_0), but do not activate coupling at $t = 0$. In subsequent steps ($t > 0$) the actual penetration is computed as follows:

$$\underbrace{\text{Actual Penetration}}_{d_a} = \underbrace{\text{Total Penetration}}_{d_T} - \underbrace{\text{Initial Penetration}}_{d_0}$$

INTFORC A flag to turn on or off the output of ALE coupling pressure and forces on the Lagrangian segments (or surfaces).

EQ.0: Off

EQ.1: On

VARIABLE	DESCRIPTION
	Note that the coupling pressures and forces are computed based on the coupling stiffness response to the ALE fluid penetration. When INFORC = 1 and a *DATABASE_BINARY_FSIFOR (DBF) card is defined, LS-DYNA writes out the segment coupling pressure and forces to the binary interface force file for contour plotting. This interface force file must be given a name on the execution line, for example: ls-dyna i=**inputfilename.k** … h=**interfaceforcefilename** The time interval between output is defined by "dt" in the DBF card. To plot the binary data in this file: ls-prepost **interfaceforcefilename**
IALESOF	An integer flag to turn ON/OFF a supplemental Lagrange multiplier FSI constraint which provides a coupling force in addition to the basic penalty coupling contribution. This is a hybrid coupling method. EQ.0: OFF (default). EQ.1: Turn ON the hybrid Lagrange-multiplier method. LAGMUL multiplier factor is read.
LAGMUL	A Lagrange multiplier factor with a range between 0.0 and 0.05 may be defined. A typical value may be 0.01. This should never be greater than 0.1. EQ.0: OFF (default). GT.0: Turn ON the Lagrange-multiplier method and use LAGMUL as a coefficient for scaling the penalty factor.
PFACMM	Mass-based penalty stiffness factor computational options. This works in conjunction with PFAC = constant (not a load curve). The coupling penalty stiffness (CPS) is computed based on an estimated effective coupling mass. EQ.0: CPS $\propto$ PFAC $\times \min(m_{\text{Lagrangian}}, m_{\text{ALE}})$, default. EQ.1: CPS $\propto$ PFAC $\times \max(m_{\text{Lagrangian}}, m_{\text{ALE}})$. EQ.2: CPS $\propto$ PFAC $\times \sqrt{m_{\text{Lagrangian}} m_{\text{ALE}}}$, geometric-mean of the masses.

VARIABLE	DESCRIPTION
	EQ.3: CPS $\propto$ PFAC $\times K_{\text{Lagrangian}}$ where K is the bulk modulus of the Lagrangian part
THKF	For all CTYPE choices except 11: A flag to account for the coupling thickness of the Lagrangian shell part. LT.0: Use positive value of |THKF| for coupling segment thickness. EQ.0: Do not consider coupling segment thickness. GT.0: Coupling segment thickness scale factor. For CTYPE = 11: This thickness is required for volume calculation. GT.0: (Fabric) Thickness scale factor. The base shell thickness is taken from the *PART definition. LT.0: User-defined (Fabric) thickness. The fabric thickness is set to |THKF|.

Porous Coupling. This card applies only to CTYPE 11 & 12. If this card is defined, Card 4 must be defined before this card.

Card 5	1	2	3	4	5	6	7	8
Variable	A1	B1	A2	B2	A3	B3		PORFINI
Type	F	F	F	F	F	F		F
Default	0.0	0.0	0.0	0.0	0.0	0.0		0.0

VARIABLE	DESCRIPTION
A1	Viscous coefficient for the porous flow Ergun equation (see Remark 13). GT.0: For CTYPE = 11 $A1 = A_n$ which is the coefficient for normal-to-segment direction.

VARIABLE	DESCRIPTION
	For CTYPE = 12 $A1 = A_x$ which is the coefficient for the x-direction in the coordinate system specified by DIREC. LT.0: If POREINI = 0.0, the coefficient is time dependent through a load curve ID defined by |A1|. If POREINI > 0.0, the coefficient is porosity dependent through a load curve ID defined by |A1|. The porosity is defined by PORE (see POREINI).
B1	Inertial coefficient for the porous flow Ergun equation (see Remark 13). GT.0: For CTYPE = 11 $B1 = B_n$ which is the coefficient for normal-to-segment direction. For CTYPE = 12 $B1 = B_x$ which is the coefficient for the x-direction of a coordinate system specified by DIREC. LT.0: If POREINI = 0.0, the coefficient is time dependent through a load curve id defined by |B1|. If POREINI > 0.0, the coefficient is porosity dependent through a load curve ID defined by |B1|. The porosity is defined by PORE (see POREINI).
A2	For CTYPE = 12 Viscous coefficient for the porous flow Ergun equation (see Remark 14). GT.0: Coefficient for the y-direction of a coordinate systems specified by DIREC. $A2 = A_y$ LT.0: If POREINI = 0.0, the coefficient is time dependent through a load curve ID defined by |A1|. If POREINI > 0.0, the coefficient is porosity dependent through a load curve ID defined by |A2|. The porosity is defined by PORE (see POREINI).

VARIABLE	DESCRIPTION
B2	For CTYPE = 12 Inertial coefficient for the porous flow Ergun equation (see Remark 14). GT.0: Coefficient for the y-direction of a coordinate system specified by DIREC. $$B2 = B_y$$ LT.0: If POREINI = 0.0 and B2 < 0, the coefficient is time dependent through a load curve ID defined by |B2|. If POREINI > 0.0 and B2 < 0, the coefficient is porosity dependent through a load curve ID defined by |B2|. The porosity is defined by PORE (see POREINI).
A3	For CTYPE = 12 Viscous coefficient for the porous flow Ergun equation (see Remark 14). GT.0: Coefficient for the z-direction of a coordinate system specified by DIREC. $$A3 = A_z$$ LT.0: If POREINI = 0.0 and A3 < 0, the coefficient is time dependent through a load curve ID defined by |A3|. If POREINI > 0.0 and A3 < 0, the coefficient is porosity dependent through a load curve ID defined by |A3|. The porosity is defined by PORE (see POREINI).
B3	For CTYPE = 12 Inertial coefficient for the porous flow Ergun equation (see Remark 14). GT.0: Coefficient for the z-direction of a coordinate system specified by DIREC. $$B3 = B_z$$ LT.0: If POREINI = 0.0 and B3 < 0, the coefficient is time dependent through a load curve ID defined by |B3|. If POREINI > 0.0 and B3 < 0, the coefficient is porosity dependent through a load curve ID defined by |B3|. The porosity is defined by PORE (see POREINI).

VARIABLE	DESCRIPTION
POREINI	For CTYPE = 11 or CTYPE = 12 POREINI is the initial volume of pores in an element. The current volume is $$\text{PORE} = \text{POREINI} \times \frac{v(t)}{v(t_0)}$$ where $v(t)$ and $v(t_0)$ are the current and initial element volumes respectively.

Venting Geometry Card(s). These card(s) set venting geometry. It is repeated NVENT times (one card for defining each vent hole). It is defined only if NVENT > 0 on Card 3. The last NVENT cards for *CONSTRAINED_LAGRANGE_IN_SOLID are taken to be Card(s) 6; therefore, Cards 4 and 5 are not mandatory when Card(s) 6 are defined.

Card 6	1	2	3	4	5	6	7	8
Variable	VENTSID	VENTYP	VTCOEF	POPPRES	COEFLC			
Type	I	I	I	F	I			
Default	0	0	0	0.0	0			

VARIABLE	DESCRIPTION
VENTSID	Set ID of the vent hole shape.
VENTYP	Vent surface area set ID type: EQ.0: Part set ID (PSID). EQ.1: Part ID (PID). EQ.2: Segment set ID (SGSID).
VTCOEF	Flow coefficient for each vent surface area.
POPPRES	Venting pop pressure limit. If the pressure inside the airbag is lower than this pressure, then nothing is vented. Only when the pressure inside the airbag is greater than POPPRES that venting can begin.
COEFLC	A time-dependent multiplier load curve for correcting the vent flow coefficient, with values ranging from 0.0 to 1.0.

Best Practices:

Due to the complexity of this card, some comments on simple, efficient and robust coupling approach are given here. These are not rigid guidelines, but simply some experience-based observations.

1. **Definition (Fluid and Structure).** The term *fluid*, in the Fluid-Structure Interaction (FSI), refers to materials with ALE element formulation, not indicating the phase (solid, liquid or gas) of those materials. In fact, solid, liquid, and gas can all be modeled by the ALE formulation. The term *structure* refers to materials with Lagrangian element formulation.

2. **Default Values (CTYPE and MCOUP).** In general, penalty coupling (CTYPE 4 & 5) is recommended, and MCOUP = negative integer is a better choice to define a specific ALE multi-material group (AMMG) to be coupled to the Lagrangian surface. At the minimum, all parameters on Card 1 are to be specified, and the default values for most are good starting choices (except MCOUP).

3. **How to Correct Leakage.** If there is leakage, PFAC, FRCMIN, NORMTYPE, and ILEAK are the 4 parameters that can be adjusted.

   a) For hard structure (steel) and very compressible fluid (air), PFAC may be set to 0.1 (or higher). PFAC = constant value.

   b) Next, keeping PFAC = constant, set PFACMM = 3 (optional Card 4a). This option scales the penalty factor by the bulk modulus of the Lagrangian structure. This new approach has also shown to be effective for some airbag applications.

   c) The next approach may be switching from constant PFAC to a load curve approach, that is, PFAC = load curve and PFACMM = 0. By looking at the pressure in the system near leakage original location, we can get a feel for the pressure required to stop it.

   d) If leakage persists after some iterations on the coupling force controls, one can subsequently try to set ILEAK = 2 in combination with the other controls to prevent leakage.

   e) If the modifications fail to stop the leakage, maybe the meshes have to be redesigned to allow better interactions between the Lagrangian and Ale materials.

   In the example below, the underlined parameters are usually defined parameters. A full card definition is shown for reference.

Remarks:

1. **Meshing.** In order for a fluid-structure interaction (FSI) to occur, a Lagrangian (structure) mesh must spatially overlap with an ALE (fluid) mesh. Each mesh should be defined with independent node IDs. LS-DYNA searches for the spatial intersection of between the Lagrangian and ALE meshes. Where the meshes overlap, there is a possibility that interaction may occur. In general, LSTRSID, ALESID, LSTRSTYP and ALESTYP are required definitions for specifying overlapping-domains coupling search.

2. **Number of Coupling Points.** The number of coupling points, NQUAD × NQUAD, is distributed over the surface of each Lagrangian segment. Generally, 2 or 3 coupling points per each Eulerian/ALE element width is adequate. Consequently, the appropriate NQUAD values must be estimated based on the *relative resolutions* between the Lagrangian and ALE meshes.

   For example, if one Lagrangian shell element spans two ALE elements, then NQUAD for each Lagrangian segment should be 4 or 6. Alternatively, if two or three Lagrangian segments span one ALE element, then maybe NQUAD = 1 would be adequate.

   If either mesh compresses or expands during the interaction, the number of coupling points per ALE element will also change. The user must account for this and try to maintain at least two coupling points per each ALE element side length during the whole process to prevent leakage. Too many coupling points can result in instability, and not enough can result in leakage.

3. **The Constraint Method.** The constraint method violates kinetic energy balance. The penalty method is therefore recommended. Historically, CTYPE = 2 was sometimes used to couple Lagrangian beam nodes to ALE or Lagrangian solids, such as for modeling rebar in concrete or tire cords in rubber. For such constraint-based coupling of beams in solids, *CONSTRAINED_BEAM_IN_SOLID and *DEFINE_BEAM_SOLID_COUPLING are now preferred.

4. **Coupling Direction.** DIREC = 2 (compression only) may be generally a more stable and robust choice for coupling direction. However, the physics of the problem should dictate the coupling direction. DIREC = 1 couples under both

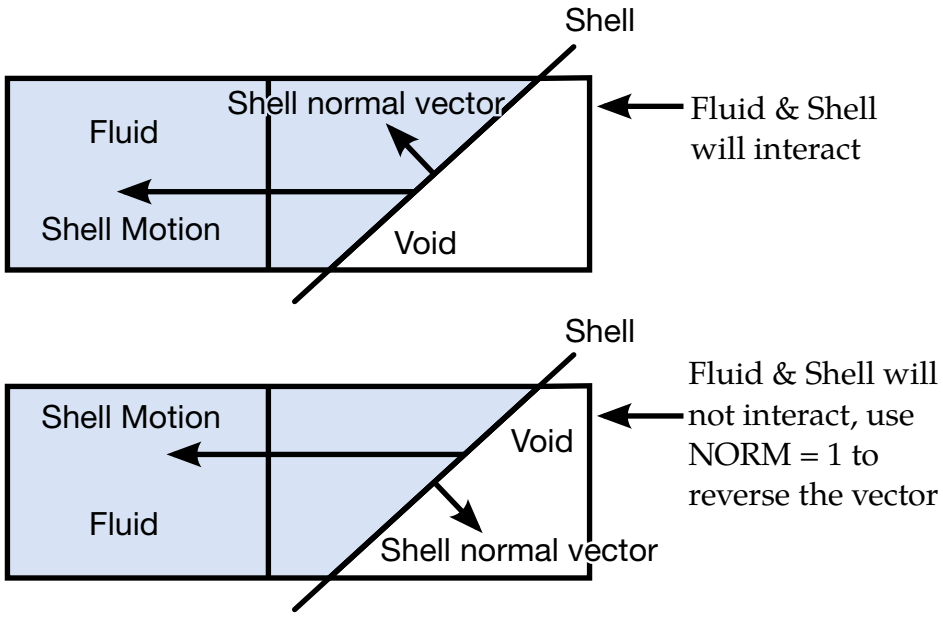

Figure 10-35. Shell Motion

tension and compression. This is sometimes useful; for example, in the case of a suddenly accelerating liquid in a container. DIREC = 3 is rarely appropriate because it models an extremely sticky fluid.

5. **Multi-material Coupling Option.** When MCOUP is a negative integer, such as MCOUP = -123, then an ALE multi-material set-ID (AMMSID) of 123 must exist. This is an ID defined by a *SET_MULTI-MATERIAL_GROUP_LIST card. This generally seems to be a better approach to couple to a specific set of AMMGs, and have a clearly defined fluid interface interacting with a Lagrangian surface. That way, any leakage may be visualized and the penalty force can be computed more precisely.

   The *Couple to all materials* option as activated by MCOUP = 0 is generally not recommended. LS-DYNA calculates the fluid coupling interface as the surface where the sum of coupled ALE materials occupies a volume fraction equal to 50%. Since MCOUP = 0 couples to all materials, the sum of all coupled ALE materials is, in this case, trivially 100%. Consequently, when MCOUP = 0, there will not be a fluid interface with which to track leakage.

6. **Normal Vector Direction.** The normal vectors (NV) of a Lagrangian shell part are defined by the order of the nodes in *ELEMENT definitions, using the right hand rule, and for a segment set, the order of nodes defined in *SET_SEGMENT. Let the side pointed to by NV be “positive”. The penalty method measure penetration as the distance the ALE fluid penetrates from the positive side to the negative side of the Lagrangian segment. Only fluid on the positive side will be “seen” and coupled to.

Therefore, all normal vectors of the Lagrangian segments should point uniformly toward the ALE fluid(s), AMMGs, to be coupled to. If NV point uniformly away from the fluid, coupling is not activated. In this case, coupling can be activated by setting NORM = 1. Sometimes a shell part or mesh is generated such that its normal vectors do not point uniformly in a consistent direction (all toward the inside or outside of a container, etc.) You should always check for the normal vectors of any Lagrangian shell part interacting with any fluid. The NORM parameter may be used to flip the normal direction of all the segments included in the Lagrangian structure set. See Figure 10-35.

7. **Coupling-Damping Factor.** The user-input coupling-damping factor (DAMP) is used to scale down the critical-damping force (~ damper constant × velocity). For a mass-to-rigid-wall system connected by a parallel-spring-damper connector, we can obtain solution for a critically-damped case. DAMP is a factor for scaling down the amount of damping, with DAMP = 1 being a critically-damped case.

8. **Heat Transfer.** The method used is similar to that done by *CONTACT_…_THERMAL_… card, except radiation heat transfer is not considered. A gap, l, is assumed to exist between the two materials undergoing heat transfer (one is Lagrangian and the other ALE). The convection heat transfer in the gap is assumed to approach simple conduction across the medium in the gap.

$$q = K\frac{dT}{dx} \sim h\Delta T \Rightarrow h \sim \frac{K}{l}$$

The heat flux is typically defined as an energy transfer rate per unit area, $q \sim \frac{[J/s]}{m^2}$. The constant K is the thermal conductivity of the material in the gap; h, is the equivalent convection heat transfer coefficient; and ΔT is the temperature difference between the ALE and Lagrangian structure sides. There are 3 possible scenarios:

$$h \sim \begin{cases} 0 & \text{HMAX} < l \\ K/l & \text{HMIN} \le l \le \text{HMAX} \\ K/\text{HMIN} & 0 < l < \text{HMIN} \end{cases}$$

The ALE fluid must be modelled using the ALE single material with void element formulation (ELFORM = 12) because the LS-DYNA thermal solver supports only one temperature per node. However, a workaround enables partial support for ELFORM = 11. Rather than using the thermal solver's nodal temperature field, the ALE temperature is derived from element's internal energy using the heat capacity. The heat is then extracted from or added to the internal energy of ALE elements. This feature was implemented to calculate the heat

exchange between a gas mixture, modeled with *MAT_GAS_MIXTURE and ALE multi-material formulation ELFORM = 11, and a Lagrangian container.

HMIN < 0 turns on constraint-based thermal nodal coupling between the Lagrangian surface nodes and ALE fluid nodes. This option only works with ALE single material with void element formulation (ELFORM = 12). Once a Lagrangian surface node is in contact with ALE fluid (gap = 0), the heat transfer described above is turned off. Instead the Lagrangian surface node temperature is constrained to the ALE fluid temperature field.

9. **Leakage Control.** The dominate force preventing leakage across a coupled Lagrangian surface should be the penalty associated with the coupling. Forces from the leakage control algorithm feature should be secondary. The *DATABASE_FSI keyword controls the "dbfsi" file, which reports both the coupling forces and the leakage control force contribution. It is useful for debugging and fine-tuning.

   ILEAK = 2 conserves energy; thus, it is better for airbag applications. Leakage control should only be enabled when (1) coupling to a specific AMMG (MCOUP as a negative integer) is activated, and (2) the fluid interface is clearly defined and tracked through the *ALE_MULTI-MATERIAL_GROUP card.

10. **Pressure Definition in Porous Flow.** There are currently two methods to model porous flow across a Lagrangian shell structure. Both methods involve defining an empirical data curve of relative porous gas velocity as a function of system pressure. The pressure definitions, however, are slightly different depending on the choice of parameter defined:

    a) When porous flow is modelled using the LCIDPOR parameter (part of *this* keyword), the velocity response curve expected to be given in terms of the pressure difference: $P_{\text{upstream}} - P_{\text{downstream}}$.

    b) When LCIDPOR is negative, porous flow is modelled using the *MAT_FABRIC material model. The FAC field in *MAT_FABRIC contains a load curve ID given in terms of absolute upstream pressure, rather than in terms of the pressure difference.

   The *AIRBAG_ALE keyword assumes that the curve referenced by FAC in *MAT_FABRIC is given in terms of absolute upstream pressure. These absolute pressure data are *required* for the CV phase. During the ALE phase, LS-DYNA automatically shifts the FAC curve left (negative) by 1 atmospheric pressure for the porous coupling calculation, which uses gauge pressure, rather than absolute pressure.

The mass flowing across a porous Lagrangian surface can be tracked by the "mout" parameter of the optional "dbfsi" ASCII output file, which may be enabled with the *DATABASE_FSI keyword.

11. **Venting.** There are 2 methods to model (airbag) venting. The accumulated mass output of both may be tracked using the *DATABASE_FSI card ("mout" parameter in the "dbfsi" ASCII output file).

    a) **Isentropic Venting.** In isentropic venting, (define NVENT on Card 3) the flow crossing the vent hole surface is estimated from the isentropic equation. All airbag shell normal vectors should point uniformly in the same direction: typically, inward. The shell elements for the vent holes, included in the Lagrangian coupling set, should also point in the same direction as the airbag meaning usually inward. For more details on isentropic venting, see *AIRBAG_WANG_NEFSKE mass flow rate equation for field OPT = 1 and 2.

    b) **Physical Venting.** Physical venting models involve holes in the Lagrangian structure (usually airbags). The shell parts representing the vent holes may be either excluded from the Lagrangian coupling set, or, if included, have normal vectors reversed from the rest of the airbag. Typically, this means the holes having outward facing normal vectors, since the rest of the airbag has inward pointing normal vectors. With either approach the holes produce no coupling force to stop fluid leakage.

    When a particular AMMG is present on both sides of the same Lagrangian shell surface, penalty coupling can break down. Therefore, it is recommended that *ALE_FSI_SWITCH_MMG_ID be used to switch the AMMG ID of the vented gas so that the vented gas outside the bag does not lead to leakage.

12. **Initial Penetration Check.** Typically, penetration check (IPENCHK) should only be used if there is high coupling force applied at $t = 0$. For example, consider a Lagrangian container, filled with non-gaseous fluid, such as ALE liquid or solid, using the *INITIAL_VOLUME_FRACTON_GEOMETRY command. Sometimes due to mesh resolution or complex container geometry, there is initial penetration of the fluid across the container surface. This can give rise to a sharp and immediate coupling force on the fluid at $t = 0$. Turning on IPENCHK may help eliminate this spike in coupling force.

13. **Porous Flow for Shell Elements.** For shell elements and CTYPE = 11, the Ergun-type empirical porous flow equation is applied to the normal flow direction across the porous surface. The pressure gradient along the segment normal direction is

$$\frac{dP}{dx_n} = A_n(\varepsilon,\mu)V_n + B_n(\varepsilon,\rho)|V_n|V_n$$

where the subscript n refers to the direction normal to the porous Lagrangian shell surface and where,

a) V_n is the relative normal-to-porous-shell-surface fluid velocity component.

b) $A_n(\varepsilon,\mu) = A_1(\varepsilon,\mu)$ is a viscous coefficient of the Ergun-type porous flow equation. As applied here, it should contain the fluid dynamic viscosity, μ , and shell porosity, ε , information.

c) $B_n(\varepsilon,\rho) = B_1(\varepsilon,\rho)$ is an inertial coefficient of the Ergun-type porous flow equation. As applied here, it should contain the fluid density, ρ, and shell porosity, ε, information.

The force increment applied per segment is

$$F_n = \frac{d\rho}{dx_n} \times \text{THKF} \times S,$$

where S is the segment surface area.

If *DEFINE_POROUS_LAGRANGIAN defines the porous properties of a Lagrangian structure element, the porous forces are computed with an equation similar to the one used in *LOAD_BODY_POROUS

NOTE: $A_i(\varepsilon,\mu)$, $B_i(\varepsilon,\rho)$, and THKF are required input for porous shell coupling.

14. **Porous Flow for Solid Elements.** For porous solid, CTYPE = 12, the pressure gradient along each global direction (i) can be computed similarly.

$$\frac{dP}{dx_i} = A_i(\varepsilon,\mu)V_i + B_i(\varepsilon,\rho)|V_i|V_i \text{ for } i = 1,2,3$$

where,

a) V_i is the relative fluid velocity component through the porous solid in the 3 global directions.

b) $A_i(\varepsilon,\mu)$ is a viscous coefficient of the Ergun-type porous flow equation in the i^{th} direction. As applied here, it should contain the fluid dynamic viscosity, μ, and shell porosity, ε, information.

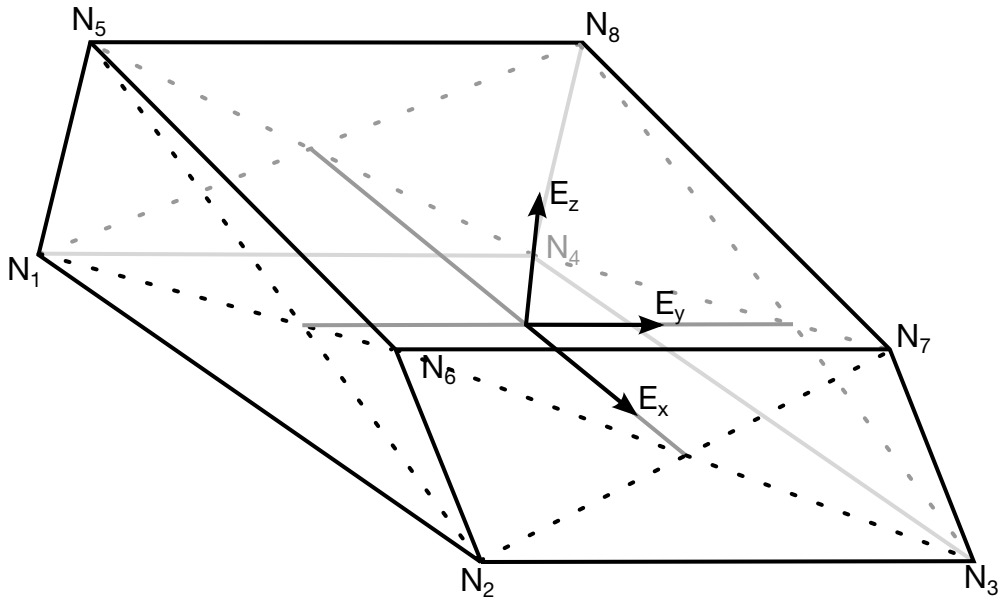

Figure 10-36. The E_x direction is aligned along the line segment connecting the centers of the 2-3-6-7 and the 1-4-8-5 faces. The E_y direction is orthogonal to the E_x direction and in the plane containing both E_x and the segment connecting the centers of the 1-2-6-5 and 3-4-8-7 faces. The E_z is normal to this plane.

c) $B_i(\varepsilon, \rho)$ is an inertial coefficient of the Ergun-type porous flow equation in the i^{th} direction. As applied here, it should contain the fluid density (ρ) and solid porosity (ε) information.

NOTE: $A_i(\varepsilon, \mu)$, and $B_i(\varepsilon, \rho)$ are required input for porous solid coupling.

If DIREC = 1, the pressure gradient in a solid is applied in a local reference coordinate system defined in Figure 10-36. If *DEFINE_POROUS_LAGRANGIAN defines the porous properties of a Lagrangian structure element, the local system can be adapted and the porous forces are computed with an equation similar to the one used in *LOAD_BODY_POROUS.

*CONSTRAINED_LINEAR_GLOBAL

Purpose: Define linear constraint equations between displacements and rotations, which can be defined in global coordinate systems.

> **WARNING:** For the explicit solver, nodes of a nodal constraint equation cannot be members of another constraint equation, a constraint set that contains the same degrees-of-freedom, tied interface, or rigid bodies. Nodes must not be subject to multiple, independent, and possibly conflicting constraints. Furthermore, care must be taken to ensure that single point constraints applied to nodes in a constraint equation do not conflict with the degrees-of-freedom constrained by the constraint equation.
>
> The same applies for the implicit solver; however multiple nodal constraint equations may be applied to the various degrees-of-freedom of the same node, provided that there are no conflicting constraints.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID							
Type	I							
Default	none							

DOF Card. Define one card for each constrained degree-of-freedom. Input is terminated at the next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	NID	DOF	COEF					
Type	I	I	F					
Default	none	0	0					

VARIABLE	DESCRIPTION
LCID	Linear constraint definition ID. This ID can be used to identify a set to which this constraint is a member.
NID	Node ID
DOF	Degree of freedom in the global coordinate system: EQ.1: Displacement along global x-direction EQ.2: Displacement along global y-direction EQ.3: Displacement along global z-direction EQ.4: Global rotation about global x-axis EQ.5: Global rotation about global y-axis EQ.6: Global rotation about global z-axis EQ.7: Nodal electric voltage of piezoelectric material; see *MAT_ADD_PZELECTRIC. The voltage of the 1st node can only be defined as a linear combination of the voltage of other nodes, meaning all DOFs must be 7 for such an application.
COEF	Nonzero coefficient, C_k

Remarks:

In this section, linear constraint equations of the form:

$$\sum_{k=1}^{n} C_k u_k = C_0$$

can be defined, where u_k are the displacements and C_k are user defined coefficients. Unless LS-DYNA is initialized by linking to an implicit code to satisfy this equation at the beginning of the calculation, the constant C_0 is assumed to be zero. The first constrained degree-of-freedom is eliminated from the equations-of-motion:

$$u_1 = C_0 - \sum_{k=2}^{n} \frac{C_k}{C_1} u_k \ .$$

Its velocities and accelerations are given by

$$\dot{u}_1 = -\sum_{k=2}^{n} \frac{C_k}{C_1} \dot{u}_k$$

$$\ddot{u}_1 = -\sum_{k=2}^{n} \frac{C_k}{C_1} \ddot{u}_k,$$

respectively. A transformation matrix, **L**, is constructed relating the unconstrained, **u**, and constrained, $\mathbf{u}_c$, degrees-of-freedom. The constrained accelerations used in the above equation are given by:

$$\ddot{\mathbf{u}}_c = \left[\mathbf{L}^{\mathrm{T}}\mathbf{M}\mathbf{L}\right]^{-1}\mathbf{L}^{\mathrm{T}}\mathbf{F}$$

where **M** is the diagonal lumped mass matrix and **F** is the right hand side force vector. This requires the inversion of the condensed mass matrix which is equal in size to the number of constrained degrees-of-freedom minus one.

Example:

*CONSTRAINED_LINEAR_LOCAL

Purpose: Define linear constraint equations between displacements and rotations which can be defined in a local coordinate system. Each node may have a unique coordinate ID.

Card 1	1	2	3	4	5	6	7	8
Variable	LCID							
Type	I							
Default	none							

DOF Cards. Define one card for each constrained degree-of-freedom. Input is terminated at next keyword ("*") card.

Card 2	1	2	3	4	5	6	7	8
Variable	NID	DOF	CID	COEF				
Type	I	I	I	F				
Default	none	0	global	0				
Remarks	1							

VARIABLE	DESCRIPTION
LCID	LCID for linear constraint definition. This ID can be used to identify a set to which this constraint is a member.
NID	Node ID
DOF	Degree-of-freedom in the local coordinate system; EQ.1: Displacement along local x-direction EQ.2: Displacement along local y-direction EQ.3: Displacement along local z-direction EQ.4: Local rotation about local x-axis

VARIABLE	DESCRIPTION
	EQ.5: Local rotation about local y-axis
	EQ.6: Local rotation about local z-axis
CID	Local coordinate system ID number. If the number is zero, the global coordinate system is used.
COEF	Nonzero coefficient, C_k

Remarks:

> **WARNING:** For the explicit solver, nodes of a nodal constraint equation cannot be members of another constraint equation, a constraint set that contains the same degrees-of-freedom, tied interface, or rigid bodies. Nodes must not be subject to multiple, independent, and possibly conflicting constraints. Furthermore, care must be taken to ensure that single point constraints applied to nodes in a constraint equation do not conflict with the degrees-of-freedom constrained by the constraint equation.
>
> The same applies for the implicit solver; however multiple nodal constraint equations may be applied to the various degrees-of-freedom of the same node, provided that there are no conflicting constraints.

With this keyword, you can define linear constraint equations of the following form:

$$\sum_{k=1}^{n} C_k \, u_k^L = C_0 \ ,$$

where u_k^L are the displacements in the local coordinate systems and C_k are user-defined coefficients. Unless you initialize LS-DYNA by linking to an implicit code to satisfy this equation at the beginning of the calculation, LS-DYNA assumes the constant C_0 is zero. The first constrained degree-of-freedom is eliminated from the equations-of-motion:

$$u_1^L = C_0 - \sum_{k=2}^{n} \frac{C_k}{C_1} u_k^L \ .$$

Its velocities and accelerations are given by

$$\dot{u}_1^L = -\sum_{k=2}^{n} \frac{C_k}{C_1} \dot{u}_k^L$$
$$\ddot{u}_1^L = -\sum_{k=2}^{n} \frac{C_k}{C_1} \ddot{u}_k^L$$

respectively. The local displacements are calculated every time step using the local coordinate systems defined by the user. More than one degree-of-freedom for a node can be constrained by specifying a card for each degree-of-freedom.

***CONSTRAINED_LOCAL**_*{OPTION}*

OPTION allows an optional ID to be given:

ID

Purpose: Define a local boundary constraint plane.

ID Card. Additional card for the ID keyword option.

Optional	1	2	3	4	5	6	7	8
Variable	ID	HEADING						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	TC	RC	DIR	X	Y	Z	CID	TOL
Type	1	1	1	F	F	F	1	F
Default	0	0	none	0.0	0.0	0.0	none	0.0

VARIABLE	DESCRIPTION
ID	Optional ID which can be referred to by *SENSOR_CONTROL. This ID must be unique and cannot be shared with *BOUNDARY_SPC.
HEADING	An optional descriptor that will be written into the d3hsp file and the spcforc file.
TC	Translational constraint in local system: EQ.0: no translational constraints EQ.1: constrained x translation EQ.2: constrained y translation EQ.3: constrained z translation EQ.4: constrained x and y translations

VARIABLE	DESCRIPTION
	EQ.5: constrained y and z translations
	EQ.6: constrained x and z translations
	EQ.7: constrained x, y, and z translations
RC	Rotational constraint in local system:
	EQ.0: no rotational constraints
	EQ.1: constrained x-rotation
	EQ.2: constrained y-rotation
	EQ.3: constrained z-rotation
	EQ.4: constrained x and y rotations
	EQ.5: constrained y and z rotations
	EQ.6: constrained z and x rotations
	EQ.7: constrained x, y, and z rotations
DIR	Direction of normal for local constraint plane:
	EQ.1: local x,
	EQ.2: local y,
	EQ.3: local z.
X	Local x-coordinate of a point on the local constraint plane
Y	Local y-coordinate of a point on the local constraint plane
Z	Local z-coordinate of a point on the local constraint plane
CID	Coordinate system ID for orientation of the local coordinate system
TOL	User-defined tolerance in length units. If non-zero, the internal mesh-size dependent tolerance gets replaced by this value.

Remarks:

Nodes within a mesh-size-dependent tolerance are constrained on a local plane. This option is recommended for use with *r*-method adaptive remeshing where nodal constraints are lost during the remeshing phase.

*CONSTRAINED_MULTIPLE_GLOBAL

Purpose: Define global multi-point constraints for imposing periodic boundary condition in displacement field.

Card 1	1	2	3	4	5	6	7	8
Variable	ID							
Type	I							
Default								

NOTE: For each constraint equation include a set of cards consisting of (1) a C*onstraint Equation Definition Card* and (2) NMP *Coefficient Cards*.

Constraint Equation Definition Card.

$$u_1^{(3)} - u_1^{(1)} - u_1^{(10)} = 0$$

$$u_1^{(8)} - u_1^{(2)} - u_1^{(11)} = 0$$

$$u_2^{(3)} - u_2^{(1)} - u_2^{(10)} = 0$$

Figure 10-37. Simple example.

VARIABLE	DESCRIPTION
ID	Constraint set identification. All constraint sets should have a unique set ID.
NMP	Number of nodes to be constrained mutually.
NID	Nodal ID
DIR	Direction in three-dimensional space to be constrained EQ.1: x direction EQ.2: y direction EQ.3: z direction

VARIABLE	DESCRIPTION
	LT.0: Extra DOFs for user defined element formulation (e.g. -1: the 1st extra DOF; -2: the 2nd extra DOF; …)
COEF	Coefficient α_{NID} in constraint equation: $\sum_{\text{NID}} \alpha_{\text{NID}} u_{\text{DIR}}^{(\text{NID})} = 0.$

Remarks:

1. Defining multi-point constraints by this keyword can be demonstrated by the following example: a two-dimensional unit square with four quadrilateral elements and 11 nodes as shown in Figure 10-37, where the nodes #10 and #11 are two dummy nodes serving as control points.

*CONSTRAINED_NODAL_RIGID_BODY_{OPTION}_{OPTION}_{OPTION}_{OPTION}

Available options include:

<BLANK>

SPC

INERTIA

OVERRIDE

TITLE

If the center of mass is constrained, use the SPC option. A description for the nodal rigid body can be defined with the TITLE option.

If the INERTIA option is *not* used, then the inertia tensor is computed from the nodal masses. Mass properties are determined from the nodal masses and coordinates. Arbitrary motion of this rigid body is allowed. If the INERTIA option is used, constant translational and rotational velocities can be defined in a global or local coordinate system.

When the OVERRIDE option is used, all conflicting rigid body or constraint definitions will be turned off automatically until the overriding nodal rigid body constraint defined with this keyword is turned off by *SENSOR_CONTROL. It can be used, for example, to rigidize the whole model when the whole model moves like a rigid body involving no deformation. When the overriding rigid body constraint is turned off, all conflicting rigid bodies and constraints will be turned back on automatically.

Purpose: Define a nodal rigid body which is a rigid body that consists of defined nodes. Unlike *CONSTRAINED_NODE_SET which permits only constraints on translational motion, here the equations of rigid body dynamics are used to update the motion of the nodes, and therefore, rotations of the nodal sets are admissible.

Card Summary:

Card Title. This card is included if and only if the TITLE keyword option is used.

TITLE

Card 1. This card is required.

PID	CID	NSID	PNODE	IPRT	DRFLAG	RRFLAG	

Card 2. This card is included if the SPC keyword option is used.

CMO	CON1	CON2					

Card 3. This card is included if the INERTIA keyword option is used.

XC	YC	ZC	TM	IRCS	NODEID		

Card 4. This card is included if the INERTIA keyword option is used.

IXX	IXY	IXZ	IYY	IYZ	IZZ		

Card 5. This card is included if the INERTIA keyword option is used.

VTX	VTY	VTZ	VRX	VRY	VRZ		

Card 6. This card is included if IRCS = 1. See Card 3.

XL	YL	ZL	XLIP	YLIP	ZLIP	CID2	

Card 7. This card is read when the OVERRIDE keyword option is used. It is optional.

ICNT	IBAG	IPSM					

Data Card Definitions:

Title Card. Additional card for the TITLE keyword option.

Card Title	1	2	3	4	5	6	7	8
Variable	TITLE							
Type	A80							

VARIABLE	DESCRIPTION
TITLE	Description for the nodal rigid body.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	CID	NSID	PNODE	IPRT	DRFLAG	RRFLAG	
Type	I	I	I	I	I	I	I	
Default	none	0	PID	0	↓	0	0	

VARIABLE	DESCRIPTION
PID	Part ID of the nodal rigid body
CID	Optional coordinate system ID for the rigid body local system; see *DEFINE_COORDINATE_OPTION. The rigid body data and the degree-of- freedom releases are output in this local system. This local system rotates with the rigid body.
NSID	Nodal set ID, see *SET_NODE_OPTION. This nodal set defines the rigid body. EQ.0: NSID = PID, that is, the node set ID and the part ID are assumed to be identical.
PNODE	An optional node (a massless node is allowed) used for post processing rigid body data. If PNODE is not located at the rigid body's center of mass, then the initial coordinates of PNODE will be reset to the center of mass. If CID is defined, the velocities and accelerations of PNODE will be output in the local system to the d3plot and d3thdt files unless PNODE is specified as a negative number, in which case the global system is used.
IPRT	Print flag. For nodal rigid bodies the following values apply: EQ.1: Write data into rbdout. EQ.2: Do not write data into rbdout. Except for in the case of two-noded rigid bodies, IPRT (if 0 or unset) defaults to the value of IPRTF in *CONTROL_OUTPUT. For two-noded rigid bodies, printing is suppressed (IPRT = 2) unless IPRT is set to 1. This is to avoid excessively large rbdout files when the model contains many two-noded welds.
DRFLAG	Displacement release flag for all nodes except the first node in the definition (see Remark 3). EQ.-7: Release x, y, and z displacement in global system EQ.-6: Release z and x displacement in global system EQ.-5: Release y and z displacement in global system EQ.-4: Release x and y displacement in global system EQ.-3: Release z displacement in global system EQ.-2: Release y displacement in global system EQ.-1: Release x displacement in global system

VARIABLE	DESCRIPTION
	EQ.0: Off for rigid body behavior
	EQ.1: Release x displacement in rigid body local system
	EQ.2: Release y displacement in rigid body local system
	EQ.3: Release z displacement in rigid body local system
	EQ.4: Release x and y displacement in rigid body local system
	EQ.5: Release y and z displacement in rigid body local system
	EQ.6: Release z and x displacement in rigid body local system
	EQ.7: Release x, y, and z displacement in rigid body local system
RRFLAG	Rotation release flag for all nodes except the first node in the definition (see Remark 3).
	EQ.-7: Release x, y, and z rotations in global system
	EQ.-6: Release z and x rotations in global system
	EQ.-5: Release y and z rotations in global system
	EQ.-4: Release x and y rotations in global system
	EQ.-3: Release z rotation in global system
	EQ.-2: Release y rotation in global system
	EQ.-1: Release x rotation in global system
	EQ.0: Off for rigid body behavior
	EQ.1: Release x rotation in rigid body local system
	EQ.2: Release y rotation in rigid body local system
	EQ.3: Release z rotation in rigid body local system
	EQ.4: Release x and y rotations in rigid body local system
	EQ.5: Release y and z rotations in rigid body local system
	EQ.6: Release z and x rotations in rigid body local system
	EQ.7: Release x, y, and z rotations in rigid body local system

Center of Mass Constraint Card. Additional card for the SPC keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	CMO	CON1	CON2					
Type	F	I	I					
Default	0.0	0	0					

VARIABLE	DESCRIPTION
CMO	Center of mass constraint option, CMO: EQ.+1.0: Constraints applied in global directions, EQ.0.0: No constraints, EQ.-1.0: Constraints applied in local directions (SPC constraint).
CON1	First constraint parameter. If CMO = +1.0, then specify global translational constraint: EQ.0: No constraints, EQ.1: Constrained *x* displacement, EQ.2: Constrained *y* displacement, EQ.3: Constrained *z* displacement, EQ.4: Constrained *x* and *y* displacements, EQ.5: Constrained *y* and *z* displacements, EQ.6: Constrained *z* and *x* displacements, EQ.7: Constrained *x*, *y*, and *z* displacements. If CMO = -1.0, then specify local coordinate system ID. See *DEFINE_COORDINATE_*OPTION*. This coordinate system is fixed in time
CON2	Second constraint parameter: If CMO = +1.0, then specify global rotational constraint: EQ.0: No constraints, EQ.1: Constrained *x* rotation, EQ.2: Constrained *y* rotation,

VARIABLE	DESCRIPTION
	EQ.3: Constrained z rotation, EQ.4: Constrained x and y rotations, EQ.5: Constrained y and z rotations, EQ.6: Constrained z and x rotations, EQ.7: Constrained x, y, and z rotations. If CMO = -1.0, then specify local (SPC) constraint: EQ.000000: No constraint, EQ.100000: Constrained x translation, EQ.010000: Constrained y translation, EQ.001000: Constrained z translation, EQ.000100: Constrained x rotation, EQ.000010 : Constrained y rotation, EQ.000001: Constrained z rotation. Any combination of local constraints can be achieved by adding the number 1 into the corresponding column.

Inertia Card 1. Additional card for the INERTIA keyword option.

Card 3	1	2	3	4	5	6	7	8
Variable	XC	YC	ZC	TM	IRCS	NODEID		
Type	F	F	F	F	I	I		
Default	0.	0.	0.	0.	0	0		

VARIABLE	DESCRIPTION
XC	x-coordinate of center of mass. If nodal point, NODEID, is defined, XC, YC, and ZC are ignored and the coordinates of the nodal point, NODEID, are taken as the center of mass.
YC	y-coordinate of center of mass
ZC	z-coordinate of center of mass

VARIABLE	DESCRIPTION
TM	Translational mass
IRCS	Flag for inertia tensor reference coordinate system: EQ.0: Global inertia tensor, EQ.1: Local inertia tensor is given in a system defined by the orientation vectors given in Card 6.
NODEID	Optional nodal point defining the CG of the rigid body. If this node is not a member of the set NSID above, its motion will not be updated to correspond with the nodal rigid body after the calculation begins. PNODE and NODEID can be identical if and only if PNODE physically lies at the mass center at time zero.

Inertia Card 2. Second additional card for the INERTIA keyword option.

Card 4	1	2	3	4	5	6	7	8
Variable	IXX	IXY	IXZ	IYY	IYZ	IZZ		
Type	F	F	F	F	F	F		
Default	none	0	0	none	0	0		

VARIABLE	DESCRIPTION
IXX	I_{xx}, xx component of inertia tensor
IXY	I_{xy}, xy component of inertia tensor
IXZ	I_{xz}, xz component of inertia tensor
IYY	I_{yy}, yy component of inertia tensor
IYZ	I_{yz}, yz component of inertia tensor
IZZ	I_{zz}, zz component of inertia tensor

Inertia Card 3. Third additional card for the INERTIA keyword option. The velocities defined below can be overwritten by the *INITIAL_VELOCITY card.

Card 5	1	2	3	4	5	6	7	8
Variable	VTX	VTY	VTZ	VRX	VRY	VRZ		
Type	F	F	F	F	F	F		
Default	0	0	0	0	0	0		

VARIABLE	DESCRIPTION
VTX	x-rigid body initial translational velocity in global coordinate system.
VTY	y-rigid body initial translational velocity in global coordinate system.
VTZ	z-rigid body initial translational velocity in global coordinate system.
VRX	x-rigid body initial rotational velocity in global coordinate system.
VRY	y-rigid body initial rotational velocity in global coordinate system.
VRZ	z-rigid body initial rotational velocity in global coordinate system.

Local Inertia Tensor Card. Additional card required for IRCS = 1 (see Inertia Card 1). Define two local vectors or a local coordinate system ID.

Card 6	1	2	3	4	5	6	7	8
Variable	XL	YL	ZL	XLIP	YLIP	ZLIP	CID2	
Type	F	F	F	F	F	F	I	
Default	CID2	CID2	CID2	CID2	CID2	CID2	0	

VARIABLE	DESCRIPTION
XL	x-coordinate of local x-axis. Origin lies at $(0,0,0)$.

VARIABLE	DESCRIPTION
YL	y-coordinate of local x-axis
ZL	z-coordinate of local x-axis
XLIP	x-coordinate of local in-plane vector
YLIP	y-coordinate of local in-plane vector
ZLIP	z-coordinate of local in-plane vector
CID2	Local coordinate system ID, see *DEFINE_COORDINATE_.... With this option leave fields 1-6 blank.

Optional synchronization card for OVERRIDE. Optional card for OVERRIDE option.

Card 7	1	2	3	4	5	6	7	8
Variable	ICNT	IBAG	IPSM					
Type	I	I	I					
Default	0	0	0					

VARIABLE	DESCRIPTION
ICNT	Flag for contact synchronization: EQ.0: No synchronization EQ.1: Since no contact exists when both the tracked and reference sides belong to the same rigid body, setting ICNT = 1 will turn off/on all contact definitions of which the tracked and reference sides belong to the same nodal rigid body PID when PID is turned on/off by *SENSOR_CONTROL. With ICNT = 1, all related contact definitions need the optional ID; see *CONTACT.
IBAG	Flag for control volume airbag synchronization: EQ.0: No synchronization EQ.1: Since airbag pressure will not change when all segments constituting the airbag belong to the same rigid body, setting IBAG = 1 will skip the control volume airbag calculations for airbags that belong to PID when PID is on. The

VARIABLE	DESCRIPTION
	airbag calculation will resume when PID is turned off by *SENSOR_CONTROL. The related airbag time-dependent curves will be offset to not include the time that PID is on. With IBAG = 1, all related airbags need the optional ID; see *AIRBAG.
IPSM	Flag for prescribed-motion synchronization: EQ.0: No synchronization EQ.1: Prescribed boundary conditions (*BOUNDARY_PRESCRIBED_MOTION) for PID will be turned off automatically when PID is turned off by *SENSOR_CONTROL. A prescribed boundary condition not for PID and not for all nodes belonging to PID, that is, boundary conditions that only apply to some of the nodes belonging to PID, will be turned off when PID is active to avoid boundary condition conflict. Those boundary conditions will be turned on when PID is turned off by *SENSOR_CONTROL. The related time-dependent curves will be offset to not include the time that PID is on. With IPSM > 0, all related boundary prescribed motion cards need the optional ID; see *BOUNDARY_PRESCRIBED. EQ.2: Same as IPSM = 1, however, without time offset when those boundary conditions not for PID are turned on.

Remarks:

1. **Local Coordinate System.** The local coordinate system is set up in the following way. After the local x-axis is defined, the local z-axis is computed from the cross-product of the local x-axis vector with the given in-plane vector. Finally, the local y-axis is determined from the cross-product of the local z-axis with the local x-axis. The local coordinate system defined by CID has the advantage that the local system can be defined by nodes in the rigid body which makes repositioning of the rigid body in a preprocessor much easier since the local system moves with the nodal points.

2. **Nodal Rigid Body Visualization.** Use PLOTEL (*CONTROL_RIGID) to visualize the nodal rigid bodies.

3. **Release Conditions.** The first node in the nodal rigid body definition is treated as the lead for the case where DRFLAG and RRFLAG are nonzero. The first node always has six degrees-of-freedom. The release conditions in the global

system are sometimes convenient in small displacement linear analysis. Otherwise, they are not recommended. We strongly recommend, especially for implicit calculations, that release conditions are only used for a two-noded nodal rigid body.

Example:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$  *CONSTRAINED_NODAL_RIGID_BODY
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  Define a rigid body consisting of the nodes in nodal set 61.
$
$  This particular example was used to connect three separate deformable
$  parts.  Physically, these parts were welded together.  Modeling wise,
$  however, this joint is quit messy and is most conveniently modeled
$  by making a rigid body using several of the nodes in the area.  Physically,
$  this joint was so strong that weld failure was never of concern.
$
*CONSTRAINED_NODAL_RIGID_BODY
$
$...>....1....>....2....>....3....>....4....>....5....>....6....>....7....>....8
$      pid       cid      nsid
        45                  61
$
$     nsid = 61   nodal set ID number, requires a *SET_NODE_option
$      cid        not used in this example, output will be in global coordinates

```

*CONSTRAINED_NODE_INTERPOLATION

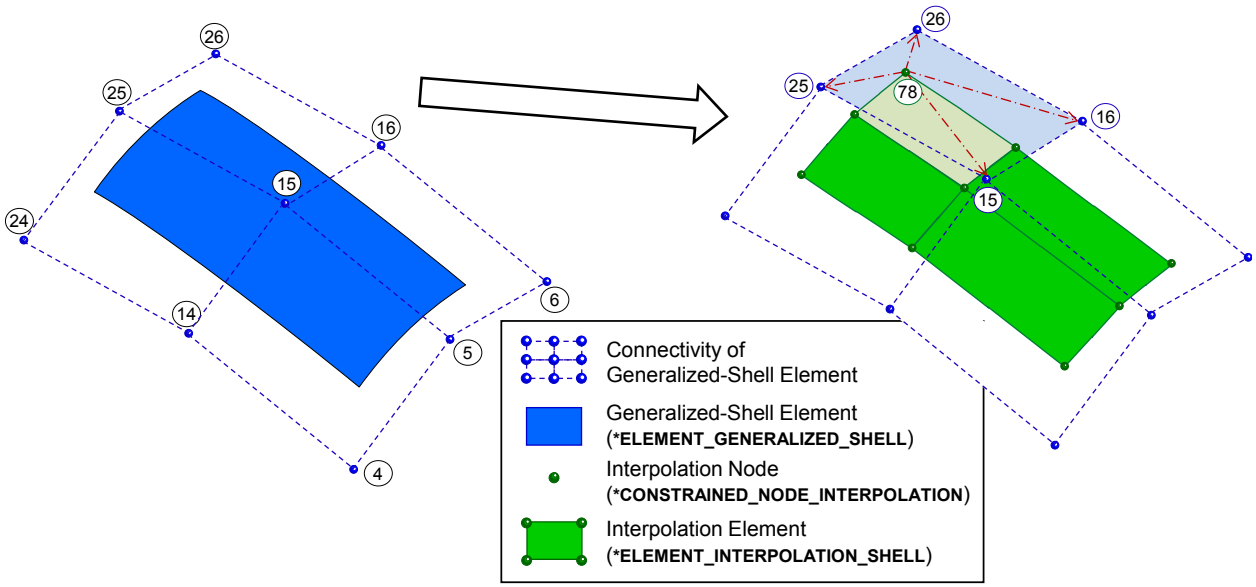
Purpose: Define constrained nodes for the use of *ELEMENT_INTERPOLATION_-SHELL and *ELEMENT_INTERPOLATION_SOLID to model contact and to visualize the results of generalized elements (see *ELEMENT_GENERALIZED_SHELL/SOLID). The displacements of these nodes are dependent on their corresponding controlling nodes.

Card 1	1	2	3	4	5	6	7	8
Variable	NID	NUMCN						
Type	I	I						
Default	none	none						

Weighting Factor Cards. Define NUMCN controlling nodes and weights (one controlling node per CN*i* and W*i* pair) to constrain NID. See Remark 2. See *ELEMENT_-GENERALIZED_SHELL/SOLID. Each Weighting Factor Card can accommodate four master nodes. Include as many Weighting Factor Cards as needed.

Card 2	1	2	3	4	5	6	7	8
Variable	CN1	W1	CN2	W2	CN3	W3	CN4	W4
Type	I	F	I	F	I	F	I	F
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
NID	Node ID of the interpolation node as defined in *NODE (see Remark 1)
NUMCN	Number of nodes controlling the interpolation node
CN*i*	Node ID of controlling node *i*
W*i*	Weighting factor of controlling node *i*



```
*CONSTRAINED_NODE_INTERPOLATION
$---+--NID----+NUMCN----+----3----+----4----+----5----+----6----+----7----+----8
        78          4
$---+--CN1----+---W1----+--CN2----+---W2----+--CN3----+---W3----+--CN4----+---W4
        26       0.35         25       0.32         15       0.18         16       0.15
```

Figure 10-38. Example of a *CONSTRAINED_NODE_INTERPOLATION card

Remarks:

1. **Nodal Definition.** The coordinates of an interpolation node must be defined in *NODE. The fields TC and RC must be both be set to 7 for the interpolation node in *NODE.

2. **Interpolation Model.** The displacements of the interpolation node, $\mathbf{d}_{\text{IN}}$, are interpolated based on the displacements of the corresponding controlling nodes, $\mathbf{d}_i$, and the appropriate weighting factors, w_i. The interpolation is computed as follows:

$$\mathbf{d}_{\text{IN}} = \sum_{i=1}^{\text{NUMCN}} w_i \mathbf{d}_i.$$

***CONSTRAINED_NODE_SET**_*{OPTION}*

To define an ID for the constrained node set the following option is available:

<BLANK>

ID

If the ID keyword option is used, an additional card is required.

Purpose: Define nodal constraint sets for translational motion in global coordinates. No rotational coupling. See Figure 10-39. Nodal points included in the sets should not be subjected to any other constraints including prescribed motion, such as motions prescribed with the *BOUNDARY_PRESCRIBED_MOTION options.

ID Card. Additional card for ID keyword option.

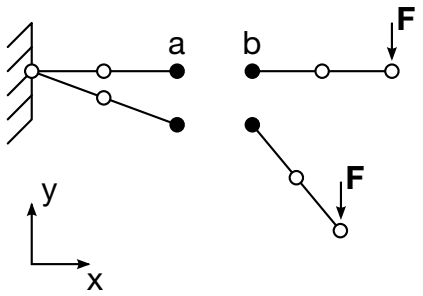
Card 1	1	2	3	4	5	6	7	8
Variable	CNSID							
Type	I							

Card 2	1	2	3	4	5	6	7	8
Variable	NSID	DOF	TF					
Type	I	I	F					
Default	none	none	10^{20}					
Remarks	1, 2		3					

VARIABLE	DESCRIPTION
CNSID	Optional constrained node set ID
NSID	Nodal set ID; see *SET_NODE_*OPTION*.

***CONTRAINED_NODE_SET**

Since no rotation is permitted, this option should *not* be used to model rigid body behavior involving rotations



***CONSTRAINED_NODAL_RIGID_BODY**
***CONSTRAINED_SPOTWELD**

Behavior is like a rigid beam. These options *may* be used to model spotwelds.

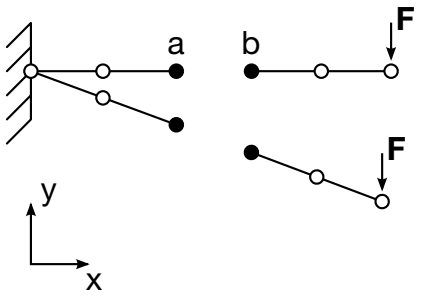


Figure 10-39. Two different ways to constrain node *a* and *b*. For rigid-body type situations this card, *CONSTRAINED_NODE_SET, may lead to un-physical results.

VARIABLE	DESCRIPTION
DOF	Applicable degrees-of-freedom: EQ.1: *x*-translational degree-of-freedom EQ.2: *y*-translational degree-of-freedom EQ.3: *z*-translational degree-of-freedom EQ.4: *x* and *y*-translational degrees-of-freedom EQ.5: *y* and *z*-translational degrees-of-freedom EQ.6: *z* and *x*-translational degrees-of-freedom EQ.7: *x*, *y*, and *z*-translational degrees-of-freedom EQ.8: Electric potential of piezoelectric material
TF	Failure time for nodal constraint set

Remarks:

1. **Mass.** The masses of the nodes are summed up to determine the total mass of the constrained set.

2. **Nodal Rigid Body.** Note that the definition of a nodal rigid body is not possible with this input. For nodal rigid bodies the keyword input *CONSTRAINED_-NODAL_RIGID_BODY_*OPTION* must be used.

3. **Failure Time.** When the failure time, TF, is reached the nodal constraint becomes inactive, and the constrained nodes may move freely.

Example:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$  *CONSTRAINED_NODE_SET
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  Constrain all the nodes in a nodal set to move equivalently
$  in the z-direction.
$
*CONSTRAINED_NODE_SET
$
$...>....1....>....2....>....3....>....4....>....5....>....6....>....7....>....8
      nsid       dof        tf
         7         3      10.0
$
$     nsid = 7    nodal set ID number, requires a *SET_NODE_option
$      dof = 3    nodal motions are equivalent in z-translation
$      tf  = 3    at time=10. the nodal constraint is removed
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
```

*CONSTRAINED_NODE_TO_NURBS_PATCH_{OPTION}

Purpose: To add additional massless nodes to the surface of a NURBS patch. The motion of the nodes is governed by the NURBS patch. Forces applied to the nodes are distributed to the NURBS patch. Penalty method is used to handle the displacement boundary conditions CON (see below) on the specified nodes.

To specify node sets instead of individual nodes use the option:

SET

Card 1	1	2	3	4	5	6	7	8
Variable	PATCHID	NSID	CON	CID	SF	DBFLG		
Type	I	I	I	I	F	I		
Default	none	none	0	none	1.0	0		

VARIABLE	DESCRIPTION
PATCHID	Patch ID.
NSID	Nodal set ID or node ID depending on the *OPTION*.
CON	Constraint parameter for extra node(s) of NSID. EQ.000000: no constraint EQ.100000: constrained x translation EQ.010000: constrained y translation EQ.001000: constrained z translation EQ.000100: constrained x rotation EQ.000010: constrained y rotation EQ.000001: constrained z rotation Any combination of local constraints can be specified by adding the number 1 into the corresponding column. For example, "1110" means constrained z-translation, x-rotation and y-rotation.
CID	Coordinate system ID for constraint
SF	Penalty force scale factor for the penalty-based constraint

VARIABLE	DESCRIPTION
DBFLG	Discrete beam flag. If CON = 0 and displacement boundary conditions are applied to nodes specified in NSID, then this flag must be set to 1. When DBFLG = 1, discrete beam elements are created to connect nodes in NSID to the patch.

*CONSTRAINED_POINTS

Purpose: Constrain two points with the specified coordinates connecting two shell elements at locations other than nodal points. In this option, the penalty method is used to constrain the translational and rotational degrees-of-freedom of the points. Force resultants are written into the swforc ASCII file for post-processing.

Card 1	1	2	3	4	5	6	7	8
Variable	CID							
Type	I							
Default	none							

Card 2	1	2	3	4	5	6	7	8	9	10
Variable	EID1	X1		Y1		Z1				
Type	I	F		F		F				
Default	none	0.		0.		0.				

Card 3	1	2	3	4	5	6	7	8	9	10
Variable	EID2	X2		Y2		Z2				
Type	I	F		F		F				
Default	none	0.		0.		0.				

Card 4	1	2	3	4	5	6	7	8
Variable	PSF	FAILA	FAILS	FAILM				
Type	F	F	F	F				
Default	1.0	0.0	0.0	0.0				

VARIABLE	DESCRIPTION
CID	Constrained points ID.
EID*i*	Shell element ID, *i* = 1, 2.
X*i*, Y*i*, Z*i*	Coordinates of the constrained points, *i* = 1, 2.
PSF	Penalty scale factor (Default = 1.0).
FAILA	Axial force resultant failure value, no failure if zero.
FAILS	Shear force resultant failure value, no failure if zero.
FAILM	Moment resultant failure value, no failure if zero.

*CONSTRAINED_RIGID_BODIES_{OPTION}

Available options include:

<BLANK>

SET

For SET option, PIDC refers to a part set.

Purpose: Merge two rigid bodies. One rigid body, called the constrained rigid body, is merged into another one, called the lead rigid body. This command applies to parts comprised of *MAT_RIGID but not to nodal rigid bodies (*CONSTRAINED_NODAL_-RIGID_BODY).

Card 1	1	2	3	4	5	6	7	8
Variable	PIDL	PIDC	IFLAG					
Type	I	I	I					
Default	none	none	0					

VARIABLE	DESCRIPTION
PIDL	Lead rigid body part ID; see *PART.
PIDC	Constrained rigid body part ID (see *PART) or constrained rigid body part set ID for the SET keyword option (see *SET_PART)
IFLAG	This flag is meaningful *if and only if* the inertia properties of the lead part, PIDL, are defined in *PART_INERTIA. See Remark 1. EQ.1: Update the center-of-gravity, the translational mass, and the inertia matrix of PIDL to reflect its merging with the constrained rigid body (PIDC). EQ.0: The merged PIDC will not affect the properties defined in *PART_INERTIA for PIDL since the properties are assumed to already account for merged parts. If the properties are not defined in a *PART_INERTIA definition, the inertia properties of PIDC will be computed from its nodal masses.

Remarks:

1. **Inertial Properties.** The constrained rigid body is merged to the lead rigid body. Unless the inertial properties of the lead rigid body are defined with *PART_INERTIA, the inertial properties computed by LS-DYNA are based on the combination of the lead rigid body plus all the rigid bodies which are constrained to it. If the inertial properties of the lead are specified with *PART_INERTIA, then the treatment of those properties depends on IFLAG. Note that a lead rigid body may have many rigid bodies constrained to it, but it may not be constrained to another rigid body.

2. **Common Nodes.** Independent rigid bodies must not share common nodes since each rigid body updates the motion of its nodes independently of the other rigid bodies. If common nodes exist between rigid bodies, the rigid bodies sharing the nodes must be merged.

3. **Completely Separated Rigid Bodies.** Completely separated rigid bodies that do not share any common nodal points or boundaries may also be merged. All actions valid for the lead rigid body, such as constraints and given velocity, are now also valid for the newly-created rigid body.

Example:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$  *CONSTRAINED_RIGID_BODIES
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  Rigidly connect parts 35, 70, 71, and 72 to part 12.
$  All parts must be defined as rigid.
$
$  This example is used to make a single rigid body out of the five parts
$  that compose the back end of a vehicle.  This was done to save cpu time
$  and was determined to be valid because the application was a frontal
$  impact with insignificant rear end deformations.  (The cpu time saved
$  was from making the parts rigid, not from merging them - merging was
$  more of a convenience in this case for post processing, for checking
$  inertial properties, and for joining the parts.)
$
*CONSTRAINED_RIGID_BODIES
$...>....1....>....2....>....3....>....4....>....5....>....6....>....7....>....8
$     pidl      pidc

Default	0	0	↓					

Card 3	1	2	3	4	5	6	7	8
Variable	PARTB	DEATHB						
Type	I	F						
Default	0	0.0						

VARIABLE	DESCRIPTION
ID	Insert ID
PIDL	Lead (die) rigid body part ID (see *PART)
PIDC	Constrained (die insert) rigid body part ID (see *PART)

VARIABLE	DESCRIPTION
COORDID	Coordinate system ID
IDIR	Direction in which the insert moves independently of the die: EQ.1: Local *x*-direction EQ.2: Local *y*-direction EQ.3: Local *z*-direction (default)
MFLAG	Motion flag: EQ.0: Relative motion is unconstrained. EQ.1: The displacement of the insert relative to the die is imposed. EQ.2: The velocity of the insert relative to the die is imposed. EQ.3: The acceleration of the insert relative to the die is imposed.
MCID	Curve defining the motion of the die insert relative to the die
DEATHM	Death time of the imposed motion. If it is equal to 0.0, the motion is imposed for the entire analysis.
PARTB	Part ID for a discrete beam connected between the insert and die
DEATHB	Death time for the discrete beam specified by PARTB

Remarks:

1. **Time Integrators.** This capability is supported by both the implicit and explicit time integrators; however, the joint death time, DEATHM, feature works only for explicit integration with the penalty method.

2. **Joint Reaction Forces.** The translational joint constraining the die and the die insert are automatically generated. The joint reaction forces will appear in the jntforc output file.

3. **Translational Degree of Freedom.** The translational motor constraining the remaining translational degree of freedom is also automatically generated, and its reaction forces also appear in the jntforc output file.

4. **Discrete Beam.** The automatically generated beam has its data written to the d3plot file and all of the optional appropriate output files.

*CONSTRAINED_RIGID_BODY_STOPPERS

Purpose: Rigid body stoppers provide a convenient way of controlling the motion of rigid tooling in metal forming applications. The motion of a "lead" rigid body is limited by load curves. This option will stop the motion based on a time dependent constraint. The stopper overrides prescribed motion boundary conditions (except relative displacement) operating in the same direction for both the lead and constrained rigid bodies. See Figure 10-40.

Card 1	1	2	3	4	5	6	7	8
Variable	PID	LCMAX	LCMIN	PSIDMX	PSIDMN	LCVMNX	DIR	VID
Type	I	I	I	I	I	I	I	I
Default	none	0	0	0	0	0	none	0

Card 2	1	2	3	4	5	6	7	8
Variable	TB	TD		STIFF				
Type	F	F		F				
Default	0	1021		0.0				

VARIABLE	DESCRIPTION
PID	Part ID of lead rigid body (see *PART)
LCMAX	Load curve ID defining the maximum coordinate or displacement as a function of time (see *DEFINE_CURVE): LT.0: Load curve ID |LCMAX| provides an upper bound for the displacement of the rigid body. EQ.0: No limitation of the maximum displacement. GT.0: Load curve ID LCMAX provides an upper bound for the position of the rigid body center of mass.
LCMIN	Load curve ID defining the minimum coordinate or displacement as a function of time (see *DEFINE_CURVE):

VARIABLE	DESCRIPTION
	LT.0: Load curve ID |LCMIN| defines a lower bound for the displacement of the rigid body. EQ.0: No limitation of the minimum displacement. GT.0: Load curve ID LCMIN defines a lower bound for the position of the rigid body center of mass.
PSIDMX	Optional part set ID of rigid bodies that are constrained in the maximum coordinate direction to the lead rigid body. The part set definition (see *SET_PART_COLUMN) may be used to define the closure distance (D_1 and D_2in Figure 10-40) which activates the constraint. The constraint does not begin to act until the lead rigid body stops. If the distance between the lead rigid body is greater than or equal to the closure distance, the constrained rigid body motion away from the lead rigid body also stops. However, the constrained rigid body is free to move towards the lead rigid body. If the closure distance is input as zero (0.0), then the constrained rigid body stops when the lead stops.
PSIDMN	Optional part set ID of rigid bodies that are constrained in the minimum coordinate direction to the lead rigid body. The part set definition, (see *SET_PART_COLUMN) may be used to define the closure distance (D_1 and D_2 in Figure 10-40) which activates the constraint. The constraint does not begin to act until the lead rigid body stops. If the distance between the lead rigid body is less than or equal to the closure distance, the constrained rigid body motion towards the lead rigid body also stops. However, the constrained rigid body is free to move away from the lead rigid part. If the closure distance is input as zero (0.0), then the constrained rigid body stops when the lead stops.
LCVMX	Load curve ID which defines the maximum absolute value of the velocity as a function of time that is allowed for the lead rigid body. See *DEFINE_CURVE: EQ.0: no limitation on the velocity.
DIR	Direction stopper acts in: EQ.1: x-translation, EQ.2: y-translation, EQ.3: z-translation, EQ.4: Arbitrary, defined by vector VID (see below),

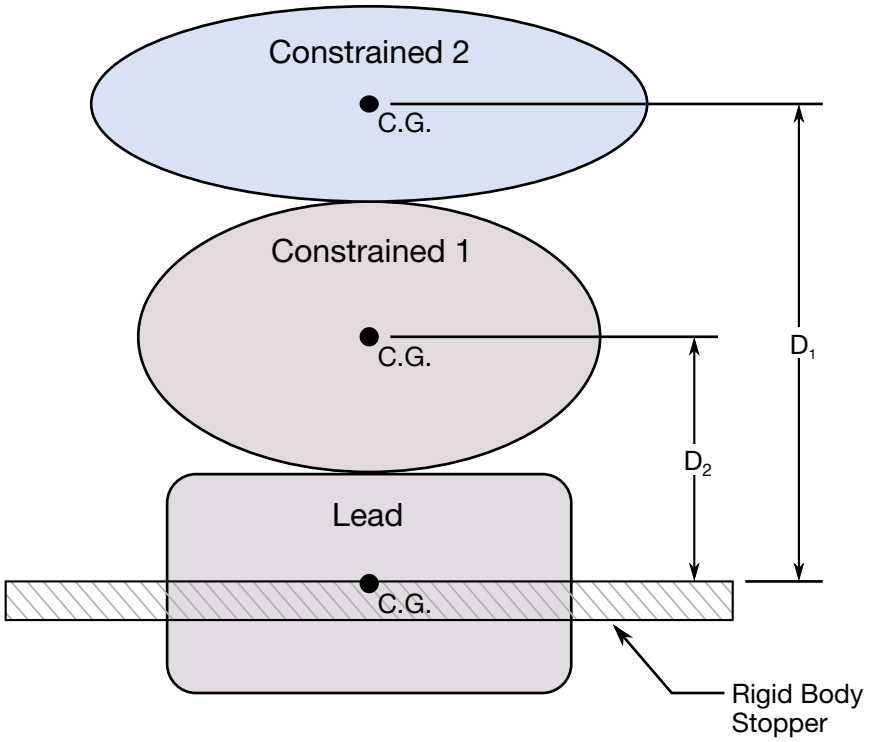

Figure 10-40. When the lead rigid body reaches the rigid body stopper, the velocity component into the stopper is set to zero. Constrained rigid bodies 1 and 2 also stop if the distance between their mass centers and the lead rigid body is less than or equal to the input values D_1 and D_2, respectively.

VARIABLE	DESCRIPTION
	EQ.5: x-axis rotation, EQ.6: y-axis rotation, EQ.7: z-axis rotation, EQ.8: Arbitrary, defined by vector VID (see below).
VID	Vector for arbitrary orientation of stopper, see *DEFINE_VECTOR.
TB	Time at which stopper is activated.
TD	Time at which stopper is deactivated.
STIFF	Augmentation stiffness for implicit; see Remark 2.

Remarks:

1. **Controlling the motion in an arbitrary direction.** By defining the optional part sets in the minimum or maximum coordinate direction (PSIDMX or PSIDMN), the motion can be controlled in an arbitrary direction.

2. **Augmentation stiffness.** For implicit, inequality constraints are imposed by using an augmented Lagrangian multiplier technique, where the augmentation stiffness can be specified with field STIFF. If STIFF is zero, then it is computed internally based on the loads and displacements associated with the stoppers. If this results in bad behavior, the stiffness may be selected so that STIFF = FORCE/DISP, where FORCE is a characteristic load and DISP is a characteristic length. A too large value may lead to inaccuracies and a too small value may lead to convergence problems. It is worth mentioning that this approach renders an indefinite matrix, and the number of negative eigenvalues seen by the linear solver is 2 (one constraint in positive and one in negative direction) per rigid body stopper.

*CONSTRAINED_RIVET_{OPTION}

To define an ID for the rivet, the following option is available:

<BLANK>

ID

If the ID is defined, an additional card is required.

Purpose: Define massless rivets between non-contiguous nodal pairs. The nodes must not have the same coordinates. The action is such that the distance between the two nodes is kept constant throughout any motion. No failure can be specified.

ID Card. Additional card for the ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	RID							
Type	I							
Default	0							

Card 1	1	2	3	4	5	6	7	8
Variable	N1	N2	TF					
Type	I	I	F					
Default	none	none	10^{20}					
Remarks	1		2					

VARIABLE	DESCRIPTION
RID	Optional rivet ID.
N1	Node ID
N2	Node ID

VARIABLE	DESCRIPTION
TF	Failure time for nodal constraint set.

Remarks:

1. **Multiple Constraints.** Nodes connected by a rivet cannot be members of another constraint set that constrain the same degrees-of-freedom, a tied interface, or a rigid body, that is, nodes cannot be subjected to multiple, independent, and possibly conflicting constraints. Also, care must be taken to ensure that single point constraints applied to nodes in a constraint set do not conflict with the constraint sets constrained degrees-of-freedom.

2. **Failure Time.** When the failure time, TF, is reached the rivet becomes inactive and the constrained nodes may move freely.

Example:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$  *CONSTRAINED_RIVET

$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
```

*CONSTRAINED_SHELL_IN_SOLID_{OPTION1}_{OPTION2}

This keyword can take the following two forms:

*CONSTRAINED_SHELL_IN_SOLID

*CONSTRAINED_SHELL_IN_SOLID_PENALTY

To define a coupling ID and heading for this keyword, the following options are available:

ID

TITLE

Purpose: Provide either constraint-based or penalty-based coupling between shells and the solids/thick shells in which the shells are embedded.

To use the constraint-based coupling, this keyword takes the form of *CONSTRAINED_SHELL_IN_SOLID. It constrains shell structures to move with Lagrangian solids/thick shells. This keyword constrains both acceleration and velocity. This keyword, together with *CONSTRAINED_BEAM_IN_SOLID, intends to sidestep certain limitations of the CTYPE = 2 implementation in *CONSTRAINED_LAGRANGE_IN_SOLID. Notable features of this keyword include:

1. **Tetrahedral and pentahedral solid elements are supported.** They are no longer treated as degenerated hexahedra as in the CTYPE = 2 implementation.

2. **Velocity/Fixed boundary condition.** The CTYPE = 2 implementation failed to constrain shell nodes that were buried inside elements whose nodes had velocity/fixed boundary conditions prescribed.

3. **Optimized Sorting.** Sorting subroutine is optimized for larger problems to achieve better performance and less memory usage.

To use the penalty-based coupling, this keyword takes the form of *CONSTRAINED_SHELL_IN_SOLID_PENALTY. A penalty spring is attached between coupling points on the shell and in the solid/thick shell element. Penalty spring stiffness is calculated based on the geometric mean of shell and solid's bulk modulus. The magnitude of this coupling force can be controlled using PSSF (penalty spring stiffness scale factor). This penalty coupling conserves kinetic energy much better in transient problems such as blast loading.

If a title is not defined, LS-DYNA will automatically create an internal title for this coupling definition.

Title Card. Additional card for TITLE and ID keyword options.

Card ID	1	2	3	4	5	6	7	8
Variable	COUPID	TITLE						
Type	I	A70						

Card 1	1	2	3	4	5	6	7	8
Variable	SHSID	SSID	SHSTYP	SSTYP				
Type	I	I	I	I				
Default	none	none	0	0				

Card 2	1	2	3	4	5	6	7	8
Variable	START	END				PSSF		
Type	F	F				F		
Default	0.	10^{20}				0.1		

VARIABLE	DESCRIPTION
COUPID	Coupling (card) ID number (I10). If not defined, LS-DYNA will assign an internal coupling ID based on the order of appearance in the input deck.
TITLE	A description of this coupling definition.
SHSID	Set ID defining a part or part set ID of the Lagrangian shell structure (see *PART, *SET_PART).
SSID	Set ID defining a part or part set ID of the Lagrangian solid elements or thick shell elements (see *PART or *SET_PART).

VARIABLE	DESCRIPTION
SHSTYP	Set type of SHSID: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID)
SSTYP	Set type of SSID: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID)
START	Start time to activate the coupling: LT.0: Start time is set to |START|. When negative, start time is followed during the dynamic relaxation phase of the calculation. After the completion of dynamic relaxation, coupling is activated regardless of the value of END. EQ.0: Start time is inactive, meaning coupling is always active GT.0: If END = -9999, START is interpreted as the curve or table ID defining multiple pairs of start-time and end-time. Otherwise, if END > 0, start time applies both during and after dynamic relaxation.
END	End time to deactivate the coupling: LT.0: If END = -9999, START is interpreted as the curve or table ID defining multiple pairs of start-time and end-time. Otherwise, negative END indicates that coupling is inactive during dynamic relaxation. After dynamic relaxation the start and end times are followed and set to |START| and |END|, respectively. EQ.0: END defaults to 10^{20}. GT.0: END sets the time at which the coupling is deactivated.
PSSF	Penalty spring stiffness scale factor. Only available in penalty form.

*CONSTRAINED_SHELL_TO_SOLID

Purpose: Define a tie between a shell edge and solid elements. Nodal rigid bodies can perform the same function and may also be used.

Card 1	1	2	3	4	5	6	7	8
Variable	NID	NSID						
Type	I	I						
Default	none	none						

VARIABLE	DESCRIPTION
NID	Shell node ID
NSID	Solid nodal set ID, see *SET_NODE_*OPTION*.

Remarks:

The shell-brick interface, an extension of the tied surface capability, ties regions of hexahedron elements to regions of shell elements. A shell node may be tied to up to nine brick nodes lying along the tangent vector to the nodal fiber. See Figure 10-41. During the

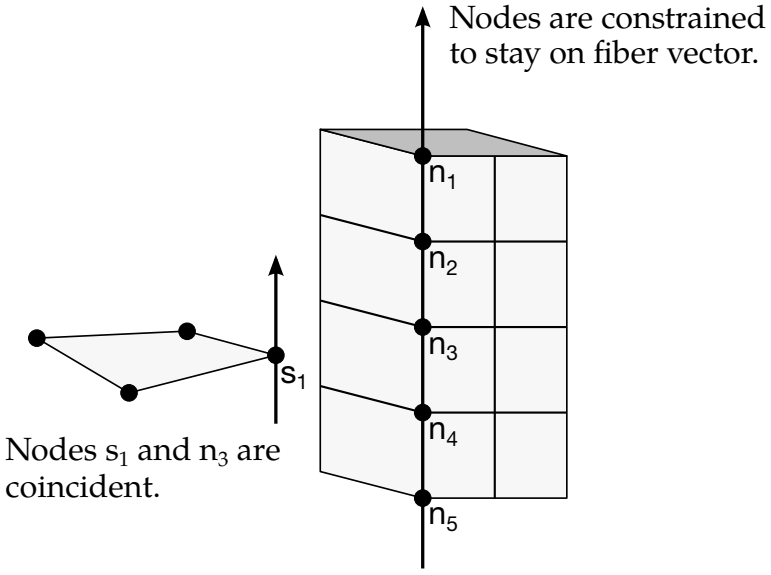

Figure 10-41. The interface between shell elements and solids ties a shell node, s_1, to a line of nodes on the solid elements, n_1 to n_5. It is very important for the nodes to be aligned.

calculation, the brick nodes thus constrained, must lie along the fiber but can move relative to each other in the fiber direction. The shell node stays on the fiber at the same relative spacing between the first and last brick node. The brick nodes must be input in the order in which they occur, in either the plus or minus direction, as one moves along the shell node fiber.

This feature is intended to tie four node shells to eight node shells or solids; it is not intended for tying eight node shells to eight node solids.

Example:

```
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$$$$  *CONSTRAINED_SHELL_TO_SOLID
$
$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$$
$
$  Tie shell element, at node 329, to a solid element at node 203.
$    - nodes 329 and 203 are coincident
$
$  Additionally, define a line of nodes on the solids elements, containing
$  node 203, that must remain in the same direction as the fiber of the shell
$  containing node 329.  In other words:
$
$    - Nodes 119, 161, 203, 245 and 287 are nodes on a solid part that
$      define a line on that solid part.
$    - This line of nodes will be constrained to remain linear throughout
$      the simulation.
$    - The direction of this line will be kept the same as the fiber of the
$      of the shell containing node 329.

***CONSTRAINED_SOIL_PILE**_{OPTION1}_{OPTION2}

Purpose: Define penalty-based coupling between 1D beam elements and 3D solid elements. The beam elements must not share nodes with the solid elements, and the beam element mesh does not have to align with the solid element mesh. The functionality is similar to *CONSTRAINED_BEAM_IN_SOLID, except that *CONSTRAINED_SOIL_-PILE is specific to geotechnical applications, such as piles in soil or anchors in rock. For general applications in which beam elements must be coupled with solids (such as reinforcement bars in concrete), *CONSTRAINED_BEAM_IN_SOLID is recommended due to its simpler input. See the general modeling requirements for *CONSTRAINED_SOIL_-PILE in Remarks 1 through 4.

The data cards described below specify the nonlinear coupling characteristics, expressing the resisting stress on the outer surface of the pile as a function of displacement of the pile relative to the soil. Movement in the axial (sliding) direction has a different coupling characteristic from movement perpendicular to the axis of the pile. In geotechnical terminology, the perpendicular coupling characteristics are sometimes described as "P-y springs" while the axial characteristics are described as "P-z springs". Additionally, a coupling characteristic is required for axial movement of the base of the pile, sometimes referred to as the "end-bearing" or the "toe" of the pile. Thus, the overall coupling depends on a set of three nonlinear coupling characteristics (Base, Axial and Perpendicular).

Where piles pass through layers of soils with different material properties, different coupling properties may be appropriate for each soil layer. To model this, include one *CONSTRAINED_SOIL_PILE keyword containing multiple sets of coupling properties. Each set of coupling properties is associated with a particular soil part ID or part set ID. LS-DYNA will then select the coupling properties for each node of the pile according to the part ID of the soil element within which that pile node is situated. LS-DYNA will automatically find the node at the free end of each pile for allocation of Base coupling properties (see description of LOCAL below for which free end will be taken as the Base).

OPTION1 specifies the format in which the coupling properties are defined on Cards 3 through 6. Available options are:

<BLANK>

CONSTANTS

CURVES

Selecting CURVES allows you to specify the properties with load curves while CONSTANTS allows you to specify the coupling with constant values. The input for the CURVES option is simpler than that of the CONSTANTS option, but the CONSTANTS option reduces the need to create load curves. If *OPTION1* is unset (<BLANK>), then the input is the same as for CONSTANTS, except that Card 2 is omitted. Card 2 allows you to add damping to the axial coupling shear stress and to pick which side of the pile is the

Base. We recommend using CONSTANTS or CURVES for *OPTION1* instead of not setting it. <BLANK> is included solely for backwards compatibility.

OPTION2 specifies whether the soil parts to which the coupling properties apply are defined by part ID (see *PART) or by part set ID (see *SET_PART). Available options are:

<BLANK>

SET

If unset (<BLANK>), part IDs are assumed.

Card Summary:

Card Sets. Include one of Cards 1 and 2 (unless *OPTION1* is unset) total. Then for each soil part/part set include one set of either Cards 3a through 6a or Cards 3b through 6b depending on *OPTION1*. Include as many sets as required to define the coupling properties for all the relevant soil layers. This input ends with the next keyword ("*") card.

Card 1. This card is required.

PBSID	DIAM		PIDNS	PIDNB	ERROR	NRING	NRINGB

Card 2. This card is included unless *OPTION1* is unset (<BLANK>).

DAMP	LOCAL	INSTRF	TIMSTR				

Card 3a. This card is included when *OPTION1* is set to CONSTANTS or not used (<BLANK>). Include as many sets of Card 3a through Card 6a as needed.

PID/PSID	ACU	BCU	LCCU	ASTIFFS	BSTIFFS	ASTIFFB	ZREF

Card 4a. This card is included when *OPTION1* is set to CONSTANTS or not used.

KBCON	KBCU	KBSX	KBSY	KBSZ	BSTFAC	BHYPER	BLC

Card 5a. This card is included when *OPTION1* is set to CONSTANTS or not used.

KVCON	KVCU	KVSX	KVSY	KVSZ	VSTFAC	VHYPER	VLC

Card 6a. This card is included when *OPTION1* is set to CONSTANTS or not used.

KHCON	KHCU	KHSX	KHSY	KHSZ	HSTFAC	HHYPER	HLC

Card 3b. This card is included when *OPTION1* is set to CURVES. Include as many sets of Card 3b through Card 6b as needed.

PID/PSID	ZREF						

Card 4b. This card is included when *OPTION1* is set to CURVES.

BLCZ	BLC	BLCSH	BLCSV				

Card 5b. This card is included when *OPTION1* is set to CURVES.

VLCZ	VLC	VLCSH	VLCSV				

Card 6b. This card is included when *OPTION1* is set to CURVES.

HLCZ	HLC	HLCSH	HLCSV				

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PBSID	DIAM	(blank)	PIDNS	PIDNB	ERROR	NRING	NRINGB
Type	I	F		I	I	I	I	I
Default	none	0.0		auto	auto	0	1	↓

VARIABLE	DESCRIPTION
PBSID	Part set ID containing beam elements for coupling (the piles). See Remarks 2 and 3.
DIAM	Pile diameter (optional). If zero or blank, the pile diameter will be taken automatically from the section properties of the beam element. See Remarks 3 and 13.
PIDNS	ID for automatically generated part containing visualization elements for perpendicular and axial coupling. If not specified, LS-DYNA will assign a part ID. See Remarks 14 and 15.
PIDNB	ID for automatically generated part containing visualization elements for base coupling. If not specified, LS-DYNA will assign a part ID. See Remarks 14 and 15.
ERROR	Action taken if any coupling point is not constrained within a soil element: EQ.0: Stop with an error message.

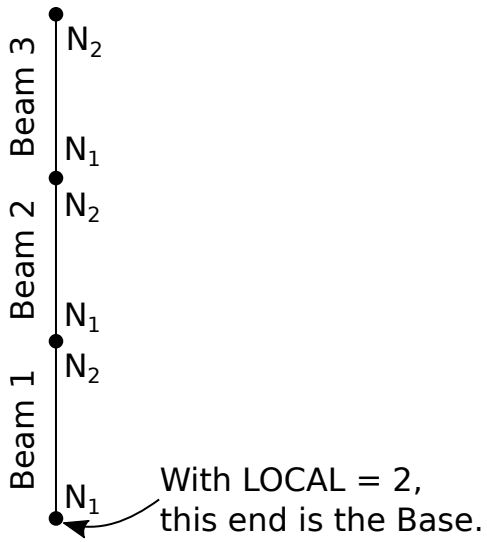

Figure 10-42. Example of a beam element topology in a pile. We recommend each beam having the same order for N_1 and N_2, so that the Base is not ambiguous for LOCAL = 2.

VARIABLE	DESCRIPTION
	EQ.1: Warn and continue.
NRING	Number of coupling points around circumference at each pile node (see Remarks 11, 12 and 13): EQ.1: One coupling point coincident with pile node GT.1: NRING coupling points equally spaced around the circumference of the pile
NRINGB	Number of extra rings of coupling points on base, in addition to those around the pile circumference. By default, NRINGB is chosen automatically to distribute the base stress as uniformly as possible (see Remarks 11 and 12).

This card is included unless *OPTION1* is unset (<blank>).

Card 2	1	2	3	4	5	6	7	8
Variable	DAMP	LOCAL	INSTRF	TIMSTR				
Type	F	I	I	F				
Default	0.0	1	0	0.0				

VARIABLE	DESCRIPTION
DAMP	Optional damping coefficient for Axial coupling (stress/velocity units). An additional axial coupling shear stress equal to DAMP times the axial velocity of the pile relative to the soil will be generated. See Remark 17.
LOCAL	Flag to identify which free end of a pile is treated as the Base: EQ.1: End with the most negative global Z-coordinate EQ.2: End which is Node 1 of the attached beam element topology. See Figure 10-42.
INSTRF	Flag to control definition of soil stress for Cards 4a through 6a and Cards 4b through 6b: EQ.0: Use time-varying soil stress. TIMSTR is ignored. EQ.1: Use time-varying soil stress until time TIMSTR. Then use the soil stress that existed at time TIMSTR for the remainder of the analysis.
TIMSTR	Time at which the effect of soil stress is frozen

CONSTANTS General Coupling Properties Card. Include a set of Cards 3a through 6a for each soil part/part set when *OPTION1* is CONSTANTS or unset. Include as many sets as needed. See Remark 6.

Card 3a	1	2	3	4	5	6	7	8
Variable	PID/PSID	ACU	BCU	LCCU	ASTIFFS	BSTIFFS	ASTIFFB	ZREF
Type	I	F	F	I	F	F	F	F
Default	none	0.0	0.0	optional	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
PID/PSID	Part ID or part set ID (depending on *OPTION2*) containing solid elements for coupling (the soil). See Remarks 4 and 16.
ACU	Constant term in depth-dependence formula. Units of stress.

VARIABLE	DESCRIPTION
BCU	Coefficient on relative Z-coordinate in depth-dependence formula. Units of stress/length. Note that soil strengths (and therefore coupling properties) generally increase with depth, meaning they increase with an increasingly negative Z-coordinate. Therefore, this term is usually negative.
LCCU	Optional load curve ID giving stress (stress units) as a function of relative Z-coordinate (length units). If defined, LCCU overrides ACU and BCU. Note that "increasing depth" corresponds to "increasingly negative relative Z-coordinate".
ASTIFFS	Generic stiffness term. Units of stress / length.
BSTIFFS	Generic Z-coordinate-dependent stiffness term. Units of stress / length^2
ASTIFFB	Base stiffness. Units of stress / length.
ZREF	Reference Z-coordinate to calculate "relative Z-coordinate". See Remark 16.

CONSTANTS Base Coupling Properties Card. Include a set of Cards 3a through 6a for each soil part/part set when *OPTION1* is CONSTANTS or unset. See Remarks 6 and 8.

Card 4a	1	2	3	4	5	6	7	8
Variable	KBCON	KBCU	KBSX	KBSY	KBSZ	BSTFAC	BHYPER	BLC
Type	F	F	F	F	F	F	F	I
Default	0.0	0.0	0.0	0.0	0.0	1.0	0.0	0

VARIABLE	DESCRIPTION
KBCON	Base coupling, constant term (stress units)
KBCU	Base coupling, coefficient for Cu (dimensionless)
KBSX	Base coupling, coefficient for effective global X-stress (dimensionless)
KBSY	Base coupling, coefficient for effective global Y-stress (dimensionless)

VARIABLE	DESCRIPTION
KBSZ	Base coupling, coefficient for effective global Z-stress (dimensionless)
BSTFAC	Base coupling, factor on elastic stiffness (dimensionless)
BHYPER	Base coupling, hyperbolic curve limit (dimensionless)
BLC	Base coupling, load curve ID for dimensionless factor on stress as a function of displacement

CONSTANTS Axial Coupling Properties Card. Include a set of Cards 3a through 6a for each soil part/part set when *OPTION1* is CONSTANTS or unset. See Remarks 6 and 9.

Card 5a	1	2	3	4	5	6	7	8
Variable	KVCON	KVCU	KVSX	KVSY	KVSZ	VSTFAC	VHYPER	VLC
Type	F	F	F	F	F	F	F	I
Default	0.0	0.0	0.0	0.0	0.0	1.0	0.0	0

VARIABLE	DESCRIPTION
KVCON	Axial coupling, constant term (stress units)
KVCU	Axial coupling, coefficient for Cu (dimensionless)
KVSX	Axial coupling, coefficient for effective global X-stress (dimensionless)
KVSY	Axial coupling, coefficient for effective global Y-stress (dimensionless)
KVSZ	Axial coupling, coefficient for effective global Z-stress (dimensionless)
VSTFAC	Axial coupling, factor on elastic stiffness (dimensionless)
VHYPER	Axial coupling, hyperbolic curve limit (dimensionless)
VLC	Axial coupling, load curve ID for dimensionless factor on stress as a function of displacement

CONSTANTS Perpendicular Coupling Properties Card. Include a set of Cards 3a through 6a for each soil part/part set when *OPTION1* is CONSTANTS or unset. See Remarks 6 and 10.

Card 6a	1	2	3	4	5	6	7	8
Variable	KHCON	KHCU	KHSX	KHSY	KHSZ	HSTFAC	HHYPER	HLC
Type	F	F	F	F	F	F	F	I
Default	0.0	0.0	0.0	0.0	0.0	1.0	0.0	none

VARIABLE	DESCRIPTION
KHCON	Perpendicular coupling, constant term (stress units)
KHCU	Perpendicular coupling, coefficient for Cu (dimensionless)
KHSX	Perpendicular coupling, coefficient for effective global *X*-stress (dimensionless)
KHSY	Perpendicular coupling, coefficient for effective global *Y*-stress (dimensionless)
KHSZ	Perpendicular coupling, coefficient for effective global *Z*-stress (dimensionless)
HSTFAC	Perpendicular coupling, factor on elastic stiffness (dimensionless)
HHYPER	Perpendicular coupling, hyperbolic curve limit (dimensionless)
HLC	Perpendicular coupling, load curve ID for dimensionless factor on stress as a function of displacement

CURVES General Coupling Properties Card. Include a set of Cards 3b through 6b for each soil part/part set when *OPTION1* is CURVES. Include as many sets as needed.

Card 3b	1	2	3	4	5	6	7	8
Variable	PID/PSID	ZREF						
Type	I	F						
Default	none	0.0						

VARIABLE	DESCRIPTION
PID/PSID	Part ID or part set ID (depending on *OPTION2*) containing solid elements for coupling (the soil). See Remarks 4 and 16.
ZREF	Reference *Z*-coordinate, used in calculation of "relative *z*-coordinate". For example, ZREF may be located at the soil surface. See Remarks 7 and 16.

CURVES Base Coupling Properties Card. Include a set of Cards 3b through 6b for each soil part/part set when *OPTION1* is CURVES. See Remarks 7 and 8.

Card 4b	1	2	3	4	5	6	7	8
Variable	BLCZ	BLC	BLCSH	BLCSV				
Type	I	I	I	I				
Default	0	0	optional	optional				

VARIABLE	DESCRIPTION
BLCZ	For base coupling, load curve ID defining ultimate strength (stress units) as a function of relative *Z*-coordinate (length units)
BLC	For base coupling, load curve ID containing normalized mobilization curve: dimensionless factor on stress as a function of displacement
BLCSH	For base coupling, optional load curve ID containing coefficient for initial effective horizontal soil stress (dimensionless) as a function

VARIABLE	DESCRIPTION
	of relative Z-coordinate
BLCSV	For base coupling, optional load curve ID containing coefficient for initial effective vertical soil stress (dimensionless) as a function of relative Z-coordinate

CURVES Axial Coupling Properties Card. Include a set of Cards 3b through 6b for each soil part/part set when *OPTION1* is CURVES. See Remarks 7 and 9.

Card 5b	1	2	3	4	5	6	7	8
Variable	VLCZ	VLC	VLCSH	VLCSV				
Type	I	I	I	I				
Default	0	0	optional	optional				

VARIABLE	DESCRIPTION
VLCZ	For axial coupling, load curve ID defining ultimate strength (stress units) as a function of relative Z-coordinate (length units)
VLC	For axial coupling, load curve ID containing normalized mobilization curve: dimensionless factor on stress as a function of displacement
VLCSH	For axial coupling, optional load curve ID containing coefficient for initial effective horizontal soil stress (dimensionless) as a function of relative Z-coordinate
VLCSV	For axial coupling, optional load curve ID containing coefficient for initial effective vertical soil stress (dimensionless) as a function of relative Z-coordinate

CURVES Perpendicular Coupling Properties Card. Include a set of Cards 3b through 6b for each soil part/part set when *OPTION1* is CURVES. See Remarks 7 and 10.

Card 6b	1	2	3	4	5	6	7	8
Variable	HLCZ	HLC	HLCSH	HLCSV				
Type	I	I	I	I				
Default	0	0	optional	optional				

VARIABLE	DESCRIPTION
HLCZ	For perpendicular coupling, load curve ID defining ultimate strength (stress units) as a function of relative Z-coordinate (length units)
HLC	For perpendicular coupling, load curve ID containing normalized mobilization curve: dimensionless factor on stress as a function of displacement
HLCSH	For perpendicular coupling, optional load curve ID containing coefficient for initial effective horizontal soil stress (dimensionless) as a function of relative Z-coordinate
HSCSV	For perpendicular coupling, optional load curve ID containing coefficient for initial effective vertical soil stress (dimensionless) as a function of relative Z-coordinate

Remarks:

1. **General Requirements.** This keyword is available only for 3D models with the explicit solver. The model's global Z-axis should be vertically upwards. If this is not the case, then it will not be possible to define depth-dependent coupling characteristics or to use the default of the LOCAL field for identifying the Base of piles.

2. **Mesh Requirements.** The beam elements must not share nodes with the solid elements. The beam element mesh does not have to align with the solid element mesh. Each pile must consist of contiguously meshed beam elements. One *CONSTRAINED_SOIL_PILE definition can connect multiple piles to multiple soil layers. Although piles are generally aligned vertically, there is no requirement for this to be the case in the model. We recommend having consistent

beam element local axes along a pile. Thus, neighboring elements should have Node 1 and Node 2 the same way around, such as Node 1 always being below Node 2.

3. **Beam Element Properties.** Beam elements must be ELFORM 1 or 2. *CONSTRAINED_SOIL_PILE treats the beams as if they have a solid circular cross-section with diameter DIAM. If DIAM is nonzero, the same value is used for all the beam elements included in the coupling. If DIAM is zero or blank, the diameter of the assumed circular cross-section is calculated for each beam element separately from the area of the cross-section given on the *SECTION card. The actual section shape may be non-circular and/or non-solid, but then the surface area of the pile assumed by *CONSTRAINED_SOIL_PILE will be different from the true surface area. This difference will result in the coupling stress being multiplied by an incorrect area to obtain the force. In these cases, DIAM should be defined such that $\pi \times$ DIAM equals the perimeter of the pile cross-section. For the beam elements, rigid material is not permitted and constraint-based features such as Nodal Rigid Bodies or SPC boundary conditions must not be present on their nodes.

4. **Solid Element Properties.** The solid elements must not have more than 8 nodes. There is no other restriction on element type or material type. Rigid material type is permitted, and there is no restriction regarding constraints or other features present on the nodes of the solids.

5. **Coupling Characteristics: General.** The coupling characteristics are defined in terms of stress on the outer surface of the pile as nonlinear functions of displacement of the pile relative to the soil. Coupling stress is calculated separately at each coupling point (coupling point locations are discussed in Remark 11). The response under monotonically increasing displacement is defined by a "backbone curve", which is defined differently according to whether *OPTION1* is CONSTANTS (Remark 6) or CURVES (Remark 7). Backbone curves for all three coupling characteristics (Base, Axial and Perpendicular) follow the same pattern but with different input parameters. Unload/reload behavior is described in Remarks 8 through 10.

6. **Backbone Coupling Curves when *OPTION1* is CONSTANTS or Unset.** The coupling follows an elastic/plastic relation with an initial elastic stiffness and a yield stress. The elastic stiffnesses (stress/displacement) for Base, Axial and Perpendicular coupling (S_{Base}, S_{Ax} and S_{Perp}, respectively) are defined as follows:

$$S_{\text{Base}} = \text{ASTIFFB} \times \text{BSTFAC}$$

$$S_{\text{Ax}} = (\text{ASTIFFB} + \text{BSTIFF} \times z_r) \times \text{VSTFAC}$$

$$S_{\text{Perp}} = (\text{ASTIFF} + \text{BSTIFF} \times z_r) \times \text{HSTFAC}$$

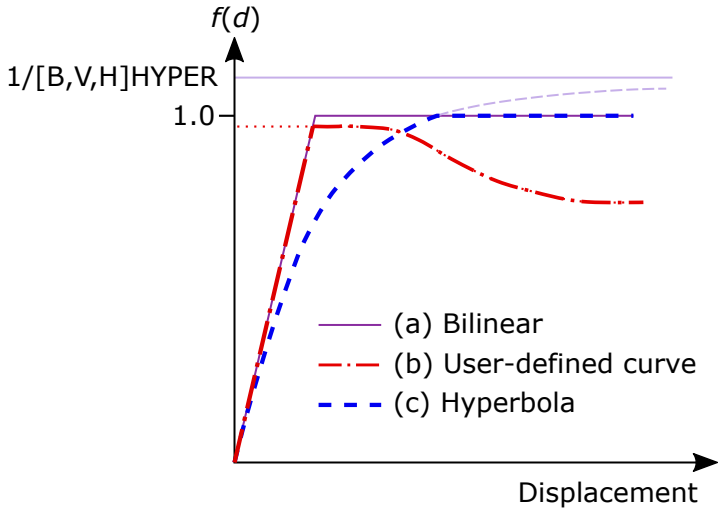

Figure 10-43. Forms of $f(d)$ available when *OPTION1* is CONSTANTS or unset.

Here z_r is the relative Z-coordinate defined as $Z_0 - \text{ZREF}$. Z_0 is the initial Z-coordinate of the pile node.

The yield stresses for Base, Axial and Perpendicular coupling ($\sigma_{Y,\,\text{Base}}$, $\tau_{Y,\,\text{Ax}}$ and $\sigma_{Y,\,\text{Perp}}$, respectively) are defined as follows:

$$\sigma_{Y,\,\text{Base}} = f(d) \times \{\text{KBCON} + \text{KBCU} \times \text{Cu}(z_r) + \text{KBSX} \times \sigma'_x + \text{KBSY} \times \sigma'_y + \text{KBSZ} \times \sigma'_z\}$$

$$\tau_{Y,\,\text{Ax}} = f(d) \times \{\text{KVCON} + \text{KVCU} \times \text{Cu}(z_r) + \text{KVSX} \times \sigma'_x + +\text{KVSY} \times \sigma'_y + \text{KVSZ} \times \sigma'_z\}$$

$$\sigma_{Y,\text{Perp}} = f(d) \times \{\text{KHCON} + \text{KHCU} \times \text{Cu}(z_r) + \text{KHSX} \times \sigma'_x + \text{KHSY} \times \sigma'_y + \text{KHSZ} \times \sigma'_z\}$$

Here d is relative displacement (see Remark 12), z_r is the relative Z-coordinate as defined above, and σ'_x, σ'_y and σ'_z are the soil stresses in the global X, Y and Z directions, respectively. Depending on INSTR and TIMSTR (see Card 2), either time-varying soil stresses or the soil stresses at time TIMSTR are used in this calculation. Note that INSTR and TIMSTR were introduced in R14. In R13, the CONSTANTS keyword option always used current (time-varying) soil stress. If pore water is modeled (see *CONTROL_PORE_FLUID), then these are "effective stresses", meaning the stress generated by the material model excluding any pore pressure. Note that *CONSTRAINED_SOIL_PILE does not require pore pressure to be modelled.

The depth-dependence function, $\text{Cu}(z_r)$, is defined as follows: If LCCU is zero or blank, $\text{Cu}(z_r) = \text{ACU} + \text{BCU} \times z_r$. Otherwise, $\text{Cu}(z_r) = \text{LCCU}(z_r)$.

The function $f(d)$ has three possible forms, illustrated here for Base coupling (input parameters BLC and BHYPER), but the same rules apply for Axial coupling (VLC and VHYPER) and Perpendicular coupling (HLC and HHYPER).

a) If BHYPER and BLC are both zero, $f(d)$ is unity, resulting in a bilinear elastic-perfectly-plastic coupling characteristic.

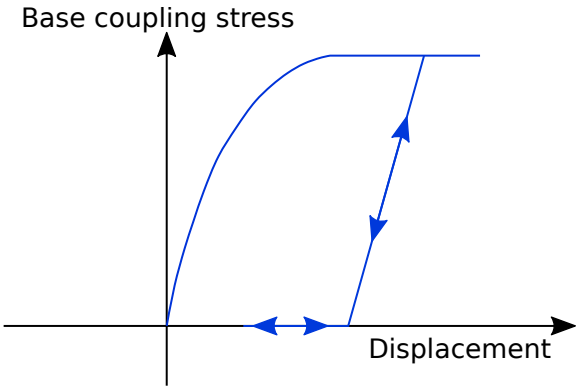

Figure 10-44. Base coupling unload/reload behavior

b) If the load curve BLC is nonzero, $f(d)$ is the value of the load curve. BLC is an optional load curve (see *DEFINE_CURVE) giving a non-dimensional factor on yield stress as a function of displacement.

c) If BHYPER is nonzero (typical value: 0.95), the stress as a function of displacement follows a hyperbolic curve:

$$f(d) = \min\left[1.0, \quad {d_{\max}}\Big/{\text{BHYPER} \times (d_{\text{elastic}} + d_{\max})}\right] .$$

Here $d_{\max}$ is the maximum displacement that has occurred so far, and d_{elastic} is the elastic displacement calculated (for the example of Base coupling) from $\sigma_{\max}/S_{\text{Base}}$. $\sigma_{\max}$ is the stress term in curly brackets in the equation for $\sigma_{Y,Base}$ above.

The three options for $f(d)$ are illustrated in Figure 10-43.

7. **Backbone Coupling Curves when *OPTION1* is CURVES.** The coupling stresses for Base, Axial and Perpendicular coupling (σ_{Base}, τ_{Ax}, and σ_{Perp}, respectively) are defined as follows:

$$\sigma_{\text{Base}} = \left\{\text{BLCZ}(z_r) + 0.5\left(\sigma'_x + \sigma'_y\right) \times \text{BLCSH}(z_r) + \sigma'_z \times \text{BLCSV}(z_r)\right\} \times \text{BLC}(d)$$
$$\tau_{\text{Ax}} = \left\{\text{VLCZ}(z_r) + 0.5\left(\sigma'_x + \sigma'_y\right) \times \text{VLCSH}(z_r) + \sigma'_z \times \text{VLCSV}(z_r)\right\} \times \text{VLC}(d)$$
$$\sigma_{\text{Perp}} = \left\{\text{HLCZ}(z_r) + 0.5\left(\sigma'_x + \sigma'_y\right) \times \text{HLCSH}(z_r) + \sigma'_z \times \text{HLCSV}(z_r)\right\} \times \text{HLC}(d)$$

Here d is relative displacement (see Remark 12). z_r is the relative Z-coordinate defined as $Z_0 - \text{ZREF}$. Z_0 is the initial Z-coordinate of the pile node). σ'_x, σ'_y and σ'_z are the *initial* stresses in the global X, Y and Z directions. Depending on INSTRF and TIMSTR (see Card 2), either time-varying soil stresses or the soil stresses at time TIMSTR are used in this calculation. Note that INSTR and TIMSTR were introduced in R14. In R13, the CURVES option always used initial soil stress (that is, the soil stress at time zero). If pore water is modeled (see *CONTROL_PORE_FLUID), then these are "effective stress" meaning the stress

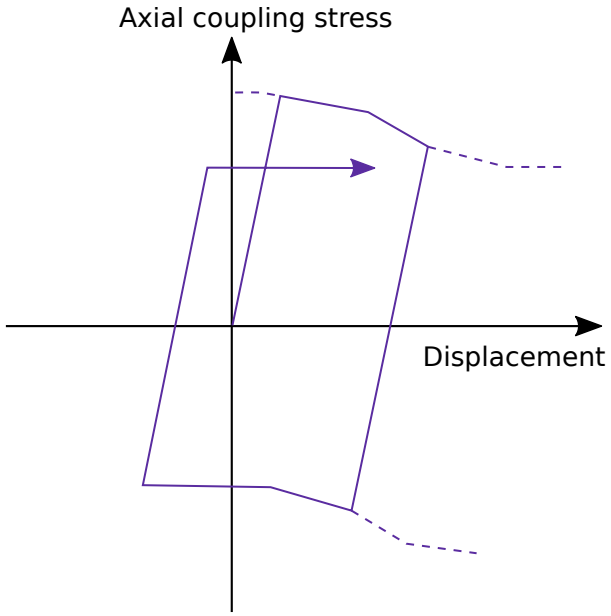

Figure 10-45. Axial coupling unload/reload behavior

generated by the material model excluding any pore pressure. Note that *CONSTRAINED_SOIL_PILE does not require pore pressure to be modelled.

The "normalized mobilization curves" BLC, VLC, HLC, if defined, must have a first point at (0,0). The initial elastic coupling stiffness is determined from the above equations using the gradient of the line between the first and second points of the normalized mobilization curve. If any of the curves (BLCZ, BLC, VLCZ, HLCSH, etc.) are left blank, the corresponding term in the above equations is set to zero. For example, if BLC is left blank, then the Base coupling stress will always be zero, meaning no Base coupling.

8. **Directionality of loading and unload/reload behavior: Base coupling.** Base coupling resists relative movement only in the axial direction corresponding to a pile being pressed downwards into the soil. This coupling results in a compressive axial load on the pile. Uplift is not resisted and results in a gap between the base of the pile and the soil. On reloading, any gap must close before compressive loading of the pile can resume. Figure 10-44 illustrates this unloading/reloading behavior for when BHYPER on Card 4a specifies the shape of the coupling.

9. **Directionality of loading and unload/reload behavior: Axial coupling.** Axial coupling shear stresses resist sliding of the pile in both axial directions. An elasto-plastic approach is adopted. Thus, if the direction of axial movement is reversed, stresses also reverse. Figure 10-45 illustrates a possible response when a user-defined mobilization curve VLC is specified.

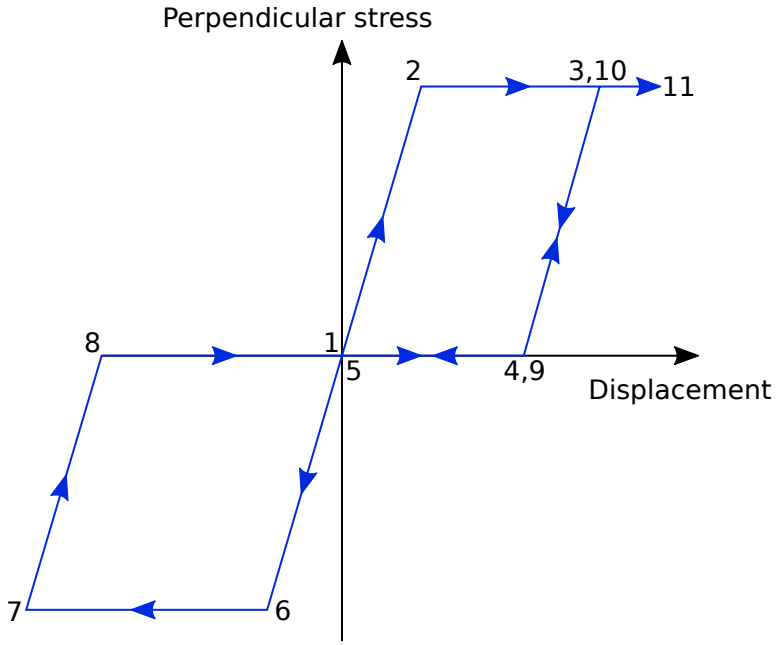

Figure 10-46. Perpendicular coupling unload/reload behavior

10. **Directionality of loading and unload/reload behavior: Perpendicular coupling.** Perpendicular coupling stresses are calculated such that, if a cyclical back-and-forth motion is applied to a pile, the effect is that of an elongating hole (sometimes called "post-hole" behavior named for the observed behavior of the hole in the ground when a fence-post is repeatedly bent in one direction and then the other). As an illustration, in Figure 10-46, HLC and HHYPER are left blank, and a cycling motion is applied.

    Movement could potentially occur at any angle in the plane perpendicular to the pile axis. LS-DYNA tracks the movement and gaps in 8 directions at 45-degree intervals around the pile circumference. For these directions, LS-DYNA applies the input coupling characteristics. For intermediate angles of movement, an interpolation method is used resulting in small differences between the input

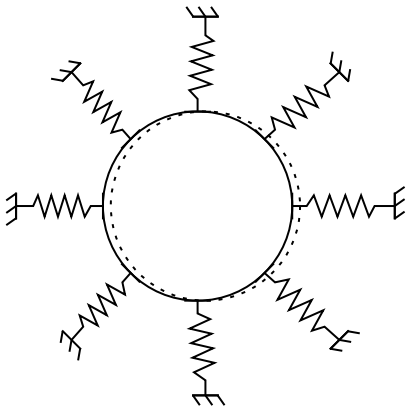

Figure 10-47. Example of how perpendicular motion in a pile is tracked.

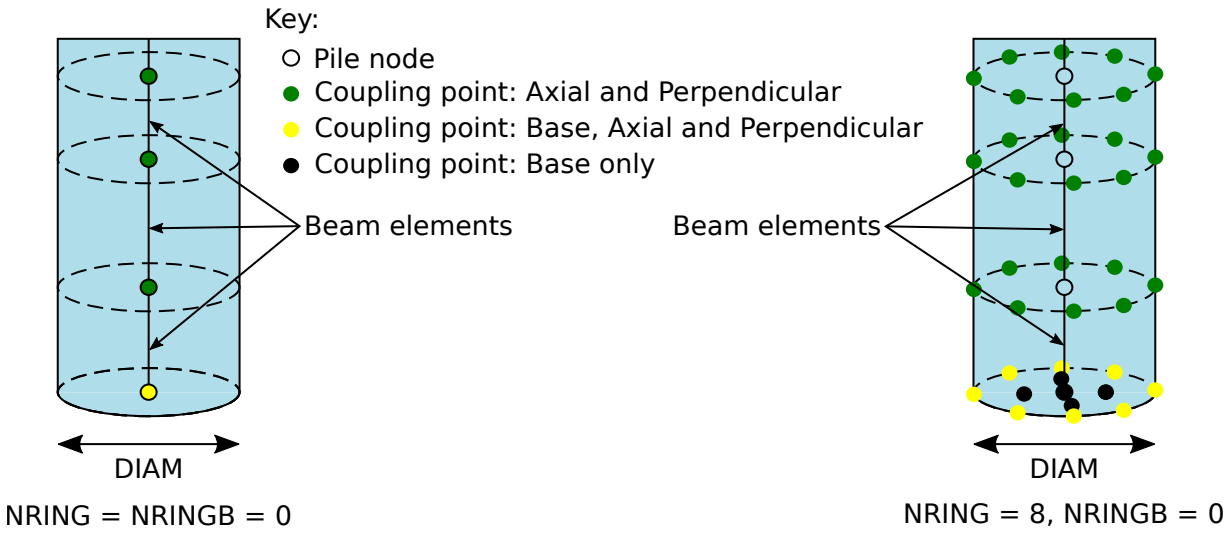

Figure 10-48. Location of coupling points

stress-displacement coupling characteristic and the one achieved by the model. For instance, the resistance to movement at 20 degrees would be a combination of that at 0-degrees and 45-degrees. See Figure 10-47.

11. **Location of coupling points.** LS-DYNA calculates the coupling stresses at each coupling point using the input coupling characteristics. By default (NRING = 0 or 1), one coupling point is coincident with each pile node. We recommend the default when the solid element size is greater than or equal to the pile diameter. Where the soil elements are smaller than the pile diameter, we recommend distributing the coupling stresses onto all the soil elements through which the outer surface of the pile passes. To do this, specify a value of NRING > 1 to define a ring of coupling points level with each pile node around the circumference of the pile. Typically, you should select a value of NRING such that about 1 or 2 coupling points are present in each soil element on the circumference of the pile. Irrespective of the setting of NRING, we recommend NRINGB = 0, meaning that the coupling points on the base of the pile are automatically chosen to obtain an approximately uniform distribution. NRING and NRINGB influence the coupling point mesh only in the plane perpendicular to the pile axis. There is no option to refine the coupling point mesh in the axial direction. See Figure 10-48 for illustration.

12. **Definition of displacement of the pile relative to the soil.** Relative displacement at a given coupling point is the difference of displacement between a pile point and a soil point. The pile point displacement is calculated as if a rigid link were present between the pile node and the coupling point. Therefore, when NRING > 1, the rotation of the pile node times the radial offset between pile node and coupling point contributes to the displacement. The soil point retains a constant relative position (iso-parametric coordinates) within the soil element.

These calculations do not create any additional constraints on the pile node or soil nodes.

13. **Relation between coupling stress and force on the pile.** The Base, Axial and Perpendicular coupling forces are calculated at each coupling point from the coupling stresses as follows:

$$F_{\text{Base}} = \sigma_{\text{Base}} A_{\text{Bp}}$$
$$F_{\text{Ax}} = \tau_{\text{Ax}} \times \pi D \times 0.5(L_1 + L_2)/\text{NRING}$$
$$F_{\text{Perp}} = \sigma_{\text{Perp}} \times D \times 0.5(L_1 + L_2)/\text{NRING}$$

Here A_{Bp} is the area associated with a Base coupling point, D is the pile diameter (DIAM), and L_1 and L_2 are the lengths of the two pile beam elements that meet at the pile node in question. Note that the axial force is based on the whole perimeter being loaded by the shear stress, while the perpendicular force is based on the stress times the area of the pile projected in the perpendicular direction.

The coupling forces are applied to the pile node and reacted on the nodes of the soil element containing the coupling point. If NRING > 1, moments arising from the coupling force times the radial offset between the pile node and the coupling point are applied to the pile node.

14. **Coupling visualization elements.** LS-DYNA automatically creates a beam element at each coupling point. These are for visualizing the coupling stresses only; they do not create additional forces in the solution. LS-DYNA automatically creates *PART, *SECTION_BEAM and *MAT_NULL cards for the visualization elements. If desired, the IDs of the automatically generated *PART cards may be specified with input fields PIDNS and PIDNB.

It is permitted, but not necessary, to define the *PART cards with IDs PIDNS and PIDNB in the keyword file. In this case, the two *PARTs should reference a *SECTION_BEAM with ELFORM = 6 and a *MAT_NULL. the density in the material keyword input, the volume in the section input, and the inertia in the section input should have small nonzero values.

15. **Viewing the coupling stresses.** In the d3plot output file, the coupling visualization beam elements contain fake forces which are actually the coupling stresses. For the elements in part PIDNS, Axial force (or X-Force) is really the Perpendicular coupling stress in the local x direction; Y-Shear (or Y-Force) is really the Perpendicular coupling stress in the local y direction; and, Z-Shear (or Z-Force) is really the Axial coupling stress.

For the elements in part PIDNB, the Axial force (or X-Force) and Y-Shear (or Y-Force) are zero, and the Z-Shear (or Z-Force) is really the Base coupling stress.

The nodes of the visualization beam elements stay coincident with the pile and soil coupling points mentioned in Remark 11 throughout the analysis, enabling visualization of the pile/soil relative displacements (see Remark 12).

16. **Depth-dependent properties.** Soil stiffness and strength generally increases with depth. Soil-pile coupling properties are related to soil properties and therefore they also tend to increase with depth. *CONSTRAINED_SOIL_PILE offers options for defining coupling properties that vary with depth (expressed via functions of Z-coordinate relative to ZREF), but depth-dependent coupling could also be achieved by defining multiple layers of soil each with a different part ID, and then defining unique but non-depth-dependent properties for each layer.

17. **Damping.** Damping of the axial response may be defined using DAMP. This is not usually required for quasi-static simulations for which other damping methods are available, so DAMP is usually set to zero. However, damping may sometimes be desirable in some dynamic simulations.

18. **Mass-scaling.** LS-DYNA checks the numerical stability of the coupling, based on the coupling stiffness and the masses of the pile and soil nodes. If the model uses mass-scaling (negative DT2MS on *CONTROL_TIMESTEP), and if a coupling point would not otherwise be stable at the current timestep, LS-DYNA will automatically add mass to the pile and soil nodes to ensure stability. The mass added by *CONSTRAINED_SOIL_PILE during the first timestep is printed to the d3hsp file; search for "added mass for *CONSTRAINED_SOIL_PILE". If the amount of added mass seems excessive, consider reducing the initial elastic coupling stiffness (described in Remarks 6 and 7).

19. **Calibration of coupling properties.** The nonlinear coupling properties in *CONSTRAINED_SOIL_PILE account for the part of the deformation of the soil that is not captured explicitly by the soil mesh. The finer the soil mesh, the more localized deformation around the pile will be captured by the soil elements, and therefore the less deformation needs to be accounted for by the coupling properties. Thus, realistic input properties for *CONSTRAINED_SOIL_PILE depend on soil mesh size. It is advisable to calibrate the input properties against a detailed model in which the pile (or part of a pile) is represented by solid elements embedded in finely-meshed soil and subjected to axial and perpendicular loading cases.

20. **Staged construction and the dynain file.** The dynain files written during a Staged Construction analysis (see *CONTROL_STAGED_CONSTRUCTION) contain a keyword called *INITIAL_SOIL_PILE_DATA which enables the *CONSTRAINED_SOIL_PILE coupling stresses and history data to be carried forward into further analyses.

*CONSTRAINED_SOLID_IN_SOLID_{OPTION1}_{OPTION2}

This keyword can take the following two forms:

*CONSTRAINED_SOLID_IN_SOLID

*CONSTRAINED_SOLID_IN_SOLID_PENALTY

To define an ID and heading, the following options are available:

ID

TITLE

Purpose: Provide either constraint-based or penalty-based coupling between solids and the solids/thick shells in which the solids are embedded. It is one of the keywords in the *CONSTRAINED_BEAM/SHELL/SOLID_IN_SOLID family.

To use the constraint-based coupling, this keyword takes the form of *CONSTRAINED_-SOLID_IN_SOLID. It constrains solid structures to move with Lagrangian solids/thick shells. This keyword constrains both acceleration and velocity. This keyword, together with *CONSTRAINED_BEAM_IN_SOLID and *CONSTRAINED_SHELL_IN_SOLID, intends to sidestep certain limitations of the CTYPE = 2 implementation in *CON-STRAINED_LAGRANGE_IN_SOLID. Notable features of this keyword include:

1. **Tetrahedral and pentahedral solid elements are supported.** They are no longer treated as degenerated hexahedra as in the CTYPE = 2 implementation.

2. **Velocity/Fixed Boundary Condition.** The CTYPE = 2 implementation fails to constrain solid nodes that are buried inside elements whose nodes have pre-scribed velocity/fixed boundary conditions.

3. **Optimized Sorting.** The sorting subroutine is optimized for larger problems to achieve better performance and less memory usage.

To use the penalty-based coupling, this keyword takes the form of *CONSTRAINED_-SOLID_IN_SOLID_PENALTY. A penalty spring is attached between coupling points on the solid and in the solid/thick shell element. Penalty spring stiffness is calculated based on the geometric mean of the two bulk moduli of the interacting elements. The magni-tude of this coupling force can be controlled using PSSF (penalty spring stiffness scale factor). This penalty coupling conserves kinetic energy much better in transient prob-lems, such as blast loading.

If a title is not defined, LS-DYNA will automatically create an internal title for this cou-pling definition.

Title Card. Additional card for TITLE and ID keyword options

Card ID	1	2	3	4	5	6	7	8
Variable	COUPID	TITLE						
Type	I	A						

Card 1	1	2	3	4	5	6	7	8
Variable	SSIDA	SSIDB	SSTYPA	SSTYPB				
Type	I	I	I	I				
Default	none	none	0	0				

Card 2	1	2	3	4	5	6	7	8
Variable	START	END				PSSF		
Type	F	F				F		
Default	0.	10^{20}				0.1		

VARIABLE	DESCRIPTION
COUPID	Coupling (card) ID number. If not defined, LS-DYNA will assign an internal coupling ID based on the order of appearance in the input deck.
TITLE	A description of this coupling definition
SSIDA	Set ID defining a part or part set ID of the Lagrangian solid structure constrained to move with solid or thick shell elements specified with SSIDB (see *PART and *SET_PART).
SSIDB	Set ID defining a part or part set ID of the Lagrangian solid elements or thick shell elements which constrain SSIDA (see *PART and *SET_PART).

VARIABLE	DESCRIPTION
SSTYPA	Set type of SSIDA: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID)
SSTYPB	Set type of SSIDB: EQ.0: Part set ID (PSID) EQ.1: Part ID (PID)
START	Start time to activate the coupling: LT.0.0: Start time is set to |START|. When negative, start time is followed during the dynamic relaxation phase of the calculation. After the completion of dynamic relaxation, coupling is active regardless of the value of END. EQ.0.0: Start time is inactive, meaning coupling is always active GT.0.0: If END = -9999, START is interpreted as the curve or table ID defining multiple pairs of start-time and end-time. Otherwise, if END > 0, start time applies both during and after dynamic relaxation.
END	End time to deactivate the coupling: LT.0.0: If END = -9999, START is interpreted as the curve or table ID defining multiple pairs of start-time and end-time. Otherwise, negative END indicates that coupling is inactive during dynamic relaxation. After dynamic relaxation, the start and end times are followed and set to |START| and |END|, respectively. EQ.0.0: END defaults to 10^{20}. GT.0.0: END sets the time at which the coupling is deactivated.
PSSF	Penalty spring stiffness scale factor. Only available in penalty form.

*CONSTRAINED_SPLINE

Purpose: Define an elastic cubic spline interpolation constraint. The displacements and slopes at the end points are continuous. The first and last nodes, which define the constraint, must be independent. The degrees-of-freedom of interior nodes may be either dependent or independent.

Card 1	1	2	3	4	5	6	7	8
Variable	SPLID	DLRATIO						
Type	I	I						
Default	0	0.10						

Node Cards. Include one card per independent/dependent node. The first and last nodes must be independent. The next keyword ("*") card terminates this input.

Card 2	1	2	3	4	5	6	7	8
Variable	NID	DOF						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
SPLID	Spline constraint ID
DLRATIO	Ratio of bending to torsional stiffness for an elastic tubular beam which connects the independent degrees-of-freedom. The default value is 0.10.
NID	Independent/dependent node ID. For explicit problems this node should not be a member of a rigid body or elsewhere constrained in the input.
DOF	Degrees-of-freedom. The list of dependent degrees-of-freedom consists of a number with up to six digits, with each digit representing a degree of freedom. For example, the value 1356 indicates

VARIABLE	DESCRIPTION
	that degrees of freedom 1, 3, 5, and 6 are controlled by the constraint. The default is 123456. Digit degree of freedom IDs: EQ.1: x EQ.2: y EQ.3: z EQ.4: Rotation about x-axis EQ.5: Rotation about y-axis EQ.6: Rotation about z-axis

***CONSTRAINED_SPOTWELD**_*{OPTION}*_*{OPTION}*

To use a time-filtered force calculation for the forced-based failure criterion, the following option is available:

FILTERED_FORCE

To define an ID for the spot weld, the following option is available:

ID

The order of the options in the keyword name is arbitrary. Both options are optional.

Purpose: Define massless spot welds between non-contiguous nodal pairs.

The spot weld is a rigid beam that connects the nodal points of the nodal pairs; thus, nodal rotations and displacements are coupled. The spot welds must be connected to nodes having rotary inertias, that is, beams or shells. If this is not the case, for example, if the nodes belong to solid elements, use the option: *CONSTRAINED_RIVET. During implicit calculations this case is treated like a rivet, constraining only the displacements. Note that shell elements do not have rotary stiffness in the normal direction and, therefore, this component cannot be transmitted.

Spot welded nodes must not have the same coordinates. Coincident nodes in a spot weld can be handled by the *CONSTRAINED_NODAL_RIGID_BODY option. Brittle and ductile failures are supported by this model. Brittle failure is based on the resultant forces acting on the weld, and ductile failure is based on the average plastic strain value of the shell elements which include the spot welded node. Spot welds, which are connected to massless nodes, are automatically deleted in the initialization phase and a warning message is printed in the messag file and the d3hsp file.

WARNING: The accelerations of spot welded nodes are output as zero into the various databases, but if the accelerations of spot welded nodes are required, use either the *CONSTRAINED_GENERALIZED_WELD or the *CONSTRAINED_NODAL_RIGID_BODY input. However, if the output interval is frequent enough, accurate acceleration time histories can be obtained from the velocity time history by differentiation in the post-processing phase.

ID Card. Additional card for the ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	WID

Type	I	I	F	F	F	F	F	F
Default	none	none	0.0	0.0	none	none	10^{20}	10^{20}

Filter Card. Additional card for the FILTERED_FORCE keyword option.

Card 2	1	2	3	4	5	6	7	8
Variable	NF	TW						
Type	I	F						
Default	none	none						

VARIABLE	DESCRIPTION
WID	Optional weld ID.
N1	Node ID. See Remarks 1 and 5.
N2	Node ID. See Remarks 1 and 5.
SN	Normal force, S_n, at spot weld failure (see Remark 2 below). EQ.0.0: The failure criterion is disabled. GT.0.0: Normal force at spot weld failure

VARIABLE	DESCRIPTION
	LT.0.0: Curve ID which specifies the normal force at spot weld failure as a function of the nodal temperature
SS	Shear force, S_s, at spot weld failure (see Remark 2 below). EQ.0.0: The failure criterion is disabled. GT.0.0: Shear force at spot weld failure LT.0.0: Curve ID which specifies the shear force at spot weld failure as a function of the nodal temperature
N	Exponent for normal spot weld force (see Remark 2 below).
M	Exponent for shear spot weld force (see Remark 2 below).
TF	Failure time for nodal constraint set. See Remark 3.
EP	Effective plastic strain at failure. See Remark 4.
NF	Number of force vectors stored for filtering.
TW	Time window for filtering.

Remarks:

1. **Spot Weld Nodes and Constraints.** Nodes connected by a spot weld cannot be members of another constraint set that constrains the same degrees-of-freedom, a tied interface, or a rigid body, i.e., nodes cannot be subjected to multiple, independent, and possibly conflicting constraints. Also, care must be taken to ensure that single-point constraints applied to nodes in a constraint set do not conflict with the constraint sets constrained degrees-of-freedom.

2. **Spot Weld Failure Criteria.** Failure of the spot welds occurs when:

$$\left(\frac{|f_n|}{S_n}\right)^n + \left(\frac{|f_s|}{S_s}\right)^m \geq 1 \ ,$$

where f_n and f_s are the normal and shear interface forces. Component f_n is nonzero for tensile values only. When SN and SM are specified by curve IDs, failure of the spot welds occurs when:

$$\left(\frac{|f_n|}{S_n(T)}\right)^n + \left(\frac{|f_s|}{S_s(T)}\right)^m \geq 1 \ ,$$

where T is the nodal temperature.

3. **Failure Time.** When the failure time, TF, is reached the spot weld becomes inactive and the constrained nodes may move freely.

4. **Material Plastic Strain Failure.** Spot weld failure due to plastic straining occurs when the effective nodal plastic strain exceeds the input value, $\varepsilon^p_{\text{fail}}$. This option can model the tearing out of a spotweld from the sheet metal since the plasticity is in the material that surrounds the spot weld, not the spot weld itself. A least squares algorithm is used to generate the nodal values of plastic strains at the nodes from the element integration point values. The plastic strain is integrated through the element and the average value is projected to the nodes via a least square fit. This option should only be used for the material models related to metallic plasticity and can result is slightly increased run times. Failures can include both the plastic and brittle failures.

5. **Thermal Problem.** The 2 nodes identified by this keyword will be constrained to the same temperature in a thermal problem or in a coupled thermal-mechanical problem.

*CONSTRAINED_SPR2

Purpose: Define a self-piercing rivet with failure. This self-piercing rivet (SPR2) model includes a plastic-like damage model that reduces the force and moment resultants to zero as the rivet fails. A diameter approximately equal to the rivet's diameter gives the domain of influence.

The location of the rivet is defined by a single node at the center of two riveted sheets. The algorithm performs a normal projection from the upper and lower sheets to the rivet node and locates all nodes within the user-defined diameter of influence. L. Olovsson of Impetus Afea developed the numerical implementation of this rivet model based on research on SPR point connector models originally carried out by SIMLab (NTNU) and SINTEF; see references by Porcaro, Hanssen, et al. [2006, 2006, 2007].

Initially, only two sheets (upper and lower) could be connected with one SPR2 node. But since release R9, up to 6 sheets can be connected with one SPR2 node by defining additional parts on optional Card 4. The following stacking sequence should be used: UPID – XPID1 – XPID2 – XPID3 – XPID4 – LPID. Omitted parts can be left blank. For instance, for a 3-sheet connection, the extra part lies between the upper and lower parts, and for a regular 2-sheet connection, Card 4 can be omitted entirely.

Starting with R13, not only shell element parts can be connected using this approach, but also solid elements. However, the new capability is still experimental and should be treated carefully. For instance, the solid element parts still having some kind of obvious planar structure is advantageous.

Card 1	1	2	3	4	5	6	7	8

Variable	XPID1	XPID2	XPID3	XPID4				
Type	I	I	I	I				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
UPID	Upper sheet part ID
LPID	Lower sheet part ID
NSID	Node set ID of rivet location nodes
THICK	Total thickness of upper and lower sheets
D	Rivet diameter

VARIABLE	DESCRIPTION
FN	Rivet strength in tension (pull-out): GT.0: Constant value LT.0: Material data from instantiation of *MAT_CONSTRAINED_SPR2 (*MAT_265) with MID of absolute value |FN|
FT	Rivet strength in pure shear
DN	Failure displacement in normal direction
DT	Failure displacement in tangential direction
XIN	Fraction of failure displacement at maximum normal force
XIT	Fraction of failure displacement at maximum tangential force
ALPHA1	Dimensionless parameter scaling the effective displacement
ALPHA2	Dimensionless parameter scaling the effective displacement
ALPHA3	Dimensionless parameter scaling the effective displacement. The sign of ALPHA3 can be used to choose the normal update procedure: GT.0: Incremental update (default) LT.0: Total update (recommended)
DENS	Rivet density (necessary for time step calculation)
INTP	Flag for interpolation: EQ.0: Linear (default), EQ.1: Uniform, EQ.2: Inverse distance weighting.
EXPN	Exponent value for load function in normal direction
EXPT	Exponent value for load function in tangential direction
PIDVB	Part ID for visualization beams representing SPR2 in post-processing. EQ.0: Part ID automatically set (default). GT.0: PIDVB defines part ID.

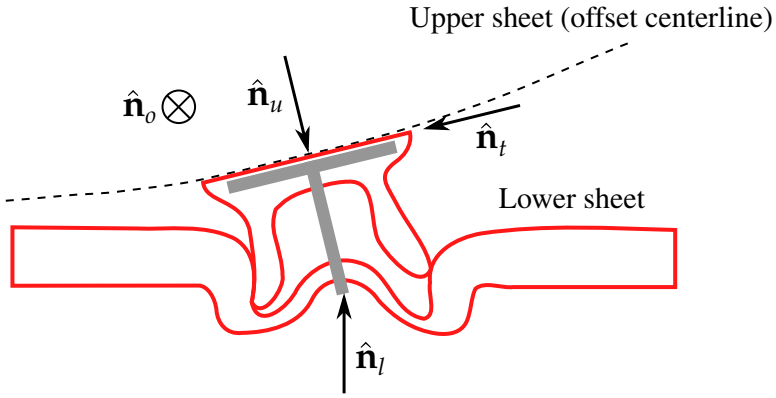

Figure 10-49. Plane of maximum opening.

VARIABLE	DESCRIPTION
XPID1	Extra part ID 1 for multi-sheet connection
XPID2	Extra part ID 2 for multi-sheet connection
XPID3	Extra part ID 3 for multi-sheet connection
XPID4	Extra part ID 4 for multi-sheet connection

Self-piercing rivets are a type of fastener that is sometimes used in place of spot welds to join sheet metal of similar or dissimilar materials. The rivet penetrates the upper sheet and expands to interlock with the lower sheet without penetration. The strength and fatigue characteristics of self-piercing rivets can meet or even exceed that of spot welds; consequently, their practical applications are expanding.

In the local description of the underlying model, all considerations are done in the plane-of-maximum opening defined by

$$\hat{\mathbf{n}}_o = \hat{\mathbf{n}}_l \times \hat{\mathbf{n}}_u \quad .$$

The unit normal vectors of the lower and upper sheets are $\hat{\mathbf{n}}_l$ and $\hat{\mathbf{n}}_u$, respectively (see Figure 10-49). The tangential unit normal vector of the rivet is

$$\hat{\mathbf{n}}_t = \hat{\mathbf{n}}_o \times \hat{\mathbf{n}}_u \quad .$$

A single-sheet rivet system is assumed, meaning the rivet translation and rotation follow the motion of the upper sheet. The opening appears on the lower sheet.

The local deformation is defined by normal stretch vector $\boldsymbol{\delta}_n$, tangential stretch δ_t and total stretch $\boldsymbol{\delta} = \boldsymbol{\delta}_n + \delta_t$ (see Figure 10-51). At any given time the total stretch is computed from the position vectors: $\boldsymbol{\delta} = \mathbf{X}_l^r - \mathbf{X}_l^l$ so that the scalar measures of normal stretch and tangential stretch are $\delta_n = \boldsymbol{\delta} \cdot \hat{\mathbf{n}}_n$ and $\delta_t = \boldsymbol{\delta} \cdot \hat{\mathbf{n}}_t$. The normal and tangential forces f_n and f_t are then determined by the material model, which will be explained next. The moments on the rivet always satisfy,

$$M_u + M_l = \frac{(h_1 + h_2) f_t}{2} \ .$$

The motion, the forces, and the moments are then distributed to the nodes within the radius of influence by a weighting function, which is, by default, linear (see parameter INTP).

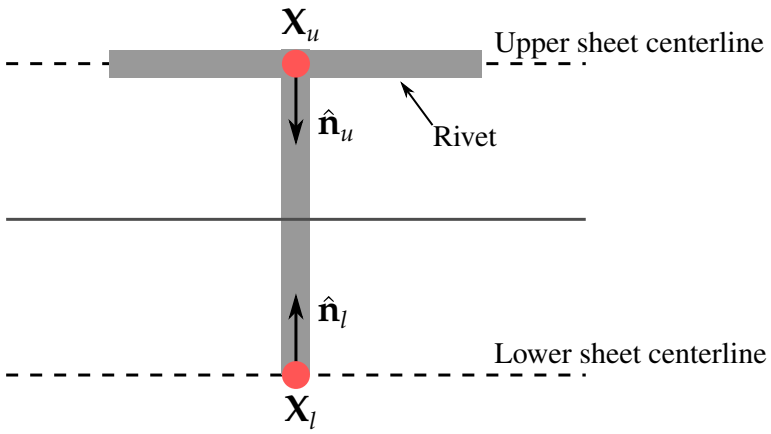

Figure 10-50. Single-sheet rivet system.

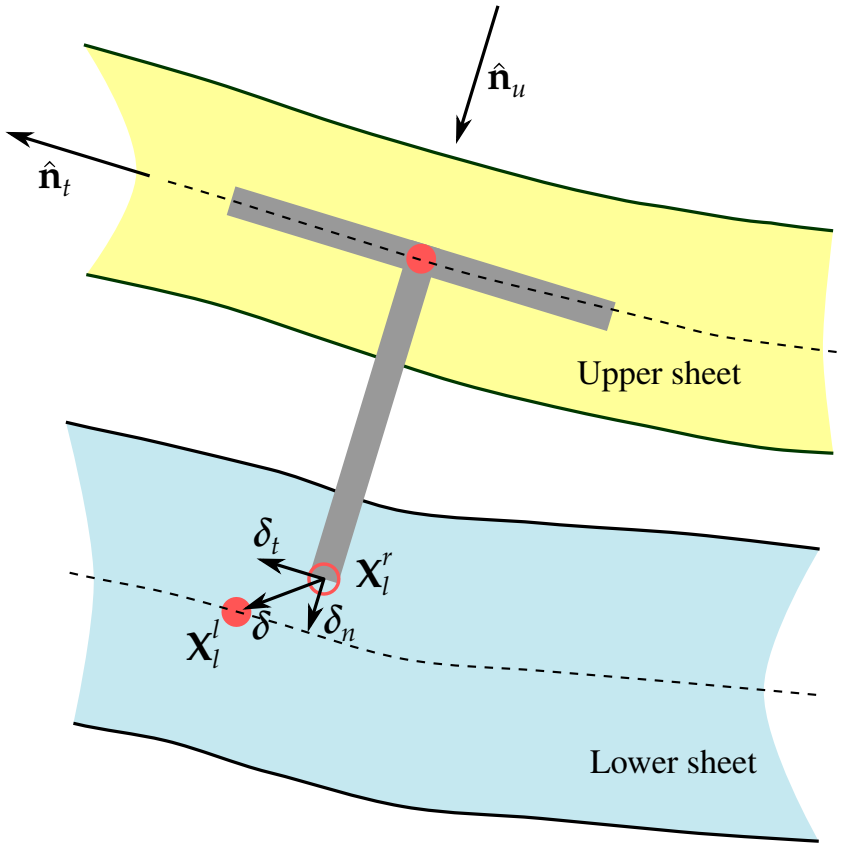

Figure 10-51. Local kinematics

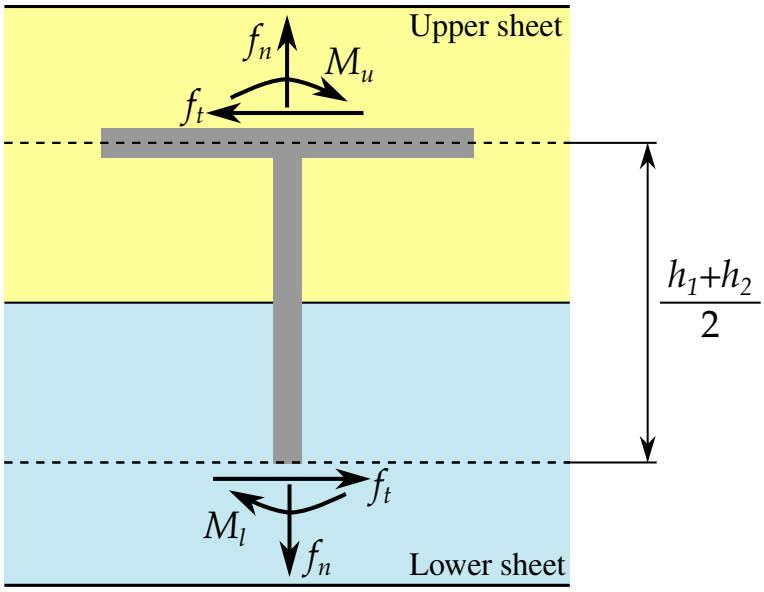

Figure 10-52. Local forces/moments

The force-deformation relationship is defined by a nonlinear damage model for arbitrary mixed-mode loading conditions (combination of tension and shear). For pure tensile and pure shear loading, the behavior is given by,

$$f_n = \frac{f_n^{\max}\delta_n}{\eta_{\max}\delta_n^{\text{fail}}}\hat{f}_n(\eta_{\max}), \qquad f_t = \frac{f_t^{\max}\delta_t}{\eta_{\max}\delta_t^{\text{fail}}}\hat{f}_t(\eta_{\max}) \tag{1}$$

respectively where,

$$\hat{f}_n(\eta_{\max}) = \begin{cases} 1 - \left(\dfrac{\xi_n - \eta_{\max}}{\xi_n}\right)^{\text{EXPN}} & \eta_{\max} \le \xi_n \\ 1 - \dfrac{\eta_{\max} - \xi_n}{1 - \xi_n} & \eta_{max} > \xi_n \end{cases}$$
$$\hat{f}_t(\eta_{\max}) = \begin{cases} 1 - \left(\dfrac{\xi_t - \eta_{\max}}{\xi_t}\right)^{\text{EXPT}} & \eta_{\max} \le \xi_t \\ 1 - \dfrac{\eta_{\max} - \xi_t}{1 - \xi_t} & \eta_{max} > \xi_t \end{cases} \tag{2}$$

In pure tension and pure shear the damage measure, $\eta_{\max}(t)$, defined in (3), simplifies to coincide with strain as indicated in Figure 10-53.

Usually, the material parameters $f_n^{\max}$, $f_t^{\max}$, δ_n^{fail}, and δ_t^{fail} can be determined directly from experiments, whereas material parameters ξ_n and ξ_t can be found by reverse engineering. For mixed-mode behavior, an effective displacement measure, $\eta(\theta)$, is given by

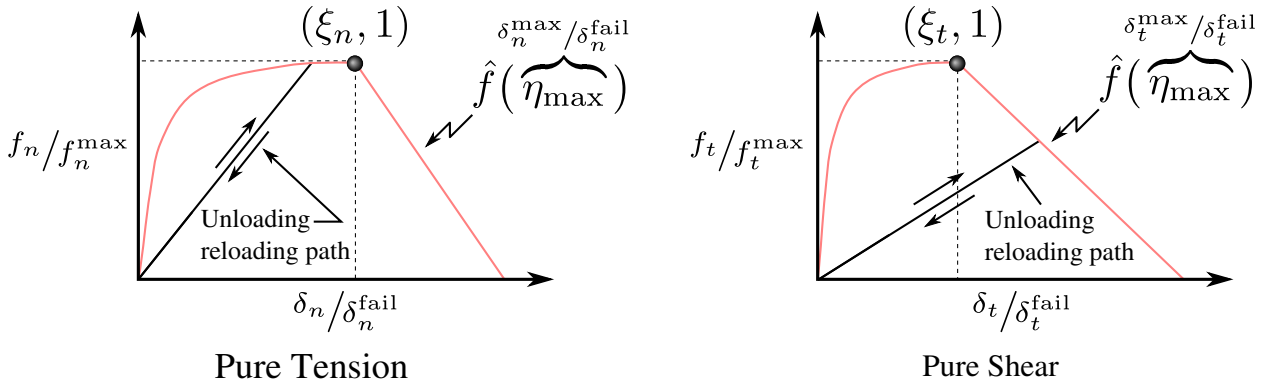

Figure 10-53. Force response of self penetrating rivet.

$$\eta(\theta, \eta_{\max}, t) = \left[\xi(\theta) + \frac{1 - \xi(\theta)}{\alpha(\eta_{\max})}\right] \sqrt{\left[\frac{\delta_n(t)}{\delta_n^{\text{fail}}}\right]^2 + \left[\frac{\delta_t(t)}{\delta_t^{\text{fail}}}\right]^2}, \tag{3}$$

where,

$$\theta = \arctan\left(\frac{\delta_n}{\delta_t}\right)$$
$$\eta_{\max}(t) = \max[\eta(t)].$$

The parameter $\xi(\theta)$ which ranges from 0 to 1 scales the effective displacement as a function of the direction of the displacement vector in the δ_n-δ_t-plane according to,

$$\xi(\theta) = 1 - \frac{27}{4}\left(\frac{2\theta}{\pi}\right)^2 + \frac{27}{4}\left(\frac{2\theta}{\pi}\right)^3. \tag{4}$$

The directional scaling of the effective displacement is allowed to change as damage develops, which is characterized by the shape coefficient $\alpha(\eta_{\max})$ defined as

$$\alpha(\eta_{\max}) = \begin{cases} \dfrac{\xi_t - \eta_{\max}}{\xi_t}\alpha_1 + \dfrac{\eta_{\max}}{\xi_t}\alpha_2 & \eta_{\max} < \xi_t \\ \dfrac{1 - \eta_{\max}}{1 - \xi_t}\alpha_2 + \dfrac{\eta_{\max} - \xi_t}{1 - \xi_t}\alpha_3 & \eta_{\max} \geq \xi_t \end{cases}, \tag{5}$$

where α_1, α_2, and α_3 are material parameters.

The directional dependency of the effective displacement is necessary for an accurate force-displacement response in different loading directions. The coefficients α_1, and α_2 decrease the forces in the peeling and oblique loading cases to the correct levels. Both parameters are usually less than 1; whereas α_3 is typically larger than 1 as its main purpose is to moderate the failure displacement in oblique loading directions. Several qualitative features captured by this model are illustrated in Figure 10-54.

For the moment distribution, the difference between the upper sheet (stronger side where the rivet is entered) and the lower sheet (weaker side) is accounted for by a gradual transfer from the lower to the upper side as damage grows:

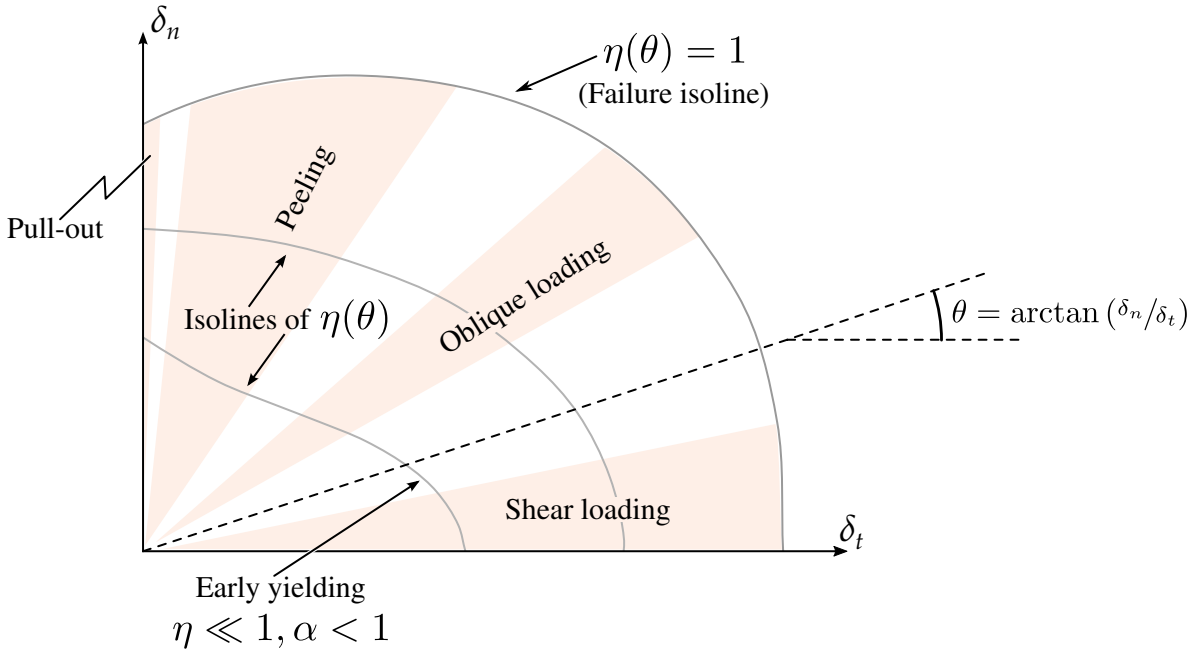

Figure 10-54. Isosurfaces of $\eta(\theta)$

$$M_u = \frac{h_1 + h_2}{4}\left(1 + \frac{\eta_{\max} - \xi_1}{1 - \xi_1}\right) f_1, \qquad M_l = \frac{h_1 + h_2}{4}\left(1 - \frac{\eta_{\max} - \xi_1}{1 - \xi}\right) f_1 \tag{6}$$

Eventually the connection to the lower sheet becomes a moment free hinge.

We recommend using the drilling rotation constraint method for the connected components in explicit analysis. To use this method, field DRCPSID of *CONTROL_SHELL should refer to all shell parts involved in SPR2 connections.

*CONSTRAINED_TIE-BREAK

Purpose: Define a tied shell edge to shell edge interface that can release locally as a function of plastic strain of the shells surrounding the interface nodes. A rather ductile failure is achieved.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID1	NSID2	EPPF					
Type	I	I	F					
Default	none	none	0.					
Remarks		1, 2	3, 4					

VARIABLE	DESCRIPTION
NSID1	Node set ID for nodes on one side of the tied shell edge to shell edge interface; see *SET_NODE_*OPTION*.
NSID2	Node set ID for nodes on the other side of the tied shell edge to shell edge interface
EPPF	Plastic strain at failure

Remarks:

1. **Node Ordering.** Nodes in NSID2 must be given in the order they appear as one moves along the edge of the surface.

2. **Restrictions.** Tie-breaks may not cross.

3. **Failure Criterion.** Tie-breaks may be used to tie shell edges together with a failure criterion on the joint. If the average volume-weighted effective plastic strain in the shell elements adjacent to a node exceeds the specified plastic strain at failure, the node is released. The default plastic strain at failure is defined for the entire tie-break but can be overridden in node set NSID1 to define a unique failure plastic strain for each node.

4. **Model Applications.** Tie-breaks may be used to simulate the effect of failure along a predetermined line, such as a seam or structural joint. When the failure

criterion is reached in the adjoining elements, nodes along the slideline will begin to separate. As this effect propagates, the tie-breaks will appear to "unzip," thus simulating failure of the connection.

*CONSTRAINED_TIED_NODES_FAILURE

Purpose: Define a tied node set with failure based on plastic strain. The nodes must be coincident.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	EPPF	ETYPE					
Type	I	F	I					
Default	none	0.	0					
Remarks	1, 2, 4							

VARIABLE	DESCRIPTION
NSID	Nodal set ID, see *SET_NODE_*OPTION*.
EPPF	Plastic strain, volumetric strain, or damage (MAT_107, MAT_110, MAT_224, or GISSMO) at failure.
ETYPE	Element type for nodal group: EQ.0: shell, EQ.1: solid element

Remarks:

1. **Materials and Failure.** This feature applies to solid and shell elements using plasticity material models and to solid elements using the honeycomb material *MAT_HONEYCOMB (EPPF = plastic volume strain). The failure variable is the volume strain for materials 26, 126, and 201. The failure variable is the damage for materials 107, 110, 224, or GISSMO, and the equivalent plastic strain is used for all other plasticity models. The specified nodes are tied together until the average volume weighted value of the failure variable exceeds the specified value. Entire regions of individual shell elements may be tied together unlike the tie-breaking shell slidelines. The tied nodes are coincident until failure. When the volume weighted average of the failure value is reached for a group of constrained nodes, the nodes of the elements that exceed the failure value are released to simulate the formation of a crack.

2. **Coincident Nodes.** To use this feature to simulate failure, each element in the failure region should be generated with unique node numbers that are coincident in space with those of adjacent elements. Rather than merging these coincident nodes, the *CONSTRAINED_TIED_NODES_FAILURE option ties the nodal points together. A separate keyword definition must be used for each cluster of coincident nodes. As plastic strain develops and exceeds the failure strain, cracks will form and propagate through the mesh.

3. **Similar Keywords.** Entire regions of individual elements may be tied together, unlike the *CONSTRAINED_TIE-BREAK option. This latter option is recommended when the location of failure is known, e.g., as in the plastic covers which hide airbags in automotive structures.

4. **Contact Algorithms.** When using surfaces of shell elements defined using the *CONSTRAINED_TIED_NODES_FAILURE option in contact, it is best to define each node in the surface as a tracked node with the NODE_TO_SURFACE contact options. If this is not possible, the automatic contact algorithms beginning with *CONTACT_AUTOMATIC_... all of which include thickness offsets are recommended.

Example:

```

*CONTACT

The keyword *CONTACT provides a way of treating interaction between disjoint parts. Different types of contact may be defined:

CONTACT_*OPTION1_{OPTION2}_{OPTION3}_{OPTION4}_{OPTION5}

*CONTACT_ADD_WEAR

*CONTACT_AUTO_MOVE

*CONTACT_COUPLING

*CONTACT_ENTITY

*CONTACT_EXCLUDE_INTERACTION

CONTACT_FORCE_TRANSDUCER_*OPTION1_{OPTION2}

CONTACT_GEBOD_*OPTION

*CONTACT_GUIDED_CABLE

*CONTACT_INTERIOR

*CONTACT_RIGID_SURFACE

*CONTACT_SPG

*CONTACT_1D

CONTACT_2D_*OPTION1_{OPTION2}_{OPTION3}

CONTACT_*OPTION1*_... is the general form for defining a 3D contact algorithm. Wear models can be associated with a contact interface using *CONTACT_ADD_WEAR. *CONTACT_AUTO_MOVE is used for sheet metal forming applications and moves a surfb surface in a contact to close a gap between the surfa and surfb at a specified time. *CONTACT_COUPLING provides a means of coupling to deformable surfaces to MADYMO. *CONTACT_ENTITY treats contact using mathematical functions to describe the surface geometry for the reference surface. Portions of the 3D contact interface can be excluded from interacting with *CONTACT_EXCLUDE_INTERACTION. *CONTACT_FORCE_TRANSDUCER measures the contact forces for 3D contacts. It is needed for measuring the forces in self-contacts since LS-DYNA does not automatically extract this data in that case.

*CONTACT_GEBOD is a specialized form of the contact entity for use with the rigid body dummies (see *COMPONENT_GEBOD). *CONTACT_GUIDED_GABLE is a sliding contact for guiding 1D elements. *CONTACT_INTERIOR is used with soft foams where element inversion is sometimes a problem. Contact between layers of brick elements is treated to eliminate negative volumes. *CONTACT_RIGID_SURFACE is for modeling road surfaces for durability and NVH calculations. *CONTACT_SPG is for contact between SPG parts. *CONTACT_1D remains in LS-DYNA for historical reasons and is sometimes still used to model rebars which run along edges of brick elements. Lastly, *CONTACT_2D is the general 2D contact algorithm based on those used previously in LS-DYNA2D.

***CONTACT**_*OPTION1_{OPTION2}_{OPTION3}_{OPTION4}_{OPTION5}_{OPTION6}*

Purpose: Define a contact interface in a 3D model. For contact in 2D models, see *CONTACT_2D_*OPTION*.

Introduction:

The *CONTACT keyword creates a *contact definition*. A contact definition associates surfaces with a *contact algorithm*. A contact algorithm is built from characteristics specified over a small number of fields in the *CONTACT data set. The number of distinct contact algorithms in LS-DYNA equals the number of allowed combinations of characteristics. Not all data fields equally impact the nature of the contact algorithm. The most important characteristics are controlled by:

1. **OPTION1**. For some values of *OPTION1*, the contact algorithm is completely specified. For other values of *OPTION1*, it is not. *OPTION1* is often referred to as the *contact type* in this document.

2. **The SOFT Field of Optional Card A.** This field does not lend itself to a concise summary, but in general, it is accurate to say that the SOFT field of Optional Card A can change the qualitative behavior of a contact algorithm. The most popular values of SOFT, namely, 0, 1, and 2, specify the kind of penalty algorithm invoked.

3. **OPTION4.** This option controls the behavior of tied contact algorithms.

The broadest categories of contact characteristics are whether a contact algorithm is penalty or constraint-based, how penetration is measured (nodes-to-segments, segments-to-segments, or segments-based), and whether the contact is nonsymmetric or symmetric:

1. **Penalty-Based and Constraint-Based Contact Algorithms.** Penalty-based contact places normal interface springs between penetrating nodes/segments and the contact surface. These springs apply a contact force to reduce penetration. In constraint-based contact, nodes penetrating the contact surface are forced to the surface and often controlled with kinematic constraints.

2. **How Penetration is Measured.** Except for segment-based contact (SOFT = 2 on Optional Card A) and segment-to-segment contact (Mortar contact), all LS-DYNA contact algorithms look for the nodes of one surface penetrating the segments of another surface. The segment-based contact algorithm searches for the segments of one surface penetrating the segments of another surface. About SOFT = 2 in the Optional Card A section briefly discusses segment-based contact. Similarly, segment-to-segment contact looks at segments penetrating segments, but it invokes an entirely different algorithm designed for Mortar contact.

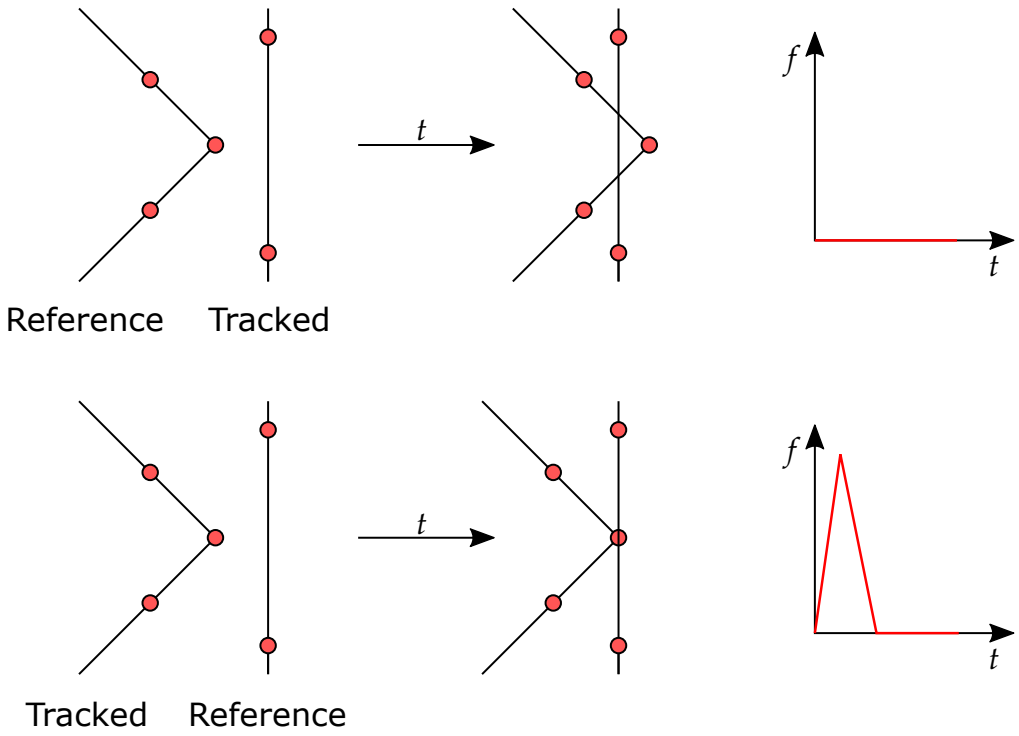

Figure 11-1. Illustration of the difference between the tracked and reference surfaces in nonsymmetric contact. In this example, nodes of the tracked surface are checked to see if they penetrate segments of the reference surface.

Mortar contact is a contact type devised to work well for the implicit solver. See Remark 14 in the General Remarks section.

3. **Nonsymmetric and Symmetric Contact.** In nonsymmetric contact, penetration is only checked in one direction. The nodes/segments of one surface (the ***tracked surface***) are checked to see if they penetrate the segments of another surface (the ***reference surface***), but the nodes/segments of the other surface are not checked to see if they penetrate the first surface. See Figure 11-1. Symmetric contact checks both surfaces for penetration, usually by running the contact algorithm twice. Thus, both surfaces are the tracked and reference surfaces depending on the context. Previously the tracked surface was known as the ***slave***, and the reference surface was known as the ***master***.

Setting the Contact Interface

Another essential consideration influenced by the contact characteristics is specifying the two sides of the contact interface. SURFA and SURFB set the two sides of the contact interface on Mandatory Card 1. SURFA is equivalent to ***SSID***, and SURFB is equivalent to ***MSID***. For nonsymmetric contact, SURFA specifies the ***tracked*** surface, while SURFB specifies the ***reference*** surface, meaning that nodes or segments of SURFA are checked to see if they penetrate SURFB. The nodes/segments of SURFB can penetrate the segments of SURFA for these kinds of contact. See Figure 11-1.

For symmetric contacts, both sides of the contact interface are checked for penetration, and contact forces are applied accordingly. The choice of SURFA and SURFB is arbitrary for symmetric contact. Depending on the context, each surface acts as the reference surface and the tracked surface. For single surface contact, only SURFA is input, and penetration is checked on both sides of the self-contact interface.

For tied contacts, nodes on SURFA are tied to segments of SURFB, usually at the beginning of the simulation. Note that there are some single surface tied contacts where only SURFA is input, and the surface is tied to itself.

DATA CARDS FOR *CONTACT KEYWORD

Cards *must* appear in the *exact* order listed below.

CARD	DESCRIPTION
ID	Card required when *OPTION3* is set to ID; otherwise, this card is omitted.
MPP 1	Card required when *OPTION5* is set to MPP.
MPP 2	Optional card that can *only* be included if *OPTION5* is set to MPP.
Card 1	Always required.
Card 2	Always required.
Card 3	Always required.
Card 4	Required for the following permutations of *CONTACT.

NOTE: The format of Card 4 (which can include multiple cards) is **different** for each option listed.

THRM 1	Required if *OPTION2* is set to either THERMAL or THERMAL_-FRICTION. Otherwise omit.
THRM 2	Required if *OPTION2* is set to THERMAL_FRICTION. Otherwise omit.
THRM 2.1	Inclusion of this card depends on the input on THRM 2.
ORFR 1, ORFR 2, ORFR 3, ORFR 4	Required if *OPTION6* is set. Otherwise omit. Contains friction coefficients.
Optional Card A	Optional parameters.

NOTE: Default values are highly optimized.

NOTE: *Required* if Optional Card B is included. If Optional Card A is a blank line, then values are set to their defaults, and Optional Card B may follow.

Optional Card B	Optional parameters. *Required* if Optional Card C is included. (See Optional Card A note; similar logic applies)
Optional Card C	Optional parameters. *Required* if Optional Card D is included. (See Optional Card A note; similar logic applies.)
Optional Card D	Optional parameters. *Required* if Optional Card E is included. (See Optional Card A note; similar logic applies.)
Optional Card E	Optional parameters

OPTIONS FOR *CONTACT KEYWORD

OPTION	REQUIRED	DESCRIPTION
OPTION1	Yes	Specifies contact type
OPTION2	No	Flag for thermal
OPTION3	No	Flag indicating ID cards follow
OPTION4	No	Offset options
OPTION5	No	Flag for MPP
OPTION6	No	Flag for orthotropic friction

Allowed values for *OPTION1*:

The following list covers the unique terminology used to describe LS-DYNA's contact types. Additional notes on contact types and a few examples are provided at the end of this manual page in "General Remarks: *CONTACT." The LS-DYNA Theoretical Manual covers the algorithms at a higher level.

Following this list are all the available values for *OPTION1*. All contact types are available for explicit and implicit calculations.

4. **Categories of contact types.** Generally, we can split the contact types specified with *OPTION1* into seven basic categories: one-way, two-way, single surface, tied, Mortar, constraint, and sliding only.

   a) One-way contact is nonsymmetric. The nodes (or segments) of SURFA cannot penetrate the segments of SURFB, but SURFB nodes and segments may penetrate SURFA. Thus, deciding on the surfaces for SURFA and SURFB is vital for this type of contact. Generally, SURFA should have a finer mesh. Compressive loads are transferred between the nodes (or segments) of SURFA and segments of SURFB when they are in contact.

   b) Two-way contact is like one-way contact, except it is symmetric. In this case, LS-DYNA checks for SURFA penetrating SURFB and then SURFB penetrating SURFA. As a result, the definitions of SURFA and SURFB are arbitrary. The cost of using this type of contact is roughly double that of one-way.

   c) Single surface contact requires only the input of SURFA. Unlike the other contact types, LS-DYNA checks the single surface for self-penetration. Its

algorithms are based on contacts with SURFACE_TO_SURFACE in the name (see the theory manual for details).

d) Tied contact is for "gluing" two surfaces together, meaning no sliding or separation. It is particularly good for tying parts with incompatible meshes. For this contact, the nodes of SURFA (tracked) are tied to and, thus, constrained to move with the segments of SURFB (reference). No sliding is allowed, except for some TIEBREAK contacts. We also have some single surface tied contacts for which only SURFA is input. In this case, the surface is tied to itself (AUTOMATIC_SINGLE_SURFACE_TIED, AUTOMATIC_GENERAL_TIEBREAK, and AUTOMATIC_SINGLE_SURFACE_TIEBREAK).

   Tying only occurs at the beginning of the simulation unless the contact type is some of the TIEBREAK versions. Thus, if a tracked node enters a reference segment's vicinity during the simulation, the node will not be tied to the segment. For tying to occur, the tracked node must lie within the orthogonal projection of a reference segment, and the gap between the node and segment must be less than a certain tolerance (see Remark 4 in General Remarks). If *OPTION4* (offsets) is used, then the tied tracked node can have an offset from the reference segment. Otherwise, during initialization, the node is moved to the surface. We recommend specifying tied contacts with node or segment sets instead of parts or part sets since they give you more control over what is tied. Identifying the surfaces this way prevents unintended tying.

   Some tied contacts constrain only translational degrees of freedom, while others additionally constrain rotational degrees of freedom. Some types of this contact allow for failure. TIEBREAK is a special case of a tied contact allowing failure in which the contact usually becomes a regular one-way, two-way, or single surface version after failure. How a TIEBREAK contact behaves after failure depends on what the contact type would be if TIEBREAK were excluded.

   Tied contacts with TIEBREAK or PENALTY in the name or ones with OFFSET and BEAM_OFFSET appended to the name using *OPTION4* are penalty-based. All others are constraint-based.

e) Mortar contact is a segment-to-segment-based contact with its own algorithms. It is designated with MORTAR in the name. It is especially well-suited for the implicit solver. It is not symmetric since segments on SURFA are not treated the same as SURFB. Mortar contact includes a single surface version (AUTOMATIC_SINGLE_SURFACE_MORTAR) where only SURFA is input to specify the contact interface. For more details about Mortar

contact, see Remark 14 in the General Remarks section and the theory manual.

f) For this discussion, constraint category contacts are ones with CONSTRAINT in the name. These contacts are constraint-based. They can be symmetric or nonsymmetric depending on the setting of KPF on Card 4. See Remark 11 in General Remarks.

g) Sliding only contact is one of the oldest types. LS-DYNA contains two versions: SLIDING_ONLY and SLIDING_ONLY_PENALTY. The first is constraint-based, while the second is penalty-based. Sliding only contact restricts the nodes of SURFA to slide along SURFB. No separation is allowed with these methods. These contact types help treat interfaces where the gaseous detonation products of a high explosive act on a solid material. See the theory manual for more details. This type of contact is only available for the explicit solver.

5. **NODES_TO_SURFACE.** Contacts with NODES_TO_SURFACE in the name are one-way or tied contacts. SURFA can be defined with a node set for these contacts, and contact is only nodes to segments (neither segment-based nor Mortar contact is available).

6. **SURFACE_TO_SURFACE.** Contacts with SURFACE_TO_SURFACE (also called surface-to-surface contact) in the name can have SURFA defined with segment sets and shell sets. SURFA cannot be represented with node sets. Note that being able to input as segments does not mean that the contact formulation is segment-based. The contact formulation for most penalty contacts depends on the value of SOFT on Optional Card A. Unless the contact formulation is segment-based (SOFT = 2) or the contact type includes MORTAR, the formulation looks at nodal penetrations into segments, not segment penetration into segments.

   SURFACE_TO_SURFACE contacts have special, advanced features compared to NODES_TO_SURFACE contact due in part to how they are defined. For instance, SURFACE_TO_SURFACE contacts support thermal transfer, while generally, NODES_TO_SURFACE contacts do not. Note that the algorithms for SINGLE_SURFACE are based on SURFACE_TO_SURFACE. Thus, parameters that apply to surface-to-surface contact apply to SINGLE_SURFACE.

7. **AUTOMATIC**. Automatic contacts are designated with AUTOMATIC in the type. The algorithms for this type are better than those for non-automatic contacts for dealing with disjoint meshes. Automatic contacts are two-sided in that the algorithms detect penetration on either side of a shell element. In contrast, non-automatic contacts are one-sided. Thus, segment orientation does not matter for automatic contact but is crucial for non-automatic contact. Therefore, automatic contacts are advantageous for crash analysis.

To detect penetration on both sides, automatic contacts include a contact thickness of half the thickness on each side of the shell midplane. They also include a contact surface on the exterior edges of a shell surface with a radius of half the contact thickness. Thus, the shell surface has a continuous contact surface. Similarly, for beam elements where beam contact is considered, the contact surface is offset from the centerline of the beam element by an equivalent radius of the beam cross-section (see the theory manual). Because of the contact surfaces, modeling appropriate gaps between parts is critical for automatic contact with beam and shell parts. See also Remark 3 in the General Remarks.

8. **ERODING.** Contact types with ERODING in the name are suitable for when elements in the contact interface fail and are deleted. These types allow for updating the contact surface due to element deletion.

9. **SMOOTH.** For SMOOTH contact, a smooth curve-fitted surface represents the reference surface segments to provide a more accurate representation of the actual surface, reduce the contact noise, and produce smoother results with coarser meshes.

   SMOOTH contact is unavailable in SMP for FORMING_SURFACE_TO_SURFACE and SURFACE_TO_SURFACE contacts.

   All contact options that include SMOOTH are available for MPP. Furthermore, for SURFACE_TO_SURFACE and SINGLE_SURFACE contacts with the SMOOTH option, both sides of the contact interface are smoothed every cycle, thereby slowing the contact treatment considerably.

   The SMOOTH option does not apply to segment-based (SOFT = 2) contacts.

10. **DRAWBEAD.** DRAWBEAD contacts are a particular type of one-way contact for simulating draw beads. SURFA should be the nodes defining the draw bead, while SURFB is the blank. See Card 4: DRAWBEAD and the theory manual for a complete description.

11. **FORMING.** Contact types that include FORMING in the name are mainly used for metal forming applications. A connected mesh is not required for the SURFB (tooling) side, but the orientation of the mesh *must* be in the same direction. These contact types are based on AUTOMATIC-type contacts, and consequently, the performance is better than the original two surface contacts.

12. **INTERFERENCE.** Contact types with INTERFERENCE are intended for modeling parts with an interference fit. Therefore, LS-DYNA does not check for initial penetrations for this contact. The overlap is instead removed by contact forces, causing stress and deformation in the interference fit parts.

Tied Contact

The following types are tied contacts (not tiebreak). Remark 7 in the General Remarks section discusses which tied contacts can be used with rigid bodies. Remark 4 in General Remarks concerns the tying criterion. For a discussion of which TIED contact to use in which situation, see Remark 5 in General Remarks. For using TIED contacts with the implicit solver, see Remark 6 in General Remarks.

Constraint Contacts

CONSTRAINT_NODES_TO_SURFACE

CONSTRAINT_SURFACE_TO_SURFACE

Sliding Only Contacts

SLIDING_ONLY

SLIDING_ONLY_PENALTY

Allowed values for *OPTION2*:

THERMAL

THERMAL_FRICTION

> **NOTE:** For sliding contacts, the *THERMAL* and *THERMAL_-FRICTION* options are restricted to contact types having *"SURFACE_TO_SURFACE"* in *OPTION1*. For tied contacts, both *"TIED_NODES_TO_SURFACE"* and *"TIED_SHELL_EDGE_TO_SURFACE"* are supported only if SURFA is *not* a node set.

Allowed value for *OPTION3*:

ID

Allowed values for *OPTION4*:

OPTION4 specifies that offsets may be used with the tied contact types. If one of these three offset options is set, then offsets are permitted for these contact types. If not, the nodes are projected back to the contact surface during the initialization phase, and a constraint formulation is used. Note that in a constraint formulation, the nodes of rigid bodies are not permitted in the definition.

OFFSET

BEAM_OFFSET

CONSTRAINED_OFFSET

OFFSET keyword option

The OFFSET option switches the formulation from a constraint-type formulation to one that is penalty-based, where discrete spring elements between the tracked nodes and reference segments transfer the force and moment (if applicable) resultants. Rigid bodies can be used with the OFFSET option.

OFFSET is available when *OPTION1* is:

TIED_NODES_TO_SURFACE

TIED_SHELL_EDGE_TO_SOLID (only applies when the solid element formulation includes nodal rotational degrees of freedom, such as ELFORMs 3, 4, 20, or 22, or when the solid part is rigid)

TIED_SHELL_EDGE_TO_SURFACE

TIED_SURFACE_TO_SURFACE

With OFFSET, no coupling occurs between the transmitted forces and moments; thus, equilibrium is not enforced. For TIED_NODES_TO_SURFACE, the moment equilibrium is enforced by setting FTORQ = 2 on Card E. For TIED_SHELL_EDGE_TO_SURFACE contact, the BEAM_OFFSET option may be preferred since corresponding moments accompany transmitted forces.

BEAM_OFFSET keyword option

The BEAM_OFFSET option switches the formulation from a constraint-type formulation to one that is penalty-based. Beam-like springs transfer force and moment resultants between the tracked nodes and the reference segments. Rigid bodies can be used with this option.

BEAM_OFFSET is available when *OPTION1* is:

TIED_SHELL_EDGE_TO_SOLID (only applies when the solid element formulation includes nodal rotational degrees of freedom, such as ELFORMs 3, 4, 20, or 22, or when the solid part is rigid)

TIED_SHELL_EDGE_TO_SURFACE

SPOTWELD

BEAM_OFFSET is also available when *OPTION1* is:

AUTOMATIC_SINGLE_SURFACE_TIEBREAK

AUTOMATIC_GENERAL_TIEBREAK

but moments are transferred only when the variable FTORQ is invoked (see Optional Card E). Those moments are transmitted to the reference surface segments through nodal forces applied to the nodes of these segments.

CONSTRAINED_OFFSET keyword option

The CONSTRAINED_OFFSET option is a constraint-type formulation. CONSTRAINED_OFFSET is available when *OPTION1* is:

TIED_NODES_TO_SURFACE

TIED_SHELL_EDGE_TO_SOLID

TIED_SHELL_EDGE_TO_SURFACE

TIED_SURFACE_TO_SURFACE

SPOTWELD

Allowed value *OPTION5*:

MPP

Allowed value for *OPTION6*:

ORTHO_FRICTION

ORTHO_FRICTION is available when *OPTION1* is:

AUTOMATIC_SURFACE_TO_SURFACE(_SMOOTH / _MORTAR)

AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE(_SMOOTH)

FORMING_ONE_WAY_SURFACE_TO_SURFACE(_SMOOTH)

ID Card:

Additional card for ID keyword option

Card ID	1	2	3	4	5	6	7	8
Variable	CID	HEADING						
Type	I	A70						

The contact ID is needed during full deck restarts for contact initialization. If the contact ID is undefined, the default ID is determined by the sequence of the contact definitions; that is, the first contact definition has an ID of 1, the second, 2, and so forth. For a successful run in a full deck restart without contact IDs, no contact interfaces can be deleted, and added contact interfaces must be placed after the last definition in the previous run. Some of the peripheral LS-DYNA codes pick up the ID and headings to aid in post-processing.

VARIABLE	DESCRIPTION
CID	Contact interface ID. This must be a unique number.
HEADING	Interface descriptor. We suggest using unique descriptions.

MPP Cards:

Variables set with these cards are only active when using MPP LS-DYNA.

MPP Card 1. Additional card for the MPP option. When SOFT = 2 on Optional Card A, this card is ignored but still read in.

MPP 1	1	2	3	4	5	6	7	8
Variable	IGNORE	BCKT	LCBCKT	NS2TRK	INITITR	PARMAX		CPARM8
Type	I	I	I	I	I	F		I
Default	0	200	none	3	2	↓		0

MPP Card 2. The keyword reader will interpret the card following MPP Card 1 as MPP Card 2 if the first column of the card is occupied by an ampersand. Otherwise, it is interpreted as Card 1. When SOFT = 2 on Optional Card A, GRPABLE is the *only* field on this card that is not ignored.

MPP 2	1	2	3	4	5	6	7	8
Variable	&	CHKSEGS	PENSF	GRPABLE				
Type		I	F	I				
Default		0	1.0	0				

VARIABLE	DESCRIPTION
IGNORE	By setting this variable to 1, the "ignore initial penetrations" option is turned on for this contact. Alternatively, this option may be turned on by setting IGNORE = 1 on Card 4 of *CONTROL_CONTACT or on Optional Card C of *CONTACT. In other words, if IGNORE is set to 1 in any of three places, initial penetrations are tracked.
BCKT	Bucket sort frequency. This parameter does not apply when SOFT = 2 on Optional Card A or to Mortar contacts. For these two exceptions, the BSORT option on Optional Card A applies instead.

VARIABLE	DESCRIPTION
LCBCKT	Load curve for bucket sort frequency. This parameter does not apply when SOFT = 2 on Optional Card A or to Mortar contacts. For the two exceptions, the negative BSORT option on Optional Card A applies instead.
NS2TRK	Number of potential contacts to track for each tracked node. The normal input for this (DEPTH on Optional Card A) is ignored.
INITITR	Number of iterations to perform when trying to eliminate initial penetrations. Note that an input of 0 means 0, not the default value (which is 2). Leaving this field blank will set INITITR to 2.
PARMAX	The parametric extension distance for contact segments. The MAXPAR parameter on Optional Card A is not used for MPP. For non-tied contacts, the default is 1.0005. For tied contacts the default is 1.035 and, the actual extension used is computed as follows:

$$\text{PARMAX}_{\text{computed}} = \begin{cases} 1.0 + \text{PARMAX} & 0.0 < \text{PARMAX} < 0.5 \\ \text{PARMAX} & 1.0 \le \text{PARMAX} \le 1.0004 \\ \max(\text{PARMAX}, 1.035) & \text{otherwise} \end{cases}$$

CPARM8 Flag for behavior of AUTOMATIC_GENERAL contacts. CPARM8's value is interpreted as two separate flags: OPT1 and OPT2 according to the rule,

$$\text{CPARM8} = \text{OPT1} + \text{OPT2}.$$

When OPT1 and OPT2 are *both* set, *both* options are active.

OPT1. Flag to exclude beam-to-beam contact from the same PID.

EQ.0: Flag is not set (default).

EQ.1: Flag is set.

EQ.2: Flag is set. CPARM8 = 2 additionally permits contact treatment of spot weld (type 9) beams in AUTOMATIC_GENERAL contacts. Spot weld beams are otherwise disregarded entirely by AUTOMATIC_GENERAL contacts.

OPT2. Flag to shift a generated beam, affecting only shell-edge-to-shell-edge treatment. See also SRNDE in Optional Card E.

EQ.10: A beam generated on an exterior shell edge will be shifted into the shell by half the shell thickness.

VARIABLE	DESCRIPTION
	Therefore, the shell-edge-to-shell-edge contact starts right at the shell edge and not at an extension of the shell edge.
CHKSEGS	If this value is nonzero, then for node-to-surface and surface-to-surface contacts LS-DYNA performs a special check at time 0 for elements that are inverted (or nearly so). These elements are removed from contact. These poorly formed elements have been known to occur on the tooling in metal forming problems, which allows these problems to run. It should not normally be needed for reasonable meshes.
PENSF	This option is used together with IGNORE for 3D forging problems. If nonzero, the IGNORE penetration distance is multiplied by this value each cycle, effectively pushing the tracked node back out to the surface. This is useful for nodes that might get generated below the reference surface during 3D remeshing. Care should be exercised, as energy may be generated, and stability may be affected for values lower than 0.95. A value in the range of 0.98 to 0.99 or higher (but < 1.0) is recommended.
GRPABLE	Set to 1 to invoke an alternate MPP communication algorithm for various SINGLE_SURFACE (including AUTOMATIC_GENERAL), NODES_TO_SURFACE, SURFACE_TO_SURFACE, ERODING and SOFT = 2 contacts. This groupable algorithm does not support all contact options, including MORTAR. It is still under development. It can be significantly faster and scale better than the normal algorithm when there are more than two or three applicable contact types defined in the model. It is intended for speeding up the contact processing without changing the behavior of the contact. See also *CONTROL_MPP_CONTACT_GROUPABLE.

Remarks:

1. **SOFT = 2.** Except the GRPABLE field, the MPP cards are ignored by the segment-based contact options that are made active by setting SOFT = 2 on Optional Card A. When SOFT = 2, the BSORT parameter on Optional Card A can be used to override the default bucket sort frequency. See About SOFT = 2 for more details about segment-based contact.

Mandatory Card 1:

> **NOTE:** SURFA is equivalent to the side of contact specified previously SSID, and SURFB is equivalent to the side of the contact specified previously with MSID.

Card 1	1	2	3	4	5	6	7	8
Variable	SURFA	SURFB	SURFATYP	SURFBTYP	SABOXID	SBBOXID	SAPR	SBPR
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none			0	0
Remarks	1	2			optional	optional		

VARIABLE	DESCRIPTION
SURFA	Segment set ID, node set ID, part set ID, part ID, shell element set ID, or branch ID for specifying the SURFA side of the contact interface (see Setting the Contact Interface). See *SET_SEGMENT, *SET_NODE_*OPTION*, *PART, *SET_PART or *SET_SHELL_*OPTION*. For ERODING_SINGLE_SURFACE and ERODING_SURFACE_TO_SURFACE contact types, use either a part ID or a part set ID. For ERODING_NODES_TO_SURFACE contact, use a node set which includes all nodes that may be exposed to contact as element erosion occurs. EQ.0: Includes all parts in the case of single surface contact types.
SURFB	Segment set ID, part set ID, part ID, shell element set ID, or branch ID for the SURFB side of the contact (see Setting the Contact Interface). EQ.0: SURFB side is not applicable for single surface contact types.
SURFATYP	ID type of SURFA: EQ.0: Segment set ID for surface-to-surface contact EQ.1: Shell element set ID for surface-to-surface contact

VARIABLE	DESCRIPTION
	EQ.2: Part set ID EQ.3: Part ID EQ.4: Node set ID for nodes-to-surface contact EQ.5: Include all (SURFA field is ignored) EQ.6: Part set ID for exempted parts. All non-exempted parts are included in the contact. EQ.7: Branch ID; see *SET_PART_TREE. For AUTOMATIC_BEAMS_TO_SURFACE contact, either a part set ID or a part ID can be specified.
SURFBTYP	ID type of SURFB: EQ.0: Segment set ID EQ.1: Shell element set ID EQ.2: Part set ID EQ.3: Part ID EQ.5: Include all (SURFB field is ignored). EQ.6: Part set ID for exempted parts. All non-exempted parts are included in the contact. EQ.7: Branch ID; see *SET_PART_TREE.
SABOXID	Include in contact definition only those SURFA nodes/segments within box SABOXID (corresponding to BOXID in *DEFINE_BOX), or if SABOXID is negative, only those SURFA nodes/segments within contact volume |SABOXID| (corresponding to CVID in *DEFINE_CONTACT_VOLUME). SABOXID can be used only if SURFATYP is set to 2, 3, or 6, that is, SURFA is a part ID or part set ID. SABOXID is not available for ERODING contact types.
SBBOXID	Include in contact definition only those SURFB segments within box SBBOXID (corresponding to BOXID in *DEFINE_BOX), or if SBBOXID is negative, only those SURFB segments within contact volume |SBBOXID| (corresponding to CVID in *DEFINE_CONTACT_VOLUME). SBBOXID can be used only if SURFBTYP is set to 2, 3, or 6, that is, SURFB is a part ID or part set ID. SBBOXID is not available for ERODING contact types.

VARIABLE	DESCRIPTION
SAPR	Include the SURFA side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files, and optionally in the dynain file for wear: EQ.0: Do not include. EQ.1: SURFA side forces included. EQ.2: Same as 1 but also allows for SURFA nodes to be written as *INITIAL_CONTACT_WEAR to dynain; see NCYC on *INTERFACE_SPRINGBACK_LSDYNA.
SBPR	Include the SURFB side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files, and optionally in the dynain file for wear: EQ.0: Do not include. EQ.1: SURFB side forces included. EQ.2: Same as 1, but also allows for SURFB nodes to be written as *INITIAL_CONTACT_WEAR to dynain; see NCYC on *INTERFACE_SPRINGBACK_LSDYNA.

Remarks:

1. **SURFA Set and Single Surface Contacts.** Setting the SURFA set ID equal to zero is valid only for the single surface contact algorithms, meaning the options:

   SINGLE_SURFACE

   AUTOMATIC_GENERAL_...

   AUTOMATIC_SINGLE_SURFACE_...

   AIRBAG_…

   ERODING_SINGLE_SURFACE

2. **SURFB Set with Single Surface Contact** A SURFB set ID is not defined for the single surface contact algorithms (including AUTOMATIC_GENERAL).

3. **Selecting Sides of Contact Interface for TIED_SURFACE_TO_SURFACE.** For *CONTACT_TIED_SURFACE_TO_SURFACE, we generally recommend making SURFA the more finely meshed part. This recommendation has exceptions. For instance, if the coarsely meshed SURFB side deforms, then the finer SURFA side will deform with high stress localizations in the folding lines.

Mandatory Card 2:

Card 2	1	2	3	4	5	6	7	8
Variable	FS	FD	DC	VC	VDC	PENCHK	BT	DT
Type	F	F	F	F	F	I	F	F
Default	0.	0.	0.	0.	0.	0	0.	10^{20}

VARIABLE	DESCRIPTION

If *OPTION1* is TIED_SURFACE_TO_SURFACE_FAILURE, then

FS Normal tensile stress at failure. Failure occurs if

$$\left[\frac{\max(0.0, \sigma_{\text{normal}})}{FS}\right]^2 + \left[\frac{\sigma_{\text{shear}}}{FD}\right]^2 > 1$$

where σ_{normal} and σ_{shear} are the interface normal and shear stresses.

FD Shear stress at failure. See FS.

Else

FS Static coefficient of friction. If FS is > 0 and not equal to 2. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact according to,

$$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}|v_{\text{rel}}|} \ .$$

The three other possibilities are:

EQ.2: For a subset of SURFACE_TO_SURFACE type contacts (see Remark 1 below), FD is a table ID (see *DEFINE_TABLE). That table specifies two or more values of contact pressure, with each pressure value in the table corresponding to a curve of friction coefficient as a function of relative velocity. Thus, the friction coefficient becomes a function of pressure and relative velocity. See Figure 11-2.

EQ.-2: If only one friction table is defined using *DEFINE_FRICTION, it will be used and there is no need to define parameter FD. If more than one friction table is defined, then the friction table ID is defined by FD below.

VARIABLE	DESCRIPTION

EQ.-1: If the frictional coefficients defined in the *PART section are to be used, set FS to -1.0.

WARNING: The FS = -1.0 and F = -2.0 options apply only to contact types:

SINGLE_SURFACE

AIRBAG_SINGLE_SURFACE

AUTOMATIC_GENERAL

AUTOMATIC_SINGLE_SURFACE

AUTOMATIC_SINGLE_SURFACE_MORTAR

AUTOMATIC_NODES_TO_SURFACE

AUTOMATIC_SURFACE_TO_SURFACE

AUTOMATIC_SURFACE_TO_SURFACE_MORTAR

AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE

ERODING_SINGLE_SURFACE

FD: Dynamic coefficient of friction. If FS > 0 and not equal to 2, the frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact according to,

$$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-DC|v_{\text{rel}}|}$$

Otherwise:

FS.EQ.-2: Friction table ID if more than one friction table is defined

FS.EQ.2: Table ID for table that specifies two or more values of contact pressure, with each pressure value in the table corresponding to a curve of friction coefficient as a function of relative velocity.

End If

DC: Exponential decay coefficient. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact

VARIABLE	DESCRIPTION

$$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}|v_{\text{rel}}|}.$$

VC — Coefficient for viscous friction. This is necessary to limit the friction force to a maximum. A limiting force is computed as $F_{\text{lim}} = \text{VC} \times A_{\text{cont}}$ with A_{cont} being the area of the segment contacted by the node in contact. The suggested value for VC is the yield stress in shear VC $= \sigma_o/\sqrt{3}$ where σ_0 is the yield stress of the contacted material.

VDC — Viscous damping coefficient in percent of critical or the coefficient of restitution expressed as percentage (see ICOR on Optional Card E). In order to avoid undesirable oscillation in contact, such as for sheet forming simulation, a contact damping perpendicular to the contacting surfaces is applied. When ICOR, the 6th column of Optional Card E, is not defined or 0, the applied damping coefficient is given by

$$\xi = \frac{\text{VDC}}{100}\xi_{\text{crit}} \ ,$$

where VDC is an integer (in units of percent) between 0 and 100. The formula for critical damping is

$$\xi_{\text{crit}} = 2m\omega,$$

where m is determined by nodal masses as

$$m = \min(m_{\text{tracked}}, m_{\text{reference}}) \ ,$$

and ω is determined from k, the interface stiffness, according to

$$\omega = \sqrt{k\frac{m_{\text{tracked}} + m_{\text{reference}}}{m_{\text{tracked}}m_{\text{reference}}}} \ .$$

PENCHK — Small penetration in contact search option. If the tracked node penetrates more than the segment thickness times the factor XPENE (see *CONTROL_CONTACT), the penetration is ignored, and the tracked node is set free. The thickness is taken as the shell thickness if the segment belongs to a shell element, or it is taken as 1/20 of its shortest diagonal if the segment belongs to a solid element. This option applies to the surface-to-surface contact algorithms. See Table 11-2 for contact types and more details.

BT — Birth time (contact surface becomes active at this time):

LT.0: Birth time is set to |BT|. When negative, birth time is followed during the dynamic relaxation phase of the

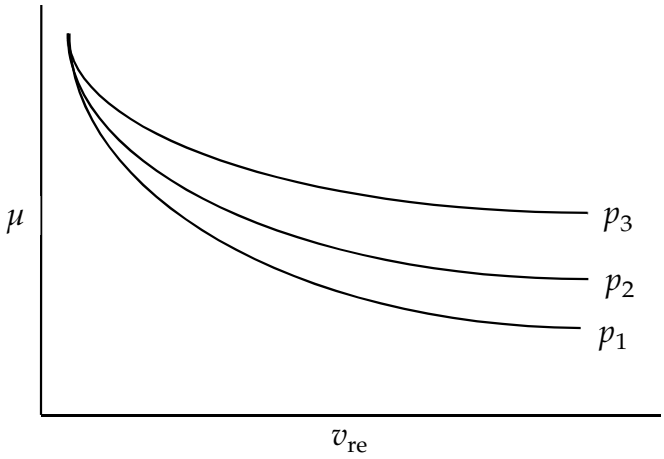

Figure 11-2. Friction coefficient, μ, can be a function of relative velocity and pressure. See Remark 1 for FS = 2.0.

VARIABLE	DESCRIPTION
	calculation. After dynamic relaxation has completed, contact is activated regardless of the value of BT. EQ.0: Birth time is inactive, meaning contact is always active GT.0: If DT = -9999, BT is interpreted as the curve or table ID defining multiple pairs of birth-time/death-time; see Remark 2 below. Otherwise, if DT > 0, birth time applies both during and after dynamic relaxation.
DT	Death time (contact surface is deactivated at this time): LT.0: If DT = -9999, BT is interpreted as the curve or table ID defining multiple pairs of birth-time/death-time. Otherwise, negative DT indicates that contact is inactive during dynamic relaxation. After dynamic relaxation the birth and death times are followed and set to |BT| and |DT|, respectively. EQ.0: DT defaults to 10^{20}. GT.0: DT sets the time at which the contact is deactivated.

Remarks:

1. **Implemented Contacts for FS = 2.** The FS = 2 method of specifying the friction coefficient as a function of pressure and relative velocity is implemented for all contact types for which SOFT = 2 (see When segment-based contact is available in the Optional Card A section) and for all Mortar contacts. When FS = 2 and

SOFT = 2, we recommend setting FNLSCL to a value in the range of 0.5 to 1.0 and setting DNLSCL to 0 (refer to Remark 5 under the description of Optional Card D for *CONTACT). For Mortar contact, these recommendations can be ignored as they do not apply.

The following ONE_WAY contact types can safely be used with FS = 2 when SOFT = 0 or 1.

ONE_WAY_SURFACE_TO_SURFACE	(SMP and MPP)
AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE	(MPP only)
FORMING_ONE_WAY_SURFACE_TO_SURFACE	(MPP only)

FS = 2 with SOFT = 0 or 1 is implemented but not advised for the following contact types:

SURFACE_TO_SURFACE	(SMP and MPP)
AUTOMATIC_SURFACE_TO_SURFACE	(MPP only)
FORMING_SURFACE_TO_SURFACE	(MPP only)

A caveat pertaining to the MPP contacts listed above is that the "groupable" option must *not* be invoked. See *CONTROL_MPP_CONTACT_GROUPABLE.

For SOFT = 0 or 1, FS = 2 is not implemented in SMP for non-Mortar AUTOMATIC and FORMING contact types. The static friction coefficient will literally be taken as 2.0 if FS is set to 2 for these SMP contacts.

2. **Contact Birth and Death Times.** If DT = -9999, BT is taken to be the ID of a curve (*DEFINE_CURVE) or the ID of a table (*DEFINE_TABLE(_2D)). The curve(s) define multiple birth-times and death-times as ordered (x, y) pairs, that is, each data point in the curve defines a time window during which the contact is active. To satisfy general curve input requirements, the curve(s) must have at least two data points. For example, a curve with two data points $(20, 30)$ and $(50, 70)$ activates the contact when $20 \leq$ time ≤ 30 and when $50 \leq$ time ≤ 70. To define two separate curves which apply to the dynamic relaxation phase and the subsequent normal phase of the analysis, respectively, BT should point to a table ID. That table should have only two VALUEs, 0 and 1. The curve corresponding to the table VALUE = 0 defines the time windows of active contact for the normal phase of the analysis and curve corresponding to the table VALUE = 1 defines the time windows of active contact for the dynamic relaxation phase of the analysis. An example follows.

```
*CONTACT_TIED_SURFACE_TO_SURFACE
3,3,0,3
```

```

Mandatory Card 3:

Card 3	1	2	3	4	5	6	7	8
Variable	SFSA	SFSB	SAST	SBST	SFSAT	SFSBT	FSF	VSF
Type	F	F	F	F	F	F	F	F
Default	1.	1.	element thickness	element thickness	1.	1.	1.	1.

VARIABLE	DESCRIPTION
SFSA	Scale factor on default SURFA penalty stiffness when SOFT = 0 or SOFT = 2; see also *CONTROL_CONTACT. For MORTAR *frictional* contact this is the stiffness scale factor for the entire contact, and SFSB does not apply.
SFSB	Scale factor on default SURFB penalty stiffness when SOFT = 0 or SOFT = 2; see also *CONTROL_CONTACT. For MORTAR *tied* contact, this is an additional stiffness scale factor, resulting in a total stiffness scale of SFSA × SFSB.
SAST	Optional contact thickness for SURFA surface (overrides default contact thickness). This option applies to contact with shell and beam elements. SAST has no bearing on the actual thickness of the elements; it only affects the location of the contact surface. For the *CONTACT_TIED_… options, SAST and SBST (below) can be defined as negative values, which will cause the determination of whether or not a node is tied to depend only on the separation distance relative to the absolute value of these thicknesses (see Remark 4 in General Remarks). More information is given under General Remarks: *CONTACT.
SBST	Optional contact thickness for SURFB surface (overrides default contact thickness). This option applies only to contact with shell elements. For the TIED options, see SAST above.
SFSAT	Scale factor applied to contact thickness of SURFA surface. This option applies to contact with shell and beam elements. SFSAT has no bearing on the actual thickness of the elements; it only affects the location of the contact surface. SFSAT is ignored if SAST is

VARIABLE	DESCRIPTION
	nonzero except in the case of MORTAR contact (see Remark 14 in the General Remarks: *Contact section).
SFSBT	Scale factor applied to contact thickness of SURFA surface. This option applies only to contact with shell elements. SFSAT has no bearing on the actual thickness of the elements; it only affects the location of the contact surface. SFSAT is ignored if SAST is nonzero except in the case of MORTAR contact (see Remark 14 in the General Remarks: *Contact section).
FSF	Coulomb friction scale factor. The Coulomb friction value is scaled as $\mu_{sc} = \text{FSF} \times \mu_c$; see Mandatory Card 2.
VSF	Viscous friction scale factor. If this factor is defined, then the limiting force becomes: $F_{\text{lim}} = \text{VSF} \times \text{VC} \times A_{\text{cont}}$; see Mandatory Card 2.

Remarks:

The fields FSF and VSF above can be overridden segment by segment on the *SET_SEGMENT or *SET_SHELL_*OPTION* cards for the **SURFA surface only** as A3 and A4, and for the **SURFB surface only** as A1 and A2. See *SET_SEGMENT and *SET_SHELL_*OPTION*.

Card 4: AUTOMATIC_…_TIEBREAK

This card 4 is mandatory for:

CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK_*{OPTION}

CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK_*{OPTION}

*CONTACT_AUTOMATIC_SINGLE_SURFACE_TIEBREAK

*CONTACT_AUTOMATIC_GENERAL_TIEBREAK

If the response parameter, OPTION, below is set to 9 or 11, three damping constants can be defined for the various failure modes. To do this, set the keyword option to

DAMPING

For OPTION = -11, -9, 2, 4, 6, 7, 8, 9 and 11 of *CONTACT_AUTOMATIC_SURFACE_-TO_SURFACE_TIEBREAK, the Mortar treatment may be activated. This is primarily intended for implicit analysis. The keyword option for this is

MORTAR

The DAMPING option cannot be combined with the MORTAR option. With the MORTAR option, the adhesive strength can be output to the intfor file by specifying NTIED on *DATABASE_EXTENT_INTFOR, which is essentially the inverse of the damage.

Card 4	1	2	3	4	5	6	7	8

Card 4.1b	1	2	3	4	5	6	7	8
Variable	G1C_0	G1C_INF	EDOT_G1	T0	T1	EDOT_T	FG1	LCG1C
Type	F	F	F	F	F	F	F	F

OPTION = 13/14 Cards. Two additional cards for the case of OPTION = 13 or 14.

Card 4.2b	1	2	3	4	5	6	7	8
Variable	G2C_0	G2C_INF	EDOT_G2	S0	S1	EDOT_S	FG2	LCG2C
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
OPTION	Response: EQ.-11: See 11. NFLS/SFLS/ERATEN/ERATES are functions of temperature. MORTAR option *only*. EQ.-9: See 9. NFLS/SFLS/ERATEN/ERATES are functions of temperature. MORTAR option only. EQ.-3: See 3. Moments are transferred. SMP only. EQ.-2: See 2. Moments are transferred. SMP only. EQ.-1: See 1. Moments are transferred. SMP only.

VARIABLE	DESCRIPTION
	EQ.1: Tracked nodes in contact and which come into contact will permanently stick. Tangential motion is inhibited.
	EQ.2: Tiebreak is active for nodes which are initially in contact. Until failure, tangential motion is inhibited. If PARAM is set to unity (1.0), shell thickness offsets are ignored, and the orientation of the shell surfaces is required such that the outward normals point to the opposing contact surface.
	EQ.3: Same as 1 above but with failure after sticking.
	EQ.4: Tiebreak is active for nodes which are initially in contact but tangential motion with frictional sliding is permitted.
	EQ.5: Tiebreak is active for nodes which are initially in contact. Stress is limited by the yield condition described in Remark 3 below. Damage behavior is modeled by a curve which defines normal stress as a function of gap (crack opening). This option can be used to represent deformable glue bonds.
	EQ.6: This option is for use with solids and thick shells only. Tiebreak is active for nodes which are initially in contact. Failure stress must be defined for tiebreak to occur. After the failure stress tiebreak criterion is met, damage is a linear function of the distance between points initially in contact. When the distance is equal to PARAM, damage is fully developed, and interface failure occurs. After failure, this option behaves as a surface-to-surface contact.
	EQ.7: Dycoss Discrete Crack Model. Type AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK is recommended for this option. See Remark 3.
	EQ.8: Similar to OPTION = 6, but it works with offset shell elements. Type AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK is recommended for this option.
	EQ.9: Discrete Crack Model with power law and B-K damage models. Type AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK is recommended for this option. See Remark 3.

VARIABLE	DESCRIPTION
	EQ.10: Similar to OPTION = 7, but it works with offset shell elements. Type AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK is recommended for this option.
	EQ.11: Similar to OPTION = 9, but it works with offset shell elements. Type AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK is recommended for this option.
	EQ.13: Elastoplastic, rate-dependent damage model based on *MAT_240. Type AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK is recommended for this option. See Remark 7.
	EQ.14: Similar to OPTION = 13, but it works with offset shell elements. Type AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK is recommended for this option.
NFLS	Normal failure stress for OPTION = 2, 3, 4, 6, 7, 8, ±9, 10 or ±11. For OPTION = 5 NFLS becomes the plastic yield stress as defined in Remark 5. For OPTION = 9 or 11 and NFLS < 0, a load curve with ID |NFLS| is referenced defining normal failure stress as a function of element size. See Remark 3. For OPTION = -9 or -11 and NFLS < 0, |NFLS| is the ID of a load curve giving normal failure stress as function of temperature; it applies to the Mortar option only.
SFLS	Shear failure stress for OPTION = 2, 3, 6, 7, 8, ±9, 10 or ±11. For OPTION = 4, SFLS is a frictional stress limit if PARAM = 1. This frictional stress limit is independent of the normal force at the tie. For OPTION = 5 SFLS becomes the curve ID which defines normal stress as a function of gap. For OPTION = 9 or 11 and SFLS < 0, |SFLS| references a load curve ID, defining shear failure stress as a function of element size. See Remark 3. For OPTION = -9 or -11 and SFLS < 0, |SFLS| is the ID of a load curve giving shear failure stress as function of temperature; it applies to the Mortar option only.

VARIABLE	DESCRIPTION
PARAM	For OPTION = 2, setting PARAM = 1 causes the shell thickness offsets to be ignored. For OPTION = 4, setting PARAM =1 causes SFLS to be a frictional stress limit. For OPTION = 6 or 8, PARAM is the critical distance, CCRIT, at which the interface failure is complete. For OPTION = 7 or 10 PARAM is the friction angle in degrees. For OPTION = 9 or 11, it is the exponent in the damage model. A positive value invokes the power law, while a negative one, the B-K model. See *MAT_138 for additional details. For OPTION = 13 or 14, it is the thickness of the tiebreak layer; a value greater than zero is recommended. Default value is 1.0 for OPTIONs 9 and 11, but otherwise default value is 0.0.
ERATEN	For OPTION = 7, ±9, 10, ±11 only. Normal energy release rate (stress × length) used in damage calculation; see Lemmen and Meijer [2001]. For OPTION = -9 or -11, this is the ID of a load curve giving normal energy release rate as function of temperature; it applies to the Mortar option only.
ERATES	For OPTION = 7, ±9, 10, ±11 only. Shear energy release rate (stress × length) used in damage calculation; see Lemmen and Meijer [2001]. For OPTION = -9 or -11, this is the ID of a load curve giving shear energy release rate as function of temperature; it applies to the Mortar option only.
CT2CN	The ratio of the tangential stiffness to the normal stiffness for OPTION = 9, 11, 13, and 14. The default is 1.0.
CN	Normal stiffness (stress/length) for OPTION = 9, 11, 13, and 14 and for OPTION = 2, 4, 6, 7, and 8 for the MORTAR option only. If CN is not given explicitly, penalty stiffness divided by segment area is used (default). This optional stiffness should be used with care since contact stability can get affected. A warning message with a recommended time step is given initially.
DMP_1	Mode I damping force per unit velocity per unit area
DMP_2	Mode II damping force per unit velocity per unit area
DMP_3	Mode III damping force per unit velocity per unit area
G1C_0, …	All variables on Cards 4.1b and 4.2b are the same as in *MAT_240.

Remarks:

1. **Contact Behavior after Failure.** After failure, this contact option behaves as a surface-to-surface contact with thickness offsets. After failure, no interface tension is possible.

2. **Restrictions.** Segment-based contact (SOFT = 2) is *not* implemented for the tiebreak option. *CONTACT_AUTOMATIC_SINGLE_SURFACE_TIEBREAK and *CONTACT_AUTOMATIC_GENERAL_TIEBREAK are supported only for OPTIONs 1 through 5 and only for MPP.

3. **Tiebreak, Failure, Damage, and Crack Initiation.** The following overviews the failure criteria for the various OPTIONs.

   a) For OPTION = 2, 3, and 6, the tiebreak failure criterion has normal and shear components:

   $$\left(\frac{|\sigma_n|}{\text{NFLS}}\right)^2 + \left(\frac{|\sigma_s|}{\text{SFLS}}\right)^2 \geq 1 \ .$$

   σ_n is the tensile normal stress and is taken as zero if the normal stress is compressive. σ_s is the shear stress.

   b) For OPTION = 4, the tiebreak failure criterion has only a tensile normal stress component:

   $$\frac{|\sigma_n|}{\text{NFLS}} \geq 1 \ .$$

   c) For OPTION = 5, the stress is limited by a perfectly plastic yield condition. For ties in tension, the yield condition is

   $$\frac{\sqrt{\sigma_n^2 + 3|\sigma_s|^2}}{\text{NLFS}} \leq 1 \ .$$

   For ties in compression, the yield condition is

   $$\frac{\sqrt{3|\sigma_s|^2}}{\text{NLFS}} \leq 1 \ .$$

   The stress is also scaled by the damage function which is obtained from the load curve. For ties in tension, both normal and shear stress are scaled. For ties in compression, only shear stress is scaled.

   d) For OPTION = 6 or 8, damage initiates when the stress meets the failure criterion. The stress is then scaled by the damage function. Assuming no load reversals, the energy released due to the failure of the interface is approximately $0.5 \times S \times$ CCRIT, where

$$S = \sqrt{\max(\sigma_n, 0)^2 + |\sigma_s|^2}$$

at the initiation of damage. This interface may be used for simulating crack propagation. For the energy release to be correct, the contact penalty stiffness must be much larger than

$$\frac{\min(\text{NFLF}, \text{SFLS})}{\text{CCRIT}} .$$

e) OPTION = 7 and 10 are implementations of the Dycoss Discrete Crack Model as described in Lemmen and Meijer [2001]. The relation for the crack initiation is given as

$$\left[\frac{\max(\sigma_n, 0)}{\text{NFLS}}\right]^2 + \left[\frac{\sigma_s}{\text{SFLS} - \sin(\text{PARAM})\min(0, \sigma_n)}\right]^2 = 1 .$$

f) OPTION = 9 and 11 are based on the fracture model in the cohesive material model *MAT_COHESIVE_MIXED_MODE, where the model is described in detail. Failure stresses/peak tractions NFLS and/or SFLS can be defined as functions of characteristic element length (square root of the reference segment area) using load curves. With these options, nearly the same global responses (for instance, load-displacement curve) can be obtained with coarse meshes compared to fine meshes. In general, lower peak tractions are needed for coarser meshes. See also *MAT_138.

4. **Determining State of Tiebreak Surface.** For OPTIONs 6 thru 11 of *CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK, the component labeled "contact gap" in the intfor database (*DATABASE_BINARY_INTFOR) indicates the condition of the tiebreak surface. The "contact gap" represents a damage value ranging from 0 (tied, no damage) to 1 (released, full damage).

5. **Automatic Tiebreak Tying Tolerance.** Tying in the AUTOMATIC_..._TIEBREAK contacts occurs if the tracked node is within a small tolerance of the reference surface *after* taking into account contact thicknesses. For MPP, the tolerance is given by

$$\text{tol} = 0.01\sqrt{2 \times \text{reference segment area}} .$$

For SMP, the tolerance is

$$0.4(\text{tracked contact thickness} + \text{reference contact thickness}) .$$

6. **Defining SURFB and SURFA Sets.** We recommend that the SURFA and SURFB sides of tiebreak contact be defined using segment sets rather than part IDs or part set IDs. By doing this, you can be more selective when choosing which segments are to be tied and ensure that contact stresses calculated from nodal contact forces are not diluted by segments that are not actually on the

actual contact surface. You also have more direct control over the contact segment normal vectors when segment sets are used. Segment normal vectors should point toward the opposing contact surface so that tension is properly distinguished from compression.

7. **Variables Applicable to OPTIONs 13 and 14.** OPTIONs 13 and 14 are based on material model 240; see LS-DYNA Keyword User's Manual, Volume II. Applicable variables are PARAM, CT2CN, CN, and the variables on optional Cards 4.1b and 4.2b NFLS, SFLS, ERATEN, and ERATES are not used.

Card 4: AUTOMATIC_..._SURFACE_TO_SURFACE_TIEBREAK_USER_...

These cards, 4.1, 4.2, and 4.3, are mandatory for:

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK_USER

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK_USER_MORTAR

*CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK_USER

Card 4.1	1	2	3	4	5	6	7	8
Variable	OPTION	NHV	CT2CN	CN	OFFSET	NHMAT	NHWLD	
Type	I	I	F	F	I	I	I	
Default	required	0	1.0	0.0	0	0	0

Variable	UP1	UP2	UP3	UP4	UP5	UP6	UP7	UP8
Type	F	F	F	F	F	F	F	F

Card 4.3	1	2	3	4	5	6	7	8
Variable	UP9	UP10	UP11	UP12	UP13	UP14	UP15	UP16
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
OPTION	User tiebreak type (101 - 105 inclusive). A number between 101 and 105 must be chosen. Corresponding subroutine `utb<OPTION>` in dyn21cnt.f will be called for the non-Mortar option while subroutine `mortar_usrtbrk` will be called for the Mortar option.
NHV	Number of history variables (maximum of 3 for non-Mortar, arbitrary for Mortar)

VARIABLE	DESCRIPTION
CT2CN	Ratio of the tangential stiffness to the normal stiffness
CN	Normal stiffness (stress/length). If CN is not given explicitly, penalty stiffness divided by segment area is used (default). This optional stiffness should be used with care since contact stability can be affected. A warning message with a recommended time step is given initially.
OFFSET	Flag for offset treatment (only for non-Mortar option): EQ.0: No offset EQ.1: With offset for shell elements
NHMAT	Number of material history variables to be read in the user tiebreak routine (Mortar option only)
NHWLD	Number of tied weld history variables to be read in the user tiebreak routine, assuming they have been carried over from a previous simulation (Mortar option only). See Remark 4.
UP1…UP16	User parameters

Remarks:

1. **User Defined Tiebreak Model.** This option allows the implementation of a user defined tiebreak model. Please check the comments in subroutine `utb101` or `mortar_usrtbrk` (dyn21cnt.f) for more information.

2. **Contact Behavior after Failure.** After failure, this contact option behaves as a surface-to-surface contact with thickness offsets. After failure, no interface tension is possible.

3. **Preferred Contact Type.** We recommend using the …_ONE_WAY_... definition for this option.

4. **Mortar Option.** Essentially the same behavior can be expected for the Mortar contact as for the non-Mortar contact. The Mortar capability, however, is accompanied with some extra features. For instance, this Mortar contact may be used to assess the adhesive properties of a preceding lamination process by reading history variables from a previous simulation that used a corresponding user Mortar tied weld model (see Card 4: AUTOMATIC_SURFACE_TO_SURFACE_..._TIED_WELD). To do this, the ID of the present tiebreak contact should be the same as the ID of the earlier tied weld contact leading up to the start of the current delamination simulation, and NHWLD should state how many

history variables to read. Furthermore, *INTERFACE_SPRINGBACK_LSDYNA with FTYPE = 3 and CFLAG = 1 should be used to create a dynain.lsda in the previous simulation which will be read with *INCLUDE in the current simulation, all in accordance with standard continuation procedures.

Card 4: AUTOMATIC_SURFACE_TO_SURFACE_COMPOSITE/LUBRICATION

This contact model is designed for simulating the processing of laminated composite materials or certain types of lubrication. Surfaces in contact may support shear up to the limit defined by MODEL and be in compression or in tension up to the tensile limit σ_f defined by TFAIL. After TFAIL is reached, the contact fails in both tension and shear. If the surfaces come back into contact, the bonding heals, and the contacting surfaces may support shear and tension.

This Card 4 is mandatory for:

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_COMPOSITE

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_LUBRICATION

Card 4	1	2	3	4	5	6	7	8
Variable	TFAIL	MODEL	CIDMU	CIDETA	D			
Type	F	I	I	I	F			
Default	required	required	required	required	0.0			

VARIABLE	DESCRIPTION
TFAIL	Tensile traction, σ_f, required for failure
MODEL	Model for shear response (see Remark 2): EQ.1: Limiting shear stress depends on CIDMU in both tension and compression. EQ.2: Limiting shear stress depends on CIDETA in tension and CIDMU in compression. EQ.3: Limiting shear stress depends on CIDETA in both tension and compression.
CIDMU	Curve ID for the coefficient of friction, $\mu(H)$, as a function of the Hershey number, H
CIDETA	Curve ID for the viscosity, $\eta(T)$, as a function of temperature, T (see Remark 1)
D	Composite film thickness

Remarks:

1. **Viscosity.** The viscosity, $\eta(T)$, is defined as a function of temperature by CIDETA. The value of the viscosity is not extrapolated if the temperature falls outside of the temperature range defined by the curve.

2. **Shear Stress Limits.** The following lists the shear stress limits for the different values of MODEL:

   a) *MODEL = 1.* The coefficient of friction, μ, for MODEL = 1 is defined in terms of the Hershey number, $H = \eta(T)V/(p + \sigma_f)$, where p is the contact pressure (positive in compression, and negative in tension) and V the relative velocity between the surfaces. The shear stress in tension and compression is limited according to

   $$\tau \le \mu(H)\left(p + \sigma_f\right) \ .$$

   b) *MODEL = 2.* The coefficient of friction, μ, for MODEL = 2 is defined in terms of the Hershey number, $H = \eta(T)V/p$. Note the definition of the Hershey number for this model differs from MODEL = 1. In compression the shear stress is limited by

   $$\tau \le \mu(H)p \ .$$

   and in tension, the shear stress is limited according to

   $$\tau \le \frac{\eta(T)V}{d} \ .$$

   c) *MODEL = 3.* The shear stress for MODEL = 3 in tension and compression is limited according to

   $$\tau \le \frac{\eta(T)V}{d} \ .$$

Card 4: AUTOMATIC_SINGLE_SURFACE_TIED

This special feature was originally implemented to allow for the calculation of eigenvalues and eigenvectors on geometries that are connected by a contact interface using the AUTOMATIC_SINGLE_SURFACE options. It also can be used in a more general sense to tie a set of parts based only on their proximity to each other in the initial geometry. This contact type does not revert to non-tied AUTOMATIC_SINGLE_SURFACE behavior at any time during the simulation.

This Card 4 is mandatory for:

*CONTACT_AUTOMATIC_SINGLE_SURFACE_TIED

Card 4	1	2	3	4	5	6	7	8
Variable	CLOSE							
Type	F							
Default	Rem 1							

VARIABLE	DESCRIPTION
CLOSE	Tolerance for tying surfaces using a penalty formulation. Surfaces closer than CLOSE are tied. Surfaces farther apart than CLOSE are not tied.

Remarks:

1. **CLOSE Default.** If a value of CLOSE is not input, the default value of CLOSE is calculated for each tracked node and is equal to 0.0106 times the square root of the area of the nearest reference segment.

2. **Rigid Body Modes.** If there is significant separation between the tied surfaces, the rigid body modes will be opposed by the contact stiffness, and the calculated eigenvalues for rigid body rotations will not be zero.

3. **Recommended Settings.** When using this contact type, we recommend setting TIEDID on Optional Card D to 1.

Card 4: AUTOMATIC_SURFACE_TO_SURFACE_..._TIED_WELD

This special feature is implemented to allow for the simulation of welding. As regions of the surfaces are heated to the welding temperature and come into contact, the nodes are tied.

This Card 4 is mandatory for:

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIED_WELD

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR_TIED_WELD

Card 4	1	2	3	4	5	6	7	8
Variable	TEMP	CLOSE	HCLOSE	NTPRM	NMHIS	NSTWH	NMTWH	TIME
Type	F	F	F	F	F	F	F	F
Default	none	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
TEMP	For the non-Mortar option, this is the minimum temperature required on both surfaces for tying. For the Mortar tied weld, surfaces tie when one of the surfaces reaches the specified temperature. Once the surfaces are tied, they remain tied even if the temperature drops. LT.0: |TEMP| represents the user tied weld ID passed to subroutine `mortar_usrtie` for defining an arbitrary condition to tie. This option is only available for MORTAR_TIED_WELD and TEMP must be between -999 and -1.
CLOSE	Surfaces closer than CLOSE are tied. If CLOSE is left as 0.0, it defaults to one percent of the mesh characteristic length scale. Nodes that are above or below the surface will be tied if they are close enough to the surface.
HCLOSE	Thermal contact conductivity for a tied interface, in case of using the option THERMAL in the contact
NTPRM	If TEMP < 0, number of user tied weld parameters; otherwise ignored. NTPRM allocates the array `cprm(*)` in subroutine `mortar_usrtie`.

VARIABLE	DESCRIPTION
NMHIS	If TEMP < 0, number of material history variables accessible from the user tied weld interface; otherwise ignored. NMHIS allocates the arrays `shis(*)` and `mhis(*)` in subroutine `mortar_usrtie`.
NSTWH	If TEMP < 0, number of SURFA tied weld history variables for the user tied weld interface. NSTWH allocates the array `shst(*)` in subroutine `mortar_usrtie`.
NMTWH	If TEMP < 0, number of SURFB tied weld history variables for the user tied weld interface. NMTWH allocates the array `mhst(*)` in subroutine `mortar_usrtie`.
TIME	This parameter applies to the Mortar tied weld contact only. The conditions above for tying/welding must be satisfied for at least TIME consecutive time units for tying/welding to occur. This option is intended to prevent premature tying/welding which may otherwise occur if only temperature is considered.

User Tied Welds Parameters Card. Insert as many cards needed to define NTPRM tied weld parameters.

Card 4.1	1	2	3	4	5	6	7	8
Variable	TPRM1	TPRM2	TPRM3	TPRM4	TPRM5	TPRM6	TPRM7	TPRM8
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

VARIABLE	DESCRIPTION
TPRM*i*	User tied welds parameter *i*

Remarks:

1. **Separation and Rigid Body Modes.** If there is significant separation between the tied surfaces, the rigid body modes will not be opposed by the contact stiffness. In other words, the offset between the surfaces is handled like the contact with OFFSET.

2. **Contact Behavior Below Welding Temperature.** If the surfaces are below the welding temperature, the surfaces interact with the standard AUTOMATIC_-SURFACE_TO_SURFACE options.

3. **MORTAR Contact.** The MORTAR option is primarily intended for implicit and is supported for SMP and MPP. With this option, the tied segments can be viewed in the intfor file by specifying NTIED on *DATABASE_EXTENT_INT-FOR. It is also possible to implement a user defined condition for tying segments, activated by TEMP < 0. See subroutine `mortar_usrtie` for comments and a sample code which is available in the source code of an object version of LS-DYNA. The history variables can subsequently be used in a Mortar tiebreak routine for assessing the quality of the lamination (see Remark 4 in the Card 4: AUTOMATIC_..._SURFACE_TO_SURFACE_TIEBREAK_USER_... section)._ .

Card 4: CONSTRAINT_..._TO_SURFACE

This card 4 is mandatory for:

*CONTACT_CONSTRAINT_NODES_TO_SURFACE

*CONTACT_CONSTRAINT_SURFACE_TO_SURFACE

Card 4	1	2	3	4	5	6	7	8
Variable	KPF							
Type	F							
Default	0.0							

VARIABLE	DESCRIPTION
KPF	Kinematic partition factor for constraint: EQ.0.0: Fully symmetric treatment EQ.1.0: One-way treatment with SURFA nodes constrained to SURFB surface. Only the SURFA nodes are checked against contact. EQ.-1.0: One-way treatment with SURFB nodes constrained to SURFA surface. Only the SURFB nodes are checked against contact.

Card 4: DRAWBEAD

This card 4 is mandatory for:

*CONTACT_DRAWBEAD

*CONTACT_DRAWBEAD_BENDING

*CONTACT_DRAWBEAD_INITIALIZE

Note that variables related to the automatic multiple draw bead feature, meaning NBEAD, POINT1, POINT2, WIDTH, and EFFHGT, only work with draw beads that are defined with node sets, not with beam elements. Also, NBEAD and the related variables on Card 4.4 can be used together with the option INITIALIZE or with the option BENDING.

The BENDING keyword option is for weakening the blank underneath the draw bead. See Weakening Effect below.

Card 4.1	1	2	3	4	5	6	7	8
Variable	LCIDRF	LCIDNF	DBDTH	DFSCL	NUMINT	DBPID	ELOFF	NBEAD
Type	I	I	F	F	I	I	I	I
Default	required	none	0.0	1.0	0	0	0	optional

Bending Card. Additional card for BENDING keyword option. This card is for modeling the draw bead weakening effect.

Card 4.2	1	2	3	4	5	6	7	8
Variable	EPM	EPSCALE	ENDING					
Type	F	F	F					
Default	none	none	10.					

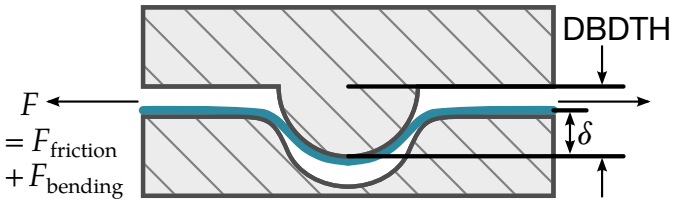

Figure 11-3. The draw bead contact model.

Initialization Card. Additional card for INITIALIZE keyword option. This card initializes the plastic strain and thickness of elements that pass under the draw bead.

Card 4.3	1	2	3	4	5	6	7	8
Variable	LCEPS	TSCALE	LCEPS2	OFFSET				
Type	I	F	I	F				
Default	required	1.0	optional	optional				

Additional card to be included if NBEAD in Card 4.1 is defined.

Card 4.4	1	2	3	4	5	6	7	8
Variable	POINT1	POINT2	WIDTH	EFFHGT				
Type	I	I	F	F				
Default	none	none	none	none				

VARIABLE	DESCRIPTION
LCIDRF	GT.0: Load curve ID giving the bending component of the restraining force, $F_{bending}$, per unit draw bead length as a function of displacement, δ; see Figure 11-3. This force is due to the bending and unbending of the blank as it moves through the draw bead. The total restraining force is the sum of the bending and friction components.
	LT.0: |LCIDRF| gives the load curve ID defining maximum bead force as a function of normalized draw bead length. The abscissa values are between zero and one and are the normalized draw bead length. The ordinate gives the maximum allowed draw bead retaining force when the bead is

VARIABLE	DESCRIPTION
	in the fully closed position. If the draw bead is not fully closed, linear interpolation is used to compute the draw bead force.
LCIDNF	Load curve ID giving the normal force per unit draw bead length as a function of displacement, δ; see Figure 11-3. This force originates from bending the blank into the draw bead as the binder closes on the die. The normal force begins to develop when the distance between the die and binder is less than the draw bead depth. As the binder and die close on the blank, this force should diminish or reach a plateau.
DBDTH	Draw bead depth; see Figure 11-3. This depth is needed to determine the correct displacement, δ, from contact displacements.
DFSCL	Scale factor for load curve (default = 1.0). This factor scales the load curve ID, LCIDRF, above.
NUMINT	Number of equally spaced integration points along the draw bead: EQ.0: Internally calculated based on element size of elements that interact with draw bead. This is necessary for the correct calculation of the restraining forces. More integration points may increase the accuracy since the force is applied more evenly along the bead.
DBPID	Optional part ID for the automatically generated truss elements used to display the draw bead during post-processing. If undefined, LS-DYNA assigns a unique part ID.
ELOFF	Option to specify an element ID offset for the truss elements that are automatically generated for displaying the draw bead during post-processing. If undefined, LS-DYNA chooses a unique offset.
NBEAD	Number of line beads. It must be an odd integer.
EPM	Maximum strain the blank will experience when it passes the bead
EPSCALE	Scale factor to weaken the stress-strain curve
ENDING	Parameter to define the length of the bead ends where the weakening effect will phase out
LCEPS	Load curve ID defining the plastic strain as a function of the parametric coordinate through the shell thickness. The parametric

VARIABLE	DESCRIPTION
	coordinate must be defined in the interval between -1 and 1 inclusive. The value of plastic strain at the integration point is interpolated from this load curve. If the plastic strain at an integration point exceeds the value of the load curve at the time initialization occurs, the plastic strain at the point will remain unchanged.
TSCALE	Scale factor that multiplies the shell thickness as the shell element moves under the draw bead
LCEPS2	Optional load curve ID defining the plastic strain as a function of the parametric coordinate through the shell thickness, which is used after an element has traveled a distance equal to OFFSET. The parametric coordinate should be defined in the interval between -1 and 1 inclusive. The value of plastic strain at the integration point is interpolated from this load curve. If the plastic strain at an integration point exceeds the value of the load curve at the time initialization occurs, the plastic strain at the point will remain unchanged. Input parameters LCEPS2 and OFFSET provides a way to model the case where a material moves under two draw beads. In this latter case the curve would be the sum of the plastic strains generate by moving under two consecutive beads.
OFFSET	If the center of an element has moved a distance equal to OFFSET, the load curve ID, LCEPS2, is used to reinitialize the plastic strain. The TSCALE scale factor is also applied.
POINT1	Node ID of the first node on a binder
POINT2	Node ID of a *matching* node on the opposing binder
WIDTH	Total bead width defining distance between the innermost and outermost bead walls
EFFHGT	Effective bead height. Draw bead restraining force starts to take effect when the binder gap is less than EFFHGT.

Overview:

For this draw bead model, the blank is the SURFB part, and the male part of the draw bead is SURFA. The male part of the draw bead, which moves with the punch, is input as a curve defined using a list of nodes or a part consisting of beams, as discussed below. Associated with this curve is a *region of influence* that is characterized by the DBDTH field of Card 4.1.

As the punch comes down and the region of influence intersects the elements on the blank, forces are applied to the blank at the points of closest approach. These forces depend on the penetration distance, δ, which is geometrically defined in Figure 11-3. The draw bead force model consists of two terms:

1. a *resisting force* which is a function of δ, and is defined through the load curve specified in the LCIDRF field. This force is applied in a direction opposite to velocity.

2. a *normal force*, which pushes the male part of the draw bead away from the blank as specified by LCIDNF. This normal force, in turn, is used to model friction, which depends on the product of the friction coefficient and the normal force.

The curve representing the male part of the draw bead can be defined in three ways:

1. a *consecutive* list of *SURFA* nodes that lie along the bead

2. a part ID of a beam that lies along the draw bead

3. a part set ID of beams that lie along the draw bead

For straight draw beads, only two nodes or a single beam need to be defined, that is, one at each end. For curved beads, many nodes or beams may be required to define the curvature of the bead geometry.

When beams are used to define the bead, each node, except for the first and last, must connect with two beam elements. Therefore, the number of SURFA nodes must equal the number of beam elements plus one.

The contact algorithm checks for penetration at the integration points. Integration points are equally spaced along the draw bead and do not depend on the nodal spacing used in the definition of the draw bead. By tying extra nodes to rigid bodies (see *CONSTRAINED_EXTRA_NODES or *CONSTRAINED_RIGID_BODIES), the draw bead nodal points do not need to belong to the element connectivities of the die and binder. The blank makes up the SURFB surface.

> **NOTE:** We recommended defining a box (see *DEFINE_BOX) around the draw bead to limit the size of the SURFB surface considered for the draw bead. This will substantially reduce the cost and memory requirements.

Multiple draw beads model:

Developed in conjunction with the *Ford Motor Company Research & Advanced Engineering Laboratory*, the multiple draw bead feature provides a simple way (1) to model the

neglected effects of the draw bead width and (2) to attenuate the bead forces when the distance between the upper and lower binders is more than the draw bead height.

1. **Draw Bead Width Correction.** As shown in Figure 11-4, a sheet blank edge often does not cross the draw bead's curve of definition but *does* fall within its width. When the bead is modelled as a 1-dimensional (no width) curve, no forces may be applied to a major portion of the blank. The neglect of width effects leads to excessive blank edge draw-ins resulting in either loose metal in the part or wrinkles on the draw wall or product surface.

   The multiple beads feature improves this shortcoming by replacing the single 1-dimensional bead with an equivalent set of beads distributed over the width of the physical bead. The bead force is distributed uniformly over the NBEAD sub-beads, such that the resultant force is equal to that of the original 1-dimensional bead. Note that NBEAD *must* be an odd integer.

   Figure 11-5 schematically represents the NBEAD = 3 case for which two additional line beads are automatically generated. The forces specified by the load curve, LCIDRF, is evenly distributed over the 3 beads. In Figure 11-6, bead forces are recovered from the ASCII rcforc files for both cases of NBEAD = 1 and 3, indicating the total force applied (shown on the left) on one single bead is distributed evenly among the three automatically generated beads for the case of NBEAD = 3.

   The stress distribution is also more realistic with multiple beads. In a channel draw (half model) as shown in Figure 11-10, no significant changes in mean stress values are found between NBEAD = 3 and one single line bead. In fact, the compressive stresses are more realistically and evenly distributed around the bead region, with stresses in NBEAD = 3 about 1/3 of those in a single line bead.

2. **Lower Binder Gap Correction.** As originally implemented, the draw bead contact model applies the draw bead forces, as specified in the load curve, when the upper binder reaches the blank, regardless of the lower binder's position. If the lower binder is not in contact with the blank, LS-DYNA still applies draw bead forces, even though it is unphysical to do so. The EFFHGT, POINT1 and POINT2 fields together provide a simple model to avoid these unphysical forces. The POINT1 and POINT2 fields are taken as nodes on the opposing binders. The draw bead contact is disabled when the Euclidean distance between POINT1 and POINT2 is greater than EFFHGT; consequently, the two nodes *must* be chosen so they converge to a single point as the draw bead closes.

   As shown in Figure 11-7, a simple model was built to verify the effectiveness of the variable EFFHGT. The upper binder is pushed down to close with the lower binder while a strip of sheet blank is being pulled in the direction indicated. The distance between the binders is 12 mm initially, as shown in Figure 11-8. The

closing gap and pulling force in the x-direction were recovered throughout the simulation. With EFFHGT set to 8 mm, the pulling force history indicates the bead forces starting to take effect after the upper binder has traveled for 4 mm as expected (see Figure 11-9).

Weakening Effect:

Without BENDING, the contact algorithm ignores the bending/unbending effect and the huge normal stress when the blank goes through the draw beads. As a result, material stretching during forming simulations cannot be predicted. The algorithm invoked with BENDING weakens the blank as it travels through the bead and stretches it when it passes through the bead.

Example:

The following partial keyword example shows how to use NBEAD with the option INITIALIZE. A total of 3 beads will be generated, including the original bead. The total bead width between the inner and outer most beads is 10.0 mm (WIDTH). The effective bead height EFFHGT is 1.11 mm, which is the gap between upper die and lower binder upon closing. Note the feature NBEAD only works with draw beads that are defined using a node set (#1001, which is used as SURFB in *CONTACT…), and the node set is constrained together with the lower binder (PID 8).

Card 4: ERODING_..._SURFACE

ERODING contacts update the active contact segments to account for erosion (deletion) of elements on the contact surface. Segments that could potentially become exposed to contact during the simulation are determined during initialization and that number of segments is reported in the contact description in d3hsp. However, at any given point in time during the simulation, only the subset consisting of currently exposed (external) segments is active in the contact evaluation.

This Card 4 is mandatory for:

*CONTACT_ERODING_NODES_TO_SURFACE

*CONTACT_ERODING_SINGLE_SURFACE

*CONTACT_ERODING_SURFACE_TO_SURFACE

Card 4	1	2	3	4	5	6	7	8
Variable	ISYM	EROSOP	IADJ					
Type	I	I	I					
Default	0	1	↓					

VARIABLE	DESCRIPTION
ISYM	Symmetry plane option: EQ.0: Off (default) EQ.1: Do not include faces with normal boundary constraints (such as segments of brick elements on a symmetry plane). This option is important for retaining the correct boundary conditions in the model with symmetry.
EROSOP	Erosion/interior node option (EROSOP is hardcoded to 1 for both SMP and MPP): EQ.0: Only exterior boundary information is saved. (This option is no longer supported.) EQ.1: Storage is allocated so that eroding contact can occur.

VARIABLE	DESCRIPTION
IADJ	Adjacent material treatment for solid elements (in the case of MPP, IADJ is hardcoded to 1): EQ.0: Solid element faces are included only for free boundaries (default for SMP). EQ.1: Solid element faces are included if they are on the boundary of the material subset. This option also allows for erosion within a body and the subsequent treatment of contact.

Remarks:

1. **Time Step.** Eroding contact may control the time step (see ECDT in *CONTROL_CONTACT).

2. **SURFA Type.** For ERODING_NODES_TO_SURFACE, define the SURFA side using a node set, not a part ID or part set ID.

3. **Negative Volume Failure Criterion.** ERODING contact automatically invokes a negative volume failure criterion for all solid elements in the model, except as overridden by PSFAIL in *CONTROL_SOLID. PSFAIL will limit the negative volume failure criterion to a set of solid parts. A negative volume failure criterion circumvents an error termination due to negative volume by deleting solid elements that develop negative volume.

4. **Contact Friction.** Contact friction is not considered by SMP LS-DYNA for *CONTACT_ERODING_NODES_TO_SURFACE and *CONTACT_ERODING_SURFACE_TO_SURFACE unless SOFT is set to 2 on Optional Card A. MPP LS-DYNA has no such exclusion for contact friction.

Card 4: SURFACE_INTERFERENCE

This Card 4 is mandatory for:

*CONTACT_NODES_TO_SURFACE_INTERFERENCE

*CONTACT_ONE_WAY_SURFACE_TO_SURFACE_INTERFERENCE

*CONTACT_SURFACE_TO_SURFACE_INTERFERENCE

Purpose: This contact option provides a means of modeling parts which are shrink fitted together and are, therefore, prestressed in the initial configuration. This option turns off the nodal interpenetration checks (which changes the geometry by moving the nodes to eliminate the interpenetration) at the start of the simulation and allows the contact forces to develop to remove the interpenetrations. The load curves defined in this section scale the interface stiffness constants such that the stiffness can increase slowly from zero to a final value with effect that the interface forces also increase gradually to remove the overlaps.

Card 4	1	2	3	4	5	6	7	8
Variable	LCID1	LCID2						
Type	I	I						
Default	0	0						

VARIABLE	DESCRIPTION
LCID1	Load curve ID which scales the interface stiffness during dynamic relaxation. This curve must originate at $(0,0)$ at time = 0 and gradually increase.
LCID2	Load curve ID which scales the interface stiffness during the transient calculation. This curve generally has a constant value of unity for the duration of the calculation if LCID1 is defined. If LCID1 = 0, this curve must originate at $(0,0)$ at time = 0 and gradually increase to a constant value.

Remarks:

1. **Shell thickness offsets.** In the case of MPP LS-DYNA, consideration of shell thickness offsets is controlled as in an "old" contact type, using SHLTHK, either

on *CONTROL_CONTACT or on Optional Card B of *CONTACT_..._INTERFERENCE.

In the case of SMP, shell thickness offsets are always considered with the lone exception being when THKOPT = 2 on Optional Card B of *CONTACT_..._INTERFERENCE.

2. **Penetrations and orientations.** The check to fix initial penetrations is skipped. Automatic orientation of shell elements is also skipped. Furthermore, segment orientation for shell elements and interpenetration checks *are skipped*. Therefore, it is necessary in the problem setup to ensure that all contact segments which belong to shell elements are properly oriented, that is, the outward normal vector of the segment based on the right-hand rule relative to the segment numbering, must point to the opposing contact surface. Consequently, automatic contact generation should be avoided for parts composed of shell elements unless automatic generation is used on the SURFA side of a nodes to surface interface.

3. **Resolving an interference during a transient phase preceded by a dynamic relaxation phase.** If LCID1 = 0 and LS-DYNA performs dynamic relaxation (such as for initializing the stresses in other components), the INTEFERENCE contact treats initial penetrations as specified by the IGNORE parameters on *CONTACT and *CONTROL_CONTACT. To make the INTERFERENCE contact inactive during a dynamic relaxation phase and resolve the penetrations during the subsequent transient phase based on the curve LCID2, use either of the two following approaches:

   a) Set the contact birth time BT equal to a negative value (BT < 0) that is in magnitude anything larger than the expected completion time of the dynamic relaxation phase. After completing dynamic relaxation, LS-DYNA activates the contact regardless of the value of BT.

   b) Specify curve LCID1 with zero ordinates (meaning a zero contact stiffness) during the dynamic relaxation phase.

   For both approaches, originate curve LCID2 at (0,0) at time = 0 and gradually increase the scale factor to a constant value.

Card 4: RIGID_TO_RIGID

This Card 4 is mandatory for:

*CONTACT_RIGID_NODES_TO_RIGID_BODY

*CONTACT_RIGID_BODY_ONE_WAY_TO_RIGID_BODY

*CONTACT_RIGID_BODY_TWO_WAY_TO_RIGID_BODY

Card 4	1	2	3	4	5	6	7	8
Variable	LCID	FCM	US		LCDC	DSF	UNLCID	
Type	I	I	F		I	F	I	
Default	required	required	LCID		optional	0.0	optional	

VARIABLE	DESCRIPTION
LCID	Load curve ID giving force as a function of penetration behavior for RIGID contact. See FCM below.
FCM	Force calculation method for RIGID contact: EQ.1: Load curve gives total normal force on surface as a function of maximum penetration of any node (RIGID_BODY_ONE_WAY only). EQ.2: Load curve gives normal force on each node as a function of the penetration of a node through the surface (all RIGID contact types). EQ.3: Load curve gives normal pressure as a function penetration of a node through the surface (RIGID_BODY_TWO_WAY and RIGID_BODY_ONE_WAY only). EQ.4: Load curve gives total normal force as a function of maximum soft penetration (RIGID_BODY_ONE_WAY only). In this case the force will be followed based on the original penetration point.
US	Unloading stiffness for RIGID contact. The default is to unload along the loading curve. This should be equal to or greater than the maximum slope used in the loading curve.

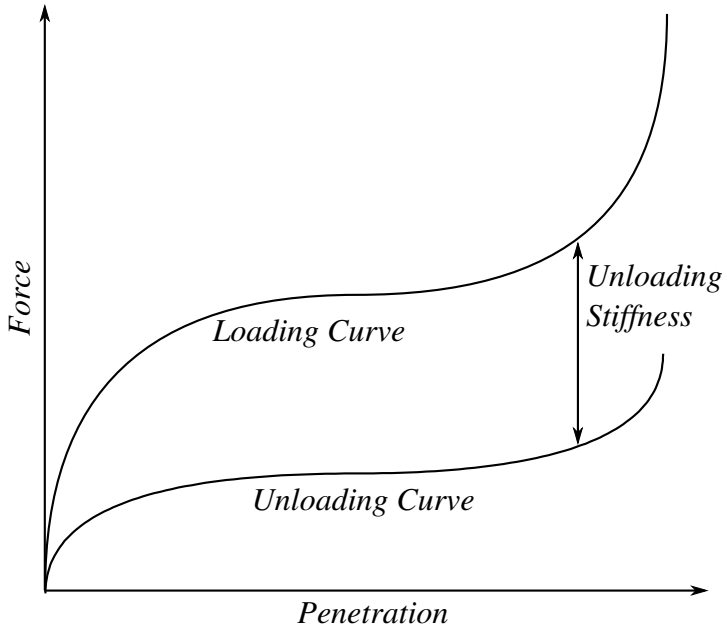

Figure 11-11. Behavior if an unloading curve is defined

VARIABLE	DESCRIPTION
LCDC	Load curve ID giving damping coefficient (DC) as a function of penetration velocity. The damping force FD is then: FD = DSF × DC × velocity.
DSF	Damping scaling factor
UNLCID	Optional load curve ID giving force as a function of penetration behavior for RIGID_BODY_ONE_WAY contact during unloading. This option requires the definition of the unloading stiffness, US. See Figure 11-11.

Card 4: TIEBREAK_NODES

This Card 4 is mandatory for:

*CONTACT_TIEBREAK_NODES_TO_SURFACE

*CONTACT_TIEBREAK_NODES_ONLY

Card 4	1	2	3	4	5	6	7	8
Variable	NFLF	SFLF	NEN	MES				
Type	F	F	F	F				
Default	required	required	2.	2.				

VARIABLE	DESCRIPTION
NFLF	Normal failure force. Only tensile failure, meaning tensile normal forces, will be considered in the failure criterion.
SFLF	Shear failure force
NEN	Exponent for normal force in the failure criterion
MES	Exponent for shear force in the failure criterion

Remarks:

1. **Node by Node Failure Attributes.** These fields can be overridden node by node with the attributes on the *SET_NODE data cards.

2. **Failure Criterion.** The tiebreak failure criterion is given as:

$$\left(\frac{|f_n|}{\text{NFLF}}\right)^{\text{NEN}} + \left(\frac{|f_s|}{\text{SFLF}}\right)^{\text{MES}} \geq 1 \ .$$

   Failure is assumed if the left side is larger than 1. f_n and f_s are the normal and shear interface force. Both NFLF and SFLF must be defined. If failure in only tension or shear is required, then set the other failure force to a large value (10^{10}).

3. **Contact Behavior after Failure.** After failure, CONTACT_TIEBREAK_-NODES_TO_SURFACE behaves as a nodes-to-surface contact with no thickness offsets (no interface tension possible) whereas the CONTACT_TIEBREAK_-

NODES_ONLY stops acting as a contact. Prior to failure, the two contact types behave identically.

Card 4: TIEBREAK_SURFACE

This Card 4 is mandatory for:

*CONTACT_TIEBREAK_SURFACE_TO_SURFACE

*CONTACT_TIEBREAK_SURFACE_TO_SURFACE_ONLY

Card 4	1	2	3	4	5	6	7	8
Variable	NFLS	SFLS	TBLCID	THKOFF				
Type	F	F	I	I				
Default	required	required	0	0				

VARIABLE	DESCRIPTION
NFLS	Tensile failure stress
SFLS	Shear failure stress
TBLCID	Optional load curve ID defining the resisting tensile stress as a function of gap opening in the normal direction for the post-failure response. This option applies only to SMP and can be used to model adhesives.
THKOFF	Thickness offsets are considered if THKOFF = 1. If shell offsets are included in the meshed geometry, this option is highly recommended since segment orientations can be arbitrary and the contact surfaces can be disjoint. This option is *not* available in the MPP version of LS-DYNA. It works by substituting with *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK (OPTION = 2 if TBLCID is not specified; OPTION = 5 if TBLCID is specified).

Remarks:

1. **Segment by Segment Failure Attributes.** The failure fields, NFLS and SFLS, can be overridden segment by segment on the *SET_SEGMENT or *SET_SHELL data cards for the SURFA surface with A1 and A2, respectively. These variables do not apply to the SURFB surface.

2. **Failure Criterion.** The tiebreak contact fails when:

$$\left(\frac{|\sigma_n|}{\text{NFLS}}\right)^2 + \left(\frac{|\sigma_s|}{\text{SFLS}}\right)^2 \geq 1 \ .$$

Both NFLS and SFLS must be defined. If failure in only tension or shear is required, then set the other failure stress to a large value (10^{10}). When used with shells, contact segment normal vectors are used to establish the tension direction (as opposed to compression). Compressive stress does not contribute to the failure equation.

3. **Contact Behavior after Failure.** After failure, *CONTACT_TIEBREAK_SURFACE_TO_SURFACE behaves as a surface-to-surface contact with no thickness offsets while *CONTACT_TIEBREAK_SURFACE_TO_SURFACE_ONLY stops acting as a contact altogether. Until failure, it ties the SURFA nodes to the SURFB segments.

4. **Contact Stiffness**. Contact stiffness is based on the SURFB side. The variables PENOPT and SOFT have no effect on contact stiffness.

Card 4: CONTRACTION_JOINT

This Card 4 is mandatory for:

*CONTACT_SURFACE_TO_SURFACE_CONTRACTION_JOINT

Purpose: This contact option turns on the contraction joint model designed to simulate the effects of sinusoidal joint surfaces (shear keys) in the contraction joints of arch dams and other concrete structures. The sinusoidal functions for the shear keys are defined according to the following three methods [Solberg and Noble 2002]:

a) *Method 1.*

$$\hat{g} = g - A\{1 - \cos[B(s_2 - s_1)]\}$$

b) *Method 2.*

$$\hat{g} = g - 2A\left|\sin\left[\frac{B(s_2 - s_1)}{2}\right]\right|$$

c) *Method 3 (default).*

$$\hat{g} = g - A\cos(Bs_2) + A\cos(Bs_1)$$

Here g is a gap function for the contact surface and $\hat{g}$ is a gap function for the joint surface. A is the key amplitude parameter, and B is the key frequency parameter. s_1 and s_2 are referential surfaces:

$$s_1 = \mathbf{X}_{\text{surface1}} \cdot \mathbf{T}_{\text{key}}$$
$$s_2 = \mathbf{X}_{\text{surface2}} \cdot \mathbf{T}_{\text{key}}$$
$$\mathbf{T}_{\text{key}} = \mathbf{T}_{\text{slide}} \times \mathbf{n}$$

$\mathbf{T}_{\text{slide}}$ is the free sliding direction of the keys and $\mathbf{n}$ is the surface normal in reference.

Card 4	1	2	3	4	5	6	7	8
Variable	MTCJ	ALPHA	BETA	TSVX	TSVY	TSVZ		
Type	I	F	F	F	F	F		
Default	0	0.0	0.0	0.0	0.0	0.0		

VARIABLE	DESCRIPTION
MTCJ	The method option for the gap function, $\hat{g}$
ALPHA	Key amplitude parameter, A

VARIABLE	DESCRIPTION
BETA	Key frequency parameter, B
TSVX	x component of the free sliding direction $\mathbf{T}_{\text{slide}}$
TSVY	y component of the free sliding direction $\mathbf{T}_{\text{slide}}$
TSVZ	z component of the free sliding direction $\mathbf{T}_{\text{slide}}$

THERMAL:

THRM 1 is mandatory for the THERMAL (and THERMAL_FRICTION) option, meaning:

*CONTACT_..._THERMAL_...

NOTE: If Card 4 is required, then it must go before THRM 1. (Card 4 is required for certain contact types.)

Thermal Card 1.

THRM 1	1	2	3	4	5	6	7	8
Variable	K	FRAD	H0	LMIN	LMAX	FTOSA	BC_FLG	ALGO
Type	F	F	F	F	F	F	I	I
Default	none	none	none	none	none	0.5	0	0

VARIABLE **DESCRIPTION**

K Thermal conductivity of fluid between the contact surfaces. If a gap with a thickness l_{gap} exists between the contact surfaces, then the conductance due to thermal conductivity between the contact surfaces is

$$h_{cond} = \frac{K}{l_{gap}} .$$

Note that LS-DYNA calculates l_{gap} based on deformation (see Remark 2).

FRAD Radiation factor, f_{rad}, between the contact surfaces:

$$f_{rad} = \frac{\sigma}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} ,$$

where

σ = Stefan-Boltman constant
ε_1 = emissivity of SURFA surface
ε_2 = emissivity of SURFB surface

LS-DYNA calculates the radiant heat transfer conductance as

$$h_{rad} = f_{rad}(T_{SURFA} + T_{SURFB})\left(T_{SURFA}^2 + T_{SURFB}^2\right) .$$

VARIABLE	DESCRIPTION
H0	Heat transfer conductance for closed gaps. Use this heat transfer conductance for gaps in the range $$0 \le l_{gap} \le l_{min} \ .$$
LMIN	Minimum gap, l_{min}. The heat transfer conductance defined above (H0) is used for gap thicknesses less than this value. If $l_{min} < 0$, then $-l_{min}$ is a load curve number defining l_{min} as a function time.
LMAX	No thermal contact if the gap is greater than this value (l_{max})
FTOSA	Fraction, f, of sliding friction energy partitioned to the SURFA surface (see Remark 3). Energy partitioned to the SURFB surface is $(1-f)$. EQ.0: Set to 0.5 (default). The sliding friction energy is partitioned 50% - 50% to the SURFA and SURFB surfaces in contact.
BC_FLAG	Thermal boundary condition flag: EQ.0: Thermal boundary conditions are on when parts are in contact. EQ.1: Thermal boundary conditions are off when parts are in contact.
ALGO	Thermal Contact algorithm type: EQ.0: Two-way contact. Both surfaces change temperature due to contact EQ.1: One-way contact. Surface of SURFB does not change temperature due to contact. Surface of SURFA does change temperature. EQ.2: Two-way edge contact EQ.3: One-way edge contact (no heat transfer into the reference side)

NOTE: For ALGO = 2 and 3, shell edges must be on the SURFA side, and solid facets and shell surface need to be on the SURFB side.

Remarks:

1. **Contact Types.** Thermal contact involves heat transfer across surfaces, so the contact definition must be of a SURFACE_TO_SURFACE type. Thus, in general the NODES_TO_SURFACE contacts cannot be used, and an error termination will be the result. The exception is TIED_NODES_TO_SURFACE and TIED_SHELL_EDGE_TO_SURFACE contacts with the SURFA side *not* defined with node sets. The TIED_NODES_TO_SURFACE and TIED_SHELL_EDGE_TO_SURFACE contacts also allow thermal contact with beam elements. These contacts can model, for instance, heat transfer through spot weld beams used for tying opposite surfaces. Thermal contact with beam elements is otherwise only supported for Mortar contacts, by inheriting the Mortar algorithms from the mechanical side of the contact.

2. **Heat Conductance.** The heat conductance is calculated as

$$h = \begin{cases} h_0 & 0 \le l_{\text{gap}} \le l_{\text{min}} \\ h_{\text{cond}} + h_{\text{rad}} & l_{\text{min}} < l_{\text{gap}} \le l_{\text{max}} \\ 0 & l_{\text{gap}} > l_{\text{max}} \end{cases}$$

   LS- DYNA calculates l_{gap} based on deformation.

3. **Sliding Friction Energy Fraction.** f can be calculated using:

$$f = \frac{1}{1 + \dfrac{\sqrt{(\rho C_p k)_{\text{SURFB side material}}}}{\sqrt{(\rho C_p k)_{\text{SURFA side material}}}}}$$

THERMAL_FRICTION:

THRM 2 is required after THRM 1 if the FRICTION suffix is added to THERMAL.

*CONTACT_…_THERMAL_FRICTION_…

The blank (or work piece) must be defined as SURFA in a metal forming model.

Purpose:

1. Used to define the mechanical static and dynamic friction coefficients as a function of temperature.
2. Used to define the thermal contact conductance as a function of temperature and pressure.

VARIABLE	DESCRIPTION
LCFST	Load curve ID for static coefficient of friction as a function of temperature. The load curve value multiplies the coefficient value FS. For Mortar contact, the static coefficient of friction can be given as a load curve or table. In the case of a load curve, it is a function of the mean temperature, $(T_{\text{SURFA}} + T_{\text{SURFB}})/2$, in the contact interface. In the case of a table, the static coefficient of friction is an arbitrary function of T_{SURFA} and T_{SURFB}; each value of T_{SURFB} should be associated with a curve having T_{SURFA} as the abscissa.
LCFDT	Load curve ID for dynamic coefficient of friction as a function of temperature. The load curve value multiplies the coefficient value FD. For Mortar contact, the dynamic coefficient of friction can be given as a load curve or table. In the case of a load curve, it is a function of the mean temperature, $(T_{\text{SURFA}} + T_{\text{SURFB}})/2$, in the contact interface. In the case of a table, the dynamic coefficient of friction is an arbitrary function of T_{SURFA} and T_{SURFB}; each value of T_{SURFB} should be associated with a curve having T_{SURFA} as the abscissa.
FORMULA	Formula that defines the contact heat conductance as a function of temperature and pressure. EQ.1: $h(P)$ is defined by load curve A, which contains data for contact conductance as a function of pressure. EQ.2: $h(P)$ is given by the following where A, B, C and D although defined by load curves are typically constants for use in this formula. The load curves are functions of temperature. $$h(P) = a + bP + cP^2 + dP^3$$ EQ.3: $h(P)$ is given by the following formula from [Shvets and Dyban 1964]: $$h(P) = \frac{\pi k_{\text{gas}}}{4\lambda}\left[1. + 85\left(\frac{P}{\sigma}\right)^{0.8}\right] = \frac{a}{b}\left[1. + 85\left(\frac{P}{c}\right)^{0.8}\right]$$ where, a: is evaluated from the load curve, A, for the thermal conductivity, k_{gas}, of the gas in the gap as a function of temperature. b: is evaluated from the load curve, B, for the parameter grouping $\pi/4\lambda$. Therefore, this load curve should be set to a constant value. λ is the surface roughness.

VARIABLE	DESCRIPTION

c: is evaluated from the load curve, C, which specifies a stress metric for deformation (such as yield) as a function of temperature.

EQ.4: $h(P)$ is given by the following formula from [Li and Sellars 1996]:

$$h(P) = a\left[1 - \exp\left(-b\frac{P}{c}\right)\right]^d$$

where,

a: is evaluated from the load curve, A, which defines a load curve as a function of temperature.

b: is evaluated from the load curve, B, which defines a load curve as a function of temperature.

c: is evaluated from the load curve, C, which defines a stress metric for deformation (such as yield) as a function of temperature.

d: is evaluated from the load curve D, which is a function of temperature.

EQ.5: $h(\text{gap})$ is defined by load curve A, which contains data for contact conductance as a function of interface gap.

LT.0: This is equivalent to defining the keyword *USER_INTERFACE_CONDUCTIVITY. The user subroutine `usrhcon` will be called for this contact interface to define the contact heat transfer coefficient.

A — Load curve ID for the *a* coefficient used in the formula

B — Load curve ID for the *b* coefficient used in the formula

C — Load curve ID for the *c* coefficient used in the formula

D — Load curve ID for the *d* coefficient used in the formula

LCH — Load curve ID for *h*. If defined, this input takes precedence over any other definitions. This parameter can refer to a curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION). When LCH is a curve ID (and a function ID) it is interpreted as follows:

GT.0: The heat transfer coefficient is defined as a function of time, *t*, by a curve consisting of $(t, h(t))$ data pairs.

VARIABLE	DESCRIPTION
	LT.0: The heat transfer coefficient is defined as a function of temperature, T, by a curve consisting of $(T, h(T))$ data pairs.

When the reference is to a function, it is prototyped as $h = h(t, T_{\text{avg}}, T_{\text{SURFA}}, T_{\text{SURFB}}, P, g)$ where:

t = solution time
T_{avg} = average interface temperature
T_{SURFA} = SURFA segment temperature
T_{SURFB} = SURFB segment temperature
P = interface pressure
g = gap distance between SURFA and SURFB segment

UC*i*	User parameters

VARIABLE	DESCRIPTION
FS*n*_SA or SB	Static coefficient of friction in the local *n* orthotropic direction for the SURFA (SA) or SURFB (SB) surface. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact, $\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}$, where the direction and surface are left off for clarity. When contacts with ORTHO_FRICTION are defined by segment sets, each segment allows the specification of an offset angle in degrees from the 1-2 side of the segment which locates the 1-direction for the friction. The offset angle is input as the first attribute of the segment in *SET_SEGMENT. The transverse direction, or 2-direction, is in the plane of the segment and is perpendicular to the 1-direction. The offset angle is taken as zero when part (set) IDs are used in the contact definition. See *DEFINE_FRICTION_ORIENTATION for remarks regarding use of *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE_ORTHO_FRICTION.
FDI_SA or SB	Dynamic coefficient of friction in the local *n* orthotropic direction
DC*n*_SA or SB	Exponential decay coefficient for the local *n* direction
VC*n*_SA or SB	Coefficient for viscous friction in the local *n* direction. See the description for VC for mandatory Card 2 above.
LC*n*_SA or SB	Table ID of a two-dimensional table (see *DEFINE_TABLE or *DEFINE_TABLE_2D) giving the friction coefficient in the local *n* direction as a function of the relative velocity and interface pressure. In this case, each curve in the table definition defines the coefficient of friction as a function of the interface pressure corresponding to a particular value of the relative velocity.

VARIABLE	DESCRIPTION
OACS_SA or SB	If the default value, 0, is active, the frictional forces acting on a node sliding on a segment are based on the local directions of the segment. If OACS is set to unity, 1, the frictional forces acting on a node sliding on a segment are based on the local directions of the sliding node. No matter what the setting for OACS, the _SA coefficients are always used for SURFA nodes and the _SB coefficients for SURFB nodes.
LCFSA or SB	Optional load curve that gives the coefficient of friction as a function of the direction of relative motion, as measured in degrees from the first orthotropic direction. If this load curve is specified, the other parameters (FS, FD, DC, VC, LC) are ignored. This is currently only supported in the MPP version.
LCPSA or SB	Optional load curve that gives a scale factor for the friction coefficient as a function of interface pressure. This is only used if LCFSA (or SB) is defined.

Remarks:

1. **Orthotropic Friction for Mortar Contact.** For Mortar contact, we consider what is going on in the plane of surface A with normal $\mathbf{n}$, and refer to Figure 11-12. The orthotropic friction law is based on an elliptic yield surface:

$$p \geq \sqrt{\left(\frac{t_\parallel}{\mu_\parallel}\right)^2 + \left(\frac{t_\perp}{\mu_\perp}\right)^2}$$

for the Coulomb friction law. This surface is a cone in the pressure-traction space as shown in Figure 11-12. We also mandate that the slip direction is associative

$$\mathbf{v} \sim \frac{\partial p}{\partial \mathbf{t}} \ ,$$

resulting in an angle δ between the slip and traction. Here p is the contact pressure, $\mathbf{t} = t_\parallel \mathbf{a}_\parallel + t_\perp \mathbf{a}_\perp$ is the traction vector and $\boldsymbol{\mu} = \{\mu_\parallel, \mu_\perp\}$ are the coefficients of friction in the orthonormal system $\mathbf{A} = \{\mathbf{a}_\parallel, \mathbf{a}_\perp\}$ of surface A. Similarly, we have the orthonormal system $\mathbf{B} = \{\mathbf{b}_\parallel, \mathbf{b}_\perp\}$ on surface B which is related to $\mathbf{A}$ by rotating it an angle γ with respect to the normal $\mathbf{n}$ of surface A. First we need to mention how these systems, $\mathbf{A}$ and $\mathbf{B}$, are constructed in the first place.

We assume that the materials of the interacting surfaces are anisotropic. Then $\mathbf{a}_\parallel$ is the *first* material direction of the material constituting surface A and $\mathbf{b}_\parallel$ is likewise the corresponding first material direction on surface B. Therefore,

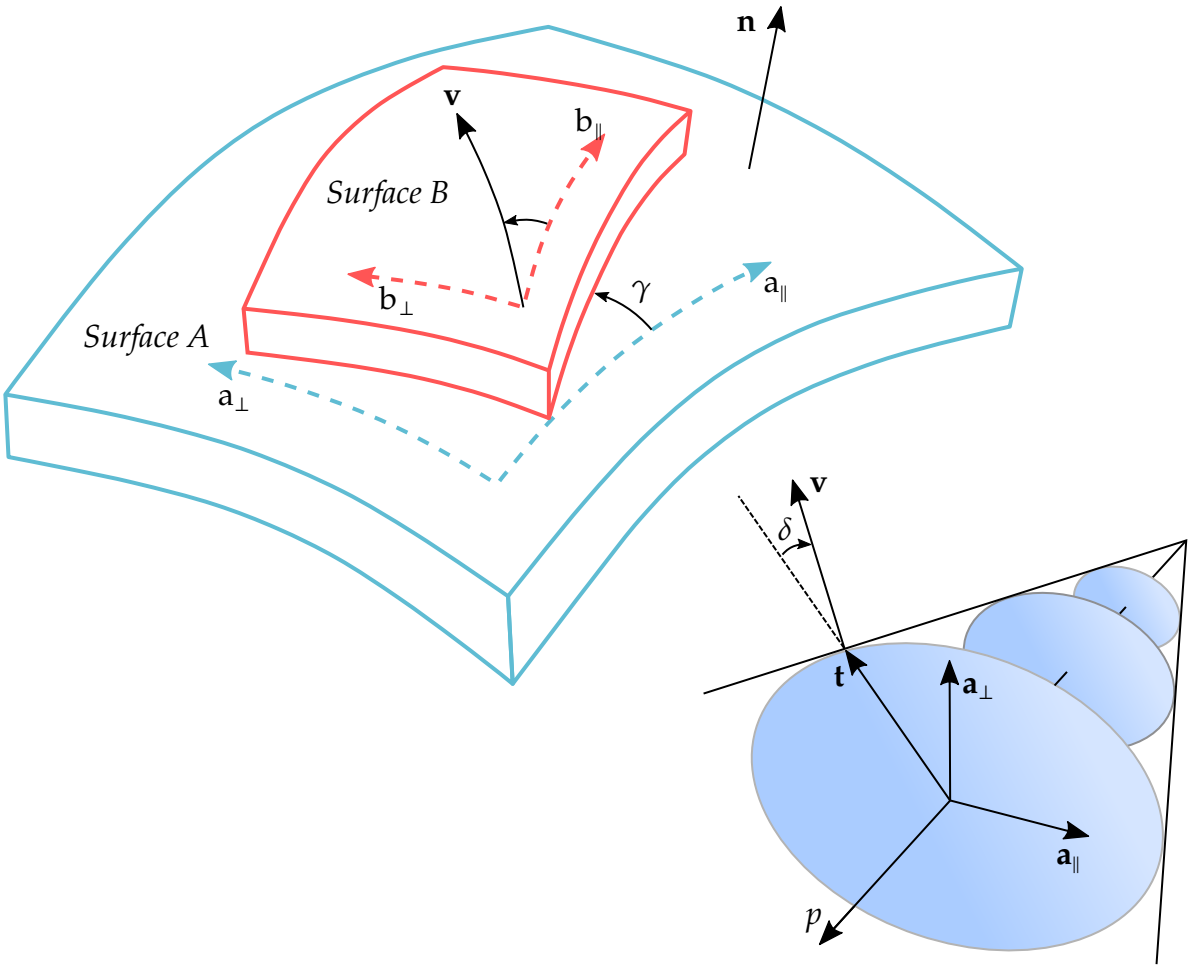

Figure 11-12. Definitions of terms for orthotropic friction in Mortar contact. Surface B with its main fibers in direction $\mathbf{b}_\parallel$ slides on surface A with its fibers in direction $\mathbf{a}_\parallel$. The contact pressure is p and the sliding velocity of surface A relative to B is in the direction $\mathbf{v}$. This results in a frictional traction, $\mathbf{t}$, on surface A directed (by and large) in the same direction as $\mathbf{v}$. The corresponding traction on surface B is in the opposite direction and of the same magnitude as $\mathbf{t}$.

currently the orthotropic directions for mortar contact are *not* set on the contact card but are inherited from the underlying materials. In Figure 11-12, **A** and **B** should not be confused with element specific directions, as this exposition is completely independent of finite elements.

The friction coefficients $\boldsymbol{\mu}$ are determined from the angle γ (see Figure 11-12) through direction cosines

$$\alpha = \cos^2\gamma = (\mathbf{a}_\parallel \cdot \mathbf{b}_\parallel)^2 = (\mathbf{a}_\perp \cdot \mathbf{b}_\perp)^2$$
$$\beta = \sin^2\gamma = (\mathbf{a}_\perp \cdot \mathbf{b}_\parallel)^2 = (\mathbf{a}_\parallel \cdot \mathbf{b}_\perp)^2$$

as

$$\mu_\parallel = \alpha \text{ FS1\_SA} + \beta \text{ FS1\_SB}$$

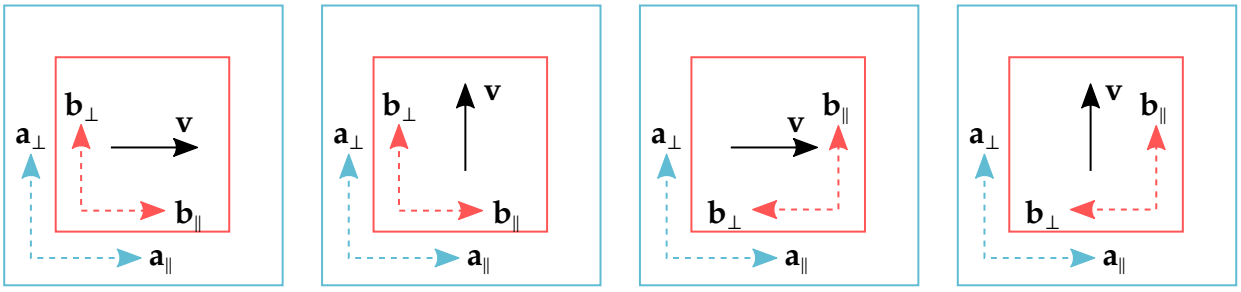

Figure 11-13. Interpretation of input parameters for Mortar orthotropic friction

$$\mu_{\perp} = \alpha \text{ FS2\_SA} + \beta \text{ FS2\_SB}.$$

It follows that the interpretation of the input parameters that are relevant for Mortar orthotropic friction are (see Figure 11-13):

a) FS1_SA being the coefficient of friction for $\mathbf{v}$ in direction $\mathbf{a}_{\parallel}$ when $\mathbf{a}_{\parallel}$ is aligned with $\mathbf{b}_{\parallel}$.

b) FS1_SB being the coefficient of friction for $\mathbf{v}$ in direction $\mathbf{a}_{\parallel}$ when $\mathbf{a}_{\parallel}$ is aligned with $\mathbf{b}_{\perp}$.

c) FS2_SA being the coefficient of friction for $\mathbf{v}$ in direction $\mathbf{a}_{\perp}$ when $\mathbf{a}_{\parallel}$ is aligned with $\mathbf{b}_{\parallel}$.

d) FS2_SB being the coefficient of friction for $\mathbf{v}$ in direction $\mathbf{a}_{\perp}$ when $\mathbf{a}_{\parallel}$ is aligned with $\mathbf{b}_{\perp}$.

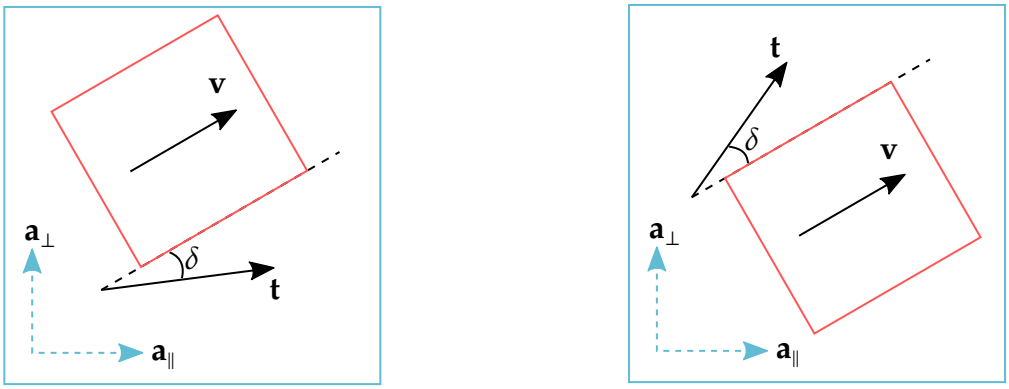
The effective friction coefficient will then be determined by the yield surface and flow rule as

$$\mu = \frac{\|\mathbf{t}\|}{p}$$

and thus, determines the relationship between contact pressure p and magnitude of sliding traction $\boldsymbol{t}$.

The behavior for relative sliding $\mathbf{v}$ in either of the main A directions $\mathbf{a}_{\parallel}$ and $\mathbf{a}_{\perp}$ is by design quite intuitive; the effective friction coefficients will be $\mu_{\parallel}$ and $\mu_{\perp}$, respectively, and the tractions $\mathbf{t}$ are collinear with the sliding. However, from the associative slip law the traction $\mathbf{t}$ and sliding $\mathbf{v}$ are not *always* pointing in the exact same direction, and this is explained best by considering two situations. With prescribed sliding $\mathbf{v}$ in some other direction than $\mathbf{a}_{\parallel}$ or $\mathbf{a}_{\perp}$, the resulting traction vector $\mathbf{t}$ will have its main component in the direction of sliding, but also a (nonzero) component towards the direction with the *largest* friction coefficient. The corresponding tendency will be seen with a prescribed traction $\mathbf{t}$, for which

the resulting sliding direction **v** will tend towards the direction with the *smallest* friction coefficient. See Figure 11-14.



$\mu_\perp < \mu_\parallel$ $\mu_\perp > \mu_\parallel$

Figure 11-14. Illustration of how direction of sliding differs from the traction direction depending on the coefficients of friction

Optional Card A:

> **NOTE:** If Card 4 is required, then it must go before this card. (Card 4 is required for certain contact types.)

Optional Card A.

Card A	1	2	3	4	5	6	7	8
Variable	SOFT	SOFSCL	LCIDAB	MAXPAR	SBOPT	DEPTH	BSORT	FRCFRQ
Type	I	F	I	F	I	I	I	I
Default	0	.1	0	1.025	2	2	10-100	1
Remarks			type a13					

VARIABLE	DESCRIPTION
SOFT	Contact formulation: EQ.0: Standard penalty formulation EQ.1: Soft constraint penalty formulation. See About SOFT = 1. EQ.2: Segment-based contact penalty formulation. See About SOFT = 2. EQ.4: Constraint approach for FORMING contacts. This formulation only applies to one-way forming contacts. You should use it when the penalty formulations result in large penetrations. The results, however, are sensitive to damping. EQ.6: Special contact algorithm to handle sheet blank edge (deformable) to gage pin (rigid shell) contact during implicit gravity loading. This applies to *CONTACT_FORMING_NODES_TO_SURFACE only. See remarks under About SOFT = 6.
SOFSCL	Scale factor for constraint forces of soft constraint option invoked with SOFT = 1 (default = 0.10). Values greater than 0.5 for single surface contact and 1.0 for one-way treatment are inadmissible.

VARIABLE	DESCRIPTION
LCIDAB	Load curve ID defining airbag thickness as a function of time for type a13 contact (*CONTACT_AIRBAG_SINGLE_SURFACE).
MAXPAR	Maximum parametric coordinate in segment search (values between 1.025 and 1.20 are recommended). This variable applies only to SMP; for MPP, see PARMAX on MPP 1. Larger values can increase the cost. If zero, MAXPAR defaults to 1.025 for most contact options. The exceptions to this are listed in the table below.

Contact Option	Default
SPOTWELD	1.006
TIED_SHELL_..._CONSTRAINED_OFFSET	1.006
TIED_SHELL_..._OFFSET	1.006
TIED_SHELL_..._BEAM_OFFSET	1.006
AUTOMATIC_GENERAL	1.100

This factor allows for an increase in the size of the segments which may be useful at sharp corners. For the SPOTWELD and …_OFFSET options larger values can sometimes lead to numerical instabilities; however, a larger value is sometimes necessary to ensure that all nodes of interest are tied.

SBOPT — Segment-based (SOFT = 2) contact options (see About SOFT = 2):

- EQ.0: Defaults to 2
- EQ.1: Pinball edge-edge contact (not recommended)
- EQ.2: Assume planer segments (default)
- EQ.3: Warped segment checking
- EQ.4: Sliding option
- EQ.5: Do options 3 and 4

DEPTH — Search depth in automatic contact to check for nodal penetration through the closest contact segments. A value of 1 (one segment) is sufficiently accurate for most crash applications and is much less expensive. By default, this value is 2 (two segments) for improved

VARIABLE	DESCRIPTION
	accuracy, except for *CONTACT_AUTOMATIC_GENERAL which has a default of 3.
	LT.0: |DEPTH| is the load curve ID defining searching depth as a function of time. (not available when SOFT = 2)
	See Fields used with SOFT = 2 under About SOFT = 2 for segment-based contact options controlled by DEPTH.
BSORT	Number of cycles between bucket sorts. Values of 25 and 100 are recommended for contact types 4 (SINGLE_SURFACE) and 13 (AUTOMATIC_SINGLE_SURFACE), respectively. Values of 10-15 are okay for surface-to-surface and node-to-surface contact. If zero, LS-DYNA determines the interval. BSORT applies only to SMP (see BCKT on MPP 1 for MPP) except in the case of SOFT = 2 or for Mortar contact, in which case BSORT applies to both SMP and MPP. For Mortar contact the default is the value associated with NSBCS on *CONTROL_CONTACT.
	LT.0: |BSORT| is the load curve ID defining bucket sorting frequency as a function of time.
FRCFRQ	Number of cycles between contact force updates for penalty contact formulations. This option can provide a significant speed-up of the contact treatment. If used, values exceeding 3 or 4 are dangerous. Considerable care must be exercised when using this option, as this option assumes that contact does not change FRCFRG cycles.
	EQ.0: FRCFRG is set to 1, and force calculations are performed each cycle (strongly recommended).

Remarks:

1. **Contact Stiffness Based on Stability.** Setting SOFT = 1 or 2 on optional contact Card A will cause the contact stiffness to be determined based on stability considerations by taking into account the time step and nodal masses. This approach is generally more effective for contact between materials of dissimilar stiffness or dissimilar mesh densities.

2. **Switching between SOFT = 1 and SOFT = 2.** By adding "soft=2to1" on the LS-DYNA execution line, all occurrences of SOFT = 2 in a model will be changed to SOFT = 1. Conversely, by adding "soft=1to2" on the execution line, all occurrences of SOFT = 1 in a model will be changed to SOFT = 2 (other variables related to SOFT = 2, such as SBOPT and DEPTH are left unchanged).

About SOFT = 1:

The soft constraint formulation (SOFT = 1) may be helpful if the material constants of the elements which make up the surfaces in contact have a wide variation in the elastic bulk moduli because the interface stiffness is based on the nodal mass and the global time step size. This method of computing the interface stiffness will typically give a much higher stiffness value than would be obtained by using the bulk modulus. Therefore, this method is the preferred approach when soft foam materials interact with metals.

Note that with this method LS-DYNA computes two contact stiffnesses, $k_{soft=0}$ and k_{cs}. These stiffnesses are the contact stiffness calculated for SOFT = 0 and the stability contact stiffness, respectively. Generally, the maximum of these two stiffness is the stiffness for SOFT = 1. See the theory manuals for details about how these contact stiffnesses are calculated.

About SOFT = 2:

What is Segment-Based Contact
Traditionally, to determine contact, the nodes of one surface are checked to see if they penetrate the segments of another surface. The direction of the applied penalty force depends on the direction of the reference segment's normal vector at the contact point. With SOFT = 2, when not specifically used with one-way contact types, the contact algorithm looks for all segment-to-segment penetration. The algorithm then decides which segments are the tracked and reference segments and thus which direction to apply the contact force. It generally chooses the segment that penetrates less as the tracked segment. Then the normal vector of the other segment gives the penalty direction. For one-way contact with SOFT = 2, SURFA and SURFB determine the tracked and reference segments, respectively.

Why use Segment-Based Contact
For certain situations, node-to-segment contact can lead to undesirable behavior. For instance, if a node of one surface contacts another surface at a corner, determining the reference segment normal is ambiguous (see Figure 11-15). Segment-based contact solves this problem. It looks at segments contacting segments and the directions of the segment normal vectors, thus making the contact direction less ambiguous.

Another problem arises when two segments come into contact at a T-intersection (see Figure 11-16). In traditional contact the tracked node would be pushed away from the reference segment in the direction normal to the reference segment. This behavior may not always be physical even in symmetric contact when both sides are checked for penetration. With segment-based contact, excluding one-way, the contact algorithm determines the tracked and reference segments. As mentioned previously, it selects the segment that penetrates less as the tracked segment. The other segment is the reference and gives the contact force direction. With Figure 11-16 as an example, the blue segment

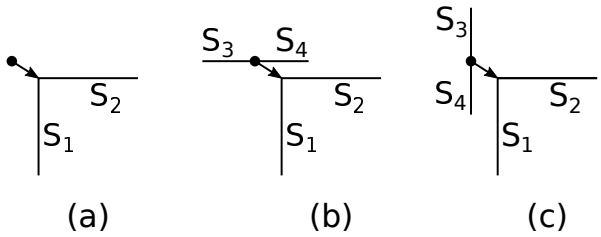


Figure 11-15. (a) illustrates the ambiguity of node to segment contact at normal since there is no knowledge about the shape of the surface impacting the corner. With segment-based contact, this difficulty is resolved since it looks at segments coming into contact with segments. Thus LS-DYNA can judge the difference between cases (b) and (c).

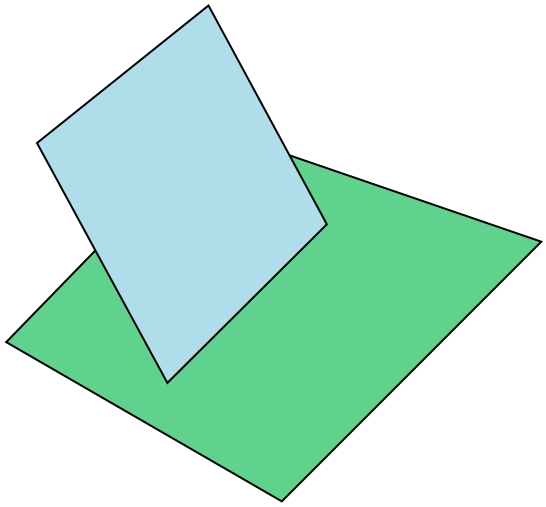

Figure 11-16. Example of two segments coming into contact at a T-intersection. The algorithms for segment-based contact would choose the direction of the contact force as the normal direction to the segment in green.

is penetrating the green segment less. Therefore, the normal direction for the contact force is chosen to be the normal vector of the green segment. Note that for one-way contact, the direction is always the normal vector to the segments in SURFB. Thus, if the segment in blue is in SURFB, unphysical results will occur.

When segment-based contact is available

Segment-based contact is for general shell and solid element contact. It is available for contact types with SURFACE_TO_SURFACE, ONE_WAY_SURFACE_TO_SURFACE, and SINGLE_SURFACE in the name that may additionally include AUTOMATIC, ERODING, and AIRBAG. When the contact type includes AUTOMATIC, the orientation of shell segment normal vectors is automatic. Otherwise, the segment or element orientations are used as input.

Fields used with SOFT = 2
Fields that do *not* apply to the supported contact types are *not* used, such as FLANGL on optional Card C. Only the GRPABLE field is supported on the MPP cards. All fields on mandatory Cards 1, 2, and 3 are active, except for VSF and PENCHK. On optional Card A, some parameters have different meanings than they do for the default contact which are discussed in detail below. The negative MAXPAR input on optional Card A is no longer supported. The data previously input with a negative MAXPAR can be input using the DTSTIF parameter on optional Card C. PENMAX, THKOPT, and SHLTHK on optional Card B are also not used (only the ISYM, I2D3D, SLDTHK, and SLDSTF parameters are active). IGNROFF on Card F is also not supported.

For SOFT = 2, the SBOPT parameter on optional Card A controls several options. Setting DEPTH = 1 for pinball edge-to-edge checking is not recommended and is included only for backward compatibility. For edge-to-edge checking setting DEPTH = 5 is recommended instead (see below). The warped segment option more accurately checks for penetration of warped surfaces. The sliding option uses neighbor segment information to improve sliding behavior. It is primarily useful for preventing segments from incorrectly catching nodes on a sliding surface.

For SOFT = 2, the DEPTH parameter controls several additional options for segment-based contact.

1. **DEPTH = 2 (default; but not recommended).** Surface penetrations measured at nodes are checked.

2. **DEPTH = 3.** Surface penetration is also measured at the edge. This option is more accurate than DEPTH = 2 and is good for a wide variety of simulations but does not check for edge-to-edge penetration.

3. **DEPTH = 5.** Both surface penetrations and edge-to-edge penetrations are checked.

4. **DEPTH = 13.** The penetration checking is the same as for DEPTH = 3, but the code has been tuned to better conserve energy.

5. **DEPTH = 15.** Behavior is the same as DEPTH = 5 from versions R4.2 and earlier. This option enables backward compatibility of results.

6. **DEPTH = 23.** The penetration checking is similar to DEPTH = 3 but uses different methods to try to improve robustness.

7. **DEPTH = 25 or 35.** The penetration checking is similar to DEPTH = 5 but uses different methods to try to improve robustness.

8. **DEPTH = 45.** The splitting pinball method [Belytschko and Yeh, 1993] is used. This method is more accurate at the cost of more CPU time. It is recommended

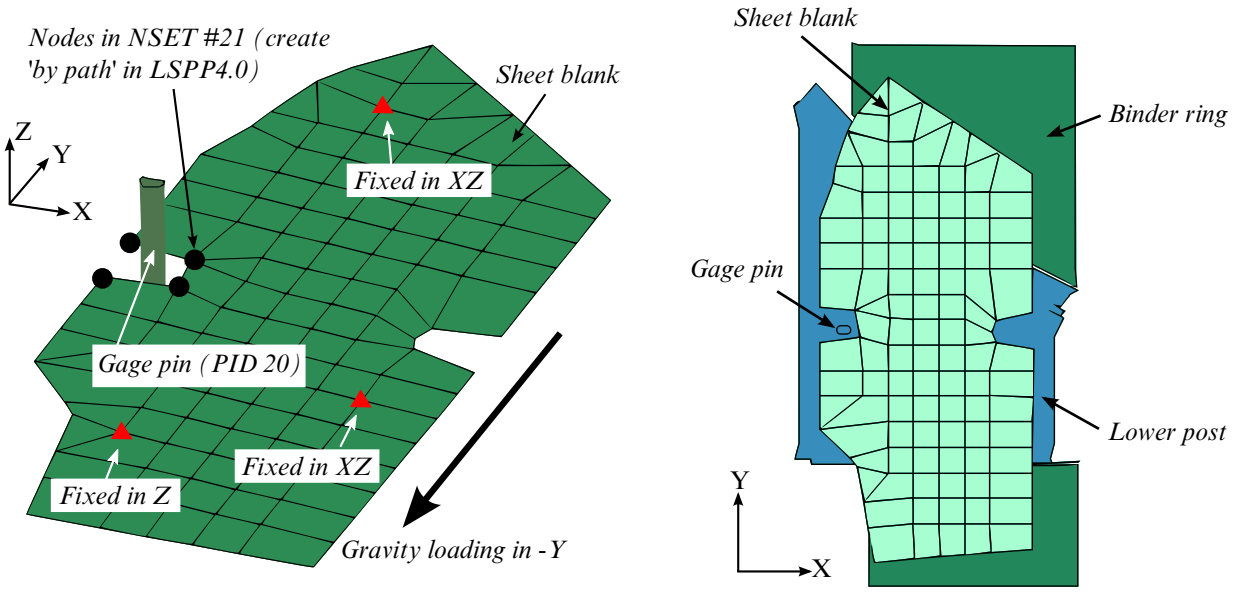

Figure 11-17. Illustrative/test model for SOFT = 6 (left) and initial blank position.

when modeling complex contacts between parts comprised of shells. It does not apply to solid or thick shell parts, but such parts can be coated with null shells to make DEPTH = 45 available.

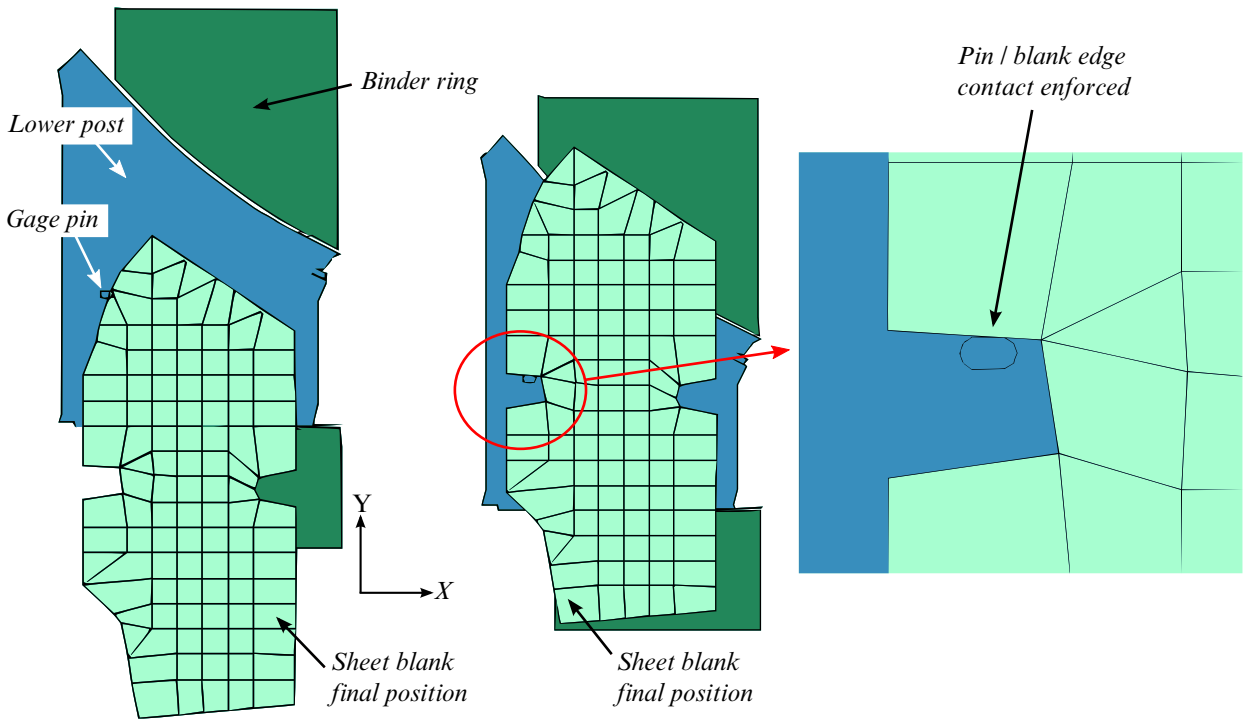
9. **DEPTH = 55.** The penetration checking is similar to DEPTH = 25 and 35, but it is robust in edge-to-edge checking. Thus, penetration is less likely.

10. **DEPTH = 1 or 4.** Airbag contact has two additional options, DEPTH = 1 and 4. DEPTH = 4 activates additional airbag logic that uses neighbor segment information when judging if the contact is between interior or exterior airbag surfaces. This option is not recommended and is maintained only for backward compatibility. Setting DEPTH = 1 suppresses all airbag logic.

About SOFT = 6:

SOFT = 6 contact addresses contact issues in situations where blank gage pins are narrow or small and blank meshes are coarse (Figure 11-17 left), leading to missing contact in some cases. This feature applies to gravity loading and forming of a sheet blank with an adaptive mesh. It can *only* be used with *CONTACT_FORMING_NODES_TO_SURFACE. In addition, the variable ORIENT in *CONTROL_CONTACT must be set to "4". Currently this feature is available in double precision, SMP only.

1. **SURFA Type.** Prior to R10.0, SURFA must be a node set that includes the nodes along the entire blank edge or the portion of the blank edge that will be in contact with gage pins (see Figure 11-17 left). The nodes in the node set must be listed in a consecutive order, as defined *by path* in LS-PrePost 4.0 or later, under *Model*



Gravity loading results without using SOFT=6; Pin/blank edge contact missed.

Gravity loading results using SOFT=6; Pin/blank edge contact sucessful.

Figure 11-18. Final blank position without (left) and with (right) SOFT = 6.

→ *CreEnt* → *Cre* → *Set Data* → **SET_NODE*. Note that the blank edge and the gage pins do not have any thickness. *Starting with Revision R10.0, SURFA in *CONTACT_FORMING_NODES_TO_SURFACE can be input as part ID (not a part set ID) of the blank, making it much easier to use SOFT = 6.*

2. **Example.** In the partial keyword example below, node set ID 21 (SURFATYP = 4) is in contact with the gage pin of part set ID 20. As shown in Figure 11-17 (left), with the boundary condition applied, a blank with a very coarse mesh is loaded with a body force. The left notch is anticipated to be in contact with the gage pins. The initial position (top view) of the test model is shown in Figure 11-17 (right) and the final gravity loaded blank positions are shown in Figure 11-18 (left) without SOFT = 6, and in Figure 11-18 (middle and right) with SOFT = 6. Without SOFT = 6 the contact between the blank edge and the pin is missed completely.

3. **Coarse Meshes and Initial Contact Penetration.** Sometimes a coarse blank mesh causes an initial contact penetration between the blank gaging hole edge and the gaging pin mesh. Starting with R11.0, LS-DYNA creates additional nodes on the blank along the hole edge and then moves the nodes to clear the initial penetration with the gage pin, as shown in Figure 11-19.

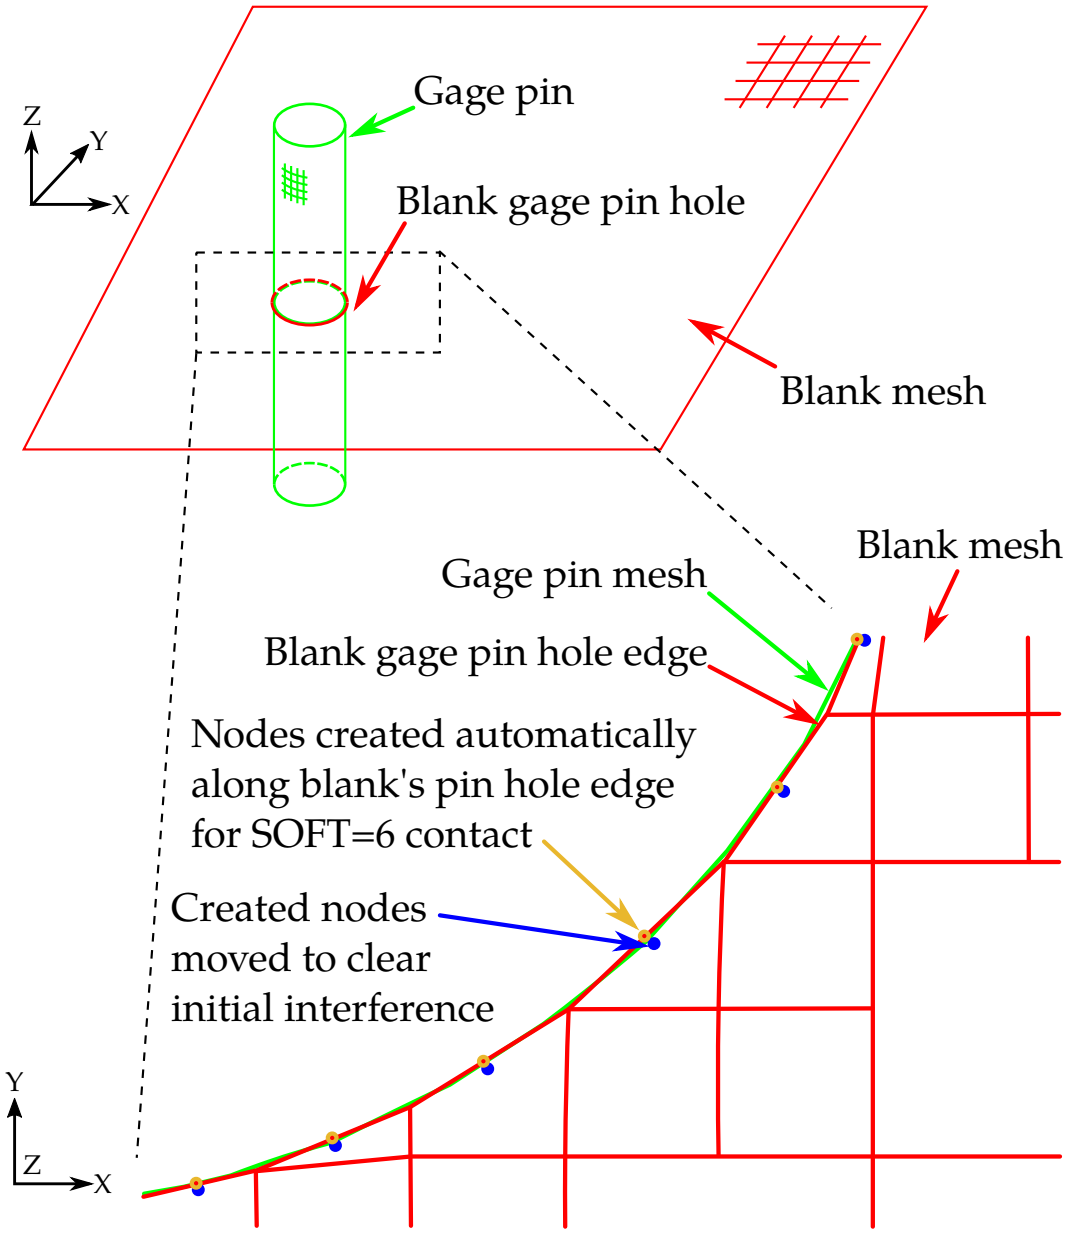

Figure 11-19. Improvement to SOFT = 6 for a coarse blank mesh

Optional Card B:

> **NOTE:** If Optional Card B is used, then Optional Card A must be defined. (Optional Card A may be a blank line.)

Optional Card B.

Card B	1	2	3	4	5	6	7	8
Variable	PENMAX	THKOPT	SHLTHK	SNLOG	ISYM	I2D3D	SLDTHK	SLDSTF
Type	F	I	I	I	I	I	F	F
Default	↓	0	0	0	0	0	0.0	0.0
Remarks		Old types 3, 5, 10	Old types 3, 5, 10					

VARIABLE	DESCRIPTION
PENMAX	For old types 3, 5, 8, 9, 10 (see Mapping of *CONTACT keyword option to "contact type" in d3hsp at the end of General Remarks) and Mortar contact, PENMAX is the maximum penetration distance. For contact types a3, a5, a10, 13, 15, and 26, the segment thickness multiplied by PENMAX defines the maximum penetration allowed (as a multiple of the segment thickness). (See Table 11-2.): EQ.0.0: For old type contacts 3, 5, and 10, use small penetration search and value calculated from thickness and XPENE; see *CONTROL_CONTACT. EQ.0.0: For contact types a3, a5, a10, 13, and 15, the default is 0.4, or 40 percent of the segment thickness EQ.0.0: For contact type 26, the default value is the segment thickness multiplied by 10. EQ.0.0: For Mortar contact, the default is a characteristic size of the element; see Theory manual.
THKOPT	Thickness option for contact types 3, 5, and 10:

VARIABLE	DESCRIPTION
	EQ.0: Default is taken from the control card; see *CONTROL_-CONTACT. EQ.1: Thickness offsets are included. EQ.2: Thickness offsets are not included (old way).
SHLTHK	Define if and only if THKOPT above equals 1. Shell thickness is considered in surface-to-surface and node-to-surface type contact options, where options 1 and 2 below activate the new contact algorithms. The thickness offsets are always included in single surface and constraint method contact types. EQ.0: Thickness is not considered. EQ.1: Thickness is considered, but rigid bodies are excluded. EQ.2: Thickness is considered including rigid bodies.
SNLOG	For SOFT = 0 or 1, SNLOG controls the shooting node logic in thickness offset contact. With the shooting node logic enabled, the first cycle that a tracked node penetrates a reference segment, that node is moved back to the reference surface without applying any contact force. EQ.0: Logic is enabled (default). EQ.1: Logic is skipped (sometimes recommended for metal forming calculations or for contact involving foam materials). For SOFT = 2, SNLOG controls the thick segment check (see Remark 1): EQ.0: Do a thick segment check but do not report the results. EQ.1: Do a thick segment check but do not report the results. EQ.2: Do a thick segment check and report the results to the d3hsp file. EQ.3: Do not do a thick segment check.
ISYM	Symmetry plane option: EQ.0: Off EQ.1: Do not include faces with normal boundary constraints (such as segments of brick elements on a symmetry plane).

VARIABLE	DESCRIPTION
	This option is important to retain the correct boundary conditions in the model with symmetry. For ERODING contacts this option may also be defined on Card 4.
I2D3D	Segment searching option: EQ.0: Search 2D elements (shells) before 3D elements (solids, thick shells) when locating segments. EQ.1: Search 3D (solids, thick shells) elements before 2D elements (shells) when locating segments.
SLDTHK	Optional solid element thickness. For non-Mortar contacts, a nonzero positive value will activate the contact thickness offsets in the contact algorithms where offsets apply. The contact treatment will then be equivalent to the case where null shell elements are used to cover the brick elements. The contact stiffness parameter below, SLDSTF, may also be used to override the default value. For Mortar contacts, SLDTHK is the offset from the solid element surface in the direction of the normal to the point where contact acts. Therefore, in this case a negative value for SLDTHK is well defined. SLDSTF is ignored for Mortar contact.
SLDSTF	Optional solid element stiffness. A nonzero positive value overrides the bulk modulus taken from the material model referenced by the solid element. For segment-based contact (SOFT = 2), SLDSTF replaces the stiffness used in the penalty equation. This parameter does not apply to Mortar contacts.

Remarks:

1. **SNLOG.** For segment-based contact that is invoked by setting SOFT = 2 on Card A, SNLOG controls the thick segment check. The thick segment check has always been done during initialization of single surface contact. It prevents possible unstable contact behavior that can occur when shell segments have thick offsets and segment dimensions are short relative to their thickness. When a pair of segments is found to be near each other when measured along the surface, and the segments in the pair are thick enough that their offsets could contact at a bend in the mesh, the pair is added to a list of pairs which will be skipped over during the simulation. Short and thick segments typically have enough stiffness that skipping contact between these pairs does not compromise the solution. However, setting SNLOG = 3 will switch off this check. Setting SNLOG = 2 will leave the check active but will output to the d3hsp file a report of the pairs of

elements which will not be checked for contact. Setting SNLOG = 0 or 1 will leave the check active and will not output a report.

Optional Card C:

> **NOTE:** If Optional Card C is used, then Optional Cards A and B must be defined. (Optional Cards A and B may be blank lines.)

Optional Card C.

Card C	1	2	3	4	5	6	7	8
Variable	IGAP	IGNORE	DPRFAC / MPAR1	DTSTIF / MPAR2	EDGEK		FLANGL	CID_RCF
Type	I	I	F	F	F		F	I
Default	1	0	0.0	0.0	0.0		0.0	0
Remarks		3	1	2	4			

VARIABLE	DESCRIPTION
IGAP	For Mortar contacts, IGAP is used to progressively increase contact stiffness for large penetrations, or use a linear relationship between penetration and contact pressure; see Remark 14 in the General Remarks section. For other contacts, IGAP can be used to improve implicit convergence at the expense of (1) creating some sticking if parts attempt to separate and (2) possibly under-reporting the contact force magnitude in the output files rcforc and ncforc. (Implicit only.) LT.0: Like IGAP = 1 except the maximum distance between contact surfaces at which stickiness is on is scaled by IGAP/10. EQ.1: Apply method to improve convergence (default). EQ.2: Do not apply method. GT.2: Set IGAP = 1 for first IGAP − 2 converged equilibrium states, then set IGAP = 2.
IGNORE	Ignore initial penetrations for the *CONTACT_AUTOMATIC options: LT.0: Applies only to the Mortar contact. When less than zero, the behavior is the same as for |IGNORE|, but contact between segments belonging to the same part is ignored.

VARIABLE	DESCRIPTION
	The main purpose of this option is to avoid spurious contact detections that otherwise could result for complicated geometries in a single surface contact, typically, when eliminating initial penetrations by interference. See IGNORE = 3 and IGNORE = 4.
	EQ.0: Take the default value from the fourth card of the *CONTROL_CONTACT input.
	EQ.1: Allow initial penetrations to exist by tracking the initial penetrations.
	EQ.2: Allow initial penetrations to exist by tracking the initial penetrations. However, penetration warning messages are printed with the original coordinates, and the recommended coordinates of each penetrating node are given. For Mortar contact, this is the default (see Remark 14 in the General Remarks section).
	EQ.3: Applies only to the Mortar contact. With this option initial penetrations are eliminated between time zero and the time specified by MPAR1. Intended for small initial penetrations. See Remark 14 in the General Remarks section.
	EQ.4: Applies only to the Mortar contact. With this option initial penetrations are eliminated between time zero and the time specified by MPAR1. In addition, a maximum penetration distance can be given as MPAR2, intended for large initial penetrations. See Remark 14 in the General Remarks section.
DPRFAC	Depth of penetration reduction factor for SOFT = 2 contact (see Remark 1 below):
	EQ.0.0: Initial penetrations are always ignored.
	GT.0.0.and.LT.1.0: Initial penetrations are penalized over time.
	GE.1.0: DPRFAC is a set ID used to limit the scope of DPRFAC.
	LE.-1.0: |DPRFAC| is the load curve ID defining DPRFAC as a function of time.
DTSTIF	Time step used in stiffness calculation for SOFT = 1 and SOFT = 2 contact (see Remark 2 below).
	EQ.0.0: Use the initial value that is used for time integration.

VARIABLE	DESCRIPTION
	GT.0.0: Use the value specified. GT.-1.0.and.LT.-0.01: Use a moving average of the solution time step (SOFT = 2 only). LE.-1.0: |DTSTIF| is the ID of a curve that defines DTSTIF as a function of time.
MPAR1	This field only applies to Mortar contact. If IGNORE = 2, MPAR1 corresponds to the initial contact pressure in interfaces with initial penetrations. For IGNORE = 3 and 4 it corresponds to the time of closure of initial penetrations. See Remark 14 in the General Remarks section. LE.-1.0: |MPAR1| is the ID of a curve defining the relative penetration reduction as function of time. This is available for the IGNORE = 3 and 4 cases.
MPAR2	For Mortar contact and IGNORE = 4, MPAR2 corresponds to a penetration depth that must be at least the penetration occurring in the contact interface. See Remark 14 in the General Remarks section.
EDGEK	Scale factor for penalty stiffness of edge-to-edge contact when SOFT = 2 and DEPTH = 5, 15, 25, or 35 (see Remark 4): EQ.0.0: Use the default penalty stiffness. GT.0.0: Scale the stiffness by EDGEK.
FLANGL	Angle tolerance in radians for feature lines option in smooth contact: EQ.0.0: No feature line is considered for surface fitting in smooth contact. GT.0.0: Any edge with an angle between two contact segments bigger than this angle will be treated as feature line during surface fitting in smooth contact.
CID_RCF	Coordinate system ID to output rcforc force resultants and ncforc data in a local system.

Remarks:

1. **DPRFAC.** DPRFAC is used only by segment-based contact (SOFT = 2); see About SOFT = 2 under optional Card A for more details about segment-based contact. By default, SOFT = 2 contact measures the initial penetration between segment pairs that are found to be in contact and subtracts the measured value

from the total penetration for as long as a pair of segments remains in contact. The penalty force is proportional to this modified value. This approach prevents shooting nodes but may allow unacceptable penetration. DPRFAC can be used to decrease the measured value over time until the full penetration is penalized. Setting DPRFAC = 0.01 will cause ~1% reduction in the measured value each cycle. We recommend a small value, such as 0.001. DPRFAC does not apply to initial penetrations at the start of the calculation, only those that are measured at later times. This prevents nonphysical movement and energy growth at the start of the calculation.

The anticipated application for the load curve option is to reduce the initial penetrations at the end of a calculation if the final geometry is to be used for a subsequent analysis. To achieve this, the load curve should have a *y*-value of zero until a time near the end of the analysis and then ramp up to a positive value, such as 0.01, near the end of the analysis.

If the value of DPRFAC is greater or equal to 1.0, then the nearest integer will be used as a set ID and DPRFAC penetration reduction will only be done for pairs of segments that are both within that set. The set can be defined by either *SET_SHELL, *SET_SEGMENT, or *SET_PART. A search for a set with that set ID will be made in that order, and the search will stop when a matching set is found. The value off the first default attribute of that set (DA1), will be used as the DPRFAC value and should be either a small positive value, or a negative value to reference a curve.

2. **DTSTIF.** DTSTIF is used only by the SOFT = 1 and SOFT = 2 contact options; see About SOFT = 1 and About SOFT = 2 under optional Card A for more details.. By default, when the SOFT option is active, the contact uses the initial solution time step to scale the contact stiffness. If the user sets DTSTIF to a nonzero value, the inputted value will be used. Because the square of the time step appears in the denominator of the stiffness calculation, a DTSTIF value larger than the initial solution time step reduces the contact stiffness and a smaller value increases the stiffness. This option could be used when one component of a larger model has been analyzed independently and validated. When the component is inserted into the larger model, the larger model may run at a smaller time step due to higher mesh frequencies. In the full model analysis, setting DTSTIF equal to the component analysis time step for the contact interface that treats the component will cause consistent contact stiffness between the analyses.

   The load curve option allows contact stiffness to be a function of time. This should be done with care as energy will not be conserved. A special case of the load curve option is when |DTSTIF| = LCTM on *CONTROL_CONTACT. LCTM sets an upper bound on the solution time step. For |DTSTIF| = LCTM, the contact stiffness time step value will track LCTM whenever the LCTM value is less than the initial solution time step. If the LCTM value is greater, the initial

solution time step is used. This option could be used to stiffen the contact at the end of an analysis. To achieve this, the LCTM curve should be defined such that it is larger than the solution time step until near the end of the analysis. Then the LCTM curve should ramp down below the solution time step causing it to decrease and the contact to stiffen. A load curve value of 0.1 of the calculated solution time step will cause penetrations to reduce by about 99%. To prevent shooting nodes, the rate at which the contact stiffness increases is automatically limited. Therefore, to achieve 99% reduction, the solution should be run for perhaps 1000 cycles with a small time step.

For segment-based contact (SOFT = 2), setting DTSTIF less than or equal to -0.01 and greater than -1.0, causes the contact stiffness to be updated based on the current solution time step. Varying the contact stiffness during a simulation can cause energy growth. Thus, this option should be used with care when extra stiffness is needed to prevent penetration and the solution time step has dropped below the initial. Because quick changes in contact stiffness can cause shooting nodes, using a moving average of the solution time step can prevent this. The value of DTSTIF determines the number of terms in the moving average where $n = 100 \times$ (-DTSTIF) such that $n = 1$ for DTSTIF = -0.01 and $n = 100$ for DTSTIF = -0.999. Setting DTSTIF = -1.0 triggers the load curve option described in the previous paragraph, so DTSTIF cannot be smaller than -0.999 for this option.

3. **IGNORE with SOFT = 2.** When SOFT = 2 on Optional Card A, treatment of initial penetrations is always like IGNORE = 1 in that initial penetrations are ignored when calculating penalty forces. If SOFT = 2 and IGNORE = 2, then a report of initial penetrations will be written to the messag file(s) in the first cycle.

4. **EDGEK.** When SOFT = 2 and DEPTH = 5, 15, 25, or 35 on Optional Card A, the EDGEK parameter will scale the contact penalty stiffness when contact is between segment edges if EDGEK > 0.0. This is true for both shell segments and solid element segments. Surface contact stiffness is unaffected by EDGEK.

Optional Card D:

> **NOTE:** If Optional Card D is used, then Optional Cards A, B, and C must be defined. (Optional Cards A, B, and C may be blank lines.)

Optional Card D.

Card D	1	2	3	4	5	6	7	8
Variable	Q2TRI	DTPCHK	SFNBR	FNLSCL	DNLSCL	TCSO	TIEDID	SHLEDG
Type	I	F	F	F	F	I	I	I
Default	0	0.0	0.0	0.0	0.0	0	0	0
Remarks	1	2	3	5	5		4	

VARIABLE	DESCRIPTION
Q2TRI	Flag to split quadrilateral contact segments into two triangles (only available when SOFT = 2): EQ.0: Off (default) EQ.1: On for all SURFA shell segments EQ.2: On for all SURFB shell segments EQ.3: On for all shell segments EQ.4: On for all shell segments of material type 34
DTPCHK	Time interval between shell penetration reports (only available for SOFT = 2): EQ.0.0: Off (default) GT.0.0: Check and report segment penetrations at time intervals equal to DTPCHK LT.0.0: Check and report segment penetrations at time intervals equal to |DTPCHK|. In addition, the calculation stops with an error at $t = 0$ if any intersections are initially present.

VARIABLE	DESCRIPTION
SFNBR	Scale factor for neighbor segment contact (only available when SOFT = 2) EQ.0.0: Off (default) GT.0.0: Check neighbor segments for contact. LT.0.0: Neighbor segment checking with improved energy balance when |SFNBR| < 1000. |SFNBR| ≥ 1000 activates a split-pinball based neighbor contact with a penalty force scale factor of |SFNBR + 1000|. For example, the force scale factor used is 2 when SFNBR = -1002.
FNLSCL	Scale factor for nonlinear force scaling, f. See Remark 5. This field only applies to segment-based contact invoked with SOFT = 2 on Optional Card A (see About SOFT = 2 under optional Card A).
DNLSCL	Distance for nonlinear force scaling, d. See Remark 5. This field only applies to segment-based contact invoked with SOFT = 2 on Optional Card A (see About SOFT = 2 under optional Card A).
TCSO	Flag to consider only contact segments (not all attached elements) when computing the contact thickness for a node or segment (for SURFACE_TO_SURFACE contact and shell elements only): EQ.0: Off (default) EQ.1: Only consider segments in the contact definition
TIEDID	Flag for incremental displacement update for tied contacts (see Remark 4 below): EQ.0: Off (default) EQ.1: On
SHLEDG	Flag for assuming edge shape for shells when measuring penetration. This is available for segment-based contact (SOFT = 2). EQ.0: Default to SHLEDG on *CONTROL_CONTACT EQ.1: Shell edges are assumed to be square and are flush with the nodes. EQ.2: Shell edges are assumed to be round with a radius equal to half the shell thickness. The edge centers lie on the lines between the segment nodes and extend outward by the radius. This option is not available for DEPTH values of 23, 33, or 35.

Remarks:

1. **Q2TRI.** Setting Q2TRI to a nonzero value causes quadrilateral shell segments to be split into two triangles. Only the contact segments are split. The elements are not changed. This option is only available for segment-based contact which is activated by setting SOFT = 2. See About SOFT = 2 under optional Card A for more details about segment-based contact.

2. **DTPCHK (Penetration Check).** Setting DTPCHK to a positive value causes a penetration check to be done periodically with the interval equal to DTPCHK. The check looks for shell segments that are penetrating the mid-plane of another shell segment. It does not report penetration of thickness offsets. The penetrating pairs are reported to the messag file or files for MPP. If at least one penetration is found, the total number of pairs is reported to the screen output. This option is only available for segment-based contact which is activated by setting SOFT = 2. See About SOFT = 2 under optional Card A for more details about segment-based contact.

3. **SFNBR.** SFNBR is a scale factor for optional neighbor segment contact checking. This is available only in segment-based (SOFT = 2) contact (see About SOFT = 2 under optional Card A for more details about segment-based contact). This is helpful when a mesh folds, such as during compression folding of an airbag. Only shell element segments are checked. Setting SFNBR to a negative value modifies the neighbor checking to improve energy balance. When used, a value between -0.5 and -1.0 is recommended.

4. **Round off in OFFSET and TIEBREAK.** There have been several issues with tied OFFSET contacts and AUTOMATIC_TIEBREAK contacts with offsets creating numerical round-off noise in stationary parts. By computing the interface displacements incrementally rather than using total displacements, the round-off errors that occur using single precision are eliminated. The incremental approach (TIEDID = 1) is available for the following contact types:

   TIED_SURFACE_TO_SURFACE_OFFSET

   TIED_NODES_TO_SURFACE_OFFSET

   TIED_NODES_TO_SURFACE_CONSTRAINED_OFFSET

   TIED_SHELL_EDGE_TO_SURFACE_OFFSET

   AUTOMATIC_..._TIEBREAK

   AUTOMATIC_SINGLE_SURFACE_TIED

5. **FNLSCL and DNLSCL.** FNLSCL = f and DNLSCL = d invoke alternative contact stiffness scaling options. These variables apply only when SOFT = 2 (see

About SOFT = 2 under optional Card A for more details about segment-based contact).

When FNLSCL > 0 and DNLSCL > 0, this feature scales the stiffness by the depth of penetration to provide smoother initial contact and a larger contact force as the depth of penetration exceeds DNLSCL. The stiffness k is scaled by the relation

$$k \rightarrow kf\sqrt{\frac{\delta}{d}} \ ,$$

where δ is the depth of penetration, making the penalty force proportional to the 3/2 power of the penetration depth. Adding a small amount of surface damping (such as VDC = 10) is advised with this feature.

For FNLSCL < 0, and DNLSCL > 0, an alternative stiffness scaling scheme is used,

$$k \rightarrow k\left[\frac{0.01|f|A_o}{d(d-\delta)}\right] \ .$$

Here A_0 is the overlap area of segments in contact. For δ greater than $0.9d$, the stiffness is extrapolated to prevent it from going to infinity.

For FNLSCL > 0, and DNLSCL = 0, the contact is scaled by the overlap area:

$$k \rightarrow kf\left(\frac{A_o}{A_m}\right) \ .$$

Here A_m is the mean area of all the contact segments in the contact interface. This third option can improve friction behavior, particularly when the FS = 2 option is used.

Optional Card E:

> **NOTE:** If Optional Card E is used, then Optional Cards A, B, C and D must be defined. (Optional Cards A, B, C and D may be blank lines.)

Optional Card E.

Card E	1	2	3	4	5	6	7	8
Variable	SHAREC	CPARM8	IPBACK	SRNDE	FRICSF	ICOR	FTORQ	REGION
Type	I	I	I	I	F	I	I	I
Default	0	0	0	0	1.	0	0	0
Remarks	1		2	3	5			4

VARIABLE	DESCRIPTION
SHAREC	Shared constraint flag (only available for segment-based contact which is activated with SOFT = 2): EQ.0: Segments that share constraints are not checked for contact. EQ.1: Segments that share constraints are checked for contact.
CPARM8	This variable is similar to CPARM8 in *CONTACT_…_MPP but applies to SMP and not to MPP. CPARM8 for SMP only controls treatment of spot weld beams in *CONTACT_AUTOMATIC_GENERAL. EQ.0: Spot weld (type 9) beams *are not* considered in the contact even if included in SURFA. EQ.2: Spot weld (type 9) beams *are* considered in the contact if included in SURFA.
IPBACK	If set to a nonzero value, creates a "backup" penalty tied contact for this interface. This option applies to constrained tied contacts only. See Remark 2.
SRNDE	Flag for non-extended exterior shell segment edges. See Remark 3 below for further information and restrictions.

VARIABLE	DESCRIPTION
	EQ.0: Exterior shell edges have their usual treatment where the contact surface extends beyond the shell edge. EQ.1: The contact surface is rounded at exterior shell edges but does not extend beyond the shell edges. EQ.2: The shell edges are square.
FRICSF	Scale factor for frictional stiffness (available for SOFT = 2 only).
ICOR	If set to a nonzero value, VDC is the coefficient of restitution expressed as a percentage. First and foremost, this option is intended only for contact between independent, unconstrained rigid bodies, and its application to any other contact situation will not render the desired effect. When SOFT = 0 or 1, ICOR applies to AUTOMATIC_NODES_TO_SURFACE, AUTOMATIC_SURFACE_TO_SURFACE and AUTOMATIC_SINGLE_SURFACE. ICOR applies to all SOFT = 2 contacts. Two proprietary implementations are available, depending on the sign of ICOR. A positive ICOR should give satisfactory results for most applications.
FTORQ	FTORQ controls transmittal of moments across the contact interface for some contact types. The moments addressed by FTORQ are those due to contact friction (or tangential forces in the case of tied/tiebreak contact). For AUTOMATIC_GENERAL in MPP, FTORQ = 1 causes the transmission of moments due to beam-to-beam friction. For MPP with contact types AUTOMATIC_SURFACE_TO_SURFACE, AUTOMATIC_SINGLE_SURFACE and AUTOMATIC_NODES_TO_SURFACE and SOFT ≠ 2, a moment due to tied/tiebreak, contact friction, or damping is transmitted when FTORQ = 1 or 2. For AUTOMATIC_SINGLE_SURFACE with SOFT ≠ 2, FTORQ = 1 differs only from FTORQ = 2 in that nodal moments are distributed to the nodes of the contact segment if the segment belongs to a shell element. Otherwise, the moment is transmitted as self-balanced nodal forces rather than as nodal moments. For AUTOMATIC_SURFACE_TO_SURFACE and AUTOMATIC_NODES_TO_SURFACE, FTORQ = 1 is the same as FTORQ = 2.

VARIABLE	DESCRIPTION
	For SMP, FTORQ = 1 and 2 are supported for AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK and AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK. FTORQ = 2 is supported for AUTOMATIC_SURFACE_TO_SURFACE and AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE. SOFT = 2 contacts support FTORQ = 2. FTORQ = 1 is not supported.
REGION	The ID of a *DEFINE_REGION which will delimit the volume of space where this contact is active. See Remark 4 below.

Remarks:

1. **SHAREC.** The SHAREC flag is a segment-based contact (SOFT = 2) option that allows contact checking of segment pairs that share a multi-point constraint or rigid body. Sharing a constraint is defined as having at least one node of each segment that belongs to the same constraint.

2. **IPBACK.** The IPBACK flag is only applicable to constraint-based tied contacts (TIED with no options, or with CONSTRAINED_OFFSET). An identical penalty-based contact is generated with type OFFSET, except in the case of SHELL_EDGE constrained contact which generates a BEAM_OFFSET type. The ID of the generated interface will be set to the ID of the original interface plus 1 if that ID is available, otherwise one more than the maximum used contact ID. For nodes successfully tied by the constraint interface, the extra penalty tying should not cause problems, but nodes dropped from the constraint interface due to rigid body or other conflicting constraints will be handled by the penalty contact. In MPP, nodes successfully tied by the constraint interface are skipped during the penalty contact phase.

3. **SRNDE.** Contact at shell edges is by default treated by adding cylindrical caps along the free edges, with the radius of the cylinder equal to half the thickness of the segment. This has the side effect of extending the segment at the free edges, which can cause problems. Setting SRNDE = 1 "rounds over" the (through the thickness) corners of the element instead of extending it. The edges of the segment are still rounded, but the overall size of the contact area is not increased. The effect is as if the free edge of the segment was moved in toward the segment by a distance equal to half the segment thickness, and then the old cylindrical treatment was performed. Setting SRNDE = 2 will treat the shell edges as square, with no extension. This variable has no effect on shell-edge-to-shell-edge interaction in AUTOMATIC_GENERAL; for that, see CPARM8 on the MPP Card.

When SOFT = 0 or SOFT = 1, the SRNDE = 1 option is available for the AUTOMATIC_SINGLE and AUTOMATIC_GENERAL contacts. The NODES_TO_SURFACE and SURFACE_TO_SURFACE contacts also support SRNDE = 1. If the GROUPABLE option is used, it is supported in MPP also. The SRNDE = 2 option is available for all these contact types in SMP. For MPP it is available only if the GROUPABLE option is enabled.

When SOFT = 2, both the SRNDE = 1 and SRNDE = 2 options are available with all keywords that are supported when SOFT = 2. Both options are available for SMP, MPP, and hybrid versions, and with and without the MPP groupable option. However, the SRNDE = 0 option is not available for DEPTH = 23, DEPTH = 33, and DEPTH = 35. For these options, SRNDE = 1 is the default value.

When SOFT = 0 or SOFT = 1, the contact algorithm is based on the node-to-surface contact. The SRNDE options are applied to the reference segment in the contact pair, but not the tracked node. For SOFT = 2, the SRNDE options are applied to both segments in the contact pair.

4. **REGION.** Setting a nonzero value for REGION does not limit or in any way alter the list of SURFA/SURFB nodes and segments. This option should not be used for that purpose. For efficiency, the smallest possible portion of the model should be defined as SURFA or SURFB using the normal mechanisms for specifying the SURFB and SURFA surfaces. Setting a nonzero value will, however, result in contact outside the REGION being ignored. As SURFA and SURFB nodes and segments pass into the indicated REGION, contact for them will become active. As they pass out of the REGION, they will be skipped in the contact calculation. This option is currently available in MPP for all SOFT options, and in SMP when SOFT = 2. Contacts of type AUTOMATIC_SINGLE_SURFACE, AUTOMATIC_..._TO_SURFACE, and ERODING_… can be modified using REGION.

5. **FRICSF.** The FRICSF factor is an optional factor to scale the frictional stiffness. FRICSF is available only when SOFT = 2 on optional Card A. With penalty contact, the frictional force is a function of the stiffness, the sliding distance, and the Coulomb limit.

Optional Card F:

> **NOTE:** If Optional Card F is used, then Optional Cards A, B, C, D and E must be defined. (Optional Cards A, B, C, D and E may be blank lines.)

Optional Card F.

Card F	1	2	3	4	5	6	7	8
Variable	PSTIFF	IGNROFF		FSTOL	2DBINR	SSFTYP	SWTPR	TETFAC
Type	I	I		F	I	I	I	F
Default	0	0		2.0	0	0	0	0.0
Remarks	1					2		

VARIABLE	DESCRIPTION
PSTIFF	Flag to choose the method for calculating the penalty stiffness. This is available for segment-based contact activated by setting SOFT = 2 on optional Card A (see About SOFT = 2 for details). EQ.0: Use the default as defined by PSTIFF on *CONTROL_-CONTACT. EQ.1: Based on nodal masses EQ.2: Based on material density and segment dimensions
IGNROFF	Flag to ignore the thickness offset for shells in the calculation of the shell contact surface. As an example, this allows shells to be used for meshing tooling surfaces without modifying the positions of the nodes to compensate for the shell thickness. This variable applies to automatic contact types, excluding segment-based (SOFT = 2) contacts. EQ.0: Use default thicknesses. EQ.1: Ignore the SURFA side thickness. EQ.2: Ignore the SURFB side thickness. EQ.3: Ignore the thickness of both sides.

VARIABLE	DESCRIPTION
FSTOL	Tolerance used with the SMOOTH option for determining which segments are considered flat. The value is in degrees and approximately represents half the angle between adjacent segments.
2DBINR	Flag to indicate that 2D belts initially inside retractors are involved in the contact. This is only available for SURFACE_TO_SURFACE contact of segment-based contact (SOFT = 2). EQ.0: No 2D belt initially inside a retractor is involved. EQ.1: 2D belts initially inside retractors are involved.
SFFTYP	Flag to determine how the SSF option on *PART_CONTACT behaves when SOFT = 2 on optional card A: EQ.0: Use SSF from the tracked segment as determined by the SOFT = 2 algorithm (see Remark 2). EQ.1: Use the larger of the SSF values.
SWTPTR	Flag to use tapered shell contact segments adjacent to segments that are thinned by the SPOTHIN option on *CONTROL_CONTACT. This option is only available when SOFT = 2 on Optional Card A. EQ.0: Use full thickness constant segments. EQ.1: Use tapered segments.
TETFAC	Scale factor for the computed volume of tetrahedral solid elements for the mass calculation in SOFT = 2 contact. By default, half the mass of a solid element is considered for the contact segment, which is reasonable for hexahedrons. In contrast, for tetrahedrons, a larger value than 0.5 would be preferrable because several tets fit into one hex. Therefore, a TETFAC value around 3.0 to 5.0 should make the contact stiffness more comparable with hex meshes. EQ.0.0: Scale factor is 0.5 (default).

Remarks:

1. **PSTIFF.** See Remark 6 on *CONTROL_CONTACT for an explanation of the PSTIFF option. Specifying PSTIFF here will override the default value as defined by PSTIFF on *CONTROL_CONTACT.

2. **SSFTYP.** SSFTYP affects how the SSF field on *PART_CONTACT is used when the contact formulation is segment-based (SOFT = 2 on optional card A). It only applies when the segments in contact belong to different parts, and the parts have different penalty scale factors. The SSF field on *PART_CONTACT assigns a penalty scale factor to a given part. For one-way segment-based contact, the SSF for SURFA is used when SSFTYP = 0. For all other segment-based contact, the contact algorithm judges for each pair of segments in contact which segment is penetrating less (the tracked segment). The other segment (reference segment) in the pair determines the contact force direction. If SSFTYP = 0, then the SSF of the tracked segment is used. If SSFTYP = 1, then the larger of the two scale factors is used regardless of the contact type.

General Remarks: *CONTACT

1. **Force Output.** Contact force data can be recorded with *DATABASE_RCFORC, *DATABASE_NCFORC, and *DATABASE_BINARY_INTFOR. Note that LS-DYNA only outputs data between a SURFA and SURFB surface. Self-contact, such as single surface contact, only has SURFA and thus no data is output by default. In this case, a *CONTACT_FORCE_TRANSDUCER_*OPTION* is needed to extract contact forces from contact types that may not otherwise be recordable.

2. **AUTOMATIC_GENERAL compared to AUTOMATIC_SINGLE_SURFACE.** *CONTACT_AUTOMATIC_GENERAL is a single surface contact similar to *CONTACT_AUTOMATIC_SINGLE_SURFACE. Both types are automatic, so they consider shell thickness and beam thickness by offsetting the contact interface from the shell midplane and the beam centerline (see Item 4 under Allowed Values for Option 1).

   *CONTACT_AUTOMATIC_GENERAL differs from *CONTACT_AUTOMATIC_SINGLE_SURFACE in how it handles beam contact and shell edge contact. *CONTACT_AUTOMATIC_GENERAL includes treatment of beam-to-beam contact in which it checks the entire length of the beam for penetration, not just the nodes of the beam. For shells, it checks for penetration along the entire length of the exterior (unshared) shell edges. *CONTACT_AUTOMATIC_GENERAL essentially adds null beams to the exterior edges of shell parts so that edge-to-edge treatment of the shell parts is handled by virtue of contact through the automatically generated null beams. By adding the word INTERIOR to *CONTACT_AUTOMATIC_GENERAL, the contact algorithm goes a step further by adding null beams to all the shell meshlines, both along the exterior, unshared edges and the interior, shared shell edges. The EDGEONLY option skips the node-to-surface contact and does only the edge-to-edge and beam-to-beam contact.

   Another distinction is the default value of PENMAX (see Optional Card A). The value of PENMAX helps determine the value of penetration that triggers the release of a penetrating node (see Table 11-2). For AUTOMATIC_GENERAL, the default value of PENMAX causes the penetration value to be effectively unlimited while for AUTOMATIC_SINGLE_SURFACE the default leads to a release condition of about half an element thickness.

   By default, the AUTOMATIC_GENERAL checks for nodal penetration through the three closest segments (DEPTH = 3 on Optional Card A). For AUTOMATIC_SINGLE_SURFACE, the default search depth is 2 segments. The three segment check is more expensive but may be more robust for contact in corners.

   Last, segment-based contact invoked with SOFT = 2 on Optional Card A is supported for AUTOMATIC_SINGLE_SURFACE but not for AUTOMATIC_GENERAL.

3. **Edge-to-Edge Contact Treatment.** All automatic contact types and contact using the segment-based (SOFT = 2) formulation include edge-to-edge capabilities. *CONTACT_SINGLE_EDGE is based on single surface contact but only treats edge-to-edge contact. It should be used with contact types that do not already have edge treatment. Note that for *CONTACT_SINGLE_EDGE contact only occurs between edges whose normal vectors (that lie in the plane of their respective shells) point toward each other (see the theory manual for illustration).

4. **Tying Distance Criterion.** Tying will only work if the surfaces are near each other. The criterion used to determine whether a tracked node is tied down is that it must be "close". For shell elements "close" is less than a distance, δ, defined as:

$$\delta_1 = 0.60 \times (\text{thickness of tracked node} + \text{thickness of reference segment})$$
$$\delta_2 = 0.05 \times \min(\text{reference segment diagonals})$$
$$\delta = \max(\delta_1, \delta_2)$$

If a node is further away, it will not be tied, and a warning message will be printed. For solid elements, the node thickness is zero and the segment thickness is the element volume divided by the segment area; otherwise, the same procedure is used.

If there is a large difference in element areas between the two sides of the contact interface, δ_2 may be too large, causing the unexpected projection of nodes that should not be tied. This can occur when adaptive remeshing is used. To avoid this difficulty, the SURFA and SURFB thicknesses can be specified as negative values on Card 3 in which case

$$\delta = \text{abs}(\delta_1) \ .$$

5. **Tied Contact Types for Different Situations**. For tying solids-to-solids, that is, for situations where none of the nodes have rotational degrees-of-freedom, use TIED_NODES_TO_SURFACE and TIED_SURFACE_TO_SURFACE type contacts. These contact types may include the OFFSET or CONSTRAINED_-OFFSET option.

For tying shells-to-shells and beams-to-shells, that is, for situations where all the nodes have rotational degrees-of-freedom, use TIED_SHELL_EDGE_TO_SURFACE type contacts. This contact type may include the OFFSET, CONSTRAINED_OFFSET, or BEAM_OFFSET option. For beam spot welds, you can use *CONTACT_SPOTWELD or *CONTACT_SPOTWELD_WITH_TORSION for beam-to-shell contact. When *MAT_SPOTWELD is used for the beam material, the material model can include failure for the spot weld.

TIED_SHELL_EDGE_TO_SOLID is intended for tying shell edges to solids or beam ends to solids.

Tied contacts with failure include TIEBREAK contacts and TIED_SURFACE_-TO_SURFACE_FAILURE. Segment orientation is important for distinguishing the direction of tension from compression when defining these contacts.

6. **Tied Contact Types and the Implicit Solver.** Nonphysical results have been observed when the implicit time integrator is used for models that combine tied contact formulations with automatic single point constraints on solid element rotational degrees of freedom (AUTOSPC on *CONTROL_IMPLICIT_-SOLVER). The following subset of tied interfaces support a *strongly objective* mode (discussed in the next paragraph) and are verified to behave correctly with the implicit time integrator:

   a) TIED_NODES_TO_SURFACE_CONSTRAINED_OFFSET
      TIED_SURFACE_TO_SURFACE_CONSTRAINED_OFFSET

   b) TIED_NODES_TO_SURFACE_OFFSET
      TIED_SURFACE_TO_SURFACE_OFFSET

   c) TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET

   d) TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET

   The first two of these ignore rotational degrees of freedom, while the third and fourth constrain rotations. The first and third are constraint-based; while the second and fourth are penalty-based. These four contact types are intended to cover most use scenarios.

   Setting IACC = 1 on *CONTROL_ACCURACY activates the *strongly objective formulation* for the above mentioned contacts (as well as for the non-offset options as a side effect, namely, *CONTACT_TIED_NODES_TO_SURFACE, *CONTACT_TIED_SURFACE_TO_SURFACE, *CONTACT_TIED_SHELL_EDGE_-TO_SURFACE, and *CONTACT_TIED_SHELL_EDGE_TO_SOLID). When active, forces and moments transform correctly under superposed rigid body motions within a single implicit step. Additionally, this formulation applies rotational constraints consistently *when, and only when, necessary*. In particular, strong objectivity is implemented so that tracked nodes without rotational degrees of freedom are not rotationally constrained, while tracked nodes with bending and torsional rotations are rotationally constrained. Additionally, strong objectivity ensures that the constraint is physically correct.

   For a reference node belonging to a *shell*, the tracked node's bending rotations (rotations in the plane of the reference segment) are constrained to match the reference segment's rotational degrees of freedom; for reference nodes *not belonging to a shell*, the tracked node's bending rotations are constrained to the reference segment rotation as determined from its individual nodal translations. The tracked node's torsional rotations (rotations with respect to the normal of

the reference segment) are *always* constrained based on the reference segment's torsional rotation as determined from its individual nodal translations, thus avoiding the relatively weak drilling mode of shells. This tied contact formulation properly treats bending *and* torsional rotations. Since the tracked node's rotational degrees of freedom typically come from shell or beam elements, the most frequently used options are:

TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET

TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET

The other two classes of "non-rotational" formulations:

TIED_NODES_TO_SURFACE_CONSTRAINED_OFFSET
TIED_SURFACE_TO_SURFACE_CONSTRAINED_OFFSET

TIED_NODES_TO_SURFACE_OFFSET
TIED_SURFACE_TO_SURFACE_OFFSET

are included for situations in which rotations do not need to be constrained at all. See the LS-DYNA Theory Manual for further details.

7. **Tying to Rigid Bodies.** The following tied contact types are constraint-based and *will not* work with rigid bodies:

TIED_NODES_TO_SURFACE

TIED_NODES_TO_SURFACE_CONSTRAINED_OFFSET

TIED_SURFACE_TO_SURFACE

TIED_SURFACE_TO_SURFACE_CONSTRAINED_OFFSET

TIED_SURFACE_TO_SURFACE_FAILURE (SMP only)

TIED_SHELL_EDGE_TO_SURFACE

TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET

TIED_SHELL_EDGE_TO_SOLID

SPOTWELD

SPOTWELD_WITH_TORSION

The following tied contact types are penalty-based and *will* work with rigid bodies:

SPOTWELD_WITH_TORSION_PENALTY

TIED_NODES_TO_SURFACE_OFFSET

TIED_SHELL_EDGE_TO_SURFACE_OFFSET

TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET

TIED_SURFACE_TO_SURFACE_OFFSET

Also, it may sometimes be advantageous to use the CONSTRAINED_EXTRA_-NODE_*OPTION* instead for tying deformable nodes to rigid bodies since in this latter case the tied nodes may be an arbitrary distance away from the rigid body.

8. **SPOTWELD_WITH_TORSION Contact.** The contact algorithm for tying spot welds with torsion, SPOTWELD_WITH_TORSION, must be used with care. Parts that are tied by this option should be subjected to stiffness proportional damping of approximately ten percent, meaning input a coefficient of 0.10. This can be defined for each part on the *DAMPING_PART_STIFFNESS input. Stability problems may arise with this option if damping is not used. This comment applies also to the PENALTY keyword option.

9. **Forming Contact Type and Surface Thickness.** For "Forming" contact, the surface thickness of SURFB is ignored (SURFB should be the rigid tooling while SURFA should be the blank). Furthermore, SURFB can be offset away from the blank by setting a negative (meaning opposite of the positive normal of the SURFB surface) value for SBST on Mandatory Card 3. A tool and die can be quickly offset (virtually, not physically) with this field.

10. **Airbag Interactions.** Modeling airbag interactions with structures and occupants using the actual fabric thickness, which is approximate 0.30 mm, may result in a contact breakdown that leads to inconsistent occupant behavior between different machines. Based on our experience, using a two-way automatic type contact definition, meaning AUTOMATIC_SURFACE_TO_SURFACE, between any airbag to structure/occupant interaction and setting the airbag fabric contact thickness to at least 10 times the actual fabric thickness has helped improved contact behavior and eliminates the machine inconsistencies. Due to a large stiffness difference between the airbag and the interacting materials, we recommend the soft constraint option (SOFT = 1) or the segment-based option (SOFT = 2). Note that with the above contact definition, only the airbag materials should be included in any *AIRBAG_SINGLE_SURFACE definitions to avoid duplicate contact treatment that can lead to numerical instabilities.

11. **Constraint Contact.** The following two contact types are constraint-based and must be used with care. The surface and the nodes which are constrained to a surface are not allowed to be used in any other CONSTRAINT_… contact definition:

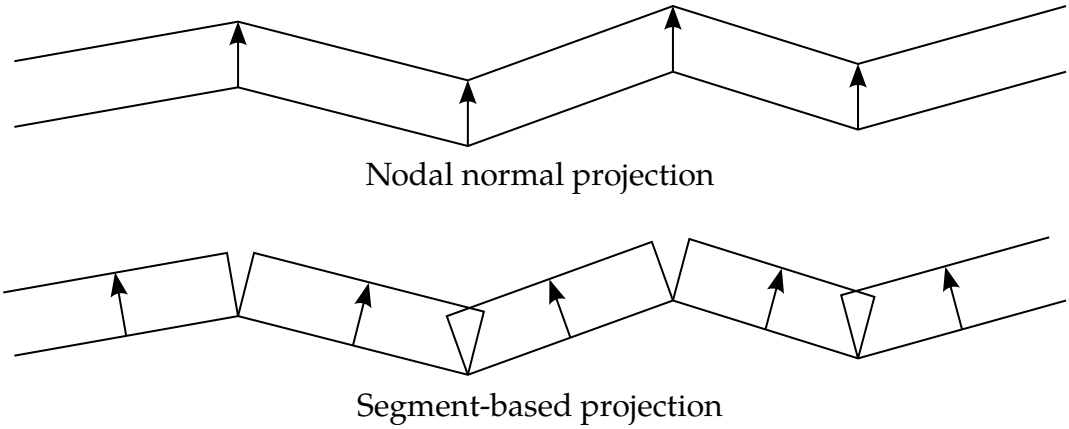

Figure 11-20. Nodal normal projection and segment-based projection used in contacts (SMP). MPP contacts use nodal normal projection exclusively.

CONSTRAINT_NODES_TO_SURFACE

CONSTRAINT_SURFACE_TO_SURFACE

If, however, contact must be defined from both sides as in sheet metal forming, one of these contact definitions can be a CONSTRAINT type; the other one could be a standard penalty type such as SURFACE_TO_SURFACE or NODES_TO_-SURFACE.

12. **Penalty-Based Contact Types and Shell Thickness.** The following penalty-based contact types consider shell thickness, that is, the contact surfaces for shells are offset from the shell midplane. This offset distance can be modified using variables on Card 3 of *CONTACT. The SHLTHK option on the *CON-TROL_CONTACT card is ignored for these contact types.

AUTOMATIC_SURFACE_TO_SURFACE

SINGLE_SURFACE

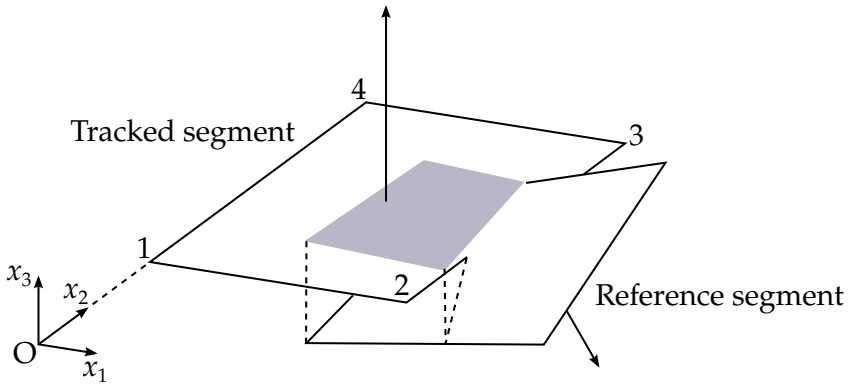

Figure 11-21. Illustration of Mortar segment-to-segment contact

A thickness that is too small may result in loss of contact while an unrealistically large thickness may result in a degradation in speed during the bucket sorts as well as nonphysical behavior. To address the latter behavior, the default setting of SSTHK in *CONTROL_CONTACT may sometimes cause the contact thickness to be reduced for certain single surface contacts (see Remark 2 of *CONTROL_CONTACT).

13. **Projecting the Contact Surface for Shell Thicknesses.** In SMP, LS-DYNA has two methods (see Figure 11-20) for projecting the contact surface to account for shell thicknesses. The method is determined by the contact type. It can influence the accuracy and cost of the calculation. Segment-based projection is used in contact types:

    AIRBAG_SINGLE_SURFACE

    AUTOMATIC_GENERAL

    AUTOMATIC_NODES_TO_SURFACE

    AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE

    AUTOMATIC_SINGLE_SURFACE

    AUTOMATIC_SURFACE_TO_SURFACE

    FORMING_NODES_TO_SURFACE

    FORMING_ONE_WAY_SURFACE_TO_SURFACE

    FORMING_SURFACE_TO_SURFACE

    The remaining contact types in SMP (and all contact types in MPP) use nodal normal projections if projections are used. The main advantage of nodal projections is that a continuous contact surface is obtained which is much more accurate in applications, such as metal forming. The disadvantages of nodal

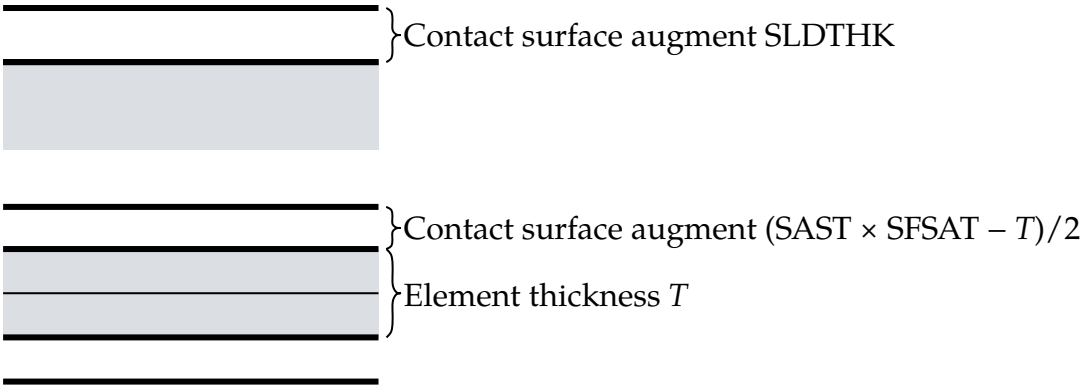

Figure 11-22. Illustration of contact surface location for automatic Mortar contact, solids on top and shells below.

projections are the higher costs due to the nodal normal calculations, difficulties in treating T-intersections and other geometric complications, and the need for consistent orientation of contact surface segments. The contact type

SINGLE_SURFACE

uses nodal normal projections and consequently is slower than the alternatives.

14. **Overview of Mortar Contact.** Mortar contact, invoked by appending the suffix MORTAR to either FORMING_SURFACE_TO_SURFACE, AUTOMATIC_SURFACE_TO_SURFACE or AUTOMATIC_SINGLE_SURFACE is a segment-to-segment penalty-based contact. For two segments on each side of the contact interface that are overlapping and penetrating, a consistent nodal force assembly taking into account the individual shape functions of the segments is performed; see Figure 11-21 for an illustration. A *CONTACT_FORCE_TRANSDUCER_PENALTY can extract forces from Mortar contacts, *but the SURFA and SURFB sides must then be defined through parts or part sets*. For the automatic Mortar contacts, support for eroded solid and shell elements is automatically invoked without the need of an ERODING option. It will also create new edge segments exposed to the exterior as shell elements erode, but beam elements are not yet supported. As for transducers, treatment of eroding requires the SURFA and SURFB sides to be defined through parts or part sets. In this respect, the results with this contact may be more accurate, especially when considering contact with elements of higher order.

By appending the suffix TIED to the *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR keyword or the suffix TIEBREAK_MORTAR (only OPTION = 2, 4, 6, 7, 8 and 9 are supported) to the *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE keyword, the contact is treated as a tied contact interface with optional failure in the latter case. For MORTAR_TIED_WELD, parts can be welded together to create a tied contact at the welded zones; segment pairs are dynamically created based on a weld criterion to make up a tied contact

element. For all these Mortar tied contacts, the tied SURFA segments can be viewed in the intfor file by specifying NTIED on *DATABASE_EXTENT_INTFOR, a convenient way to know which segments. This contact is intended for implicit analysis in particular but is nevertheless supported for explicit analysis as well. For explicit analysis, the bucket sort frequency is 100 if not specified.

FORMING *Mortar* contact, in contrast to other forming contacts, does *not* assume a rigid SURFB side, but, if this side consists of shell elements, the normal vector should be oriented towards the SURFA side. Furthermore, no shell thickness is considered on the SURFB side. The SURFA side is assumed to be a deformable part, and the orientation of the elements does not matter. However, each FORMING contact definition should be such that contact occurs with ONE deformable SURFA side only, which obviously leads to multiple contact definitions if two-sided contact is presumed.

AUTOMATIC contact is supported for solids, shells, thick shells, and beams. Here the thicknesses are considered both for rigid and deformable parts. Flat edge contact is supported for shell elements and contact with beams occurs on the lateral surface area as well as on the end tip. The contact assumes that the beam has a cylindrical shape[1] with a cross sectional area coinciding with that of the underlying beam element. The contact surface can be augmented with the aid of parameters SAST and SFSAT for shells and beams, while SLDTHK is used for solids and thick shells. For shells/beams SAST corresponds to the contact thickness of the element (SBST likewise for the SURFB side); by default, this is the same as the element thickness. This parameter can be scaled with aid of SFSAT (SFSBT for the SURFB side) to adjust the location of the contact surface; see Figure 11-22.

For all unilateral Mortar contacts (meaning non-tied contacts), FS and FD on Mandatory Card 2 are supported and work like similar non-Mortar contacts. If implicit statics is used, the dynamic friction coefficient is set equal to the static coefficient.

For solids PENMAX on Optional Card B can be used to determine the maximum penetration. It also determines the search depth for finding contact pairs. If set, it should correspond to a characteristic thickness in the model. Also, the contact surface can be adjusted with the aid of SLDTHK if it is of importance to reduce the gap between parts; see Figure 11-22. This may be of interest if initial gaps result in free objects undergoing rigid body motion and thus preventing convergence in implicit. SLDTHK may be set to a negative number, meaning that the contact surface will be offset in the negative direction of the normal by the amount specified. This option may be useful for instance if mesh coarseness prevents concentric cylinders from rotating freely with respect to each other.

[1] Internally the cylinder is faceted as described in the Theory Manual, chapter Mortar Contact.

For the TIED option, the criterion for tying two contact surfaces is by default that the distance should be less than 0.05 × T, that is, within 5% of the element thickness (characteristic size for solids). In this case PENMAX can be used to set the tying distance, meaning if PENMAX is positive then segments are tied if the distance is less than PENMAX.

If initial penetrations are detected (reported in the messag file), then by default these penetrations will be given zero contact stress. This treatment is due to IGNORE = 2 being the default for Mortar contact. IGNORE = 2 behaves differently for Mortar contacts than for other contacts. For this option, the penetrations are not tracked, but the contact surface is fixed at its initial location. In addition, for IGNORE = 2, an initial contact pressure can be imposed on the interface by setting MPAR1 to the desired contact pressure. Any rigid body motion due to initial contact gaps can be properly eliminated with these settings. If you want initial penetrations to result in contact pressure (the "old" IGNORE = 0 behavior), use IGNORE = 2 and set MPAR1 to a large number; the contact stress cannot be higher than that allowed for the given penetration. IGNORE = 1 is similar to IGNORE = 2, except the penetrations will be tracked. Thus, if the surfaces separate, the contact surface locations are updated accordingly. In the event of surfaces separating enough to form gaps, the contact is restored to as if there were no initial penetrations in the first place.

A third option is IGNORE = 3, for which prestress can be applied. This allows initial penetrations to exist which are closed during the time between zero and the value given by MPAR1. It works like the INTERFERENCE option, except that the closure is linear in time. Initial penetrations, however, must be small enough for the contact algorithm to detect them. For this option MPAR1 can be chosen negative, meaning that the reduction factor is specified as a load curve as function of time. This load curve should increase from 0 to 1, where 1 means that all initial penetrations have been removed.

For large penetrations IGNORE = 4 is recommended (this can only be used if the SURFA side consists of solid elements). This option does pretty much the same thing as IGNORE = 3, but you may provide a penetration depth with MPAR2. This depth must be at least as large as (and preferably in the order of) the maximum initial penetration in the contact interface; otherwise, an error termination will be the result. This parameter helps the contact algorithm locate the contact surface and thus estimate the initial penetration. With this option the contact surfaces are pushed back and placed in incident contact at places where initial penetrations are present which can be done for (more or less) arbitrary initial penetration depths. Like IGNORE = 3, the contact surfaces will be restored linearly in the time given by MPAR1, but here the load curve option is not applicable.

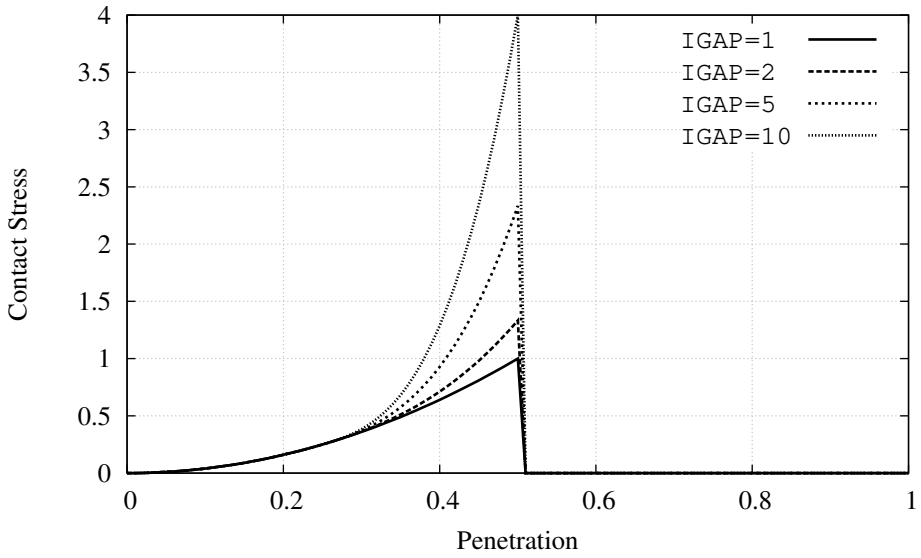

Figure 11-23. Mortar contact stress as function of penetration

Mortar contacts in implicit analysis can cause the contact pressure to locally be very high which leads to the release of large enough penetrations in subsequent steps. Penetration information can be requested on MINFO on *CONTROL_OUTPUT which issues a warning if there is a danger of this happening. To prevent contact release, you may increase IGAP which penalizes large penetrations without affecting small penetration behavior and thereby overall implicit performance. Figure 11-23 shows the contact pressure as function of penetration for the Mortar contact, including the effect of increasing IGAP. It also shows that for sufficiently large penetrations the contact is not detected in subsequent steps which is something to avoid. In addition, a negative IGAP can be used to render a linear relationship between the penetration and contact pressure. This might be helpful if relatively large penetrations are observed for small contact pressures.

Table 11-1 below lists fields on the mandatory and optional cards that apply to MORTAR contact. Any parameter not mentioned in this list is ignored. See a similar table on the manual page for *CONTROL_CONTACT.

Data Card	Comment
Mandatory Card 1	Apply as for any other contact. Parts or part sets are recommended. Contact stiffness is taken from the SURFA side of the contact.
Mandatory Card 2	Except for PENCHK, these fields also apply as for any other contact. PENCHK is ignored.

Data Card	Comment
Mandatory Card 3	Except for SFSB, FSF and VSF, these also apply as for any other contact. SFSB, FSF and VSF are ignored.
Optional Card A	Only BSORT applies. All others are ignored. BSORT is the bucket sort frequency.
Optional Card B	Only PENMAX and SLDTHK apply. All others are ignored. PENMAX is the contact search depth for solid element segments, and SLDTHK is the distance by which solid element segments are offset in the direction of the segment normal.
Optional Card C	First four parameters apply, others are ignored. IGAP is a stiffness parameter for large penetrations which is usually not needed. IGNORE deals with initial penetrations as described above, and MPAR1/MPAR2 are parameters associated with the choice of IGNORE.
Optional Cards D, E, and F	No parameter applies. Shell edges are always flat.

Table 11-1. Fields related to Mortar contact

INTERFACE TYPE ID	PENCHK	ELEMENT TYPE	FORMULA FOR RELEASE OF PENETRATING NODAL POINT
1, 2, 6, 7	-	———	———
3, 5, 8, 9, 10 (without thickness)	0	solid	d = PENMAX if PENMAX > 0 d = 10^{10} if PENMAX = 0
		shell	d = PENMAX if PENMAX > 0 d = 10^{10} if PENMAX = 0
	1	solid	d = XPENE × thickness of solid element
		shell	d = XPENE thickness of shell element
	2	solid	d = 0.05 × minimum diagonal length
		shell	d = 0.05 × minimum diagonal length
3, 5, 10 (thickness), 17 and 18	-	solid	d = XPENE × thickness of solid element
		shell	d = XPENE × thickness of shell element
a3, a5, a10, 13, 15	-	solid	d = PENMAX × thickness of solid element *[default: PENMAX = 0.5]*
		shell	d = PENMAX × (tracked thickness + reference thickness) *[default: PENMAX = 0.4]*
4	-	solid	d = 0.5 × thickness of solid element
		shell	d = 0.4 × (tracked thickness + reference thickness)
26	———	solid	d = PENMAX × thickness of solid element *[default: PENMAX = 10.0]*
		shell	d = PENMAX × (tracked thickness + reference thickness) *[default: PENMAX = 10.]*

Table 11-2. Criterion for node release for nodal points which have penetrated too far. This criterion does not apply to SOFT = 2 contact. Larger penalty stiffnesses are recommended for the contact interface which allows nodes to be released. For node-to-surface type contacts (5, 5a), the element thicknesses which contain the node determines the nodal thickness. The parameter is defined on the *CONTROL_CONTACT input.

Mapping of *CONTACT keyword option to "contact type" in d3hsp:

*CONTACT_ADD_WEAR

Purpose: Associate a wear model to a contact interface.

Wear is associated with friction, so the frictional coefficient *must* be nonzero for the associated contact interface. This feature calculates the wear depth, sliding distance and possibly user defined wear history variables according to the specified model which are then written to the intfor database (see *DATABASE_EXTENT_INTFOR) for post-processing. Note that this data is *not* written unless the parameter NWEAR and/or NWUSR are set on the *DATABASE_EXTENT_INTFOR card. *H*-adaptive remeshing is supported with this feature. Implicit analysis is supported, for which mortar is the preferred contact.

For positive CID values, this keyword does not affect the results of a simulation and only provides wear quantities for post-processing. For negative CID values, the contact surface is perturbed internally based on the wear depth so that the contact behavior is affected by the wear on the surface.

Card 1	1	2	3	4	5	6	7	8
Variable	CID	WTYPE	P1	P2	P3	P4	P5	P6
Type	I	I	F	F	F	F	F	F
Default	none	0	none	none	↓	↓	↓	↓

User Defined Wear Parameter Cards. Define as many cards as needed to define P1 parameters if and only if WTYPE < 0.

Card 2	1	2	3	4	5	6	7	8
Variable	W1	W2	W3	W4	W5	W6	W7	W8
Type	F	F	F	F	F	F	F	F

VARIABLE	DESCRIPTION
CID	Contact interface ID, see *CONTACT_… LT.0: Perturb contact surface according to wear values (see Remark 5). GT.0: Calculate wear properties for post-processing only.

VARIABLE	DESCRIPTION
WTYPE	Wear law: LT.0: User defined wear law; value specifies type used in subroutine. EQ.0: Archard's wear law
P1	First wear parameter: WTYPE.EQ.0: Dimensionless scale factor k. If negative, the absolute value specifies a table ID with $k = k(p, \dot{d})$ as a function of contact pressure $p \geq 0$ and relative sliding velocity $\dot{d} \geq 0$. The table should be defined such that for each specified value of $\dot{d}$, there exists a curve such that k (ordinate) is a function of p (abscissa). WTYPE.LT.0: Number of user wear parameters for this interface
P2	Second wear parameter: WTYPE.EQ.0: SURFA surface hardness parameter H_A. If negative, the absolute value specifies a curve ID with $H_A = H_A(T_A)$ as function of SURFA node temperature T_A. WTYPE.LT.0: Number of user wear history variables per contact node. These can be output to the intfor file; see NWUSR on *DATABASE_EXTENT_INTFOR.
P3	Third wear parameter: WTYPE.EQ.0: SURFB surface hardness parameter H_B. If negative, the absolute value specifies a curve ID with $H_B = H_B(T_B)$ as function of SURFB node temperature T_B. WTYPE.LT.0: Not used
P4 - P6	Not used
Wn	nth user defined wear parameter.

Remarks:

1. **Archard's Wear Law.** Archard's wear law (WTYPE = 0) states that the wear depth w at a contact point evolves with time as

$$\dot{w} = k\frac{p\dot{d}}{H}$$

where $k > 0$ is a dimensionless scale factor, $p \geq 0$ is the contact interface pressure, $\dot{d} \geq 0$ is the relative sliding velocity of the points in contact and $H > 0$ is the surface hardness (force per area). The wear depth for a node in contact is incremented in accordance with this formula, accounting for the different hardness of the SURFA and SURFB side, H_A and H_B, respectively. By using negative numbers for wear parameters P1, P2 or P3, the corresponding parameter is defined by a table or a curve. For P1, the value of k is taken from a table with contact pressure p and sliding velocity $\dot{d}$ as arguments, while for P2 or P3, the corresponding hardness H is taken from curves with the associated contact nodal temperature T as argument. That is, the SURFA side hardness will be a function of the SURFA side temperature, and vice versa.

2. **User Defined Wear Laws.** Customized wear laws may be specified as a user-defined subroutine called userwear. This subroutine is called when WTYPE < 0. This subroutine is passed wear parameters (see P1) for this interface as well as number of wear history variables (see P2) per contact node. The wear parameters are defined on additional cards (see WN) and the history variables are updated in the user subroutine. The history variables can be output to the intfor file, see NWUSR on *DATABASE_EXTENT_INTFOR. WTYPE may be used to distinguish between different wear laws, and consequently any number of different laws can be implemented within the same subroutine. For more information, we refer to the source code which contains extensive commentaries and two sample wear laws.

3. **Using Wear Laws.** Only one wear law per contact interface can be specified. The procedure for activating this feature involves

   a) Using the present keyword to associate wear to a contact interface

   b) Setting NWEAR and/or NWUSR on the *DATABASE_EXTENT_INTFOR card.

   c) Having a contact interface with friction of a type that is supported. If SOFT = 2 on optional card A of the contact data, then any valid keyword option is supported. If SOFT = 0 or SOFT = 1, then the following list is supported.

      *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE

*CONTACT_FORMING_SURFACE_TO_SURFACE

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE

*CONTACT_FORMING_SURFACE_TO_SURFACE_MORTAR

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR

*CONTACT_AUTOMATIC_SINGLE_SURFACE_MORTAR

4. **Limitations.** The following are not supported with this keyword.

   a) _SMOOTH option

   b) MPP "groupable" option

5. **Negative CID Option.** For this option, the wear is accounted for by perturbing the contact surface internally (not by updating the node positions). As such, no changes to the element geometry will be observed due to wear, however increased part penetrations and stress redistributions will occur, as well as redistribution of contact pressure and wear depth in the intfor results. The method is only physically justified for relatively small wear depths. Care must therefore be taken in selecting the wear parameters to ensure that the wear depth does not exceed the maximum penetration associated with the contact. This option is available for SMP, MPP and Hybrid versions when SOFT = 2 on optional card A of the *CONTACT card but is only available for the SMP version when SOFT = 0 or 1.

*CONTACT_AUTO_MOVE

Purpose: Automatically move the surfb surface in a contact definition to close an unspecified gap between the surfa and surfb surfaces. The gap may result from loading the surfa part with an initial gravity load. The gap will be closed at a specified time to save CPU time. The surfb surface in metal forming applications is typically the upper cavity while the surfa part is the blank. This feature is only applicable to sheet metal forming application.

Cards 1	1	2	3	4	5	6	7	8
Variable	ID	CONTID	VID	LCID	ATIME	OFFSET		
Type	I	I	I	I	F	F		
Default	none	none	none	0	0.0	0.0		

VARIABLE	DESCRIPTION
ID	Move ID for this automatic move input: GT.0: Velocity controlled tool kinematics (the variable VAD = 0 in *BOUNDARY_PRESCRIBED_MOTION_RIGID) LT.0: Displacement controlled tool kinematics (VAD = 2)
CONTID	Contact ID, as in *CONTACT_FORMING_..._ID, which defines the surfa and surfb part set IDs.
VID	Vector ID of a vector oriented in the direction of movement of the surfb surface, as in *DEFINE_VECTOR. The origin of the vector is unimportant since the direction cosines of the vector are computed and used.
LCID	Load curve defining tooling kinematics, either by velocity as a function of time or by displacement as a function of time. This load curve will be adjusted automatically during a simulation to close the empty tool travel.
ATIME	Activation time specifying the moment the surfb surface (tool) will be moved

VARIABLE	DESCRIPTION
OFFSET	Time at which a surfb surface will move to close a gap distance, which may happen following the move of another surfb surface. This is useful for sequential multiple flanging or press hemming simulations. Simulation time (CPU) is much faster based on the shortened tool travel (no change to the termination time).

Example: gravity loading and closing with implicit static

Referring to the partial input deck below and Figure 11-24, a combined simulation of gravity loading and binder closing of a fender outer is demonstrated on the NUMISHEET 2002 benchmark. In this multistep implicit static set up, the blank is allocated 0.3 "time" units (3 implicit steps for DT0 = 0.1) to be loaded with gravity. At the end of gravity loading, a gap of 12mm was created between the upper die and the blank (see Figure 11-25). The upper die is set to be moved at 0.3 "time" units, closing the gap caused by the gravity effect on the blank (see Figure 11-26 left). An intermediate closing state is shown at $t = 0.743$ (see Figure 11-26 right) while the final completed closing is shown in Figure 11-27. It is noted that the upper die is controlled with displacement (VAD = 2) in the shape of a right triangular in the displacement versus "time" space as defined by load curve #201, and the ID in *CONTACT_AUTO_MOVE is set to "-1".

Example: tool delay in sequential flanging process with explicit dynamic:

The following example demonstrates the use of the variable OFFSET. As shown in Figure 11-28 (left), a total of 5 flange steels are auto-positioned initially according to the initial blank shape. Upon closing the pressure pad, the first set of 4 flanging steels moves to home, completing the first stage of the stamping process (see Figure 11-28 right).

The gap created by the completion of the first flanging process is closed automatically at a time defined using variables ATIME/OFFSET (see Figure 11-29 left). During the second stage of the process, flanging steel *&flg5pid* moves to home completing the final flanging (see Figure 11-29 right). An excerpt from the input deck for this model can be found below. This deck was created using LS-PrePost's eZ-Setup feature (http://ftp.lstc.com/-anonymous/outgoing/lsprepost/), with two additional keywords added:*CONTACT_-AUTO_MOVE and *DEFINE_VECTOR.

Flanging steel #5 is set to move in a cam angle defined by vector #7 following the completion of the flanging (straight down) process of flanging steel #2. The variables ATIME and OFFSET in *CONTACT_AUTO_MOVE are both defined as &endtim4, which is calculated based on the automatic positioning of tools/blank using *CONTROL_FORMING_AUTOPOSITION. At a defined time, flanging steel #5 'jumps' into position to where

it just comes into contact with the partially formed down-standing flange, saving some CPU times (see Figure 11-29 left). Flanging steel #5 continues to move to its home position completing the simulation (see Figure 11-29 right). The CPU time saving is 27% in this case.

*CONTACT_COUPLING

Purpose: Define a coupling surface for MADYMO to couple LS-DYNA with deformable and rigid parts within MADYMO. In this interface, MADYMO computes the contact forces acting on the coupling surface, and LS-DYNA uses these forces in the update of the motion of the coupling surface for the next time step. Contact coupling can be used with other coupling options in LS-DYNA.

Card 1	1	2	3	4	5	6	7	8
Variable	ID							
Type	I							
Default	none							

Set Cards. Include on card for each coupled set. The next keyword ("*") card terminates this input.

Card 2	1	2	3	4	5	6	7	8
Variable	SID	STYPE						
Type	I	I						
Default	none	0						

VARIABLE	DESCRIPTION
SID	Set ID for coupling. See Remark 1 below.
STYPE	Set type: EQ.0: part set EQ.1: shell element set EQ.2: solid element set EQ.3: thick shell element set

Remarks:

1. **Coupling Surface.** Only one coupling surface can be defined. If additional surfaces are defined, the coupling information will be added to the first definition.

2. **Units.** The units and orientation can be converted by using the *CONTROL_COUPLING keyword. It is not necessary to use the same system of units in MADYMO and in LS-DYNA if unit conversion factors are defined.

*CONTACT_ENTITY

Purpose: Define a contact entity. Geometric contact entities treat the impact between a deformable body, defined as a set of tracked nodes or nodes in a shell part set, and a rigid body. The shape of the rigid body is determined by attaching geometric entities. Contact between these geometric entities and the tracked nodes is a penalty formulation. The penalty stiffness is optionally maximized within the constraint of the Courant criterion. As an alternative, a finite element mesh made with shells can be used as geometric entity. Also, axisymmetric entities with arbitrary shape made with multi-linear polygons are possible. The latter is particularly useful for metal forming simulations. See *DATABASE_GCEOUT for contact force output.

> **WARNING:** If the problem being simulated involves dynamic motion of the entity, care should be taken to ensure that the inertial properties of the entity are correct. These properties may need to be specified with *PART_INERTIA.

Figure 11-30. Contact Entities

Data Card Definitions:

Card 1	1	2	3	4	5	6	7	8
Variable	PID	GEOTYP	SURFA	SURFATYP	SF	DF	CF	INTORD
Type	I	I	I	I	F	F	F	I
Default	none	none	none	0	1.	0.	0.	0

VARIABLE	DESCRIPTION
PID	Part ID of the rigid body to which the geometric entity is attached, see *PART.
GEOTYP	Type of geometric entity (see Figure 11-30): EQ.1: Plane, EQ.2: Sphere, EQ.3: Cylinder, EQ.4: Ellipsoid, EQ.5: Torus, EQ.6: CAL3D/MADYMO Plane, see Appendix I, EQ.7: CAL3D/MADYMO Ellipsoid, see Appendix I, EQ.8: VDA surface, see Appendix L, EQ.9: Rigid body finite element mesh (shells only), EQ.10: Finite plane, EQ.11: Load curve defining line as surface profile of axisymmetric rigid bodies.
SURFA	Tracked surface set ID, see *SET_NODE_*OPTION*, *PART, or *SET_PART.
SURFATYP	Tracked surface set type: EQ.0: Node set EQ.1: Part EQ.2: Part set

VARIABLE	DESCRIPTION
SF	Penalty scale factor. Useful to scale maximized penalty.
DF	Damping option (see description for *CONTACT_*OPTION*): EQ.0: No damping, GT.0: Viscous damping in percent of critical, e.g., 20 for 20% damping, LT.0: DF must be a negative integer. -DF is the load curve ID giving the damping force as a function of relative normal velocity (see Remark 1 below).
CF	Coulomb friction coefficient. See Remark 2 below. EQ.0: No friction GT.0: Constant friction coefficient LT.0: CF must be a negative integer. -CF is the load curve ID giving the friction coefficient as a function of time.
INTORD	Integration order (tracked materials only). This option is not available with entity types 8 or 9 where only nodes are checked: EQ.0: check nodes only, EQ.1: 1 point integration over segments, EQ.2: 2×2 integration, EQ.3: 3×3 integration, EQ.4: 4×4 integration, EQ.5: 5×5 integration. This option allows a check of the penetration of the rigid body into the deformable (tracked) material. Then virtual nodes at the location of the integration points are checked.

Card 2	1	2	3	4	5	6	7	8
Variable	BT	DT	SO	GO	ITHK	TPR		
Type	F	F	I	I	I	I		
Default	0.	10^{20}	0	0	0	0		

VARIABLE	DESCRIPTION
BT	Birth time
DT	Death time
SO	Flag to use penalty stiffness as in surface-to-surface contact: EQ.0: Contact entity stiffness formulation, EQ.1: Surface to surface contact method, EQ.2: Normal force is computed via a constraint-like method. The contact entity is considered to be infinitely massive, so this is recommended only for entities with constrained motion. LT.0: SO must be an integer. -SO is the load curve ID giving the force versus the normal penetration. See Remark 1.
GO	Flag for automatic meshing of the contact entity for entity types 1 - 5 and 10 - 11. GO = 1 creates null shells for visualization of the contact entity. Note these shells have mass and will affect the mass properties of the rigid body PID unless *PART_INERTIA is used for the rigid body. EQ.0: Mesh is not generated. EQ.1: Mesh is generated.
ITHK	Flag for considering thickness for shell tracked nodes (applies only to entity types 1, 2, 3; SURFATYP must be set to zero). EQ.0: Shell thickness is not considered. EQ.1: Shell thickness is considered.
SAPR	Include the tracked side in *DATABASE_BINARY_INTFOR interface force files; valid only when SURFATYP > 0: EQ.1: Tracked side forces included.

Card 3	1	2	3	4	5	6	7	8

ZC	z-center, z_c. See Remark 3.
AX	x-direction for local axis **A**, A_x. See Remark 3.
AY	y-direction for local axis **A**, A_y. See Remark 3.
AZ	z-direction for local axis **A**, A_z. See Remark 3.
BX	x-direction for local axis **B**, B_x. See Remark 3.
BY	y-direction for local axis **B**, B_y. See Remark 3.
BZ	z-direction for local axis **B**, B_z. See Remark 3.

Card 5	1	2	3	4	5	6	7	8
Variable	INOUT	G1	G2	G3	G4	G5	G6	G7
Type	I	F	F	F	F	F	F	F
Default	0	0.	0.	0.	0.	0.	0.	0.

VARIABLE	DESCRIPTION
INOUT	In-out flag. Allows contact from the inside or the outside (default) of the entity: EQ.0: Tracked nodes exist outside of the entity. EQ.1: Tracked nodes exist inside the entity.
G1	Entity coefficient g_1 (CAL3D/MADYMO plane or ellipse number) for coupled analysis (see Appendix I). See Geometric Contact Entity Coefficients below.
G2	Entity coefficient g_2. See Geometric Contact Entity Coefficients below.
G3	Entity coefficient g_3. See Geometric Contact Entity Coefficients below.
G4	Entity coefficient g_4. See Geometric Contact Entity Coefficients below.
G5	Entity coefficient g_5. See Geometric Contact Entity Coefficients below.
G6	Entity coefficient g_6. See Geometric Contact Entity Coefficients below.
G7	Entity coefficient g_7. See Geometric Contact Entity Coefficients below.

Remarks:

1. **Damping and Contact Load Curves.** The optional load curves that are defined for damping versus relative normal velocity and for force versus normal penetration should be defined in the positive quadrant. The sign for the damping

force depends on the direction of the relative velocity and the treatment is symmetric if the damping curve is in the positive quadrant. If the damping force is defined in the negative and positive quadrants, the sign of the relative velocity is used in the table look-up.

2. **Friction Coefficient.** If at any time the friction coefficient is ≥ 1.0, the force calculation is modified to a constraint like formulation which allows no sliding. This is only recommended for entities with constrained motion since the mass of the entity is assumed to be infinite.

3. **Geometric Entity Coordinate System.** The coordinates, (x_c, y_c, z_c), are the positions of the local origin of the geometric entity in global coordinates. The entity's local A-axis is determined by the vector (A_x, A_y, A_z) and the local B-axis by the vector (B_x, B_y, B_z).

   Cards 3 and 4 define a local to global transformation. The geometric contact entities are defined in a local system and transformed into the global system. For the ellipsoid, this is necessary because it has a restricted definition for the local position. For the plane, sphere, and cylinder, the entities can be defined in the global system and the transformation becomes $(x_c, y_c, z_c) = (0,0,0)$, $(A_x, A_y, A_z) = (1,0,0)$, and $(B_x, B_y, B_z) = (0,1,0)$.

Geometric Contact Entity Coefficients:

Figure 11-30 shows the definitions of the geometric contact entities. The relationships between the entity coefficients and the Figure 11-30 variables are as described below. Note that (P_x, P_y, P_z) defines a point and (Q_x, Q_y, Q_z) is a direction vector.

GEOTYP = 1

$g_1 = P_x$
$g_2 = P_y$
$g_3 = P_z$
$g_4 = Q_x$
$g_5 = Q_y$
$g_6 = Q_z$
$g_7 = L$

If automatic generation is used, a square plane of length L on each edge is generated which represents the infinite plane. If generation is inactive, then g_7 may be ignored.

GEOTYP = 2

$g_1 = P_x$
$g_2 = P_y$
$g_3 = P_z$
$g_4 = r$

GEOTYP = 3

$g_1 = P_x$
$g_2 = P_y$
$g_3 = P_z$
$g_4 = Q_X$
$g_5 = Q_y$
$g_6 = Q_z$
$g_7 = r$

If automatic generation is used, a cylinder of length $\sqrt{Q_x^2 + Q_y^2 + Q_z^2}$ and radius r is generated which represents the infinite cylinder. The midpoint of the displayed cylinder is at point P.

GEOTYP = 4

$g_1 = P_x$
$g_2 = P_y$
$g_3 = P_z$
$g_4 = a$
$g_5 = b$
$g_6 = c$
$g_7 = n$ (order of the ellipsoid)

GEOTYP = 5

g_1 = Radius of torus
$g_2 = r$
g_3 = number of elements along minor circumference
g_4 = number of elements along major circumference

GEOTYP = 8

g_1 = Blank thickness (option to override true thickness)
g_2 = Scale factor for true thickness (optional)
g_3 = Load curve ID defining thickness versus time. (optional)

GEOTYP = 9

g_1 = Shell thickness (option to override true thickness).
g_2 = Scale factor for true thickness (optional)
g_3 = Load curve ID defining thickness versus time. (optional)

Note: The shell thickness specification is necessary if the tracked surface is generated from solid elements.

GEOTYP = 10

g_1 = Length of edge along X' axis
g_2 = Length of edge along Y' axis

GEOTYP = 11

g_1 = Load curve ID defining axisymmetric surface profile about the Z-axis. Load curves defined by the keywords *DEFINE_CURVE or *DEFINE_CURVE_ENTITY can be used.

g_2 = Number of elements along circumference

EQ.0: default set to 10

g_3 = Number of elements along axis

EQ.0: default set to 20

EQ.-1: the elements generated from points on the load curve

g_4 = Number of sub divisions on load curve used to calculate contact

EQ.0: default set to 1000

*CONTACT_EXCLUDE_INTERACTION

Purpose: Specify portions of a contact interface to exclude from having a contact interaction. The portions of the interface are specified with sets. If a single set is given, then all contact with segments in that set will be excluded. If two sets are defined, then only contact between segments in set one will be excluded from contact with segments in set two. See Remarks 1 and 2. This option is only available for the segment-to-segment contact that is invoked by setting SOFT = 2 on optional card A.

Card 1	1	2	3	4	5	6	7	8
Variable	CEID	CID						
Type	I	I						
Default	none	none						

Set Cards. Include as many lines as needed to specify different portions of the interface to be excluded from contact. The next keyword ("*") card terminates this input.

Card 2	1	2	3	4	5	6	7	8
Variable	SID2	SID1	TYPE2	TYPE1				
Type	I	I	I	I				
Default	0	0						

VARIABLE	DESCRIPTION
CEID	Contact exclusion ID for output only
CID	Contact interface ID for limiting exclusions to an interface
SID2	Set ID of set 2
SID1	Set ID of set 1
TYPE2	ID type of set SID2: EQ.0: Segment set EQ.1: Shell element set

VARIABLE	DESCRIPTION
	EQ.2: Part set
TYPE1	ID type of set SID1: EQ.0: Segment set EQ.1: Shell element set EQ.2: Part set

Remarks:

1. **Excluded Interactions.** A search of contact interface CID is made for segments within SID2 and SID1. If both SID2 and SID1 are defined, then segments in set SID1 will be excluded from contact with segments in set SID2. If SID2 is omitted, then segments in SID1 will be excluded from contact with all segments in the interface. Similarly, if SID1 is omitted, then segments in SID2 will be excluded from contact with all segments in the interface.

2. **How to Specify Excluded Sets for Different Contact Types.** If CID is surface-to-surface type contact, then segments defined by SURFA on *CONTACT will be searched for the segments in SID2, and segments defined by SURFB on *CONTACT will be searched for segments in SID1. If CID is a single surface contact, then segments defined by SURFA on contact will be searched for segments in both SID1 and SID2.

CONTACT_FORCE_TRANSDUCER_*OPTION1_{OPTION2}

Purpose: Create a force transducer to measure the contact force of a 3D contact. LS-DYNA only outputs data between a SURFA and SURFB surface. Self-contact, such as single surface contact, only has a SURFA definition. In the case of self-contact, force transducers provide a means to record the self-contact forces. Force transducers are not needed for other types of contact. However, they may be useful for extracting the contact forces for any part of the model. For instance, if you have two-way contact, you may only want to extract the forces on a section of SURFB. Force transducers do not apply any force to the model nor do they have any effect on the solution.

This keyword is *not* implemented for 2D contact.

Available options for *OPTION1* are:

CONSTRAINT

PENALTY

The CONSTRAINT option extracts forces from constraint-based contact types while the PENALTY option extracts forces only from penalty-based contacts.

Available options for *OPTION2* are:

ID

In the output files, the contact ID identifies the results from the force transducer measurements. If the contact ID is undefined, the default ID is determined by the sequence of the contact definitions, that is, the first contact definition has an ID of 1, the second, 2, and so forth. The ID and heading are picked up by some of the peripheral LS-DYNA codes to aid in post-processing.

Card ID. Additional card for ID keyword option

Type								

VARIABLE	DESCRIPTION
CID	Contact interface ID. This must be a unique number.
HEADING	Interface descriptor. We suggest using unique descriptions.
SURFA	Segment set ID, node set ID, part set ID, part ID, or shell element set ID specifying the SURFA side of the force transducer; see *SET_SEGMENT, *SET_NODE_*OPTION*, *PART, *SET_PART or *SET_SHELL_*OPTION*. EQ.0: Includes all parts.
SURFB	Segment set ID, node set ID, part set ID, part ID, or shell element set ID specifying the SURFB side of the force transducer. A SURFB set is not required for force transducers, See Remark 1.

VARIABLE	DESCRIPTION
SURFATYP	ID type of SURFA: EQ.0: Segment set ID EQ.1: Shell element set ID EQ.2: Part set ID EQ.3: Part ID EQ.4: Node set ID. See Remark 2. EQ.5: Include all (SURFA is ignored) EQ.6: Part set ID for exempted parts. All non-exempted parts are included in the force transducer. EQ.7: Branch ID; see *SET_PART_TREE.
SURFBTYP	ID type of SURFB: EQ.0: Segment set ID EQ.1: Shell element set ID EQ.2: Part set ID EQ.3: Part ID EQ.4: Node set ID. See Remark 2. EQ.5: Include all (SURFB is ignored). EQ.6: Part set ID for exempted parts. All non-exempted parts are included in the force transducer. EQ.7: Branch ID; see *SET_PART_TREE.
SABOXID	Include in force transducer definition only those SURFA nodes/segments within box SABOXID (corresponding to BOXID in *DEFINE_BOX), or if SABOXID is negative, only those SURFA nodes/segments within contact volume |SABOXID| (corresponding to CVID in *DEFINE_CONTACT_VOLUME). SABOXID can be used only if SURFATYP is set to 2 or 3, that is, SURFA is a part ID or part set ID
SBBOXID	Include in force transducer definition only those SURFB segments within box SBBOXID (corresponding to BOXID in *DEFINE_BOX), or if SBBOXID is negative, only those SURFB segments within contact volume |SBBOXID| (corresponding to CVID in *DEFINE_CONTACT_VOLUME). SBBOXID can be used only if SURFBTYP is set to 2 or 3, that is, SURFB is a part ID or part set ID.

VARIABLE	DESCRIPTION
SAPR	Include the SURFA side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files, and optionally in the dynain file for wear: EQ.0: Do not include. EQ.1: SURFA side forces included. EQ.2: Same as 1 but also allows for SURFA nodes to be written as *INITIAL_CONTACT_WEAR to dynain; see NCYC on *INTERFACE_SPRINGBACK_LSDYNA.
SBPR	Include the SURFB side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files, and optionally in the dynain file for wear: EQ.0: Do not include. EQ.1: SURFB side forces included. EQ.2: Same as 1, but also allows for SURFB nodes to be written as *INITIAL_CONTACT_WEAR to dynain; see NCYC on *INTERFACE_SPRINGBACK_LSDYNA.

Remarks:

1. **SURFB set with force transducers.** A SURFB set ID (SURFB and SURFBTYP) is optional for force transducers. If the contact forces acting between two particular surfaces are needed, a SURFB surface should be defined. In this case, only the contact forces applied between SURFA and SURFB are recorded. Otherwise, the contact forces between SURFA and any surface are output. If a transducer is used for extracting forces from Mortar contacts, the SURFA and SURFB sides *must* be defined through parts or part sets; segment and node sets will not gather the correct data.

> **NOTE:** The SURFB surface option of FORCE_TRANSDUCER is only implemented for the PENALTY option. It works only in conjunction with Mortar contacts, AUTOMATIC_SURFACE_TO_SURFACE, ERODING_SINGLE_SURFACE, AUTOMATIC_SINGLE_SURFACE contact types, and groupable AUTOMATIC_GENERAL contact types (MPP only), except as noted in the next remark.

2. **SURFA/SURFB node sets.** Using node sets to specify the surfaces requires the PENALTY keyword option. Additionally, if either SURFA or SURFB is a node set, both must be node sets. Node sets allow the transducer to give correct results for eroding materials. The node sets should include all nodes that may be exposed as erosion occurs.

3. **Force output.** Contact force data can be recorded with *DATABASE_RCFORC, *DATABASE_NCFORC, and *DATABASE_BINARY_INTFOR. The contact energy data for force transducers can be recorded with *DATABASE_SLEOUT, but this data is only recorded for MPP.

***CONTACT_GEBOD**_*OPTION*

Purpose: Define contact interaction between the segment of a GEBOD dummy and parts or nodes of the finite element model. This implementation follows that of the contact entity, however, it is specialized for the dummies. Forces may be output using the *DATABASE_GCEOUT command. See *COMPONENT_GEBOD and Appendix N for further details.

Conventional *CONTACT_*OPTION* treatment (surface-to-surface, nodes-to-surface, etc.) can also be applied to the segments of a dummy. To use this approach, the part ID assignments must be first determined by running the model through LS-DYNA's initialization phase.

The following options are available and refer to the ellipsoids which comprise the dummy. Options involving HAND are *not* applicable for the child dummy since its lower arm and hand share a common ellipsoid.

Card 1	1	2	3	4	5	6	7	8
Variable	DID	SURFA	SURFATYP	SF	DF	CF	INTORD	
Type	I	I	I	F	F	F	I	
Default	none	none	none	1.	20.	0.5	0	

VARIABLE	DESCRIPTION
DID	Dummy ID, see *COMPONENT_GEBOD_*OPTION*.
SURFA	Tracked surface set ID, see *SET_NODE_*OPTION*, *PART, or *SET_PART.
SURFATYP	SURFA set type: EQ.0: Node set EQ.1: Part EQ.2: Part set
SF	Penalty scale factor. Useful to scale maximized penalty.
DF	Damping option, see description for *CONTACT_*OPTION*: EQ.0.0: No damping, GT.0.0: Viscous damping in percent of critical, e.g., 20 for 20% damping, LT.0.0: DF must be an integer. -DF is the load curve ID giving the damping force as a function of relative normal velocity (see Remark 1 below).
CF	Coulomb friction coefficient (see Remark 2 below). Assumed to be constant.
INTORD	Integration order (tracked materials only). EQ.0: Check nodes only, EQ.1: 1 point integration over segments, EQ.2: 2×2 integration, EQ.3: 3×3 integration, EQ.4: 4×4 integration, EQ.5: 5×5 integration. This option allows a check of the penetration of the dummy segment into the deformable (tracked) material. Then virtual nodes at the location of the integration points are checked.

Card 2	1	2	3	4	5	6	7	8
Variable	BT	DT	SO					
Type	F	F	I					
Default	0.	10^{20}	0					

VARIABLE	DESCRIPTION
BT	Birth time
DT	Death time
SO	Flag to use penalty stiffness as in surface-to-surface contact: EQ.0: Contact entity stiffness formulation, EQ.1: Surface to surface contact method, LT.0: In this case SO must be an integer. |SO| references the load curve ID which defines the force as a function of the normal penetration. See Remark 1.

Remarks:

1. **Load Curves.** The optional load curves that are defined for damping as a function relative normal velocity and for force as a function of normal penetration should be defined in the positive quadrant. The sign for the damping force depends on the direction of the relative velocity and the treatment is symmetric if the damping curve is in the positive quadrant. If the damping force is defined in the negative and positive quadrants, the sign of the relative velocity is used in the table look-up.

2. **Friction and Contact.** Insofar as these ellipsoidal contact surfaces are continuous and smooth it may be necessary to specify Coulomb friction values larger than those typically used with faceted contact surfaces.

*CONTACT_GUIDED_CABLE_{OPTION1}_{OPTION2}

Purpose: Define a sliding contact that guides 1D elements, such as springs, trusses, and beams, along a path defined by a set of nodes. Only one 1D element can be in contact with any given node in the node set at a given time. If for some reason, a node is in contact with multiple 1D elements, one guided contact definition must be used for each contact. The ordering of the nodal points and 1D elements in the input is arbitrary.

OPTION1 specifies that a part set ID is given with the single option:

<BLANK>

SET

If not used, a part ID is assumed.

OPTION2 specifies that the first card read defines the heading and ID number of the contact interface and takes the single option:

ID

Title Card. Additional card for ID keyword option.

Card ID	1	2	3	4	5	6	7	8
Variable	CID	HEADING						
Type	I	A70						

VARIABLE	DESCRIPTION
CID	Contact interface ID. This must be a unique number.
HEADING	Interface descriptor. We suggest using unique descriptions.

Card 1	1	2	3	4	5	6	7	8
Variable	NSID	PID/PSID	SOFT	SSFAC	FRIC	ENDTOL		
Type	I	I	I	F	F	F		
Default	none	none	0	1.0	none	↓		

VARIABLE	DESCRIPTION
NSID	Node set ID that guides the 1D elements
PID/PSID	Part ID or part set ID if SET is included in the keyword line
SOFT	Flag for soft constraint option. Set to 1 for soft constraint.
SSFAC	Stiffness scale factor for penalty stiffness value. The default value is unity. This applies to SOFT set to 0 and 1.
FRIC	Contact friction
ENDTOL	Tolerance, in length units, applied at the ends of the cable elements beyond which contact will pass to the next cable element. The default is 0.002 times the element length.

*CONTACT_INTERIOR

Purpose: Define interior contact for solid elements. Frequently, when soft materials are compressed under high pressure, the solid elements used to discretize these materials may invert leading to negative volumes and error terminations. To keep these elements from inverting, it is possible to consider interior contacts between layers of interior surfaces made up of the faces of the solid elements. Since these interior surfaces are generated automatically, the part (material) ID's for the materials of interest are defined here, prior to the interface definitions.

Define as many cards as necessary. Input ends at the next keyword ("*") card. Multiple instances of this keyword may appear in the input.

Card 1	1	2	3	4	5	6	7	8
Variable	PSID1	PSID2	PSID3	PSID4	PSID5	PSID6	PSID7	PSID8
Type	I	I	I	I	I	I	I	I
Default	none	none	none	none	none	none	none	none

VARIABLE	DESCRIPTION
PSID*	Part set ID for which interior contact is desired.

Four attributes should be defined for each part set:

Attribute 1: PSF, penalty scale factor (Default = 1.00).

Attribute 2: Activation factor, F_a (Default = 0.10). When the crushing of the element reaches F_a times the initial thickness, the contact algorithm begins to act.

Attribute 3: ED, Optional modulus for interior contact stiffness.

Attribute 4: TYPE, Formulation for interior contact.

EQ.1.0: Default, recommended for uniform compression

EQ.2.0: Designed to control the combined modes of shear and compression. Works for type 1 brick formulation and type 10 tetrahedron formulation.

Define each part set with the *SET_PART_COLUMN option to specify independent attribute values for each part in the part set.

Remarks:

The interior penalty is determined by the formula:

$$K = \frac{\text{SLSFAC} \times \text{PSF} \times \text{Volume}^{2/3} \times \text{E}}{\text{Min. Thickness}}$$

where SLSFAC is the value specified on the *CONTROL_CONTACT card, volume is the volume of the brick element, E is a constitutive modulus, and min. thickness is approximately the thickness of the solid element through its thinnest dimension. If ED is defined above, the interior penalty is then given instead by:

$$K = \frac{\text{Volume}^{2/3} \times \text{ED}}{\text{Min. Thickness}}$$

where the scaling factors are ignored. Generally, ED should be taken as the locking modulus specified for the foam constitutive model.

Caution should be observed when using this option since if the time step size is too large an instability may result. The time step size is not affected by the use of interior contact.

*CONTACT_RIGID_SURFACE

Purpose: Define rigid surface contact. The purpose of rigid surface contact is to model large rigid surfaces, such as road surfaces, with nodal points and segments that require little storage and are written out at the beginning of the binary databases. The rigid surface motion, which can be optionally prescribed, is defined by a displacement vector which is written with each output state. The nodal points defining the rigid surface must be defined with *NODE_RIGID_SURFACE. These rigid nodal points do not contribute degrees-of-freedom.

Card 1	1	2	3	4	5	6	7	8
Variable	CID	PSID	BOXID	SSID	FS	FD	DC	VC
Type	I	I	I	I	F	F	F	F
Default	none	none	0	none	0.	0.	0.	0.

Card 2	1	2	3	4	5	6	7	8
Variable	LCIDX	LCIDY	LCIDZ	FSLCID	FDLCID			
Type	I	I	I	I	I			
Default	0	0	0	0	0			

Card 3	1	2	3	4	5	6	7	8
Variable	SFS	STTHK	SFTHK	XPENE	BSORT	CTYPE		
Type	F	F	F	F	I	I		
Default	1.0	0.0	1.0	4.0	10	0		

VARIABLE	DESCRIPTION
CID	Contact interface ID. This must be a unique number.

VARIABLE	DESCRIPTION
PSID	Part set ID of all parts that may contact the rigid surface. See *SET_PART.
BOXID	Include only nodes of the part set that are within the specified box, see *DEFINE_BOX, in contact. If BOXID is zero, all nodes from the part set, PSID, will be included in the contact.
SSID	Segment set ID defining the rigid surface. See *SET_SEGMENT.
FS	Static coefficient of friction. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact, $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$ If FSLCID is defined, see below, then FS is overwritten by the value from the load curve.
FD	Dynamic coefficient of friction. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact, $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$ If FDLCID is defined, see below, then FD is overwritten by the value from the load curve.
DC	Exponential decay coefficient. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$
VC	Coefficient for viscous friction. This is necessary to limit the friction force to a maximum. A limiting force is computed, $$F_{\text{lim}} = \text{VC} \times A_{\text{cont}} \ .$$ A_{cont} being the area of the segment contacted by the node in contact. The suggested value for VC is to use the yield stress in shear VC $= \sigma_0/\sqrt{3}$ where σ_0 is the yield stress of the contacted material.
LCIDX	Load curve ID defining x-direction motion. If zero, there is no motion in the x-coordinate system.
LCIDY	Load curve ID defining y-direction motion. If zero, there is no motion in the y-coordinate system.
LCIDZ	Load curve ID defining z-direction motion. If zero, there is no motion in the z-coordinate system.

VARIABLE	DESCRIPTION
FSLCID	Load curve ID defining the static coefficient of friction as a function of interface pressure. This option applies to shell segments only.
FDLCID	Load curve ID defining the dynamic coefficient of friction as a function of interface pressure. This option applies to shell segments only.
SFS	Scale factor on default tracked surface penalty stiffness, see also *CONTROL_CONTACT.
STTHK	Optional thickness for tracked surface (overrides true thickness). This option applies to contact with shell, solid, and beam elements. True thickness is the element thickness of the shell elements. Thickness offsets are not used for solid element unless this option is specified.
SFTHK	Scale factor for tracked surface thickness (scales true thickness). This option applies only to contact with shell elements. True thickness is the element thickness of the shell elements.
XPENE	Contact surface maximum penetration check multiplier. If the penetration of a node through the rigid surface exceeds the product of XPENE and the tracked node thickness, the node is set free. EQ.0.0: default is set to 4.0.
BSORT	Number of cycles between bucket sorts. The default value is set to 10 but can be much larger, e.g., 50-100, for fully connected surfaces.
CTYPE	Contact formulation: EQ.0: Equivalent to the ONE_WAY_SURFACE_TO_SURFACE formulation (default) EQ.1: Penalty formulation. If the tracked surface belongs to a rigid body, this formulation must be used.

Remarks:

Thickness offsets do not apply to the rigid surface. There is no orientation requirement for the segments in the rigid surface, and the surface may be assembled from disjoint, but contiguous, arbitrarily oriented meshes. With disjoint meshes, the global searches must be done frequently, about every 10 cycles, to ensure a smooth movement of a tracked node between mesh patches. For fully connected meshes this frequency interval can be safely set to 50-200 steps between searches.

The modified binary database, d3plot, contains the road surface information prior to the state data. This information includes:

NPDS = Total number of rigid surface points in problem.

NRSC = Total number of rigid surface contact segments summed over all definitions.

NSID = Number of rigid surface definitions.

NVELQ = Number of words at the end of each binary output state defining the rigid surface motion. This equals 6 × NSID if any rigid surface moves or zero if all rigid surfaces are stationary.

PIDS = An array equal in length to NPDS. This array defines the ID for each point in the road surface.

XC = An array equal in length to 3 × NPDS. This array defines the global x, y, and z coordinates of each point.

For each road surface define the following NSID sets of data:

ID = Rigid surface ID.

NS = Number of segments in rigid surface.

IXRS = An array equal in length to 4 × NS. This is the connectivity of the rigid surface in the internal numbering system.

At the end of each state, 6 × NVELQ words of information are written. For each road surface the x, y, and z displacements and velocities are written. If the road surface is fixed, a null vector should be output. Skip this section if NVELQ = 0. LS-PrePost currently displays rigid surfaces and animates their motion.

*CONTACT_SPG

Purpose: Define contact between SPG particles from different SPG parts or self-contact of SPG particles from the same SPG part. This keyword was developed for high-speed deformations, such as projectile impact penetration problems.

Card 1	1	2	3	4	5	6	7	8
Variable	PID1	PID2	PID3	PID4	PID5	PID6	PID7	PID8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

Card 2	1	2	3	4	5	6	7	8
Variable	ISELF1	ISELF2	ISELF3	ISELF4	ISELF5	ISELF6	ISELF7	ISELF8
Type	I	I	I	I	I	I	I	I
Default	0	0	0	0	0	0	0	0

Card 3	1	2	3	4	5	6	7	8
Variable	PFAC1	PFAC2	PFAC3	PFAC4	PFAC5	PFAC6	PFAC7	PFAC8
Type	F	F	F	F	F	F	F	F
Default	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

Card 4	1	2	3	4	5	6	7	8
Variable	FS	FD	DC	NFREQ				
Type	F	F	F	F				
Default	0.0	0.0	0.0	0.0				

VARIABLE	DESCRIPTION
PID*i*	Part ID of the SPG parts in particle contact.
ISELF*i*	Self-contact flag for PID*i*: EQ.0: No self-contact allowed for PIDi EQ.1: Self-contact allowed for PIDi
PFAC*i*	Penalty factor *i*
FS	Static coefficient of friction
FD	Dynamic coefficient of friction
DC	Exponential decay coefficient. The frictional coefficient is assumed to be dependent on the relative velocity, v_{rel}, of the surfaces in contact: $\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}$.
NFREQ	Contact searching frequency

*CONTACT_1D

Purpose: Define one-dimensional slide lines for rebar in concrete.

Card 1	1	2	3	4	5	6	7	8
Variable	NSIDR	NSIDC	ERR	SIGC	GB	SMAX	EXP	
Type	I	I	F	F	F	F	F	
Default	none	none	0.	0.	0.	0.	0.	

VARIABLE	DESCRIPTION
NSIDR	Nodal set ID for the rebar nodes that slide along the concrete; see *SET_NODE.
NSIDC	Nodal set ID for the concrete nodes that the rebar nodes may slide along; see *SET_NODE.
ERR	External radius of rebar
SIGC	Unconfined compressive strength of concrete, f_c
GB	Bond shear modulus
SMAX	Maximum shear strain
EXP	Exponent in damage curve

Remarks:

With this option the concrete is defined with solid elements and the rebar with truss elements, each with their own unique set of nodal points. A string of spatially consecutive nodes related to the truss elements (NSIDR) may slide along another string of spatially consecutive nodes related to the solid elements (NSIDC). The sliding commences after the rebar debonds.

The bond between the rebar and concrete is assumed to be elastic perfectly plastic. The maximum allowable slip strain is given as:

$$u_{\max} = \text{SMAX} \times e^{-\text{EXP} \times D}$$

where D is the damage parameter $D_{n+1} = D_n + \Delta u$. The shear force, acting on area A_S, at time $n + 1$ is given as:

$$f_{n+1} = \min[f_n - \mathrm{GB} \times A_s \times \Delta u, \mathrm{GB} \times A_s \times u_{\max}]$$

CONTACT_2D_*OPTION1_{OPTION2}_{OPTION3}

Purpose: Define a two-dimensional contact interface or slide line. This option is to be used with two-dimensional solid and shell elements using the plane stress, plane strain or axisymmetric formulations; see *SECTION_SHELL and *SECTION_BEAM.

All the two-dimensional contacts are supported in SMP. Only *CONTACT_2D_AUTOMATIC_SINGLE_SURFACE and *CONTACT_2D_AUTOMATIC_SURFACE_TO_SURFACE are supported for MPP, with and without the option MORTAR.

OPTION1 specifies the contact type. The following options activate kinematic constraints and should be used with deformable materials only but may be used with rigid bodies if the rigid body is the reference surface, and all rigid body motions are prescribed. Kinematic constraints are recommended for high pressure hydrodynamic applications.

SLIDING_ONLY

TIED_SLIDING

SLIDING_VOIDS

AUTOMATIC_TIED_ONE_WAY

The following option uses both kinematic constraints and penalty constraints.

AUTOMATIC_TIED

The following options are penalty-based. These methods have no rigid-material limitations. We recommend them for lower pressure solid mechanics applications.

PENALTY_FRICTION

PENALTY

AUTOMATIC_SINGLE_SURFACE

AUTOMATIC_SINGLE_SURFACE_MORTAR

AUTOMATIC_SURFACE_TO_SURFACE

AUTOMATIC_SURFACE_TO_SURFACE_MORTAR

AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE

AUTOMATIC_SURFACE_IN_CONTINUUM

The following two contacts are used for SPH particles in contact with two-dimensional continuum elements (shell formulations 13, 14, 15). These contacts do not apply to two-dimensional shell elements (beam formulations 7, 8).

NODE_TO_SOLID

NODE_TO_SOLID_TIED

The following option is used to measure contact forces that are reported as RCFORC output.

FORCE_TRANSDUCER

OPTION2 specifies a thermal contact and takes the single option:

THERMAL

Only the AUTOMATIC contact options: SINGLE_SURFACE, SURFACE_TO_SURFACE, and ONE_WAY_SURFACE_TO_SURFACE including the Mortar contact versions may be used with the THERMAL option.

OPTION3 specifies that the first card to read defines the title and ID number of contact interface and takes the single option:

TITLE

Title Card. Additional card for the TITLE keyword potion.

Card Title	1	2	3	4	5	6	7	8
Variable	CID	TITLE						
Type	I	A70						

Two-dimensional contact may be divided into 3 groups, each with a unique input format.

1. The first group were adopted from LS-DYNA2D and originated in the public domain version of DYNA2D from the Lawrence Livermore National Laboratory. Contact surfaces are specified as ordered sets of nodes. These sets define either contact surfaces or slide lines. The keyword options for the first group are:

   SLIDING_ONLY

   TIED_SLIDING

   SLIDING_VOIDS

   PENALTY_FRICTION

PENALTY

> **NOTE:** We do not recommend TIED_SLIDING, PENALTY_-FRICTION and PENALTY since easier to use automatic options with same functionality exist in the second group.

2. The second group contains the automatic contacts. These contact surfaces may be defined using part sets or unordered node sets. Segment orientations are determined automatically. The keywords for these are:

   AUTOMATIC_SINGLE_SURFACE

   AUTOMATIC_SINGLE_SURFACE_MORTAR

   AUTOMATIC_SURFACE_TO_SURFACE

   AUTOMATIC_SURFACE_TO_SURFACE_MORTAR

   AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE

   AUTOMATIC_SURFACE_IN_CONTINUUM

   AUTOMATIC_TIED

   AUTOMATIC_TIED_ONE_WAY

   FORCE_TRANSDUCER

3. The third group is for contact between SPH particles and continuum elements:

   NODE_TO_SOLID

   NODE_TO_SOLID_TIED

Each of the 3 groups has a section below with a description of input and additional remarks.

CONTACT_2D_[SLIDING, TIED, & PENALTY]_*OPTION

This section documents the *CONTACT_2D variations derived from DYNA2D:

SLIDING_ONLY

TIED_SLIDING

SLIDING_VOIDS

PENALTY_FRICTION

PENALTY

Card 1	1	2	3	4	5	6	7	8
Variable	SURFA	SURFB	TBIRTH	TDEATH				
Type	I	I	F	F				
Default	none	none	0.	10^{20}				

Card 2	1	2	3	4	5	6	7	8
Variable	EXT_PAS	THETA1	THETA2	TOL_IG	PEN	TOLOFF	FRCSCL	ONEWAY
Type	I	F	F	F	F	F	F	F
Default	none	none	none	0.001	0.1	0.025	0.010	0.0

Friction Card. Additional card for the PENALTY_FRICTION keyword option.

Card 3	1	2	3	4	5	6	7	8
Variable	FRIC	FRIC_L	FRIC_H	FRIC_S				
Type	F	F	F	F				

VARIABLE	DESCRIPTION
SURFA	Nodal set ID for the SURFA nodes, see *SET_NODE. The surface specified with SURFA must be to the left of the surface specified with SURFB. For nonsymmetric contact, this surface is the tracked surface (all contacts in this section except PENALTY and PENALTY_FRICTION).
SURFB	Nodal set ID for the SURFB nodes, see *SET_NODE. For nonsymmetric contact, this surface is the reference surface (all contacts in this section except PENALTY and PENALTY_FRICTION).
TBIRTH	Birth time for contact
TDEATH	Death time for contact
EXT_PAS	Slide line extension bypass option. EQ.0: Extensions are used. EQ.1: Extensions are not used.
THETA1	Angle in degrees of slide line extension at first SURFB node. EQ.0: Extension remains tangent to first SURFB segment.
THETA2	Angle in degrees of slide line extension at last SURFB node. EQ.0: Extension remains tangent to last SURFB segment.
TOL_IG	Tolerance for determining initial gaps. EQ.0.0: default set to 0.001
PEN	Scale factor or penalty. EQ.0.0: default set to 0.10
TOLOFF	Tolerance for stiffness insertion for implicit solution only. The contact stiffness is inserted when a node approaches a segment a distance equal to the segment length multiplied by TOLOFF. The stiffness is increased as the node moves closer with the full stiffness being used when the nodal point finally makes contact. EQ.0.0: default set to 0.025.
FRCSCL	Scale factor for the interface friction. EQ.0.0: Default set to 0.010

VARIABLE	DESCRIPTION
ONEWAY	Flag for one way treatment. If set to 1.0, the nodal points on SURFA are constrained to SURFB. This option is generally recommended if SURFB is rigid. EQ.1.0: Activate one way treatment.
FRIC	Coefficient of friction
FRIC_L	Coefficient of friction at low velocity
FRIC_H	Coefficient of friction at high velocity
FRIC_S	Friction factor for shear

Remarks:

1. **Option Descriptions.** The following are descriptions of the DYNA2D variations:

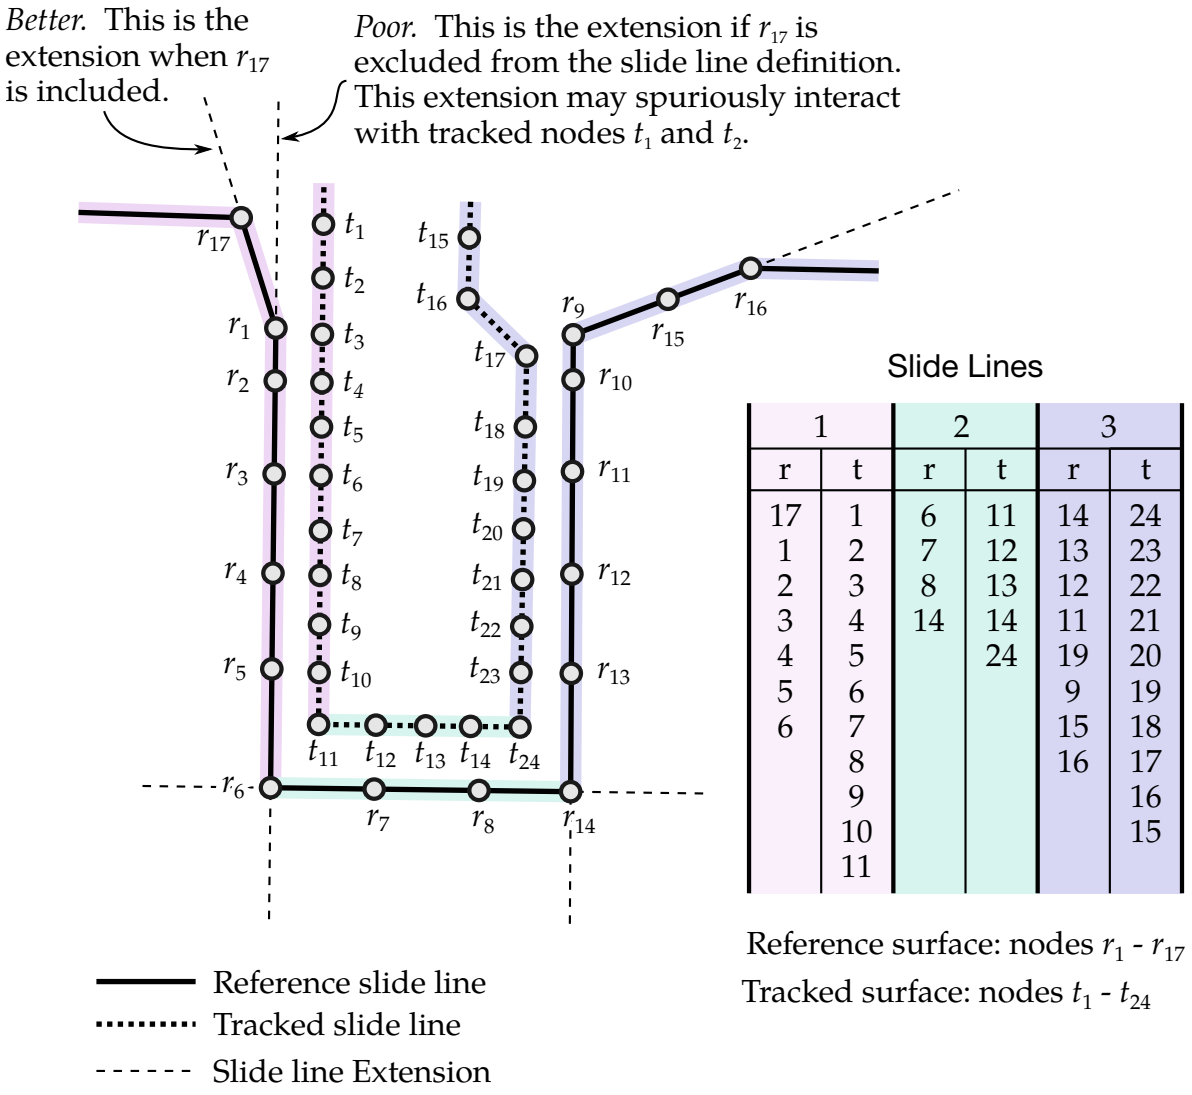
   a) The SLIDING_ONLY option is a two-surface method based on a kinematic formulation. The two surfaces can slide arbitrarily large distances without friction but are not permitted to separate or interpenetrate. Surfaces should be initially in contact. This option performs well when extremely high interface pressures are present. The more coarsely meshed surface should be chosen as the reference surface (SURFB) for best performance.

   b) The TIED_SLIDING option joins two parts of a mesh with differing mesh refinement. It is a kinematic formulation, so the more coarsely meshed surface should be chosen as the reference surface (SURFB).

   c) The SLIDING_VOIDS option is a kinematic formulation without friction which permits two surfaces to separate if tensile forces develop across the interface. The surfaces may be initially in contact or initially separated.

   d) The PENALTY_FRICTION and PENALTY options are penalty formulations, so the designation of SURFA and SURFB is not important. The two bodies may be initially separate or in contact. A rate-dependent Coulomb friction model is available for PENALTY_FRICTION.

2. **Slide Line.** Consider two slide line surfaces in contact. It is necessary to designate one as a tracked surface and the other as a reference surface. Nodal points defining the tracked surface are called tracked nodes, and similarly, nodes defining the reference surface are called reference nodes. Each tracked-reference surface combination is referred to as a slide line.



Slide Lines

1		2		3	
r	t	r	t	r	t
17	1	6	11	14	24
1	2	7	12	13	23
2	3	8	13	12	22
3	4	14	14	11	21
4	5		24	19	20
5	6			9	19
6	7			15	18
	8			16	17
	9				16
	10				15
	11				

Reference surface: nodes r_1 - r_{17}
Tracked surface: nodes t_1 - t_{24}

Figure 11-31. *Slide line Example.* Note: (1) as recommended, for 90° angles each facet is assigned a distinct slide line; (2) the reference slide line is more coarsely meshed; (3) the tracked slide line is to the left of the reference (following the node ordering, see inset table); (4) as shown for tracked nodes 1 and 2 it is important the slide line extension does not spuriously come into contact.

3. **Modeling Precautions.** Many potential problems with the options can be avoided by observing the following precautions:

   a) Metallic materials should contain the reference surface along high explosive-metal interfaces.

   b) SLIDING_ONLY type slide lines are appropriate along high explosive-metal interfaces. The penalty formulation is not recommended along such interfaces.

c) If one surface is more finely zoned, it should be used as the tracked surface (SURFA). If penalty slide lines, PENALTY and PENALTY_FRICTION, are used, then the tracked-reference distinction is irrelevant.

d) A tracked node may have more than one reference segment and may be included as a member of a reference segment if a slide line intersection is defined.

e) Angles in the reference side of a slide line that approach 90° must be avoided.

Whenever such angles exist in a reference surface, two or more slide lines should be defined. This procedure is illustrated in Figure 11-31. An exception for the foregoing rule arises if the surfaces are tied. In this case, only one slide line is needed.

f) Whenever two surfaces are in contact, the smaller of the two surfaces should be used as the tracked surface. For example, in modeling a missile impacting a wall, the contact surface on the missile should be used as the tracked surface.

g) Care should be used when defining a reference surface to prevent the extension from interacting with the solution. In Figures 11-31 and 11-32, slide line extensions are shown.

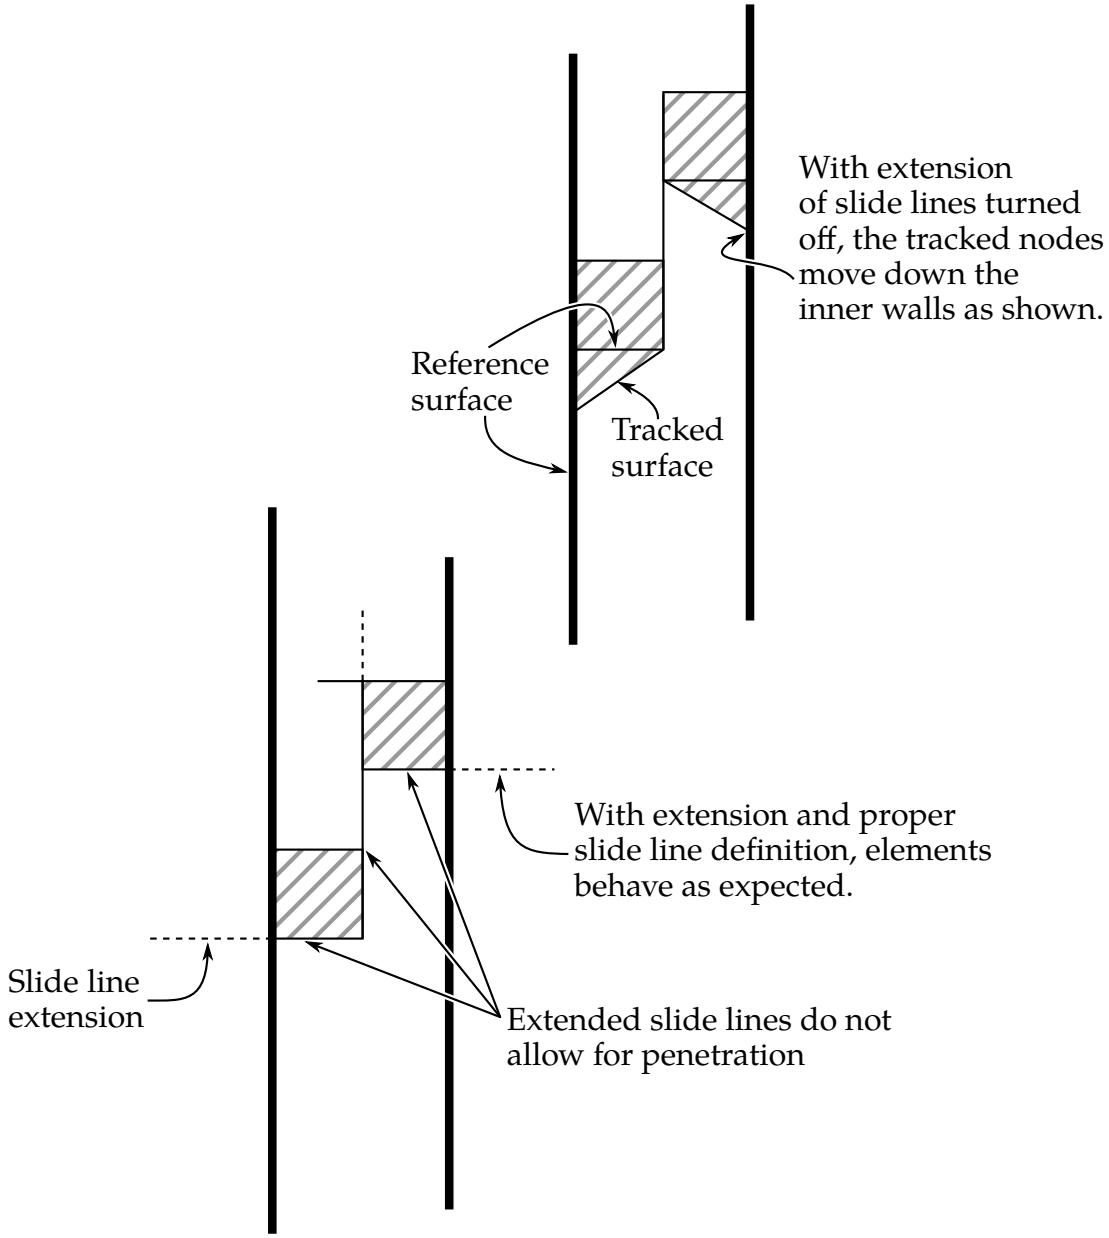


Figure 11-32. *With and without extension.* Extensions may be turned off by setting EXT_PAS (card 2), but, when turned off, tracked nodes may "leak" out as shown in the upper version of the figure.

CONTACT_2D_[AUTOMATIC & FORCE_TRANSDUCER]_*OPTION

This section documents the following variations of *CONTACT_2D:

AUTOMATIC_SINGLE_SURFACE

AUTOMATIC_SINGLE_SURFACE_MORTAR (see Remark 12)

AUTOMATIC_SURFACE_TO_SURFACE

AUTOMATIC_SURFACE_TO_SURFACE_MORTAR (see Remark 12)

AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE

AUTOMATIC_SURFACE_IN_CONTINUUM (see Remark 11)

AUTOMATIC_TIED

AUTOMATIC_TIED_ONE_WAY

FORCE_TRANSDUCER (see Remark 2)

VARIABLE	DESCRIPTION
SURFA	Set ID for SURFA. If SURFA > 0, a part set is assumed; see *SET_PART. If SURFA < 0, a node set with ID equal to the absolute value of SURFA is assumed; see *SET_NODE. For nonsymmetric contact, this surface is the tracked surface.
SURFB	Set ID to define the SURFB surface. If SURFB > 0, a part set is assumed; see *SET_PART. If SURFB < 0, a node set with ID equal to the absolute value of SURFB is assumed; see *SET_NODE. Do not define for single surface contact. For nonsymmetric contact, this surface is the reference surface.
SFACT	Scale factor for the penalty force stiffness
FREQ	Search frequency. The number of timesteps between bucket sorts. For implicit contact this parameter is ignored, and the search frequency is 1. EQ.0: Default set to 50.
FS	Static coefficient of friction. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact according to the relation given by: $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$
FD	Dynamic coefficient of friction. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$ This parameter does not apply to mortar contact.
DC	Exponential decay coefficient. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$ This parameter does not apply to mortar contact.
TBIRTH	Birth time for contact
TDEATH	Death time for contact
SOA	Surface offset from midline for two-dimensional shells of SURFA surface:

VARIABLE	DESCRIPTION
	EQ.0.0: Default to 1.0. GT.0.0: Scale factor applied to actual thickness LT.0.0: Absolute value is used as the offset
SOB	Surface offset from midline for 2D shells of SURFB surface: EQ.0.0: Default to 1.0. GT.0.0: Scale factor applied to actual thickness LT.0.0: Absolute value is used as the offset
NDA	Normal direction flag for two-dimensional shells of SURFA surface: EQ.0: Normal direction is determined automatically. EQ.1: Normal direction is in the positive direction. EQ.-1: Normal direction is in the negative direction.
NDB	Normal direction flag for two-dimensional shells of SURFB surface: EQ.0: Normal direction is determined automatically. EQ.1: Normal direction is in the positive direction. EQ.-1: Normal direction is in the negative direction.
COF	Closing/opening flag for implicit contact: EQ.0: Recommended for most problem where gaps are only closing. EQ.1: Recommended when gaps are opening to avoid sticking. This parameter does not apply to mortar contact.
INIT	Special processing during initialization: EQ.0: No special processing EQ.1: Forming option
K	Thermal conductivity (k) of fluid between the slide surfaces. If a gap with a thickness l_{gap} exists between the slide surfaces, then the conductance due to thermal conductivity between the slide surfaces is

VARIABLE	DESCRIPTION
	$$h_{\text{cond}} = \frac{k}{l_{\text{gap}}}$$ Note that LS- DYNA calculates l_{gap} based on deformation.
RAD	Radiation factor, f, between the slide surfaces. A radiant-heat-transfer coefficient (h_{rad}) is calculated (see *BOUNDARY_RADIATION). If a gap exists between the slide surfaces, then the contact conductance is calculated by $$h = h_{\text{cond}} + h_{\text{rad}}$$
H	Heat transfer conductance (h_{cont}) for closed gaps. Use this heat transfer conductance for gaps in the range: $$0 \le l_{\text{gap}} \le l_{\text{min}} \ ,$$ where l_{min} is GCRIT defined below.
LMIN	Critical gap (l_{min}), use the heat transfer conductance defined (HTC) for gap thicknesses less than this value.
LMAX	No thermal contact if gap is greater than this value (l_{max}).
CHLM	Multiplier used on the element characteristic distance for the search routine. The characteristic length is the largest interface surface element diagonal. EQ.0: Default set to 1.0
BC_FLAG	Thermal boundary condition flag: EQ.0: Thermal boundary conditions are on when parts are in contact. EQ.1: Thermal boundary conditions are off when parts are in contact.
VC	Coefficient for viscous friction. This is used to limit the friction force to a maximum. A limiting force is computed $$F_{\text{lim}} = \text{VC} \times A_{\text{cont}}.$$ A_{cont} being the area of contacted between segments. The suggested value for VC is to use the yield stress in shear: $$\text{VC} = \frac{\sigma_o}{\sqrt{3}} \ ,$$ where σ_o is the yield stress of the contacted material.

VARIABLE	DESCRIPTION
VDC	Viscous damping coefficient in percent of critical for explicit contact. This parameter does not apply to Mortar contact.
IPF	Initial penetration flag (see Remark 14): EQ.0: Allow initial penetrations to remain. GE.1: Push apart initially penetrated surfaces.
SLIDE	Sliding option: EQ.0: Off EQ.1: On
ISTIFF	Stiffness scaling option: EQ.0: Use default option. EQ.1: Scale stiffness using segment masses and explicit time step (default for explicit contact). EQ.2: Scale stiffness using segment stiffness and dimensions (default for implicit contact).
TIEDGAP	Search gap for tied contacts. EQ.0: Default, use 1% of the SURFB segment length GT.0: Use the input value LT.0: Use –TIEDGAP % of the SURFB segment length.
IGAPCL	Flag to close gaps in tied contact: EQ.0: Default, allow gaps to remain EQ.1: Move SURFA nodes to SURFB segments to close gaps
TIETYP	Flag to control constraint type of tied contact: EQ.0: Default, use kinematic constraints when possible EQ.1: Use only penalty type constraints
SLDSOA	Solid surface offset for the SURFA surface
SLDSOB	Solid surface offset for the SURFB surface

VARIABLE	DESCRIPTION
TDPEN	Time span of penetration removal for 2D Mortar contacts. Each initial penetration will be gradually reduced linearly in time, so that it is removed by time TDPEN. For instance, if a given penetration has an initial distance D, then the penetration distance over time, $d(t)$ will be $d(t) = \frac{D}{\text{TDPEN}}(\text{TDPEN} - t)$. This is the interference option analogue to MPAR1 for IGNORE = 3 in 3D automatic Mortar contacts.

Remarks:

1. **Penalty Force Methods.** The SINGLE_SURFACE, SURFACE_TO_SURFACE, and ONE_WAY_SURFACE_TO_SURFACE options use penalty forces to prevent penetration between two-dimensional shell elements and external faces of two-dimensional continuum elements. Contact surfaces are defined using SURFA and SURFB to reference either part sets or node sets. If part sets are used, all elements and continuum faces of the parts in the set are included in contact. If node sets are used, elements or continuum faces that have both nodes in the set are included in the contact surface. The SINGLE_SURFACE option uses only the SURFA set and checks for contact between all elements and continuum faces in the set. If SURFA is blank or zero, contact will be checked for all elements and continuum faces in the model. With the other options, both SURFA and SURFB are required.

2. **Force Transducer.** The FORCE_TRANSDUCER option should be used in conjunction with at least one AUTOMATIC contact option. It does nothing to prevent penetration but measures the forces generated by other contact definitions. The FORCE_TRANSDUCER option requires only SURFA. SURFB is optional. If only SURFA is defined, the force transducer measures the resultant contact force on all the elements and continuum faces in the SURFA surface. If both SURFA and SURFB are defined, then the force transducer measures contact forces between the elements and continuum faces in the SURFA surface and SURFB surface. The measured forces are included in the rcforc output. In the case of an axisymmetric analysis, values output to rcforc and ncforc are in units of force per radian (this includes both shell types 14 and 15).

3. **Normal Direction.** By default, the normal direction of 2D shell elements is evaluated automatically for SINGLE_SURFACE, SURFACE_TO_SURFACE and ONE_WAY_SURFACE_TO_SURFACE contact. You can override the automatic algorithm using NDA or NDB, and contact will occur with the positive or negative face of the element.

4. **Shell Thickness.** By default, the true thickness of two-dimensional shell elements is taken into account for the SURFACE_TO_SURFACE, SINGLE_SURFACE, and ONE_WAY_SURFACE_TO_SURFACE options. You can override the true thickness by using SOA and SOB. If the surface offset is reduced to a small value, the automatic normal direction algorithm may fail, so it is best to specify the normal direction using NDA or NDB.

5. **AUTOMATIC Contact and Erosion.** For all AUTOMATIC contact options, eroding materials are treated by default. At present, subcycling is not possible.

6. **Thin Solid Parts and Contact Interface.** The INIT parameter activates a forming option that is intended for implicit solutions of thin solid parts when back side segments may interfere with the solution. It automatically removes back side segments during initialization. Alternatively, the user can input INIT = 0, and use node set input to limit the contact interface to just the front of a thin part.

7. **THERMAL Option.** For the THERMAL option:

   $h = h_{\text{cont}}$, if the gap thickness is $0 \le l_{\text{gap}} \le l_{\text{min}}$

   $h = h_{\text{cond}} + h_{\text{rad}}$, if the gap thickness is $l_{\text{min}} \le l_{\text{gap}} \le l_{\text{max}}$

   $h = 0$, if the gap thickness is $l_{\text{gap}} > l_{\text{max}}$

8. **Sliding with Kinks and Corners.** The SLIDE parameter activates a sliding option which uses additional logic to improve sliding when surfaces in contact have kinks or corners. This option is off by default.

9. **Penalty Stiffness Control.** The ISTIFF option allows control of the equation used in calculating the penalty stiffness. For backward compatibility, the default values are different for implicit and explicit solutions. When ISTIFF = 1 is used, the explicit time step appears in the stiffness equation, regardless of whether the calculation is implicit or explicit.

10. **Kinematic Constraints.** The TIED_ONE_WAY contact creates two degree of freedom translational kinematic constraints to nodes on the SURFA surface which are initially located on or near SURFB segments. The TIED option creates kinematic constraints between SURFA nodes and SURFB segments and creates penalty constraints between SURFB nodes and SURFA segments. With either contact option, a kinematic constraint may be switched to penalty if there is a conflict with another constraint. The TIEDGAP parameter determines the maximum normal distance from a segment to a node for a constraint to be formed. Nodes will not be moved to eliminate an initial gap, and the initial gap will be maintained throughout the calculation. If TIETYP = 1, then only penalty constraints will be used.

11. **SURFACE_IN_CONTINUUM Option.** Note that the SURFACE_IN_CONTINUUM option has been deprecated in favor of the *CONSTRAINED_LAGRANGE_IN_SOLID keyword which allows coupling between fluids and structures. However, this option is maintained to provide backward compatibility for existing data.

    For the SURFACE_IN_CONTINUUM option, penalty forces prevent the flow of tracked element material (the continuum) through the reference surfaces. Flow of the continuum tangent to the surface is permitted. Only two-dimensional solid parts are permitted in the tracked part set. Both 2D solid and 2D shell parts are permitted in the reference part set. Flow through two-dimensional shell elements is prevented in both directions by default. If NDB is set to ±1, flow in the direction of the normal is permitted. Thickness of two-dimensional shell elements is ignored.

    When using the SURFACE_IN_CONTINUUM option, you do not need to mesh the continuum around the structure because contact is not with continuum nodes but with material in the interior of the continuum elements. The algorithm works well for Eulerian or ALE elements since the structure does not interfere with remeshing. However, a structure will usually not penetrate the surface of an ALE continuum since the nodes are Lagrangian normal to the surface. Therefore, if using an ALE fluid, the structure should be initially immersed in the fluid and remain immersed throughout the calculation. Penetrating the surface of an Eulerian continuum is not a problem.

12. **Mortar Contact.** Mortar contact (MORTAR) is available for implicit and explicit calculations in SMP and MPP. The apparent behavior compared to non-Mortar contact is very similar; the difference lies in details concerning the constitutive relation (contact stress as a function of the relative motion of contact surfaces) and the kinematics (the relative motion of contact surfaces as function of nodal coordinates). Mortar contact is designed for continuity and smoothness which is beneficial for an implicit solution scheme. It is intended to enhance robustness for implicit. For details regarding the two-dimensional mortar contact, see the LS-DYNA Theory Manual.

13. **Segment Thickness.** By default, segments on the surface of two-dimensional continuum elements have zero thickness, so the contact surface is the line between the nodes. The contact surface can be optionally offset from this line by using the SLDSOA and SLDSOB parameters. If set to a positive number, SLDSOA is the offset for two-dimensional continuum element segments on the SURFA surface, and SLDSOB is the offset for two-dimensional continuum element segments on the SURFB surface. The SOA and SOB parameters provide similar options for segments on two-dimensional shell elements.

14. **IPF.** If a segment pair is detected to be in contact, and the penetration depth exceeds the penetration that has occurred since the last solution cycle, then the excess initial penetration will not be penalized for as long as the segment pair remains in contact. This is done to prevent spikes in contact forces and possible shooting nodes. If IPF > 0, then the excess penetration will be penalized, but the penalty force is ramped up from zero. The value of IPF is the additional percentage of excess initial penetration will be penalized each cycle. For example, IPF = 1 penalizes 1% and IPF = 2 penalizes 2%. We do not recommend larger values. The IPF flag is available for the SURFACE_TO_SURFACE and SINGLE_SURFACE type contact options when used in explicit dynamic solutions. For Mortar contacts we recommend using TDPEN instead of IPF.

CONTACT_2D_NODE_TO_SOLID_*OPTION

This section documents the following variations of *CONTACT_2D:

NODE_TO_SOLID

NODE_TO_SOLID_TIED

Card 1	1	2	3	4	5	6	7	8
Variable	SPH	SOLID	TBIRTH	TDEATH				
Type	I	I	F	F				
Default	none	None	0.	10^{20}				

Card 2	1	2	3	4	5	6	7	8
Variable	SOFT	MAXPAR	VC	OFFD	PEN	FS	FD	DC
Type	I	F	F	F	F	F	F	F
Default	0	1.05	0.0	0.0	↓	0.0	0.0	0.0

VARIABLE	DESCRIPTION
SPH	Nodal set ID or part set ID for the SPH nodes, If SPH > 0, a nodal set ID is assumed. If SPH < 0, a part set ID is assumed.
SOLID	Solid part set ID. SOLID < 0 since only part set is allowed.
TBIRTH	Birth time for contact
TDEATH	Death time for contact
SOFT	Soft constraint option: EQ.0: Penalty formulation EQ.1: Soft constraint formulation

VARIABLE	DESCRIPTION
	The soft constraint may be necessary if the material constants of the parts in contact have a wide variation in the elastic bulk moduli. In the soft constraint option, the interface stiffness is based on the nodal mass and the global time step size. The soft constraint option is also recommended for axisymmetric simulations.
MAXPAR	Maximum parametric coordinate in segment search (values between 1.025 and 1.20 are recommended). If zero, the default is set to 1.05. This factor allows an increase in the size of the segments which may be useful at sharp corners.
VC	Coefficient for viscous friction. This is used to limit the friction force to a maximum. A limiting force is computed $$F_{\text{lim}} = \text{VC} \times A_{\text{cont}} \ .$$ A_{cont} being the area of contacted between segments. The suggested value for *VC* is to use the yield stress in shear: $$\text{VC} = \frac{\sigma_o}{\sqrt{3}} \ ,$$ where σ_o is the yield stress of the contacted material.
OFFD	Contact offset distance for SPH nodes. It does not currently apply to tied contacts. Recommended to be half of the original particle spacing in contact direction.
PEN	Scale factor for penalty. EQ.0.0: default set to 1.0 for penalty formulation, or 0.1 for soft constraint formulation.
FS	Static coefficient of friction. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact according to the relationship given by: $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$
FD	Dynamic coefficient of friction. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$

VARIABLE	DESCRIPTION
DC	Exponential decay coefficient. The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact $$\mu_c = \text{FD} + (\text{FS} - \text{FD})e^{-\text{DC}\lvert v_{\text{rel}}\rvert}.$$

Remarks:

NODE_TO_SOLID contact is a penalty-based contact type used only for SPH particles with solid elements using the plane stress, plane strain or axisymmetric formulation. NODE_TO_SOLID_TIED contact is used only for SPH particles tied with solid elements, an offset of distance h (smooth length) is adopted for each SPH particle.

*CONTROL

The keyword control cards are optional and can be used to change defaults. They can also activate solution options, such as mass scaling, adaptive remeshing, and the implicit solver (see the *CONTROL_IMPLICIT section for details). We do, however, suggest defining the *CONTROL_TERMINATION card. *The order of the control cards in the input file is arbitrary. To avoid ambiguities, define no more than one control card of each type.*

Purpose: Define control parameters that can improve the accuracy of the calculation.

Card 1	1	2	3	4	5	6	7	8
Variable	OSU	INN	PIDOSU	IACC	EXACC			
Type	I	I	I	I	F			
Default	0	↓	optional	0	0.0			

VARIABLE	DESCRIPTION
OSU	Global flag for 2nd order objective stress updates (see Remark 1 below). Generally, for explicit calculations only those parts undergoing large rotations, such as rolling tires, need this option. Objective stress updates can be activated for a subset of part IDs by defining the part set in columns 21-30. EQ.0: Off (default) EQ.1: On
INN	Invariant node numbering for shell and solid elements. (See Remarks 2 and 3). EQ.-4: On for both shell and solid elements except triangular shells EQ.-2: On for shell elements except triangular shells EQ.1: Off (default for explicit) EQ.2: On for shell and thick shell elements (default for implicit) EQ.3: On for solid elements EQ.4: On for shell, thick shell, and solid elements
PIDOSU	Part set ID for objective stress updates. If this part set ID is given only those part IDs listed will use the objective stress update; therefore, OSU is ignored.
IACC	Implicit accuracy flag, turns on some specific accuracy considerations in implicit analysis at an extra CPU cost. See Remark 4. EQ.0: Off (default)

VARIABLE	DESCRIPTION
	EQ.1: On (only for implicit)
	EQ.2: On (partially also for explicit, for compatibility when switching between implicit and explicit)
EXACC	Explicit accuracy parameter:
	EQ.0.0: Off (default)
	GT.0.0: On (see Remark 5)

Remarks:

1. **Second Order Objective Stress Update.** Second order objective stress updates are occasionally necessary. Some examples include spinning bodies such as turbine blades in a jet engine, high velocity impacts generating large strains in a few time steps, and large time step sizes due to mass scaling in metal forming. There is a significantly added cost which is due in part to the added cost of the second order terms in the stress update when the Jaumann rate is used and the need to compute the strain-displacement matrix at the mid-point geometry. This option is available for the following element types:

   a) one point brick elements

   b) the selective-reduced integrated brick element which uses eight integration points

   c) fully integrated plane strain and axisymmetric volume weighted (type 15) 2D solid elements

   d) the thick shell elements

   e) Belytschko-Tsay shell elements

   f) Belytschko-Tsay shell elements with warping stiffness

   g) Belytschko-Chiang-Wong shell elements

   h) S/R Hughes-Liu shell elements

   i) type 16 fully integrated shell element

2. **Invariant Node Numbering for Shell Elements.** Invariant node numbering for shell and thick shell elements affects the choice of the local element shell coordinate system. The orientation of the default local coordinate system is based on the shell normal vector and the direction of the 1-2 side of the element. If the

element numbering is permuted, the results will change in irregularly shaped elements. With invariant node numbering, permuting the nodes shifts the local system by an exact multiple of 90 degrees. In spite of its higher costs [<5%], the invariant local system is recommended for several reasons. First, element forces are nearly independent of node sequencing; secondly, the hourglass modes will not substantially affect the material directions; and, finally, stable calculations over long time periods are achievable. The INN parameter has no effect on thick shell form 2 which is always invariant and thick shell form 3 which is never invariant.

3. **Invariant Node Numbering for Solid Elements.** Invariant node numbering for solid elements is available for anisotropic materials only. This option has no effect on solid elements of isotropic material. This option is recommended when solid elements of anisotropic material undergo significant deformation.

4. **Implicit Calculations.** All other things being equal, a single time step of an implicit analysis usually involves a larger time increment and deformation than an explicit analysis. Many of the algorithms in LS-DYNA have been heavily optimized for explicit analysis in ways that are inappropriate for implicit analysis. While an implicit analysis, by default, invokes many measures to ensure accuracy, certain corrections associated with unusual applications or with large computational expense are invoked only by setting IACC = 1. A list of features that are included with this option follows at the end of this remarks section. The explicit column indicates features that are also active when IACC = 2. IACC = 2 is primarily intended for when switching between implicit and explicit and maintaining compatibility between features.

5. **EXACC.** The EXACC option is developed to improve the numerical accuracy for an explicit analysis. Currently, nodal coordinates are computed and stored in double precision in all versions. In most cases, this is sufficiently accurate and EXACC is recommended to be off. However, in some cases, particularly when initial coordinates are large and displacements are small, EXACC can increase the accuracy of computations. To use this option, the EXACC parameter should be set to a positive value which is a characteristic element length for the mesh. For example, if the typical edge length in a model is 5.0 mm and the length units are millimeters, then set EXACC = 5.0.

   To translate a model or a component of a model, keyword *INCLUDE_TRANSFORM is recommended because the 10-digit or 20-digit formats in keyword *NODE are not enough to represent a double precision value without round off error. Using *INCLUDE_TRANSFORM together with EXACC can yield a solution that is more consistent with the original result before the transformation.

Element features activated for IACC = 1	*Implicit*	*Explicit*
Strong objectivity, meaning that large rotations do not induce spurious strains and stresses, enforced for ◦ 1D seatbelts ◦ 2nd order shells (types 23 and 24) ◦ 1st order shells (types -16, 4 and 16) ◦ 1st order solids (types -2, -1, 1, 2, 13, 15, and 16) ◦ cohesive solids (types 19 and 20) ◦ beam elements (types 1, 2, and 9)	Yes	No
Assumed strain formulation of 2nd order triangular shell (type 24)	Yes	No
Thickness is involved in solution process for shell thickness update (see ISTUPD on *CONTROL_SHELL) and not imposed as a post-processing step. This is for shell type 16 and allows contact to act on updated geometry, thus avoiding large contact stresses at beginning of steps.	Yes	No
Allow beam types 1, 2 and 11 in implicit linear analyses	Yes	No
Linear element formulations in linear implicit, meaning that results are scaled linearly with respect to scaling of boundary conditions, of ◦ 1st order shells (types 13, 15, 16) ◦ 1st order solids (types -2, -1, 1, 2).	Yes	No
Switch low order quadrilateral shell elements (types 1, 2, 6, 7, 8, 10, 11) to type 16, solid element type 1 to type 2 for material 83 and beam types 4 and 5 to type 1. ESORT on *CONTROL_SOLID and *CONTROL_SHELL is still honored, and a nonzero ISOLID/ISHELL/IBEAM on *CONTROL_IMPLICIT_EIGENVALUE has precedence and thus overrides the automatic switch mentioned here.	Yes	No
Activate solid element 13 for all materials	Yes	Yes

Contact features activated for IACC = 1	*Implicit*	*Explicit*
Strong objectivity in tied contacts listed on *CONTACT, meaning that large rotations will not induce contact stresses. These contacts also include bending and torsional constraints whenever those are physically justified.	Yes	Yes

Material features activated for IACC = 1	*Implicit*	*Explicit*
Large strain/temperature accuracy in some materials (types 4 shells/solids, 60 solids, 106 solids).	Yes	No
Stiffness smoothing of tension/compression transition in material 83, for enhanced implicit convergence characteristics.	Yes	No
Accurate Jacobi iterations in some hyperelastic material models (type 30 solids, 77 solids, 83 solids), for better strain assessment and implicit convergence characteristics.	Yes	No
Fully iterative plasticity in some metallic material models (type 3 solids, 24 shells/solids, 123 shells/solids), for enhanced accuracy and implicit convergence.	Yes	No
Consistent tangent modulus in material 24, accounting for relatively large plastic strains.	Yes	No
Switch FORM to 14 for fabric material, *MAT_FABRIC, when not set to either 14 or -14.	Yes	No
Switch material 57 to an equivalent material 83 whenever applicable, due to better implicit treatment.	Yes	No

Miscellaneous feature activated for IACC = 1	*Implicit*	*Explicit*
Steady state thermal solution allowed in coupled simulations, for compatibility with implicit mechanical statics; see ATYPE on *CONTROL_THERMAL_SOLVER.	Yes	No
Consistent nodal forces from body loads for high order elements, accounting for isoparametric shape functions; see *LOAD_BODY.	Yes	No

Miscellaneous feature activated for IACC = 1	*Implicit*	*Explicit*
Allow point constraints on rigid body nodes, without transferring it to rigid body center of mass. Use with care, so as to not overconstrain the system; see *BOUNDARY_SPC.	Yes	No
Strongly objective joint stiffness formulation; see *CONSTRAINED_JOINT_STIFFNESS.	Yes	No
Sparse matrix treatment of control volume airbags for efficiency; see *AIRBAG.	Yes	No

*CONTROL_ACOUSTIC

Purpose: Define control parameters for transient acoustic solutions.

Card 1	1	2	3	4	5	6	7	8
Variable	MACDVP							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
MACDVP	Calculate the nodal displacements and velocities of *MAT_ACOUSTIC volume elements for inclusion in d3plot and time-history files. EQ.0: Acoustic nodal motions will not be calculated EQ.1: Acoustic nodal motions will be calculated

Remarks:

1. **Solution Costs.** Acoustic simulations using *MAT_ACOUSTIC volume elements (ELFORM = 8 and ELFORM = 14) solve for the displacement potential. The infinitesimal motions of the acoustic nodes can then be found from the gradient of the displacement and velocity potentials. This is purely a post-processing endeavor and has no effect on the predicted pressures and structural response. Calculating these motions will, however, roughly double the cost of the acoustic solution, so it is not done by default.

2. **Model Validity.** The acoustic theory underpinning *MAT_ACOUSTIC volume elements presumes infinitesimal motions. In the presence of larger motions the pressure calculations will proceed regardless, but the calculation of acoustic nodal motions can then be unreliable.

*CONTROL_ACOUSTIC_COUPLING

Purpose: Alter default parameters for keywords *BOUNDARY_ACOUSTIC_COUPLING_MISMATCH and *BOUNDARY_ACOUSTIC_COUPLING_SPECTRAL. Changing these parameters is not generally recommended.

Default	3	1.5	0.79	0.5	0.95			

VARIABLE	DESCRIPTION
MACCPL	Coupling method: EQ.3: Projection with areal equilibration to enhance enforcement of the zero moments. The equilibration test examines the moments generated by the coupling matrix when the acoustic pressure is constant. If these moments are not zero (rare), then an attempt is made to adjust the coupling coefficients, so the moments are minimized. EQ.4: Projection with no areal equilibration
ACECF1	Multiplier on proximity test
ACECF2	Angle between normal vectors in an orientation test
ACECF3	Multiplier on ceiling test
ACECF4	Area equilibration threshold. The equilibration test is skipped when the accumulated area of the coupling matrix is less than the area of the structural face. This normally occurs with partial coverage.

*CONTROL_ACOUSTIC_SPECTRAL

Purpose: Request an acoustic spectral element analysis instead of the default isoparametric, acoustic finite element analysis. This keyword is only available for double precision. See Appendix W for a list of keywords this feature supports.

Card 1	1	2	3	4	5	6	7	8
Variable	MASEORD	MASEHRF	MASEKFL	MASEIGX				
Type	I	I	I	I				
Default	none	0	0	1				

VARIABLE	DESCRIPTION
MASEORD	Spectral element integration order ($2 \le$ MASEORD ≤ 15). See Remark 2.
MASEHRF	Optional *h*-refinement (see Remark 3): EQ.0: No splitting unless tetrahedra or pentahedra are present EQ.1: Split all elements once into hexahedra EQ.2: Split each element a second time into 8 hexahedra EQ.3: Split each element a second time into 27 hexahedra
MASEKFL	Dump flag for *h*-refined and spectral element meshes: EQ.1: Dump keyword deck of acoustic mesh after *h*-refinement EQ.10: Dump keyword deck of spectral acoustic element mesh (generated by LS-DYNA) EQ.11: Dump both meshes for review
MASEIGX	Approach to element time step calculation (see Remark 4): EQ.1: Gerschgorin theorem EQ.2: Maximum element eigenvalue

Remarks:

1. **Elements Types.** This keyword applies to all elements with ELFORM = 8 in the model. Those elements may be hexahedra, tetrahedra, or pentahedra. No acoustic pyramids may be used in spectral element solutions.

2. **Integration Order.** Spectral elements have extra degrees of freedom. Second-order integration results in 27 degrees of freedom per element. 15^{th} order integration results in 4096 degrees of freedom per element. Only the degrees of freedom at the corner nodes are visible to you for d3plot visualization. One element per wavelength with 8^{th} order integration typically gives a very accurate solution over hundreds of cycles of time.

3. ***h*-refinement.** If pentahedra or tetrahedra are used anywhere in the acoustic fluid mesh, then all acoustic fluid elements are split once into hexahedra. This feature supports additional splitting. For example, you may use it to accommodate the extreme mesh refinement that is often required in ultrasonic wave propagation problems. With this field you do not have to generate and manipulate an extremely large and unwieldy mesh.

4. **Critical Time Step.** The Gerschgorin theorem is a faster estimation method and will yield a more conservative time step. Typically, the conservative time step is also less dispersive and more accurate.

*CONTROL_ADAPSTEP

Purpose: Define control parameters for contact interface force update during each adaptive cycle.

Card 1	1	2	3	4	5	6	7	8
Variable	FACTIN	DFACTR						
Type	F	F						
Default	1.0	0.01						

VARIABLE	DESCRIPTION
FACTIN	Initial relaxation factor for contact force during each adaptive remesh. To turn this option off set FACTIN = 1.0. Unless stability problems occur in the contact, FACTIN = 1.0 is recommended since this option can create some numerical noise in the resultant tooling forces. A typical value for this parameter is 0.10.
DFACTR	Incremental increase of FACTIN during each time step after the adaptive step. FACTIN is not allowed to exceed unity. A typical value might be 0.01.

Remarks:

1. **Contact Types.** This command applies to contact with thickness offsets including contact types:

   *CONTACT_FORMING_…_

   *CONTACT_NODES_TO_SURFACE_

   *CONTACT_SURFACE_TO_SURFACE

   *CONTACT_ONE_WAY_SURFACE_TO_SURFACE.

*CONTROL_ADAPTIVE

Purpose: Activate adaptive meshing for applications, such as sheet metal forming or bulk metal forming. The field ADPOPT in *PART identifies the part(s) whose mesh to be adapted, and to some extent the type of adaptivity applied. The field ADPTYP in this keyword, *CONTROL_ADAPTIVE, also helps determine the type of mesh adaptivity to perform.

Available adaptivity types:

- Shell splitting or shell *h*-adaptivity
- Solid *r*-adaptivity in which a new mesh of tetrahedrons is created
- *r*-adaptivity of continuum shells in which a new mesh of quads is created
- The mesh of a composite sandwich, comprised of a solid core merged to shell face plates, can be refined by setting the fields IFSAND to "1" and ADPTYP to "1" or "2".
- 3D axisymmetric (or orbital) adaptivity of axisymmetric geometries comprised of hexahedral and/or pentahedral solids.
- Shell mesh fusion (which has long been available in SMP but only became available in MPP starting with R11.0).

Related keywords include:

1. *CONTROL_ADAPTIVE_CURVE: refines mesh along a curve. This feature tends to generate too many elements along the curve and therefore, negatively affects the computational speed.

2. *DEFINE_CURVE_TRIM: when used together with *CONTROL_ADAPTIVE_-CURVE, pre-refines mesh in the area within a specific distance (TCTOL) from both sides of a curve. With this feature you have more control over how many elements will be generated along the curve.

3. *DEFINE_BOX_ADAPTIVE: uses one box for fission and another box for fusion. Boxes can translate or remain stationary. Applies to both shell *h*-adaptivity and tet *r*-adaptivity.

4. *DEFINE_BOX_NODES_ADAPTIVE: defines a moving tube along a tool path for mesh fission in front of the tool and fusion behind the tool. This is useful in cases where the tool path is curved, such as in roller hemming simulations.

5. *DEFINE_CURVE_BOX_ADAPTIVITY: defines a polygon adaptive box within which you can control mesh refinement level. This feature is useful when deformation is concentrated in a localized region (such as in a line die simulation).

Remeshing hyperelastic materials or material models based on a total Lagrangian formulation may lead to numerical instabilities or inaccurate results.

For alternative forms of adaptivity based solely on mesh refinement, see *CONTROL_REFINE.

Card Summary:

Card 1a. This card is included if ADPTYP = 1, 2 or 4 (*h*-adaptivity for shells).

ADPFREQ	ADPTOL	ADPTYP	MAXLVL	TBIRTH	TDEATH	LCADP	IOFLAG

Card 1b. This card is included if ADPTYP = 7 (3D *r*-adaptive remeshing of solid elements).

ADPFREQ		ADPTYP		TBIRTH	TDEATH	LCADP	

Card 1c. This card is included if |ADPTYP| = 8 (2D *r*-adaptive remeshing for plane stress, plane strain, and axisymmetric continuum elements).

ADPFREQ	ADPTOL	ADPTYP	MAXLVL	TBIRTH	TDEATH	LCADP	

Card 2a. This card is optional. It is read if ADPTYP = 1, 2, or 4.

Card 5. This card is optional.

INMEMRY							

Data Card Definitions:

This card is included if ADPTYP = 1, 2, or 4.

Card 1a	1	2	3	4	5	6	7	8
Variable	ADPFREQ	ADPTOL	ADPTYP	MAXLVL	TBIRTH	TDEATH	LCADP	IOFLAG
Type	F	F	I	I	F	F	I	I
Default	none	10^{20}	1	3	0.0	10^{20}	0	0

VARIABLE	DESCRIPTION
ADPFREQ	Time interval between adaptive refinements; see Figures 12-1 and 12-2.
ADPTOL	Adaptive error tolerance; ADPTOL is in degrees for ADPTYP set to 1 or 2
ADPTYP	Adaptive options. ADPTYP = 1, 2 and 4 refer to *h*-adaptivity for shells. ADPTYP = 1 and 2 refer to *h*-adaptivity for shell / solid / shell sandwich composites. EQ.1: Angle change in degrees per adaptive refinement relative to the surrounding shells for each shell to be refined EQ.2: Total angle change in degrees relative to the surrounding shells for each shell to be refined. For example, if

VARIABLE	DESCRIPTION
	APDTOL = 5 degrees, the shell will be refined to the second level when the total angle change reaches 5 degrees. When the angle change is 10 degrees, the shell will be refined to the third level.
	EQ.4: Adapts when the shell error in the energy norm, Δe, exceeds ADPTOL/100 times the mean energy norm within the part, which is estimated as: $$\Delta e = \left(\int_{\Omega_e} \frac{\|\Delta\sigma\|^2}{E} d\Omega \right)^{1/2} .$$ Here E is the Young's modulus. The error of the stresses, $\Delta\sigma$, is defined as the difference between the recovered solution $\sigma^\star$ and the numerical solution, σ^h, that is, $\Delta\sigma \equiv \sigma^\star - \sigma^h$. Various recovery techniques for $\sigma^\star$ and error estimators for Δe are defined by ADPERR. This option works for shell types 2, 4, 16, 18, and 20.
MAXLVL	Maximum number of refinement levels. Values of 1, 2, 3, 4, … allow a maximum of 1, 4, 16, 64, … shells, respectively, to be created for each original shell. The refinement level can be overridden by *DEFINE_BOX_ADAPTIVE or *DEFINE_SET_ADAPTIVE.
TBIRTH	Birth time at which the adaptive remeshing begins; see Figures 12-1 and 12-2.
TDEATH	Death time at which the adaptive remeshing ends; see Figures 12-1 and 12-2.
LCADP	Load curve ID, defining how the adaptive interval is changed as a function of time. If this option is nonzero, the ADPFREQ will be replaced by LCADP. The x-axis is time, and the y-axis is the varied adaptive time interval.
IOFLAG	Flag to generate adaptive mesh at exit, including *NODE, *ELEMENT_SHELL_THICKNESS, *BOUNDARY_*OPTION*, and *CONSTRAINED_ADAPTIVITY, which is to be saved in the file, adapt.msh:
	EQ.1: Generate h-adapted mesh.

This card is included if ADPTYP = 7.

Card 1b	1	2	3	4	5	6	7	8
Variable	ADPFREQ		ADPTYP		TBIRTH	TDEATH	LCADP	
Type	F		I		F	F	I	
Default	none		1		0.0	10^{20}	0	

VARIABLE	DESCRIPTION
ADPFREQ	Time interval between adaptive refinements; see Figures 12-1 and 12-2.
ADPTYP	Adaptive options: EQ.7: 3D *r*-adaptive remeshing for solid elements. Tetrahedrons are used in the adaptive remeshing process (solid formulation 10 or 13, or if EFG, formulation 42), or in the case of 3D axisymmetry (orbital) adaptivity, hexahedral and pentahedral elements are used in the adaptive remeshing. A completely new mesh is generated which is initialized from the old mesh using a least squares approximation. The mesh size is currently based on the minimum and maximum edge lengths defined on the *CONTROL_REMESHING keyword input. This option remains under development, and we are improving its reliability on complex geometries.
TBIRTH	Birth time at which the adaptive remeshing begins; see Figures 12-1 and 12-2.
TDEATH	Death time at which the adaptive remeshing ends; see Figures 12-1 and 12-2.
LCADP	Load curve ID, defining how the adaptive time interval is changed as a function of time. If this option is nonzero, the ADPFREQ will be replaced by LCADP. The *x*-axis is time, and the *y*-axis is the varied adaptive time interval.

This card is included if |ADPTYP| = 8.

Card 1c	1	2	3	4	5	6	7	8
Variable	ADPFREQ	ADPTOL	ADPTYP	MAXLVL	TBIRTH	TDEATH	LCADP	
Type	F	F	I	I	F	F	I	
Default	none	10^{20}	1	3	0.0	10^{20}	0	

VARIABLE	DESCRIPTION
ADPFREQ	Time interval between adaptive refinements; see Figures 12-1 and 12-2.
ADPTOL	Characteristic element size
ADPTYP	Adaptive options: EQ.±8: 2D *r*-adaptive remeshing for plane stress, plane strain, and axisymmetric continuum elements, that is, shell formulations 12 through 15. A completely new mesh is generated which is initialized from the old mesh using a least squares approximation. The mesh size is currently based on the value, ADPTOL, which gives the characteristic element size. This option is based on earlier work by Dick and Harris [1992]. If ADPTYP is negative, then self-contacting material will not be merged together. The self-merging is often preferred since it eliminates sharp folds in the boundary; however, if the sharp fold is being simulated, unexpected results are generated.
MAXLVL	Maximum number of refinement levels. Values of 1, 2, 3, 4, … allow a maximum of 1, 4, 16, 64, … shells, respectively, to be created for each original shell. The refinement level can be overridden by *DEFINE_BOX_ADAPTIVE, or *DEFINE_SET_ADAPTIVE.
TBIRTH	Birth time at which the adaptive remeshing begins; see Figures 12-1 and 12-2.
TDEATH	Death time at which the adaptive remeshing ends; see Figures 12-1 and 12-2.
LCADP	Load curve ID, defining how the adaptive interval is changed as a function of time. If this option is nonzero, the ADPFREQ will be

VARIABLE	DESCRIPTION
	replaced by LCADP. The x-axis is time, and the y-axis is the varied adaptive time interval.

This card is optional. It is read if ADPTYP = 1, 2, or 4.

Card 2a	1	2	3	4	5	6	7	8
Variable	ADPSIZE	ADPASS	IREFLG	ADPENE	ADPTH	MEMORY	ORIENT	MAXEL
Type	F	I	I	F	F	I	I	I
Default	inactive	0	0	0.0	inactive	inactive	0	inactive

VARIABLE	DESCRIPTION
ADPSIZE	Minimum shell size to be adapted based on element edge length. If undefined, the edge length limit is ignored. LT.0: Absolute value defines the minimum characteristic element length to be adapted based on square root of the element area, that is, instead of comparing the shortest element edge with ADPSIZE, it compares the square root of the element area with |ADPSIZE|, whenever ADPSIZE is defined by a negative value.
ADPASS	One or two pass flag for h-adaptivity: EQ.0: Two pass adaptivity as shown in Figure 12-1 EQ.1: One pass adaptivity as shown in Figure 12-2
IREFLG	If positive, the mesh is refined uniformly by IREFLG levels at time = TBIRTH. A value of 1, 2, 3, … creates 4, 16, 64, … shells, respectively, for each original shell. MAXLVL must be greater than or equal to IREFLG for this to work. If negative, |IREFLG| is taken as a curve ID. The curve specifies the minimum element size as a function of time. If the ordinate values (minimum element size) are positive, those values will override other element size criteria. If the ordinate values are negative, the absolute value of the ordinate is the element size used for refinement.

VARIABLE	DESCRIPTION
ADPENE	For shells, *h*-adapt the mesh when the FORMING contact surfaces approach or penetrate the tooling surface depending on whether the value of ADPENE is positive (*approach*) or negative (*penetrates*), respectively. The tooling adaptive refinement is based on the curvature of the tooling. If ADPENE is positive the refinement generally occurs before contact takes place; consequently, it is possible that the parameter ADPASS can be set to 1 in invoke the one pass adaptivity.
ADPTH	Thickness below which adaptive remeshing begins: EQ.0.0: This parameter is ignored. GT.0.0: Absolute shell thickness level below which adaptive remeshing should begin. LT.0.0: |ADPTH| is the element thickness reduction ratio. If the ratio of the element thickness to the original element thickness is less than 1.0 + ADPTHK, the element will be refined. This option works only if ADPTOL is nonzero. If thickness based adaptive remeshing is desired without angle changes, then set ADPTOL to a large angle for ADPTYP = 1 or 2.
MEMORY	This flag can have two meanings depending on whether the memory environmental variable is or is not set. The command "setenv LSTC_MEMORY auto" (or for bourne shell "export LSTC_MEMORY=auto") sets the memory environmental variable which causes LS-DYNA to expand memory automatically. Note that automatic memory expansion is not always 100% reliable depending on the machine and operating system level; consequently, it is not yet the default. To see if this is set on a particular machine type the command "env". If the environmental variable *is not set* then when memory usage reaches this percentage, MEMORY, further adaptivity is prevented to avoid exceeding the memory specified at execution time. Caution is necessary since memory usage is checked after each adaptive step, and, if the memory usage increases by more than the residual percentage, 100-PERCENT, the calculation will terminate. If the memory environmental variable *is set* then when the number of words of memory allocated reaches or exceeds this value, MEMORY, further adaptivity is stopped.

VARIABLE	DESCRIPTION
ORIENT	This option applies to the FORMING contact option only. If this flag is set to one (1), the user orientation for the contact interface is used. If this flag is set to zero (0), LS-DYNA sets the global orientation of the contact surface the first time a potential contact is observed after the birth time. If tracked nodes are found on both sides of the contact surface, the orientation is set based on the principle of "majority rules." Experience has shown that this principle is not always reliable.
MAXEL	If this number of shells is exceeded, adaptivity is stopped.

This card is optional. It is read if ADPTYP = 7.

Card 2b	1	2	3	4	5	6	7	8
Variable				ADPENE		MEMORY		
Type				F		I		
Default				0.0		inactive		

VARIABLE	DESCRIPTION
ADPENE	For three dimensional *r*-adaptive solid remeshing (ADPOPT = 2 in *PART), the mesh refinement is based on the curvature of the tooling when ADPENE is positive. See Remark 9.
MEMORY	This flag can have two meanings depending on whether the memory environmental variable is or is not set. The command "setenv LSTC_MEMORY auto" (or for bourne shell "export LSTC_MEMORY=auto") sets the memory environmental variable which causes LS-DYNA to expand memory automatically. Note that automatic memory expansion is not always 100% reliable depending on the machine and operating system level; consequently, it is not yet the default. To see if this is set on a particular machine type the command "env". If the environmental variable *is not set* then when memory usage reaches this percentage, MEMORY, further adaptivity is prevented to avoid exceeding the memory specified at execution time. Caution is necessary since memory usage is checked after each adaptive step, and, if the memory usage increases by more than the residual percentage, 100-PERCENT, the calculation will terminate.

VARIABLE	DESCRIPTION
	If the memory environmental variable *is set* then when the number of words of memory allocated reaches or exceeds this value, MEMORY, further adaptivity is stopped.

This card is optional. It is read if |ADPTYP| = 8.

Card 2c	1	2	3	4	5	6	7	8
Variable	ADPSIZE	ADPASS				MEMORY		MAXEL
Type	F	I				I		I
Default	inactive	0				inactive		inactive

VARIABLE	DESCRIPTION
ADPSIZE	Minimum shell size to be adapted based on element edge length. If undefined, the edge length limit is ignored. LT.0: Absolute value defines the minimum characteristic element length to be adapted based on square root of the element area, that is, instead of comparing the shortest element edge with ADPSIZE, it compares the square root of the element area with |ADPSIZE|, whenever ADPSIZE is defined by a negative value.
ADPASS	One or two pass flag for *h*-adaptivity: EQ.0: Two pass adaptivity as shown in Figure 12-1 EQ.1: One pass adaptivity as shown in Figure 12-2
MEMORY	This flag can have two meanings depending on whether the memory environmental variable is or is not set. The command "setenv LSTC_MEMORY auto" (or for bourne shell "export LSTC_MEMORY=auto") sets the memory environmental variable which causes LS-DYNA to expand memory automatically. Note that automatic memory expansion is not always 100% reliable depending on the machine and operating system level; consequently, it is not yet the default. To see if this is set on a particular machine type the command "env". If the environmental variable *is not set* then when memory usage reaches this percentage, MEMORY,

VARIABLE	DESCRIPTION
	further adaptivity is prevented to avoid exceeding the memory specified at execution time. Caution is necessary since memory usage is checked after each adaptive step, and, if the memory usage increases by more than the residual percentage, 100-PERCENT, the calculation will terminate. If the memory environmental variable *is set* then when the number of words of memory allocated reaches or exceeds this value, MEMORY, further adaptivity is stopped.
MAXEL	If this number of shells is exceeded, adaptivity is stopped.

This card is optional. It is read if ADPTYP = 1, 2, or 4.

Card 3a	1	2	3	4	5	6	7	8
Variable	IADPN90	IADPGH	NCFREQ	IADPCL	ADPCTL	CBIRTH	CDEATH	LCLVL
Type	I	I	I	I	F	F	F	F
Default	0	0	none	1	none	0.0	10^{20}	

VARIABLE	DESCRIPTION
IADPN90	Fission control flag around radii: GT.0: Maximum number of shells after fission covering the entire radius from starting tangent to ending tangent EQ.-1: This setting works with look-forward adaptivity, making more consistent mesh adaptivity along the radius from starting tangent to ending tangent. The actual number of elements covering the radius, will be controlled by ADPSIZE and MAXLVL. Note this setting also works to prevent the "kinks" that are likely to happen along the draw wall in the deep drawing scenario, under which the parameter ADPFREQ needs to be set fine enough for fission as the blank draws into the die radius. Also see Remark 5.
IADPGH	Fission flag for neighbor splitting: EQ.0: Split all neighbor shells

VARIABLE	DESCRIPTION
	EQ.1: Do not split neighbor shells
NCFREQ	Frequency of fission to fusion steps. For example, if NCFREQ = 4, then fusion will occur on the fourth, eighth, twelfth, etc., fission steps, respectively. If this option, is used NCFREQ > 1 is recommended.
IADPCL	Fusion will not occur until the fission level reaches IADPCL. Therefore, if IADPCL = 2 and MAXLVL = 5, any shell can be split into 256 shells. If the surface flattens out, the number of elements will be reduced if the fusion option is active, i.e., the 256 elements can be fused and reduced to 16.
ADPCTL	Adaptivity error tolerance in degrees for activating fusion. It follows the same rules as ADPTYP as defined in Card 2a.
CBIRTH	Birth time for adaptive fusion. If ADPENE > 0, look-ahead adaptivity is active. In this case, fission, based on local tool curvature, will occur while the blank is still relatively flat. The time value given for CBIRTH should be set to a time later in the simulation after the forming process is well underway.
CDEATH	Death time for adaptive fusion
LCLVL	Load curve ID of a curve that defines the maximum refinement level as a function of time

This card is optional and blank. It is read if ADPTYP = 7, 8, or -8. It should be included if Cards 4c or 4d are included.

Card 3b	1	2	3	4	5	6	7	8
Variable								
Type								

This card is optional. It is read if ADPTYP = 1 or 2.

Card 4a	1	2	3	4	5	6	7	8
Variable						D3TRACE		IFSAND
Type						I		I
Default						0		0

VARIABLE	DESCRIPTION
D3TRACE	Output flag: EQ.0: No additional output states EQ.1: A d3plot state will be output just before and after an adaptive step even though it may not be requested. You may want this output so that the LS-PrePost particle trace algorithm will work in the case of adaptivity.
IFSAND	Set this flag to "1" for forming of sandwich composites. For details, see Remark 6.

This card is optional. It is read if ADPTYP = 4.

Card 4b	1	2	3	4	5	6	7	8
Variable					ADPERR	D3TRACE		
Type					I	I		
Default					0	0		

VARIABLE	DESCRIPTION
ADPERR	3-digit number, as "*XYY*", where "*X*" and "*YY*" define the options for the recovery techniques and the error estimators, respectively: For *X*: EQ.0: Superconvergent patch recovery (SPR) (default) EQ.1: The least square fit of the stress to the nodes (Global L2)

VARIABLE	DESCRIPTION
	EQ.2: Error density SPR, as $\Delta\tilde{e} = \Delta e / \text{Area}_{\text{element}}$
	EQ.3: Self-weighted SPR, as $\Delta\hat{e} = \sqrt{\Delta e \times e}$
	For YY:
	EQ.00: Energy norm (default)
	EQ.01: Cauchy σ_x
	EQ.02: σ_y
	EQ.03: σ_z
	EQ.04: τ_{xy}
	EQ.05: τ_{yz}
	EQ.06: τ_{zx}
	EQ.07: Effective plastic strain, ε_{ep}
	EQ.08: Pressure
	EQ.09: von Mises
	EQ.10: Principal deviator stress S_{11}
	EQ.11: S_{22}
	EQ.12: S_{33}
	EQ.13: Tresca
	EQ.14: Principal stress σ_{11}
	EQ.15: σ_{22}
	EQ.16: σ_{33}
	EQ.20: User subroutine uadpval to extract the numerical solutions for recovery and uadpnorm to provide an error estimator.
D3TRACE	Output flag:
	EQ.0: No additional output states
	EQ.1: A d3plot state will be output just before and after an adaptive step even though it may not be requested. You may want this output so that the LS-PrePost particle trace algorithm will work in the case of adaptivity.

This card is optional. It is read if ADPTYP = 7.

Card 4c	1	2	3	4	5	6	7	8
Variable						D3TRACE	IADPCF	
Type						I	I	
Default						0	0	

VARIABLE	DESCRIPTION
D3TRACE	Output flag: EQ.0: No additional output states EQ.1: A d3plot state will be output just before and after an adaptive step even though it may not be requested. You may want this output so that the LS-PrePost particle trace algorithm will work in the case of adaptivity.
IADPCF	Flag to enable adaptive user control files: EQ.0: No user control files EQ.1: Perform run-time control on 3D adaptivity through control files For details about user control files, see Voume IV of the Keyword User's Manual (Multiscale Solvers).

This card is optional. It is read if |ADPTYP| = 8.

Card 4d	1	2	3	4	5	6	7	8
Variable	CNLA			MMM2D		D3TRACE		
Type	F			I		I		
Default	110.0			0		0		

VARIABLE	DESCRIPTION
CNLA	Limit angle for corner nodes. See Remark 10.

VARIABLE	DESCRIPTION
	GT.0.0: CNLA is the limit angle. Simplified boundary lines for straight sections are used as remeshing basis. LT.0.0: |CNLA| is the limit angle and accurate boundary lines are used as remeshing basis (recommended, with CNLA = -110 being a good choice).
MMM2D	If non-zero, common boundaries of all adapted parts will be merged. This is true even if the parts did not share a boundary at the beginning of the calculation but come into contact later.
D3TRACE	Output flag: EQ.0: No additional output states EQ.1: A d3plot state will be output just before and after an adaptive step even though it may not be requested. You may want this output so that the LS-PrePost particle trace algorithm will work in the case of adaptivity.

This card is optional.

Card 5	1	2	3	4	5	6	7	8
Variable	INMEMRY							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
INMEMRY	Flag to determine the way shell *h*-adaptivity is performed (see Remark 8): EQ.0: Traditional out-of-core adaptivity (default). EQ.1: In-core adaptivity (under development). This approach is only supported in MPP and only for ADPTYP = 2. It does not apply to composite sandwich *h*-adaptivity.

Remarks:

Remarks about *h*-adaptivity

1. **Restarting.** The d3dump and runrsf files contain all information necessary to restart an adaptive run. This did not work in version 936 of LS-DYNA.

2. **Related Field in *PART.** In order for this control card to work, the field ADPOPT = 1 must be set in the *PART definition. Otherwise, adaptivity will not function.

3. **Contact Types and Options.** In order for adaptivity to work optimally, the parameter SNLOG = 1, must be set on Optional Control Card B in the *CONTACT Section. On disjoint tooling meshes the contact option *CONTACT_FORMING_… is recommended.

4. **Root ID (RID) File.** A file named "adapt.rid" is left on disk after the adaptive run is completed. This file contains the root ID of all elements that are created during the calculation, and it does not need to be kept if it is not used in post-processing.

5. **Note About IADPN90 Field.** For all metal forming simulation, IADPN90 should be set to -1.

6. **Mesh Adaptivity for Sandwiched Parts.** Mesh adaptivity can be applied to sandwich composites consisting of layer(s) of solid elements (core) sandwiched by one layer of shell elements each on the top and bottom surfaces of the core. Nodes must be shared at the solid-to-shell interfaces. Prior to R11.0, this mesh adaptivity is limited to only one layer of solid elements with in-plane mesh refinements for both solids and shells. Starting with R11.0 [Zhu et al, 2017], it applies to multiple layers of solid elements; see Figure 12-3.

   After adaptive refinement of the shell faces, the solid elements of the core are created by sweeping the shells through the thickness (Figure 12-4). So, if quad shells are used and refined into smaller quads, matching hexahedral solids are created for the core. Similarly, if triangular shells are used and refined into smaller triangular shells, matching pentahedral solids are created for the core. The number of layers of the solids in the core does not change due to adaptivity. By allowing multiple layers of solids in the thickness direction, different materials may be used through the core thickness. Moreover, this adaptive approach serves to provide better resolution in local areas of interest while keeping the computational cost to a reasonable level.

   The adapted sandwich composite may be trimmed by setting ITYP = 1 in keyword *CONTROL_FORMING_TRIMMING and with keyword *DEFINE_-

CURVE_TRIM. Trimming of sandwiched parts allows for multiple layers of solids.

In a typical forming set up, the following cards need to be changed to activate the sandwiched part mesh adaptivity:

```
*CONTROL_ADAPTIVE
$# adpfreq    adptol    adptyp    maxlvl    tbirth    tdeath     lcadp    ioflag
   0.00223       4.0         2         4     0.0001.0000E+20         0         0
$# adpsize    adpass    ireflg    adpene     adpth    memory    orient     maxel
   0.90000         1            10.00000     0.000         0         0         0
$# ladpn90    ladpgh    ncfred    ladpcl    adpctl    cbirth    cdeath     lclvl
        -1         0         0         1     0.000     0.0001.0000E+20         0
$                                                                        IFSAND
                                                                              1
*PART
Mid-core layer of solid elements
$       PID     SECID       MID     EOSID      HGID      GRAV    ADPOPT      TMID
         1         1         1                                       1
Top layer of shell elements
       100       100         1                                       1
Bottom layer of shell elements
       101       100         1                                       1
```

Note: IFSAND in *CONTROL_ADAPTIVE is set to “1” to activate the composite sandwich adaptivity; each ADPOPT under *PART is set to “1” to activate the adaptivity.

7. **Mesh Fusion in MPP.** Starting with R11.0, mesh fusion in MPP is available. A mesh fusion example is shown in Figure 12-5, and a partial keyword example is provided below:

```
*CONTROL_ADAPTIVE
$  ADPFREQ    ADPTOL    ADPTYP    MAXLVL    TBIRTH    TDEATH     LCADP    IOFLAG
    0.0024       4.0         2         3       0.0      70.0         0         1
$  ADPSIZE    ADPASS    IREFLG    ADPENE    ADPTH     MEMORY     ORIENT   MAXEL
       0.9         1         0       5.0       0.0
$  IADPN90    IADPGH    NCFREQ    IADPCL    ADPCTL    CBIRTH     CDEATH   LCLVL
        -1         0         2         0       8.0      0.00       70.0
```

In this keyword, NCFREQ defines the fusion frequency, ADPCTL defines the fusion criterion, and CBIRTH and CDEATH define when the fusion starts and ends, respectively.

Based on an extensive study [Fan et al, 2017], the fusion feature reduces the computation time notably (average around 25%) and has little effects on formability analysis, such as thinning and effective strain predictions. The mesh fusion effect on springback prediction is found to be smaller than 10%. Therefore, you can apply fusion extensively in all formability related simulations since the leading formability indicators are little affected while the calculation can be sped-up by a factor of 25%. In springback simulations, however, you should use fusion with caution. Using this feature depends on the required simulation accuracy. You can apply this feature if the springback results are to be used for a quick

and rough estimation; however, if the results are to be used for compensating dies and for re-machining, then fusion may not be appropriate

8. **Adaptivity Algorithm.** Out-of-core adaptivity requires dumping the mesh out to disk and restarting the program with a newly created input deck at each adaptive step. This method is computationally expensive due to the I/O, keyword processing, and MPP decomposition time. In-core adaptivity defined with INMEMRY = 1 does not require exiting the solution loop and can maximize the performance of the CPUs employed. This method is under development, so many features are not yet supported. It is currently supported for basic metal forming. It also maintains the loading condition from *LOAD_SHELL_SET upon adaptivity.

Remarks about *r*-adaptivity

9. **Contact and ADPENE.** In three dimensions when ADPENE > 0, the solid part to be adapted is assumed to be on the SURFA side of a contact while the "tooling", consisting of a shell surface, is assumed to be on the SURFB side of that same contact. ADPENE > 0 represents a distance from the tooling surface within which the adapted mesh refinement of the SURFA part is influenced by the radius of curvature of the tooling surface. This feature is currently *unavailable* in SMP and for SOFT = 2 in *CONTACT.

10. **CNLA.** In two dimensions *r*-adaptive remeshing (|ADPTYP| = 8), the generated mesh should have a node at each corner so that the corners are not smooth. By default, the mesher will assume a corner wherever the interior angle between adjacent edges is smaller than 110 degrees. Setting CNLA larger than 110 enables angles larger than 110 to be corners. Care should be taken to avoid an unnecessarily large value of CNLA as this may prevent the mesher from generating smooth meshes.

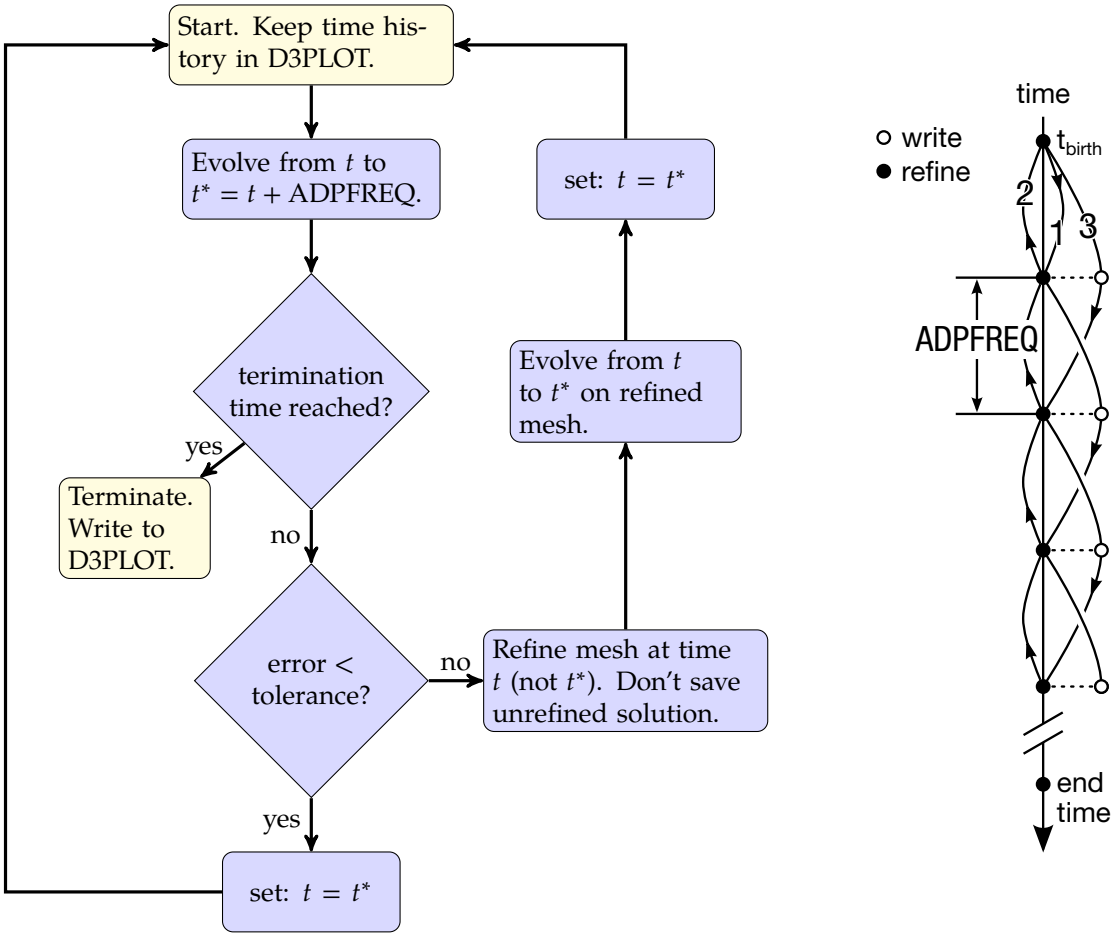

Figure 12-1. Flowchart for ADPASS = 0. While this option is *sometimes* more accurate, ADPASS = 1 is *much* less expensive and recommended when used *with* ADPENE.

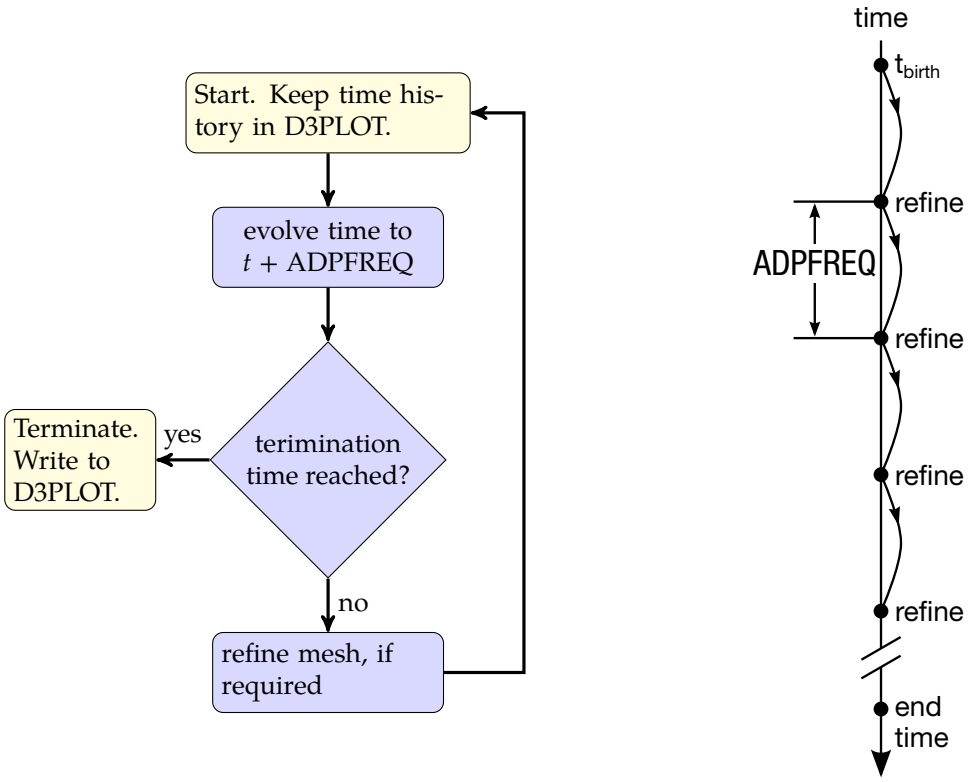

Figure 12-2. Flow chart for ADPASS = 1. This algorithm may be summarized as "periodically refine." This method is recommended over ADPASS = 0 when used *with* ADPENE, which implements look ahead.

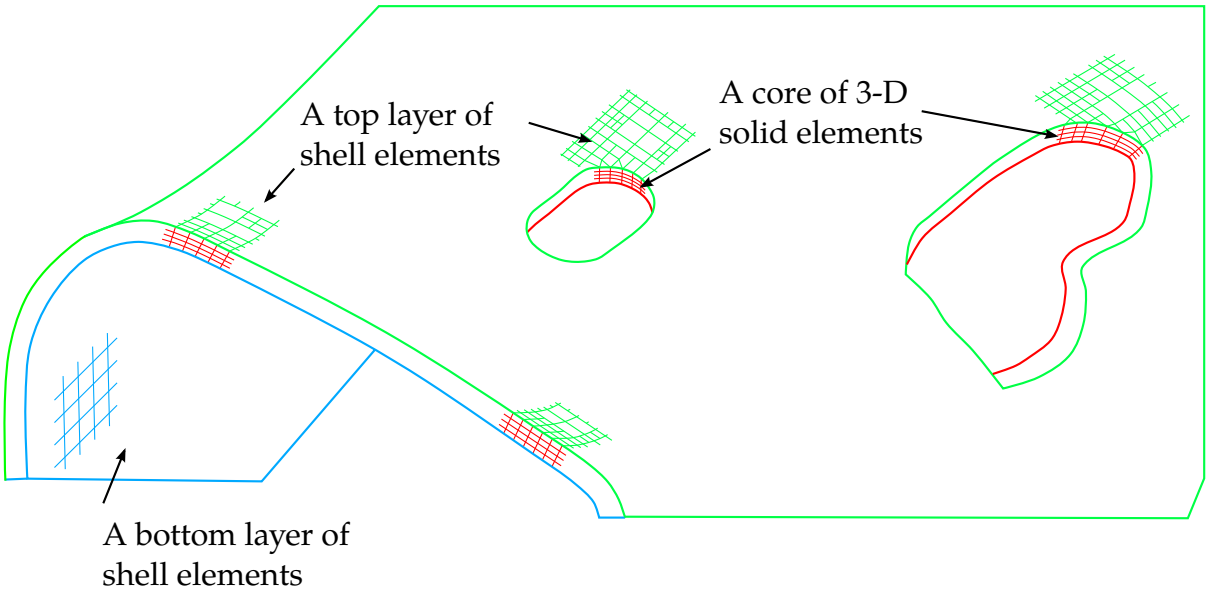

Figure 12-3. Activate sandwich composite mesh adaptivity by setting IFSAND = 1. Before R11.0, adaptivity is limited to only one layer of solid elements; starting with R11.0 adaptive meshing applies to multiple layers of solid elements.

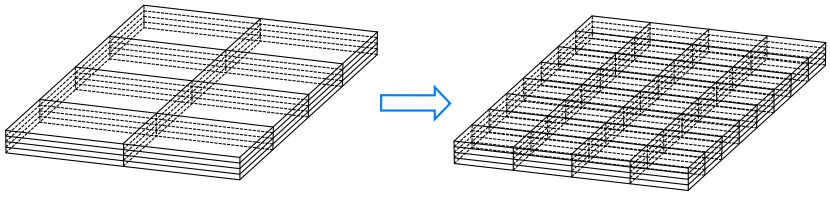

Figure 12-4. Mesh fission for sandwich part. Sweeping the top and bottom adaptive shell elements through the thickness, a total of 32 hexahedral elements are refined into 128 of the same type. The number of layers of the solids always remains the same.

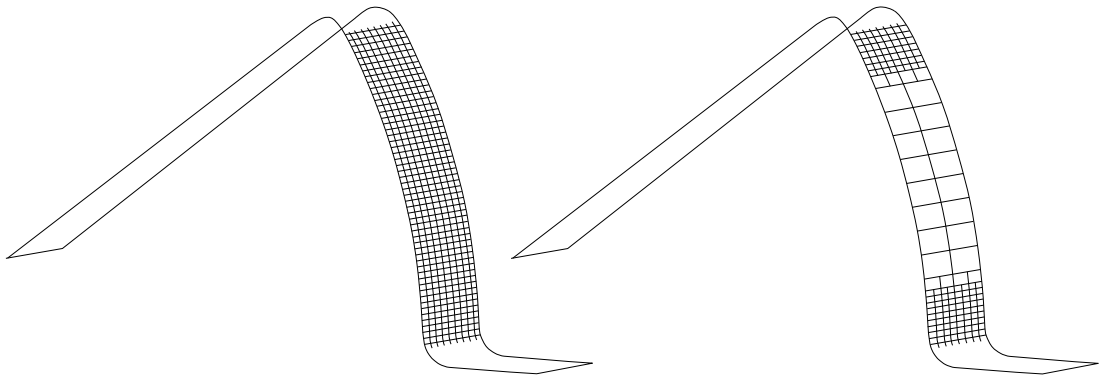

Figure 12-5. Comparison of final mesh pattern between adaptive mesh without fusion and with fusion, on a hat-section draw-bending (half-symmetric model shown).

*CONTROL_ADAPTIVE_CURVE

Purpose: To refine the element mesh along a curve during or prior to a sheet metal forming simulation. All curves defined by the keyword *DEFINE_CURVE_TRIM are used in the refinement. This option provides additional refinement to that generated by *CONTROL_ADAPTIVE. Additionally, pre-mesh refinement along a curve with specific distance/range on both sides of the curve can be modeled when this keyword is used together with *DEFINE_CURVE_TRIM_3D (by activating the field TCTOL). Lastly, this keyword can be used to refine the mesh along a curve during trimming when used together with the keyword *ELEMENT_TRIM. This feature only applies to shell elements and *h*-adaptivity.

Card 1	1	2	3	4	5	6	7	8
Variable	IDSET	ITYPE	N	SMIN	ITRIOPT			
Type	I	I	I	F	I			

VARIABLE	DESCRIPTION
IDSET	Set ID
ITYPE	Set type: EQ.1: IDSET is shell set ID. EQ.2: IDSET is part set ID.
N	Refinement option: EQ.1: Refine until there are no adaptive constraints remaining in the element mesh around the curve, subjected to the maximum refinement level of 5. GT.1: Refine no more than N levels.
SMIN	If the element dimension is smaller than this value, do not refine.
ITRIOPT	Option to refine an enclosed area of a trim curve. EQ.0: Refine the elements along the trim curve. EQ.1: Refine the elements along the trim curve and enclosed by the trim curve. Under the keyword *DEFINE_CURVE_TRIM_3D, the variable TCTOL must be set to "2" and a seed node NSEED1 must be defined inside the curve loop.

Adaptive mesh refinement along a curve during the beginning of a simulation:

The Figure 12-6 top right mesh refinement illustrates mesh adaptivity along an enclosed curve as done by the partial input example below. Since the mesh refinement is controlled by either the refinement level N or smallest element size SMIN, care should be taken so not too many elements are generated in the model.

The partial keyword input example below refines the mesh by four levels along both sides of the curve defined by the IGES file adpcurves.iges. If an element edge length is shorter than 0.3 mm, then the element is not refined.

```
*INCLUDE
drawn.dynain
*DEFINE_CURVE_TRIM_3D
$      TCID     TCTYPE       TFLG       TDIR      TCTOL

*CONTROL_ADAPTIVE_CURVE
$     IDSET     ITYPE          N       SMIN
         1          2          4        0.3
```

Adaptive mesh refinement inside a curve loop during the beginning of a simulation:

Figure 12-6 bottom left mesh refinement illustrates refining the mesh inside the closed curve from the partial input below. The original mesh (Figure 12-6 top left) is refined by either six levels or to no smaller than 3.2 mm element edge length inside the curve loop defined by the IGES file area.iges. TCTYPE may be set to either 1 or 2, but TCTOL must be set to 2, and NSEED1 (106877) must be defined inside the curve loop. Note this feature is available starting in Revision 115142.

```

Adaptive mesh along a curve with refinement controlled by a distance during the

beginning of a simulation:

This feature was added to limit the number of elements created.

When *CONTROL_CURVE_TRIM_3D is used with *CONTROL_ADAPTIVE_CURVE, TCTOL is interpreted as the total width the mesh will be refined centered on the defined curve during the beginning of a simulation; in other words, on each side of the curve the mesh will be refined to a distance of half TCTOL. Figures 12-7 and 12-8 illustrate this. This feature *only* works with the 3D option.

The curve needs to be sufficiently close to the part. Since the curve is often made from some feature lines of forming tools, the curve must be re-positioned closer to the blank, or better yet, projected onto the blank; otherwise the refinement will not take place. The curve can be moved closer to the part with LS-PrePost 4.0 using *GeoTol* → *Project* → *Closest Proj* → *Project to Element* → *By Part*.

The partial input example below refines the mesh 2.0 mm (TCTOL = 4.0) on each side of the curve defined by the file adpcurves.iges. The maximum refinement level is 4, and the minimum element size allowed is 0.3 mm.

```
*INCLUDE
drawn.dynain
*DEFINE_CURVE_TRIM_3D
$      TCID    TCTYPE      TFLG      TDIR     TCTOL
         1         2         0         0     4.000
adpcurves.iges
*CONTROL_ADAPTIVE_CURVE
$     IDSET     ITYPE         N      SMIN
         1         2         4       0.3
```

Mesh refinement along a curve is very useful during line die simulations. For example, in a flanging simulation, a trimmed blank, that is mostly flat in the flanging break line in draw die, can be refined using a curve generated from the trim post radius. In LS-PrePost 4.0, the curve can be generated using *Curve* → *Spline* → *From Mesh* → *By Edge*, check *Prop*, and defining a large *Ang* to create a continuous curve along element edge. This curve can then be projected onto the blank mesh using *GeoTol* → *Project* feature which will then be used as the curve file adpcurves.iges here. The mesh pre-refinement along curves are implemented in the flanging process starting with LS-PrePost4.0 *eZSetup* for metal forming applications. In LS-PrePost4.3 *eZSetup*, improvements are made so adaptive mesh refinement along a curve can be made without the need to define any tools.

In Figures 12-9, 12-10, 12-11, 12-12and 12-13, mesh pre-refinement along a curve is demonstrated on a fender outer case in which the effect of different TCTOL values can be seen.

The keyword *INCLUDE_TRIM is recommended to be used at all times to include the dynain file from a previous simulation, except when the to-be-adapted sheet blank has no stress and strain information; that is, no *INITIAL_STRESS_SHELL, and *INITIAL_-

STRAIN_SHELL cards present in the sheet blank keyword or dynain file. For this case, the keyword *INCLUDE must be used instead.

Adaptive mesh refinement along a curve during trimming:

When the keyword *ELEMENT_TRIM is present, this keyword is used to refine meshes during a trimming simulation. Coarse meshes along the trim curve can be refined prior to trimming, causing a more detailed and distinctive trim edge. A partial example input deck is shown below:

```
*INCLUDE_TRIM
drawn.dynain
*ELEMENT_TRIM
         1
*DEFINE_CURVE_TRIM_2D
$#     TCID    TCTYPE      TFLG      TDIR     TCTOL      TOLN    NSEED1    NSEED2
         1         2                    0     0.250         1
doubletrim.iges
*DEFINE_TRIM_SEED_POINT_COORDINATES
$     NSEED        X1        Y1        Z1        X2        Y2        Z2
         1  -184.565    84.755
*CONTROL_ADAPTIVE_CURVE

         1         2         3       3.0         0
*CONTROL_CHECK_SHELL
$#     PSID    IFAUTO    CONVEX      ADPT     ARATIO    ANGLE      SMIN
         1         1         1         1       0.25    150.0      0.18
```

The keyword *ELEMENT_TRIM defines a deformable part set to be trimmed. The keyword *DEFINE_CURVE_TRIM_2D defines the trim curve and type, along with trim tolerance, etc. The keyword *DEFINE_TRIM_SEED_POINT_COORDINATES indicates which side of the part will remain after trimming by specifying a seed node. The keyword *CONTROL_ADAPTIVE_CURVE specifies the adaptive mesh refinement level and minimum element size along the trim curve. Finally, the keyword *CONTROL_CHECK_SHELL repairs and fixes trimmed elements, so they are suitable for next simulation. More details can be found in each of the corresponding keyword manual sections.

Revision Information:

1. Revision 65630: use of TCTOL as a distance for mesh refinement (when used together with *CONTROL_ADAPTIVE_CURVE). TCTOL is the distance from the curve to the edge of the refinement.

2. Revision 113756: some improvements to TCTOL. TCTOL becomes the distance of the entire width of the refinement.

3. Revision 115142: ITRIOPT = 1 and TCTOL = 2 are available for mesh refinement along and inside a curve loop.

*CONTROL_AIRBAG

Purpose: Global control parameters for CV AIRBAG.

Card 1	1	2	3	4	5	6	7	8
Variable	CKERR							
Type	I							
Default	0							

VARIABLE	DESCRIPTION
CKERR	Flag to check the bag of a CV airbag for (a) open (free) edges and (b) segments not associated with shell or solid elements: EQ.0: Do not check (default). EQ.1: Check for free edges and segments not associated with elements. If the airbag surface contains a free edge, LS-DYNA will output the nodes of the free edge to d3hsp, issue a warning, and *continue* the run. If a segment in the segment set defining the airbag is not associated with an element, LS-DYNA will output the segment to d3hsp, issue an error message, and *terminate* the run. EQ.2: Check for free edges and segments not associated with elements. If the airbag surface contains a free edge, LS-DYNA will output the nodes of the free edge to d3hsp, issue a warning, and *terminate* the run. If a segment in the segment set defining the airbag is not associated with an element, LS-DYNA will output the segment to d3hsp, issue an error message, and *terminate* the run.

Remarks:

CKERR = 1 or 2 causes LS-DYNA to check the integrity of the airbag model. The airbag must be specified as a closed bag (no free edges) using a part set or segments set (SIDTYP of *AIRBAG_*OPTION*) for correct results. If it has a free edge, then the calculated values for the airbag, such as pressure, volume, and temperature, will be incorrect. If the airbag is defined using a segment set, the segments in the set must be associated with a element. Otherwise, LS-DYNA cannot capture the physics of the airbag.

*CONTROL_ALE

Purpose: Set global control parameters for the Arbitrary Lagrangian-Eulerian (ALE) and Eulerian calculations. This command is required when solid element formulation 5, 6, 7, 11, or 12 is used. Parallel processing using SMP is not recommended when using these element formulations, rather it is better to use MPP for good parallel processing performance. See *CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_ALE_ELEMENTS.

Variable	OPTIMPP	IALEDR	BNDFLX	MINMAS				
Type	I	I	I	F				
Default	0	0	0	10^{-5}				

VARIABLE	DESCRIPTION
DCT	Flag to invoke alternate advection logic for ALE (see Remark 2): NE.-1: Use default advection logic. EQ.-1: Use alternate (improved) advection logic; generally recommended, especially for simulation of explosives. Note that for S-ALE DCT is ignored and the alternative advection option is always used.
NADV	Number of cycles between advections (almost always set to 1).
METH	Advection method: EQ.1: Donor cell with Half Index Shift (HIS), first order accurate. EQ.2: Van Leer with HIS, second order accurate (default). EQ.-2: Van Leer with HIS. Additionally, the monotonicity condition is relaxed during the advection process to better preserve *MAT_HIGH_EXPLOSIVE_BURN material interfaces (see Remark 3). EQ.3: Donor cell with HIS modified to conserve total energy over each advection step, in contrast to METH = 1 which conserves internal energy (see Remark 4). EQ.6: Finite volume method with a flux corrected transport. Only supported for ideal gases: the finite volume method is only applied to ALE elements fully filled with materials using *EOS_IDEAL_GAS or *EOS_001 for ideal gases. The advection in mixed ALE elements is handled by a donor cell method.

VARIABLE	DESCRIPTION
AFAC	ALE smoothing weight factor - Simple average EQ.-1.0: Turn smoothing off. See Remark 5.
BFAC	ALE smoothing weight factor - Volume weighting
CFAC	ALE smoothing weight factor - Isoparametric
DFAC	ALE smoothing weight factor - Equipotential
EFAC	ALE smoothing weight factor - Equilibrium
START	Start time for ALE smoothing or start time for ALE advection if smoothing is not used.
END	End time for ALE smoothing or end time for ALE advection if smoothing is not used. LT.0.0: The ALE mesh is removed after |END|.
AAFAC	ALE advection factor (donor cell options, default = 1.0). This field is obsolete.
VFACT	Volume fraction limit for stresses in single material and void formulation. All stresses are set to zero for elements with lower volume fraction than VFACT. EQ.0.0: Set to default 10^{-6}
PRIT	A flag to turn on or off the pressure equilibrium iteration option for multi-material elements (see Remark 6): EQ.0: Off (default) EQ.1: On
EBC	Automatic Eulerian boundary condition (see Remark 7): EQ.-2: Generate *ALE_ESSENTIAL_BOUNDARY with slip condition for mesh boundaries that do not already have segment boundary conditions, such as *BOUNDARY_NON_REFLECTING, *LOAD_BLAST_SET_SEGMENT, *BOUNDARY_SPC_SET, or *LOAD_SEGMENT_SET, applied EQ.0: Off EQ.1: On with stick condition

VARIABLE	DESCRIPTION
	EQ.2: On with slip condition
PREF	A pseudo reference pressure equivalent to an environmental pressure that is applied to the free surfaces of the ALE domain or mesh (see Remark 8)
NSIDEBC	A node set ID (NSID) which is to be excluded from the EBC constraint.
NCPL	Number of Lagrangian cycles between coupling calculations. This is typically done every cycle; therefore, its default is 1.
NBKT	Number of Lagrangian cycles between global bucket-sort searches to locate the position of the Lagrangian structure (mesh) relative to the ALE fluid (mesh). Default is 50. LT.0: |NBKT| is a *DEFINE_CURVE ID defining a table: time vs NBKT as defined above. EQ.0: NBKT = 50 (default): If the mesh is moving, NBKT is adapted for the buckets to follow the mesh more closely. GT.0: NBKT remains constant.
IMASCL	A flag for turning ON/OFF mass scaling for ALE parts. The global mass scaling control parameter DT2MS for the *CONTROL_TIMESTEP keyword must be nonzero. If the ALE time step becomes smaller than the mass scaling time step (DT2MS), then IMASCL has the following effects: EQ.0: No mass scaling for ALE parts (default). The DTMS time step will be used for the calculation. Note that because the DTMS time step is larger than the ALE time step, the CFL condition will not be satisfied the ALE domain potentially causing instability. Print out maximum 20 warnings. EQ.1: No mass scaling for ALE parts. Stop the run. EQ.2: Do mass scaling for ALE parts (the result may not be correct due to this scaling). EQ.3: No mass scaling for ALE parts. Use the ALE time step. This time step may be small enough to substantially increase calculation run time.

VARIABLE	DESCRIPTION
CHECKR	A parameter for reducing or eliminating an ALE pressure locking pattern. It may range from 0.01 to 0.1 (See Remark 9).
BEAMIN	Flag to align the dynamics of plain strain and axisymmetric beams in 2D FSI ALE models to their shell counterparts in 3D FSI ALE models: EQ.0.0: Off (default) EQ.1.0: On
MMGPREF	A flag to select the method for assigning a reference pressure to multiple ALE multi-material groups (see Remark 8). EQ.0: Off (default). PREF applies to every AMMG in the model. LT.0: |MMGPREF| is an ID of either a curve defined using *DEFINE_CURVE or a table defined using *DEFINE_TABLE. If it is a curve, then its abscissa contains the multi-material group IDs (AMMGID) and the ordinates are the constant reference pressures values associated with each of those AMMGIDs. This is the PREF = constant case for each AMMG. If it is a table, then a load curve for PREF as a function of time must be defined for each AMMGID (the value in the table) in the model.
PDIFMX	Maximum of pressure difference between neighboring ALE elements under which the nodal forces are zeroed out: EQ.0: Off (default) GT.0: On
DTMUFAC	Scale a time step called DTMU that depends on the dynamic viscosity μ, the initial density ρ, and an element characteristic length ℓ: $$\text{DTMU} = \frac{\rho \ell^2}{2\mu}$$ DTMU is emitted by the element to the solver as an element time step, thereby making DTMU an upper bound on the global time step. EQ.0: Off (default) GT.0: On

VARIABLE	DESCRIPTION
OPTIMPP	Optimize the MPP communications in the penalty coupling (*CONSTRAINED_LAGRANGE_IN_SOLID, CTYPE = 4) and group ALE parts together for the element processing. EQ.0: Off (default) EQ.1: On
IALEDR	Include ALE computations in the dynamic relaxation analysis (*CONTROL_DYNAMIC_RELAXATION). EQ.0: Off (default) EQ.1: On
BNDFLX	Multi-Material ALE group set ID selecting only the materials in elements at mesh boundaries with influxes that can flow in. By default, when the flow is inwards at boundary faces of ALE elements, every material in these elements flows in. This option can select only a few of these ALE groups. EQ.0: Off (default) GT.0: *SET_MULTI-MATERIAL_GROUP_LIST ID EQ.-1: No influx
MINMAS	Factor of the minimum mass allowed in an element: MINMAS×initial density×element volume

Remarks:

1. **Recommended Starting Point Settings.** Although this keyword has many fields, only a few are required input. As a starting point, you can try setting DCT = -1, NADV = 1, METH = 1, AFAC = -1, and the rest as "0". When needed, PREF should also be defined. These settings are adequate for most cases. Depending on the physics, you may also need to change METH to 2 or 3.

2. **The DCT Field.** For the general ALE solver in both 2D and 3D, the DCT field specifies the advection scheme. By default, the solver uses the original advection scheme. Setting DCT = -1 invokes the improved advection scheme. The S-ALE solver in both 2D and 3D always uses the improved advection scheme (DCT is ignored).

   We recommend DCT = -1 over the default scheme, especially for simulating explosives. This scheme includes the following major changes:

a) Relaxes an artificial limit on the expansion ratio limit. The default limit improves stability in some situations but can overestimate the explosive impulse.

b) Corrects redundant out-flux of material at corner elements. The redundancy can lead to negative volume.

c) Removes several artificial constraints in the advection which were originally implemented to assist in stability but are no longer needed.

3. **METH = -2.** The METH = -2 advection type is the same as METH = 2 with only one exception. It employs a looser constraint on monotonicity requirement during ALE advection. When METH = 2, for each advection process along three directions (front/back, top/bottom, left/right), the maximum/minimum values for advected history variables in the three elements along that direction are capped. METH = -2 relaxed the monotonicity condition so that the advected value is capped at the maximum/minimum value in the element itself and its neighboring 26 elements. This option, in certain conditions, can better preserve the material interface for materials defined with *MAT_HIGH_EXPLOSIVE_BURN.

4. **METH = 3 for Conserving Total Energy.** Generally, it is not possible to conserve both momentum and kinetic energy (KE) at the same time. Typically, internal energy (IE) is conserved and KE may not be. This may result in some KE loss (hence, total energy loss). For many analyses this is tolerable, but for airbag application, this may lead to the reduction of the inflating potential of the inflator gas. METH = 3 tries to eliminate this loss in KE over the advection step by storing any loss KE under IE, thus conserving total energy of the system.

5. **Smoothing Factors.** All the smoothing factors (AFAC, BFAC, CFAC, DFAC, EFAC) are generally most applicable to ELFORM = 5 (single material ALE formulation). The ALE smoothing feature is *not* supported by MPP versions.

6. **The PRIT Field.** Most of the fast transient applications do not need this feature. It could be used in specific slow dynamic problems for which material constitutive laws with very different compressibility are linear and the stresses in multimaterial elements require to be balanced.

7. **The EBC Field.** This option is used for EULER formulations. It automatically defines velocity boundary condition constraints for the user. The constraints, once defined, are applied to all nodes on free surfaces of an Eulerian domain. For problems where the normal velocity of the material at the boundary is zero such as injection molding problems, the automatic boundary condition parameter is set to 2. This will play the same role as the nodal single point constraint. For EBC = 1, the material velocity of all free surface nodes of an Eulerian domain is set to zero.

8. **Environmental Pressure.** By default, the pressure outside the ALE mesh is assumed to be zero. Any material with a pressure higher than zero will have the tendency to flow out of the ALE domain. Therefore, when there is any ALE material with initialized pressure greater than zero, defined using the *EOS keyword, PREF should be defined to prevent that ALE material from leaving the ALE domain.

   To provide the effect of environmental pressure loading to all the free surfaces of the ALE mesh, the code performs an equivalent calculation. It subtracts PREF from the diagonal components of the stresses tensor of each material before computing the internal forces. Thus, defining PREF is equivalent to applying *LOAD_SEGMENT cards to balance the internal pressure along the free ALE mesh boundaries. By default, PREF is applied to all the materials in the ALE domain. When PREF is a constant value, then a fixed value of ambient pressure is applied. When PREF is a load curve, then the ambient pressure is a function of time.

   MMGPREF cannot be used to set the initial pressure for a material. The initial pressure must be set using the *EOS or *MAT keyword for the material. The shift of the stresses by PREF cannot be seen in the LS-PrePost fringe of the pressures.

   When MMGPREF < 0, there are 2 possible cases, assigning (a) PREF = constant or (b) PREF = PREF(t) (reference pressure as a function of time) to each AMMG.

```
[Example 1]
Consider for example, if a model has 3 ALE groups:
- AMMG1 = air        (with reference pressure for AMMG1 = PREF1 = 1.0 bar)
- AMMG2 = explosive  (with reference pressure for AMMG2 = PREF2 = 0.0 bar)
- AMMG3 = water      (with reference pressure for AMMG3 = PREF3 = 0.0 bar)

Here is how it may be defined in the input file.
PREF    = 0.0 bar
MMGPREF = -LCID
where LCID is the ID of the following curve:
$---+----1----+----2----+----3----+----4----+----5----+----6----+----7----+--
*DEFINE_CURVE
       LCID
$              AMMGID                PREF
                    1                 1.0
                    2                 0.0
                    3                 0.0
$---+----1----+----2----+----3----+----4----+----5----+----6----+----7----+--
```

```
[Example 2]
Consider a model also having 3 ALE groups where each group may have a
different reference pressure as a function of time.  One scenario may be that
of a pre-pressurized container.  Another may be the simulation of some
reservoir conditions.  Assume for this example that we have a pressurized
container.  All 3 AMMGs are intialized to 4 bars at t=0.0. Then, we lower the
environmental pressure of the oustside air from 4.0 bars to 1.0 over a short
time.  Over this duration, the FSI will have time to build up the pre-stressed
state in the container before another dynamic process is introduced, such as
an impact.
```

```
- AMMG1 = air outside                          (with PREF1=PREF1(t))
- AMMG2 = pressurized gas    inside container (with PREF2=PREF2(t))
- AMMG3 = pressurized liquid inside container (with PREF3=PREF3(t))

```

9. **CHECKR Field for One Point Integration.** Due to one point integration, ALE elements may experience a spatial instability in the pressure field referred to as checker boarding. CHECKR is a scale for diffusive flux calculation to alleviate this problem.

10. **Pressure Checker Boarding.** Because the internal forces are located at the nodes, while the pressure is stored at the element center, sometimes a "checker-board pattern" arises in the pressure distribution. It is a kind of locking effect that normally occurs only in problems having very small volumetric strains, i.e., at small pressures. “CHECKR” is designed for alleviating this problem.

*CONTROL_BULK_VISCOSITY

Purpose: Reset the default values of the bulk viscosity coefficients globally. This may be advisable for shock wave propagation and some materials. Bulk viscosity is used to treat shock waves. A viscous term, q, is added to the pressure to smear the shock discontinuities into rapidly varying but continuous transition regions. With this method the solution is unperturbed away from a shock, the Hugoniot jump conditions remain valid across the shock transition, and shocks are treated automatically.

Card 1	1	2	3	4	5	6	7	8
Variable	Q1	Q2	TYPE	BTYPE	TSTYPE			
Type	F	F	I	I	I			
Default	1.5	.06	1	0	0			

VARIABLE	DESCRIPTION
Q1	Default quadratic viscosity coefficient.
Q2	Default linear viscosity coefficient.
TYPE	Default bulk viscosity type, IBQ (default = 1): EQ.-2: same as -1 but the internal energy dissipated by the viscosity in the shell elements is computed and included in the overall energy balance. EQ.-1: same as 1 but also includes viscosity in shell formulations 2, 4, 10, 16, and 17. The internal energy is not computed in the shell elements. EQ.1: standard bulk viscosity. Solid elements only and internal energy is always computed and included in the overall energy balance. EQ.2: Richards-Wilkins bulk viscosity. Two-dimensional plane strain and axisymmetric solid elements only. Internal energy is always computed and included in the overall energy balance.
BTYPE	Beam bulk viscosity type (default = 0): EQ.0: the bulk viscosity is turned off for beams.

VARIABLE	DESCRIPTION
	EQ.1: the bulk viscosity is turned on for beam types 1 and 11. The energy contribution is not included in the overall energy balance.
